Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in *Table 1878* and *Table 1880*, respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

69.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

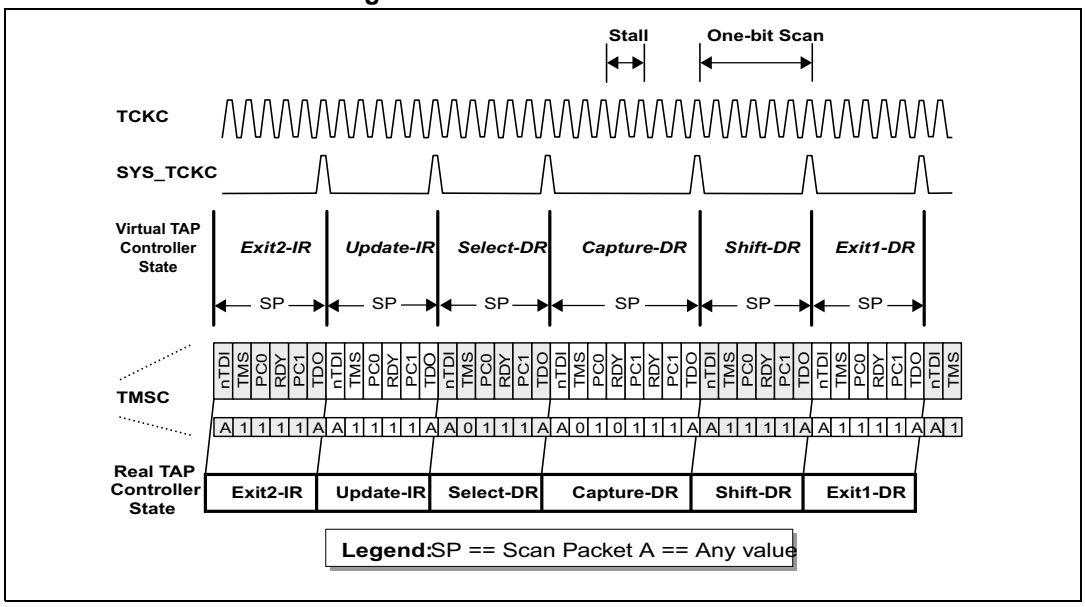

Table 1878. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 1879. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

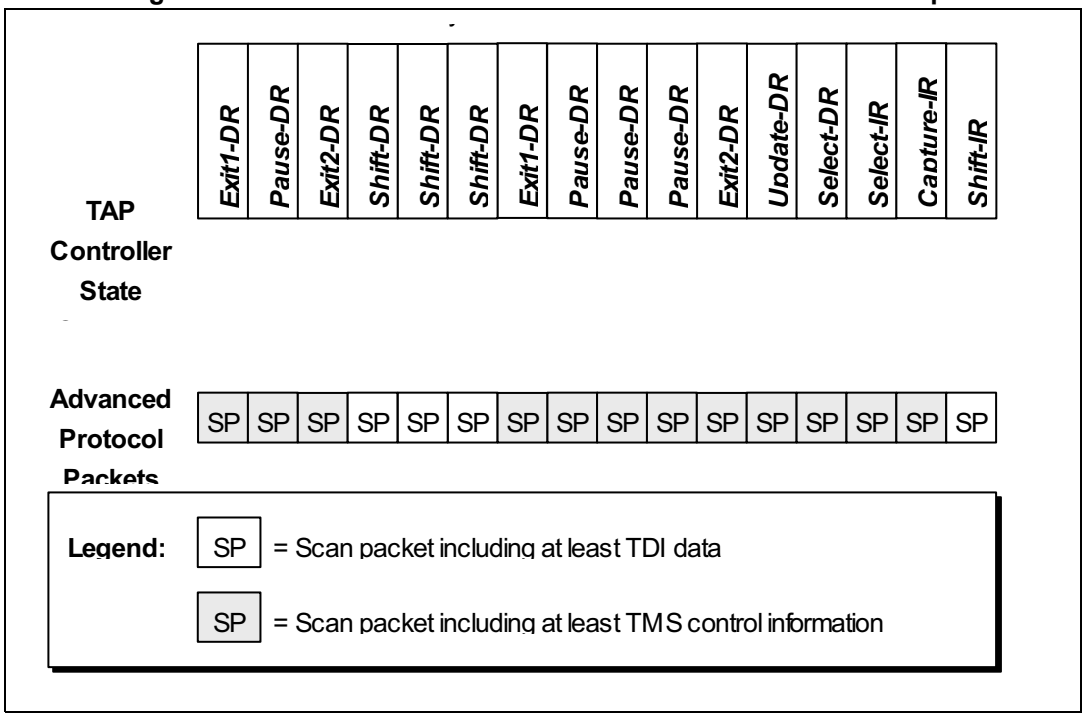

Figure 1934. MScan Transaction

69.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 1935. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in *Table 1880*.

Table 1880. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

69.8 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

69.8.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in *Section 69.6.1.4: Control levels*.

After the control level is set to control level 2, TAP.7 commands can be executed as described in *Section 69.6.3: EPU Commands*. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in *Section 69.7.5.3: Control Process Active (CPA) Function* and *Section 69.7.6: Configuration Change Packets (CP)*. Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in *Section 69.6.3.5.1.3: Store Conditional 2-bit (STC2)*.

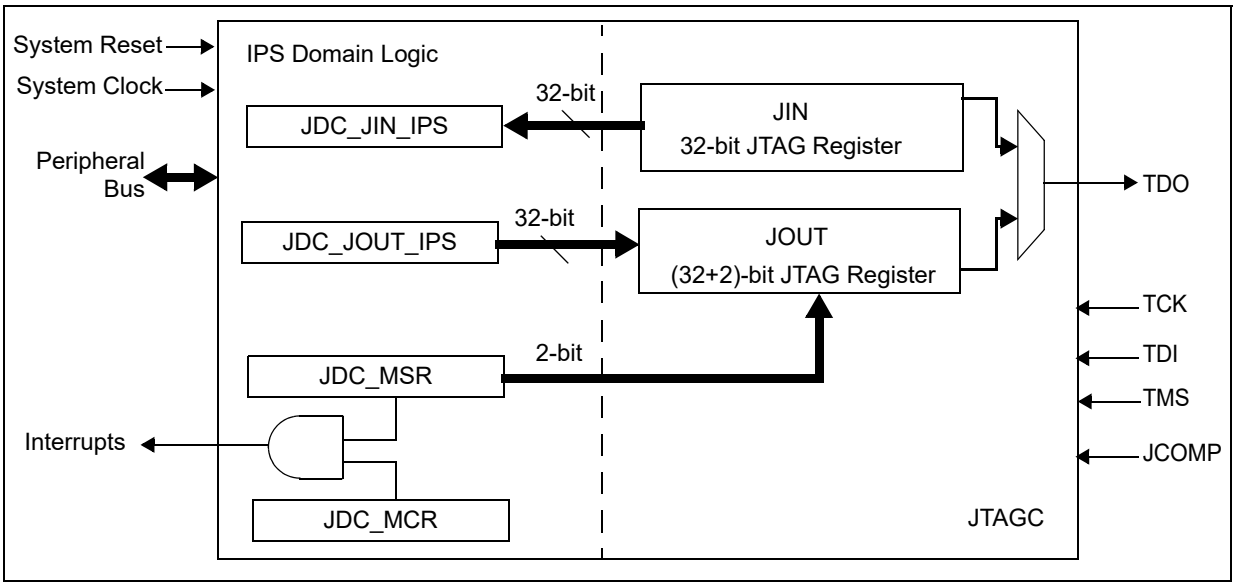
70 JTAG Data Communication (JDC)

70.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

70.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.



The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 1936*.

Figure 1936. JDC block diagram

70.3 Register definition

Table 1882 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1882. JDC memory map

Address offset	Register	Access	Reset value	Location
0x0	Module Configuration Register (JDC_MCR)	R/W	0x0000_0000	*Section 70.3.1.1*

The JDC_JOUT_IPS register is described in *Table 1885*.

Table 1885. JDC_JOUT_IPS register field descriptions

Field	Description
0:31 DATA	Contains JOUT_IPS data.

70.3.1.4 JTAG input IPS data register (JDC_JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JDC_JIN_IPS register, where it can be read via IPS. *Figure 1940* shows the format of the JDC_JIN_IPS register. This register is reset by system destructive reset.

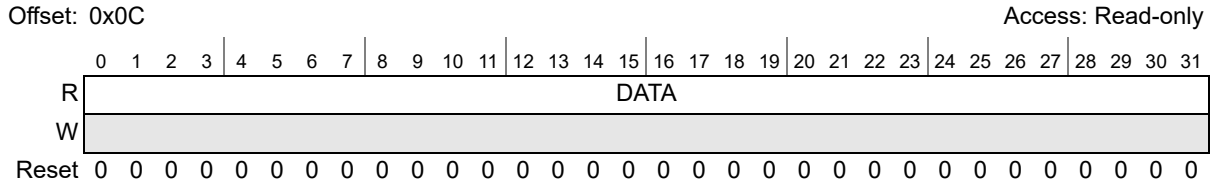

Figure 1940. JDC_JIN_IPS register

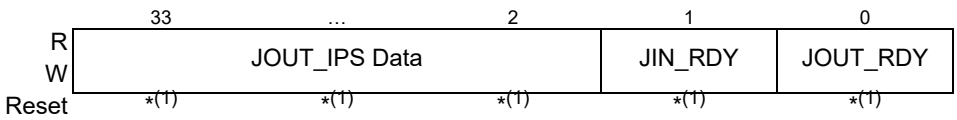
The JDC_JIN_IPS register is described in *Table 1886*.

Table 1886. JDC_JIN_IPS register field descriptions

Field	Description
0:31 DATA	Contains JIN_IPS data.



70.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

70.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JDC_JIN_RDY and JDC_JOUT_RDY status bits. *Figure 1941* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

Figure 1941. JOUT JTAG register

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in *Table 1887*.

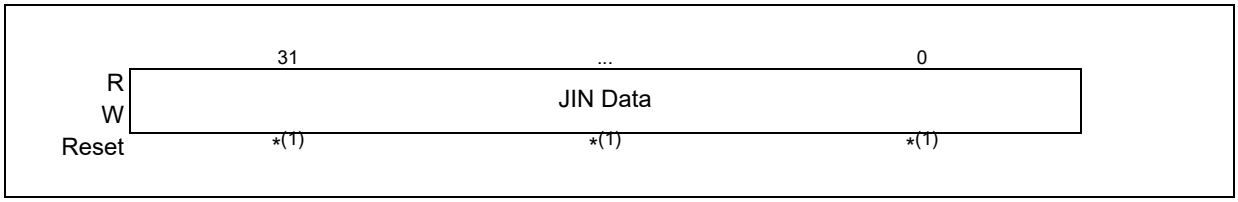


Table 1887. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

70.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 1942* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

Figure 1942. JIN JTAG Register

1. The reset value of the JIN register is 32'b0.

The JIN register is described in *Table 1888*.

Table 1888. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JDC_JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

70.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data

is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

70.4.1 IPS register access

IPS access is available to the registers described in *Section 70.3.1*.

70.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

70.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 1889*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1889. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

70.5 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The JDC_MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate

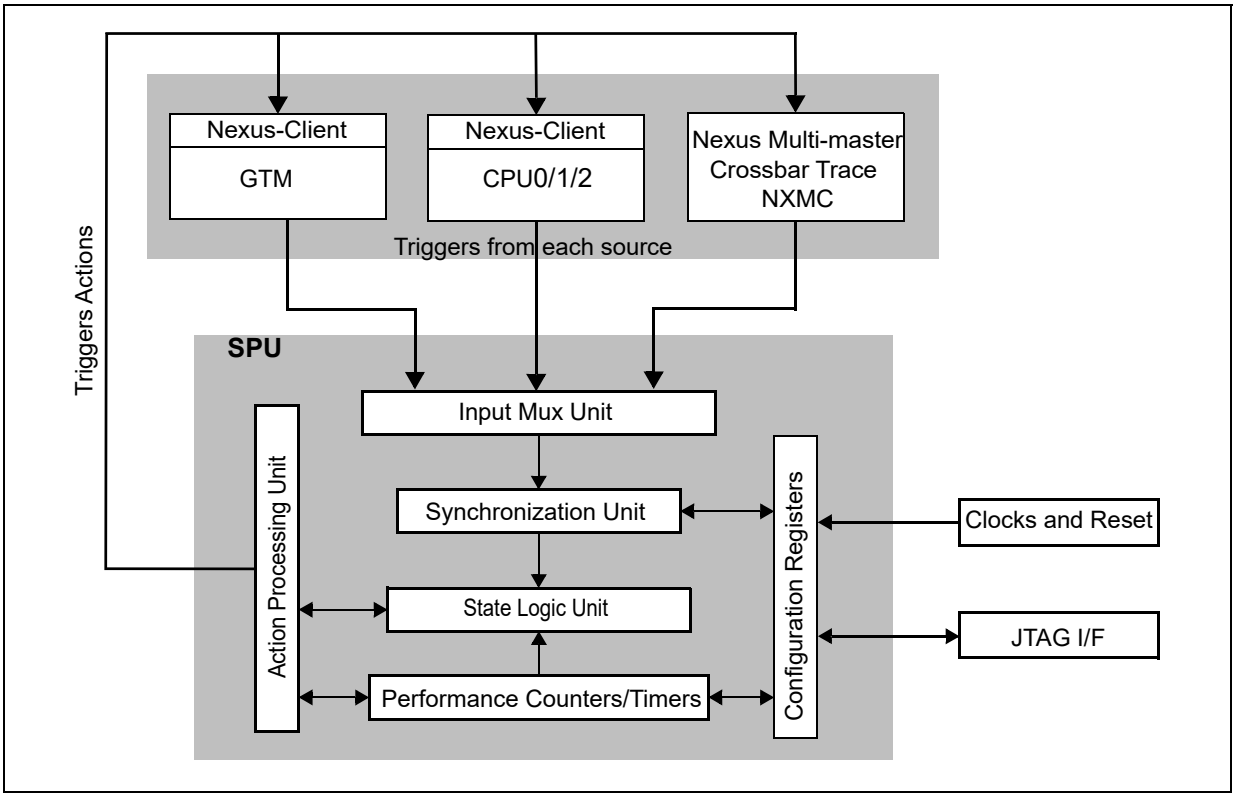
the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the JDC_MCR[JOUT_IEN] is set.

7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

71 Sequence Processing Unit (SPU)

71.1 Introduction



The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores, GTM, or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

71.1.1 SPU block diagram

Figure 1943 shows a top-level block diagram of the SPU.

Figure 1943. SPU block diagram

71.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, GTM, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 1982*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 1983*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 1984* and *Figure 1985*. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU writes to VariableB. If CPU writes a value to VariableB which is 0x100, then enable trace for the GTM and halt CPU.

The SPU consists of the following sub-blocks:

- Input Mux Unit: receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 1982*.
- State Logic Units (SLU): responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan's law, allows for generalized signal combinations. This is shown in *Figure 1983*.
- Action Processing Unit: takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers: the SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

71.1.3 Features

The features of the SPU are as follows:

- clients:
  - 3 CPUs
  - 1 GTM
  - 5 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics

  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
  - Access to timer/counter values via JTAG
- Prescaler for timer mode only
  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from GTM
  - SPU to/from NAR
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces

  - GTM
  - System bus
  - NAR
  - DCI
- Configuration registers: 32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions: SPU block triggers various actions based on the derived events, these actions are defined in *Section 71.2*

71.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Halt1: single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2: single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Single interrupt for INTC to interrupt a CPU: de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin: output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source: Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals): four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

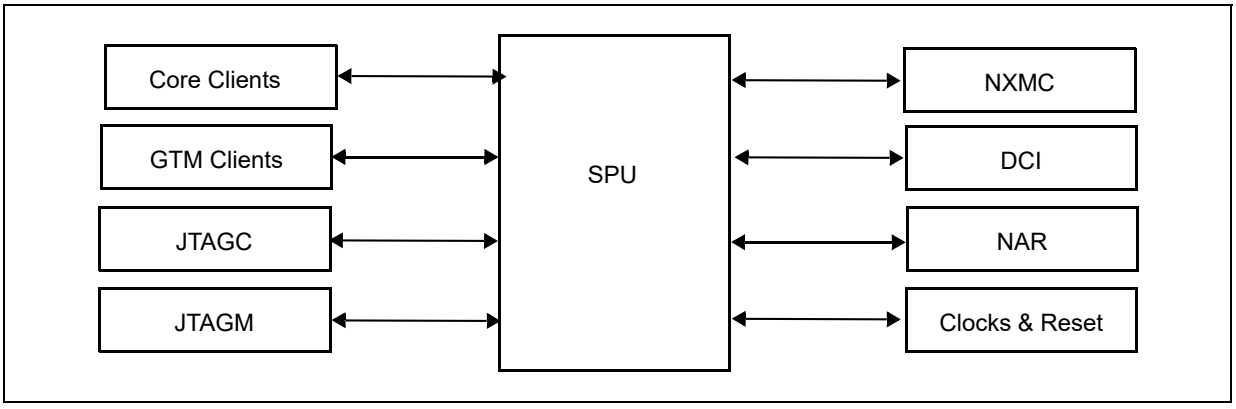
In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

71.3 Operation mode

71.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:



- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

71.4 SPU module interface

The SPU is connected to many clients such as the cores, GTM, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 1944*.

Figure 1944. SPU module interface

71.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 1890 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x01–0x49) registers is 4'h3.
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x01–0x72) is 4'h2.

71.5.1 Registers description

71.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 1982*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

71.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 1945 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see Calibration and Debug (or Debug and Trace) chapter that describes how the modules are configured.

24:31 CPU2	CPU2 Priority Interrupt Selection

71.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 71.5.1.1: Level1 input Mux configurations registers*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 1961* for State0. Similar logic is provided for States 1 to 7.

Figure 1961. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

71.5.1.2.1 Level2 Mux state n selection 0 (L2nSEL0)

71.5.1.3 Sequence unit registers

71.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 1966* shows the format of the IOICn register where the state number, n = 0 to 7.

Offset: 0x37 n*0x1 (n=0 to 7) Access: Read/Write

71.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 1967* shows the format of the SCTRL register.

Table 1904. SCTRL register field descriptions (continued)

Field	Description
25:27 S1ST2	Sequence 1 End State 000 State 0 is the Stop state for sequence 1 001 State 1 is the Stop state for sequence 1 010 State 2 is the Stop state for sequence 1 011 State 3 is the Stop state for sequence 1 100 State 4 is the Stop state for sequence 1 101 State 5 is the Stop state for sequence 1 110 State 6 is the Stop state for sequence 1 111 State 7 is the Stop state for sequence 1
28:30 S1ST1	Sequence 1 Start State 000 State 0 (Always)
31 S1ST0	Sequence1 Enable/Disable(2) Once enabled, this bit is disabled at the end of the Sequence 1. 0 Sequence 1 is disabled 1 Sequence 1 is enabled

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.
2. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.

71.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 1968 shows the format of the SnGC register where the state number, n = 0 to 7.

Offset: 0x40 +n*0x1 (n= 0 to 7) Access: Read/Write

Figure 1968. State n goto control (SnGC)

The SnGC register fields are described in *Table 1905*.

Table 1905. SnGC register field descriptions

Field	Description
24:26 NF	Next State on False Condition Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
27 FE	GOTO Control of State Under False Condition Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5]. If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition. 0 Disable Goto control 1 Enable Goto control
28:30 NT	Next State on True Condition Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
31 TE	GoTo Control of State Under True Condition Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition. 0 Disable Goto control 1 Enable Goto control

71.5.1.4 SLU status register (SS)

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. *Figure 1969* shows the format of the SS register.

Figure 1970. SPU enable register (SE)

The SE register fields are described in *Table 1907*.

Table 1907. SE register field descriptions

Field	Description
30 DIV	Div Option Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required
31 SED	SPU Enable/Disable This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled

Note: Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

71.5.1.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

71.5.1.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example, if there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

71.5.1.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in *Section 71.2*.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in *Section 71.2*, becomes redundant with Div4 option.

71.5.1.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 71.2*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 1908* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 1908. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment	
00	Client group	00000	CPU0	0000	No action	—	0=Stop 1=Start
		00001	CPU1	0001	DTM/gtm_gen0 trace	Valid for Cores, AHB, GTM and trace group actions	
		00010	CPU2	0010	OTM/gtm_gen1 trace

				1010	Core INTR	—	
				1011–1111	Reserved	—	—
11	Reserved						

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

71.5.1.7.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a true condition of every state. All the possible actions and their encoding are listed in *Table 1908*. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

Figure 1971 shows the format of the SnTA0 register where the state number, n = 0 to 7.

71.5.1.7.3 State n false action 0 (SnFA0)

The SPU can be programmed to enable up to four different actions against a false condition of every state. All the possible actions and their encoding are listed in *Table 1908*. A total of 12 bits are needed to code every action. The first two actions for a false condition are defined in SnFA0 and the next two actions are defined in SnFA1. *Figure 1973* shows the format of the SnFA0 register where the state number, n = 0 to 7.

71.5.1.7.5 Trace group configuration registers (DTMTGC, PTMTGC, OTMTGC, WTMTGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace: clients are configured with the DTM trace group configuration (DTMTGC) register
- PTM trace: clients are configured with the PTM trace group configuration (PTMTGC) register
- OTM trace: clients are configured with the OTM trace group configuration (OTMTGC) register
- WTM trace: clients are configured with the WTM trace group configuration (WTMTGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 1975 shows the format of the trace group configuration registers.

Offset: 0x21 (DTMTGC)
0x22 (PTMTGC)

71.5.1.7.6 Interrupt status (INTS)

The status of the external interrupt request to the processor core through the JTAGM is registered in the Interrupt status (INTS) register. This status bit is cleared when the acknowledge is received from the JTAGM. *Figure 1976* shows the format of the INTS register.

Offset: 0x25 Access: Read/Write

71.5.1.8 Counters control n registers (CCTRLn)

There are 16 configurable counters/timers in the SPU. Configuration control of these counters is defined in the counter control registers. *Figure 1977* shows the format of the CCTRLn registers where the counter number, n = 0 to 15.

Offset: 0x26 + n*0x1 (n = 0 to 15) Access: Read/Write

25:27 PRESCALING	Prescaling Divides the timer clock by a defined value. 000 No scaling, divide by 1 001 Divide by 4 010 Divide by 16 011 Divide by 32 100 Reserved 101 Reserved 110 Reserved 111 Reserved

Table 1915. CCTRLn register field descriptions (continued)

Field	Description
29 COUNT_INCR	Count Increment 0 Increment the counter based on the actions generated from the sequences 1 Increment the counter based on the PMC input. The mapping of the PMC inputs with the counters is shown in *Figure 1989*.
30 MODE	Mode Select Select counter or timer operation. 0 Counter 1 Timer
31 ENABLE	Enable 0 Counter disabled 1 Counter enabled

71.5.1.9 Counters compare n registers (CCMPn)

A 32-bit comparator value can be programmed for each of the counters. This value is compared with the corresponding counter/timer to generate an event for the SPU. *Figure 1978* shows the format of the CCMPn registers where the counter number, n = 0 to 15.

Offset: 0x36 + n*0x1 (n = 0 to 15) Access: Read/Write

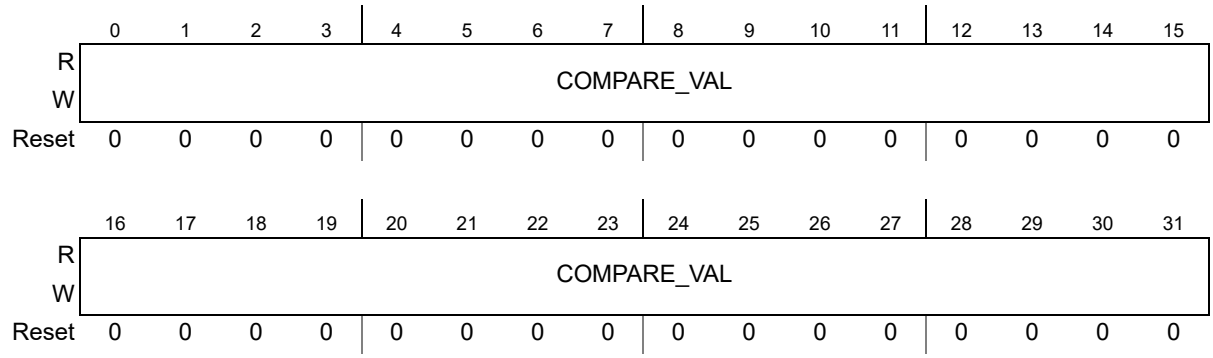

Figure 1978. Counters compare n registers (CCMPn)

The CCMPn register fields are described in *Table 1916*.

Table 1916. CCMPn register field descriptions

Field	Description
0:31 COMPARE_VAL	Compare value This value is compared with the corresponding counter/timer value to generate an event for the SPU.

71.5.1.10 Status registers

71.5.1.10.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. *Figure 1979* shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in *Table 1917*.

Note: Counter compare values and other settings are not recommended to change dynamically, so w1c on CCOMS should be performed in either condition:

- *Counter is in disabled state (ENABLE bit of CCTRLn set to 0)*
- *SW-Reset bit (SW_RESET) is set*

Offset: 0x46 Access: Read/Write

71.5.1.10.3 Counter capture status (CCAPS)

Whenever a counter value is captured, the corresponding capture status register bit for that counter is set. If the counter capture value causes a FIFO overflow, the captured value is lost and the status bit is not set. The bits in this register can be cleared by writing a 1 to them. *Figure 1981* shows the format of the CCAPS register.

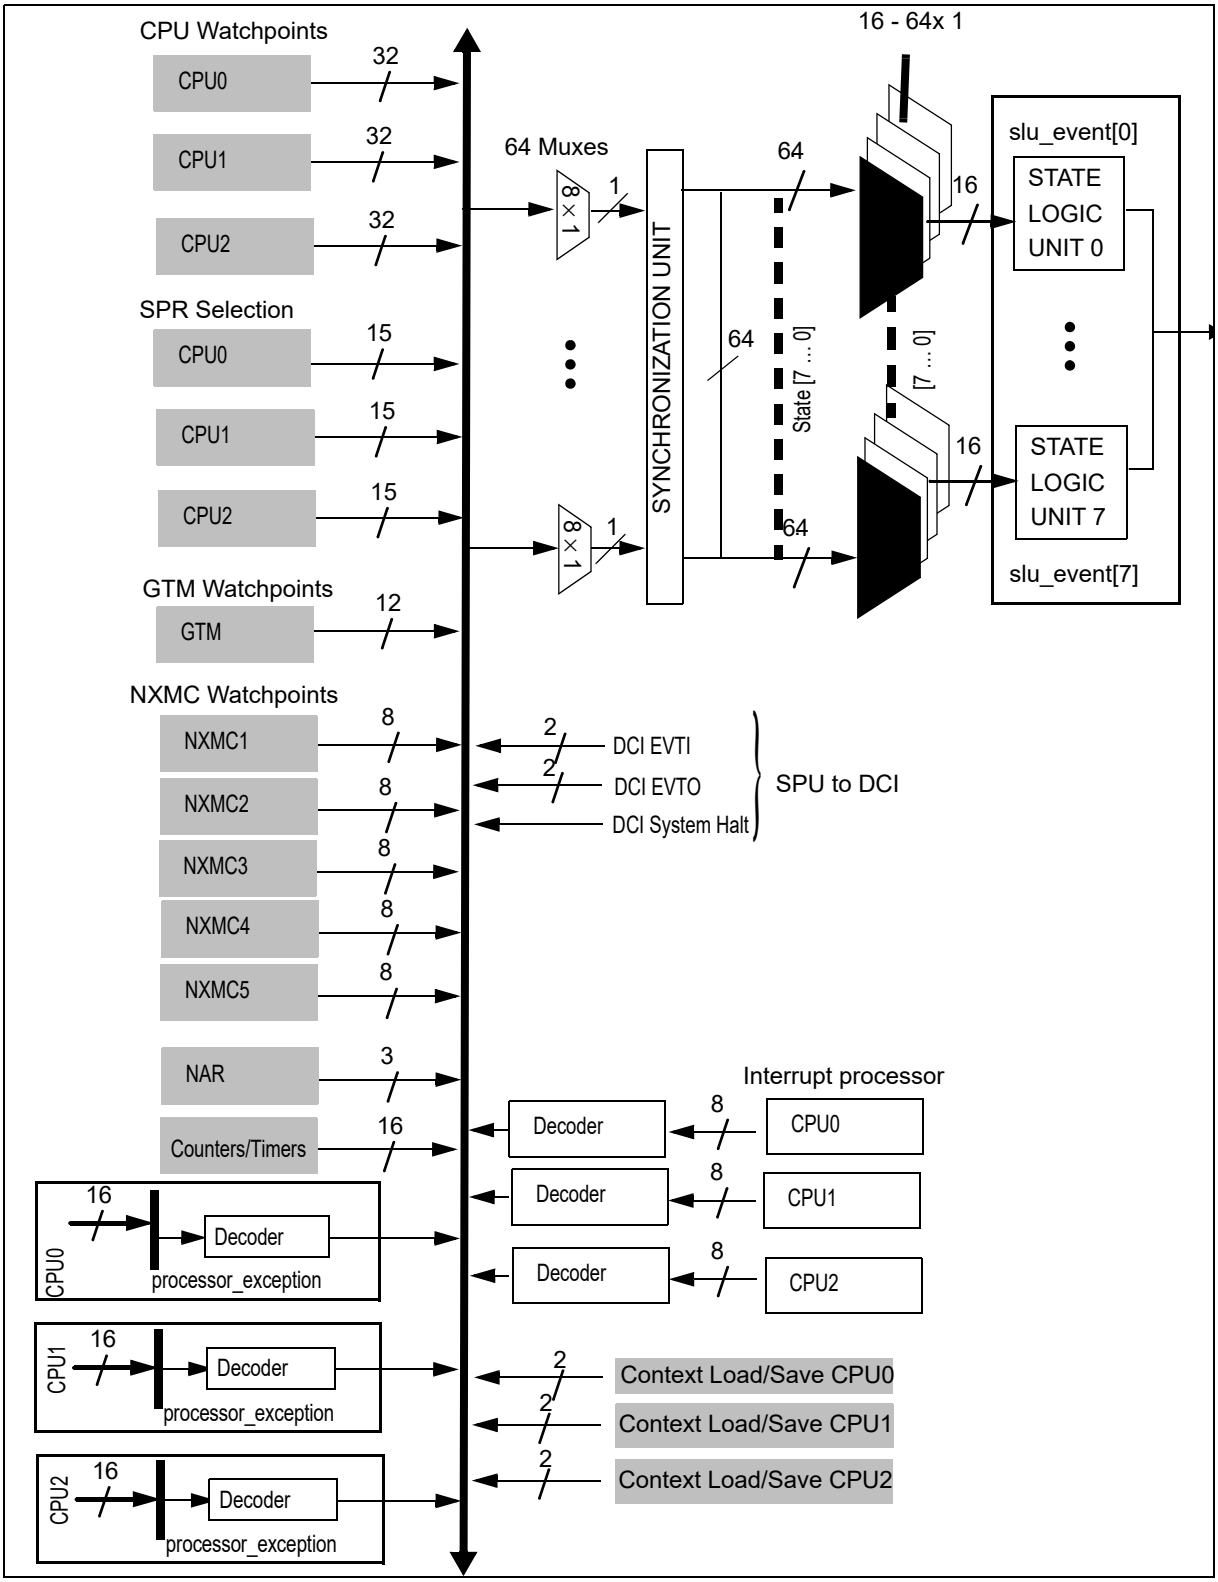
71.6 Functional description



71.6.1 Input Mux unit

The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two levels of muxing both of which are shown in *Figure 1982*.

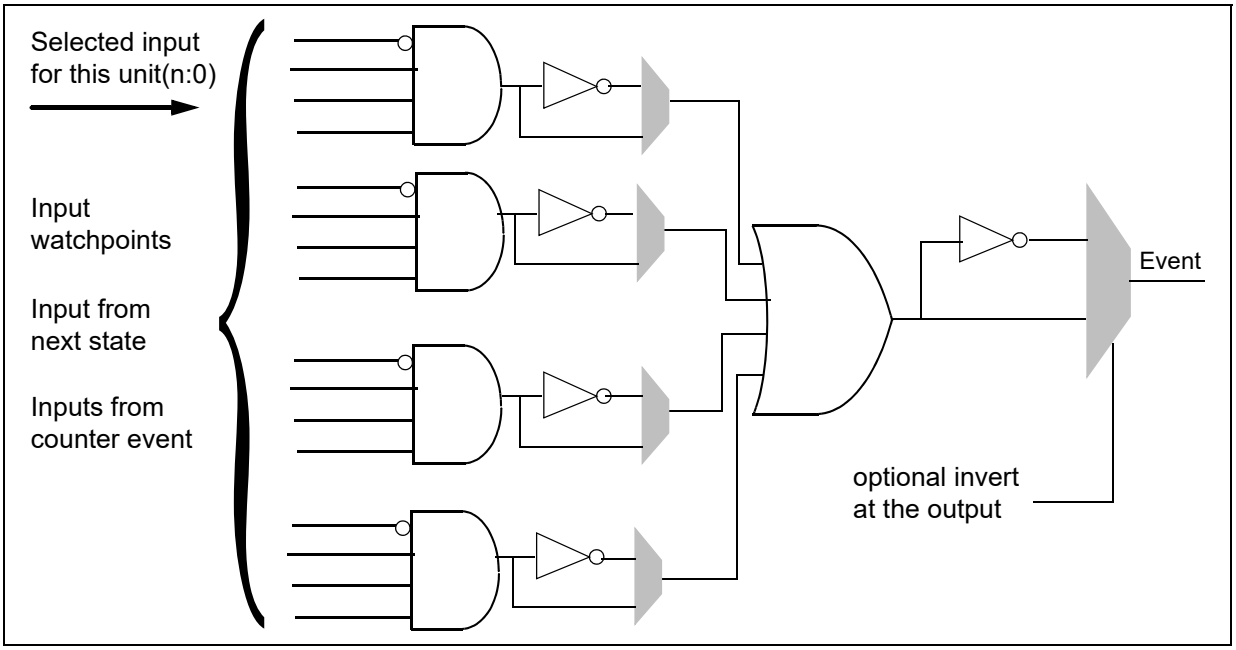
- Level 1 Muxing: At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 1982*.
- Level 2 Muxing: At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.
  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be taken to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16×8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 1982*.

Figure 1982. Input Mux unit block diagram

71.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input condition as shown in *Table 1920*. The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0 to 2) registers as shown in *Table 1920*.

Table 1920. Processor exception processing conditions



CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input: autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input: autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input: vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input: vectored

71.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 1983*.

Figure 1983. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

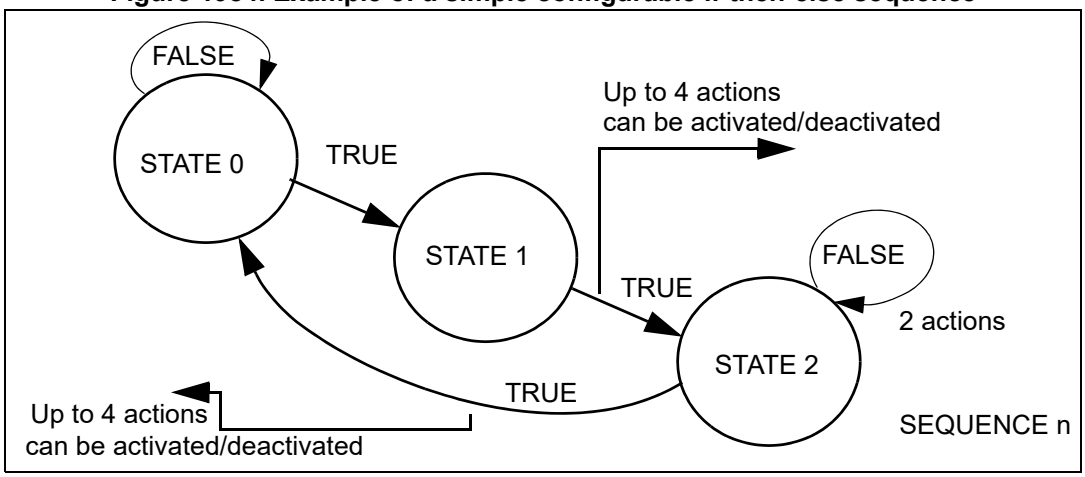
An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

71.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.



For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 1984*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic.

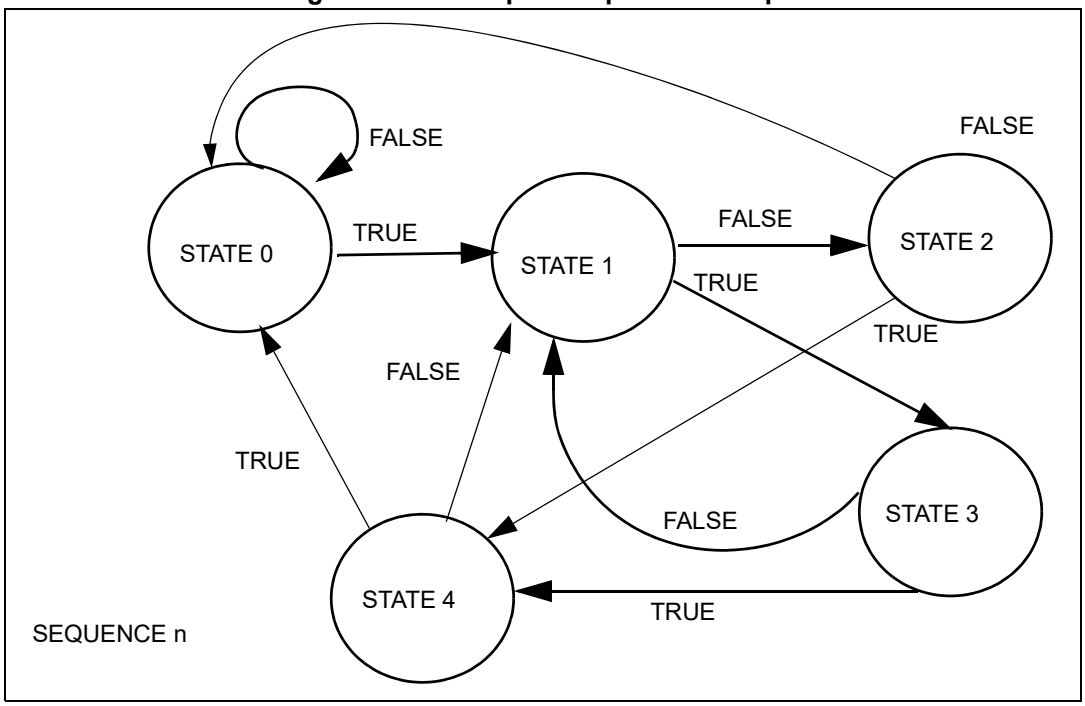


Figure 1984. Example of a simple configurable if-then-else sequence

71.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 1985*.

Figure 1985. Complex sequence example

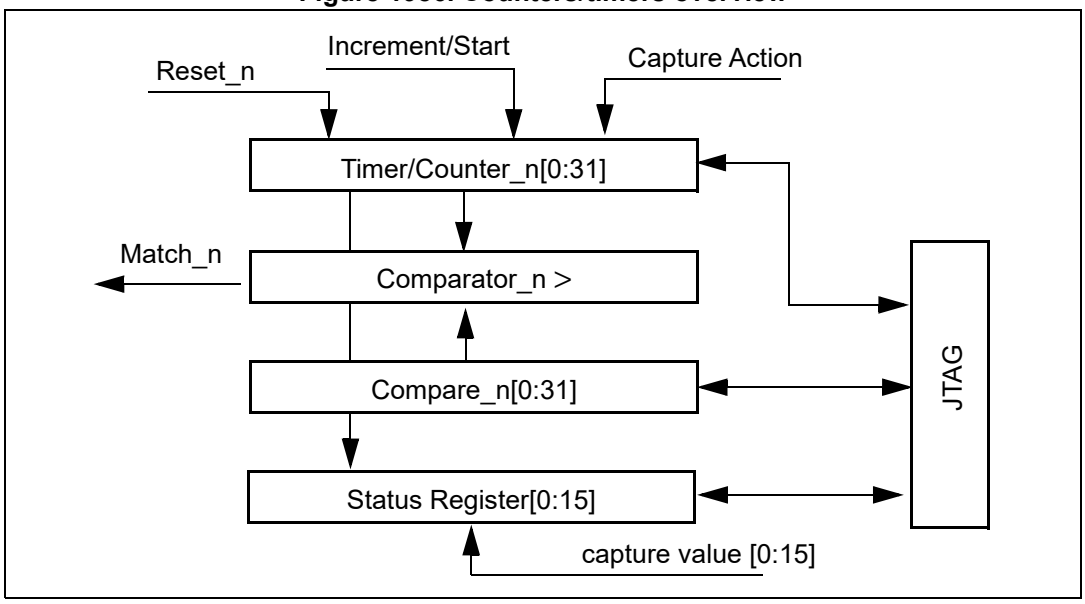
71.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurrence of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

71.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:



- States: each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register
- Sequence status: each sequence has a field indicating the active state of the state machine. This is a read only field

71.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 1986*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

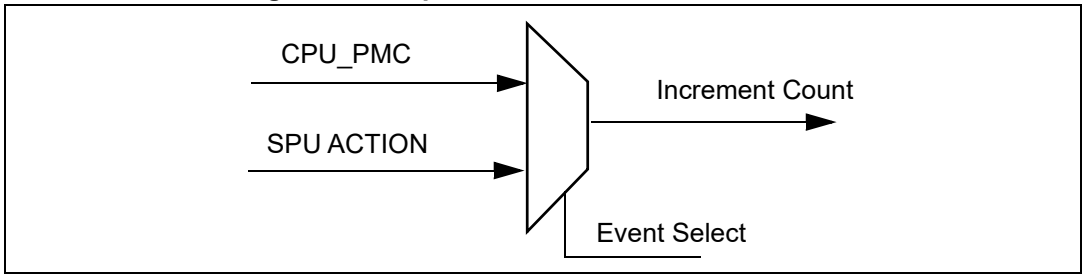
Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 1986. Counters/timers overview

71.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are type write 1 to clear (W1C).

There are two classes of signals, actions and events:



- Actions: each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.
- Event: on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

71.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 1987*. These inputs include signals from the primary SPU muxes or SPU events of counters.

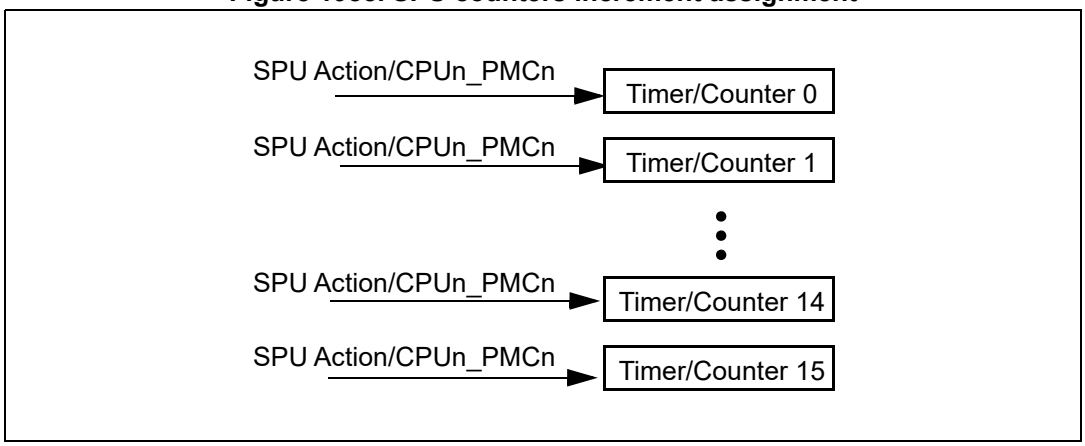


Figure 1987. nput selection for count increment

71.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 1988*.

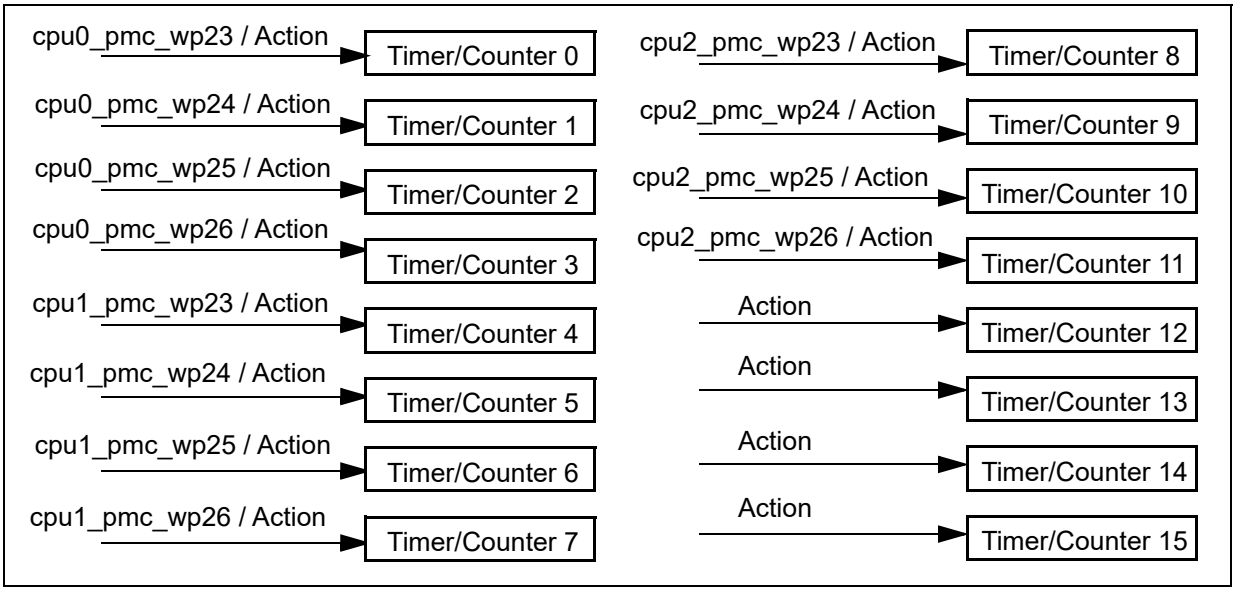

Figure 1988. SPU counters increment assignment

71.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 1989*.

Figure 1989. CPU PMC mapping inside the SPU unit

71.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 71.2*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers**.** Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

71.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers, defined in *Table 1913*, are available where the user can group the different traces from same or different clients.

71.6.8 Format for CKSRC & CKDATA Values

The format of the CKSRC is defined for the SPU Peripheral (as In-Circuit trace client):

Table 1921. CKSRC format

ICT CLIENTS	CKSRC Value
SPU Counter Trace Client	b00_0000
Reserved	b00_0001–b11_1111

The format for the CKDATA field for the SPU Counter trace client is:

Table 1922. CKDATA format

CKDATA	
CKDATA[CTR_Index]	CKDATA[CTR_VALUE]
4 bits	32-bits

72 JTAG Master (JTAGM)

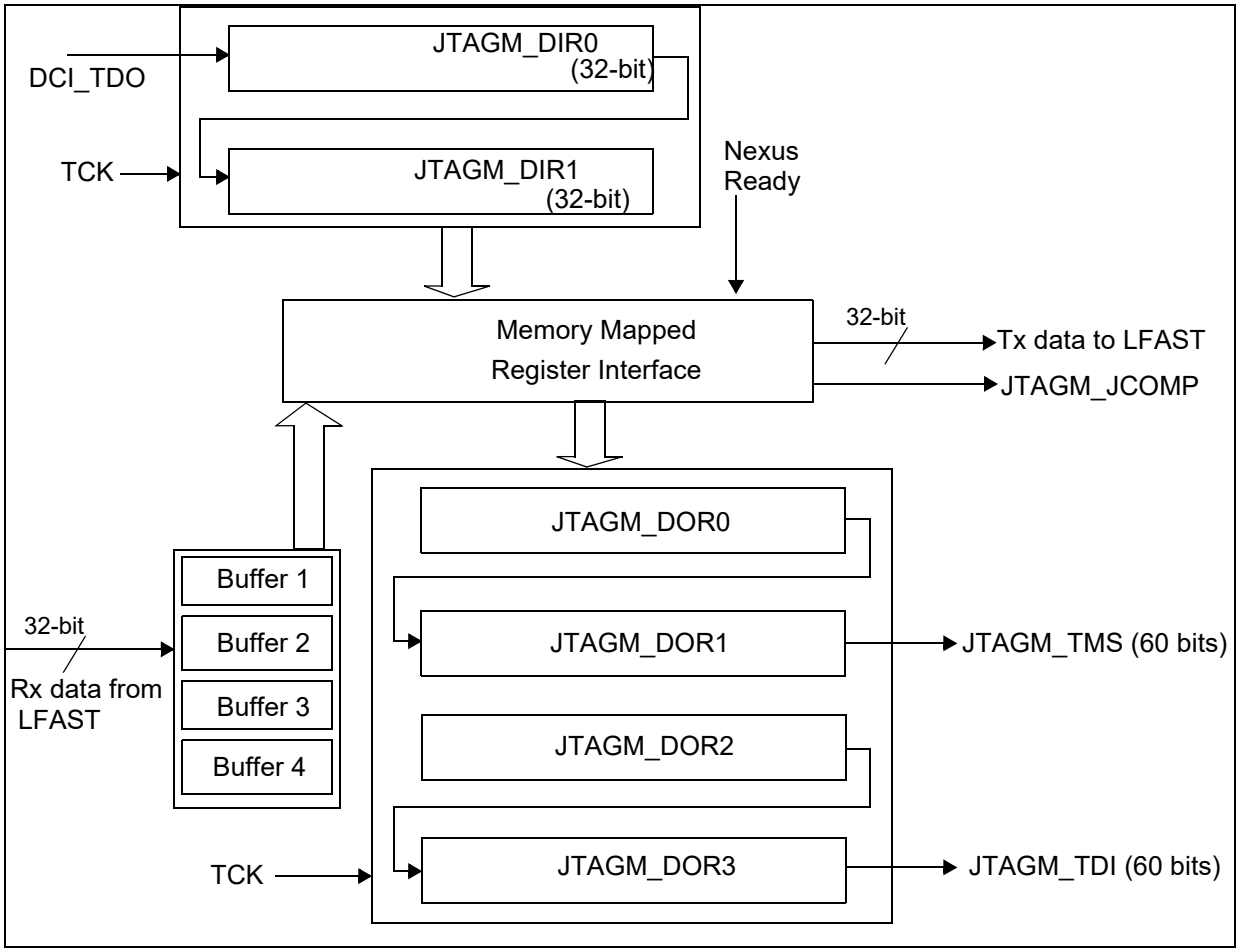
72.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

72.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RXCRC receive register
- Two data input registers

All these registers, described in detail in *Section 72.4*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 1990 shows the block diagram of the JTAGM.

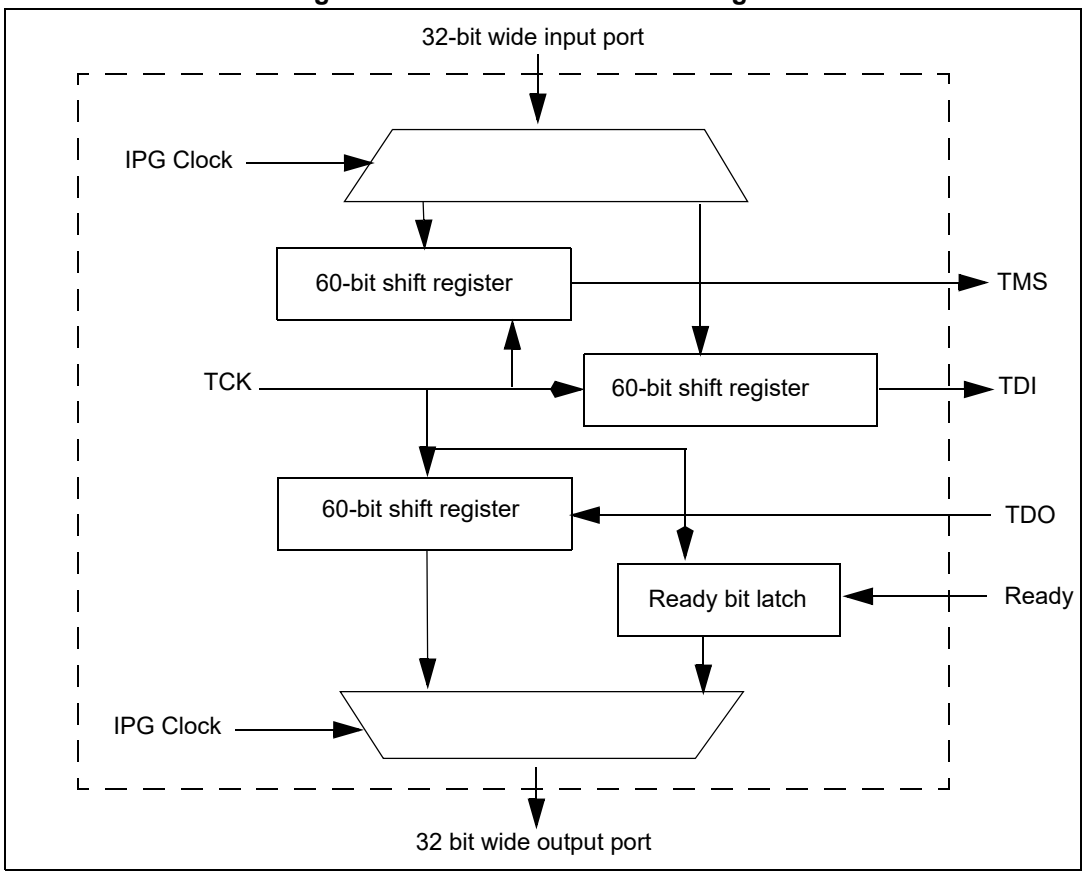
Figure 1990. JTAGM block diagram

72.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

72.2 Functional description



72.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 1991 shows the flow diagram of the LFAST to DCI connection.

Figure 1991. LFAST-to-DCI flow diagram

72.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

72.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

72.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

72.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

72.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has

toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

72.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

72.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

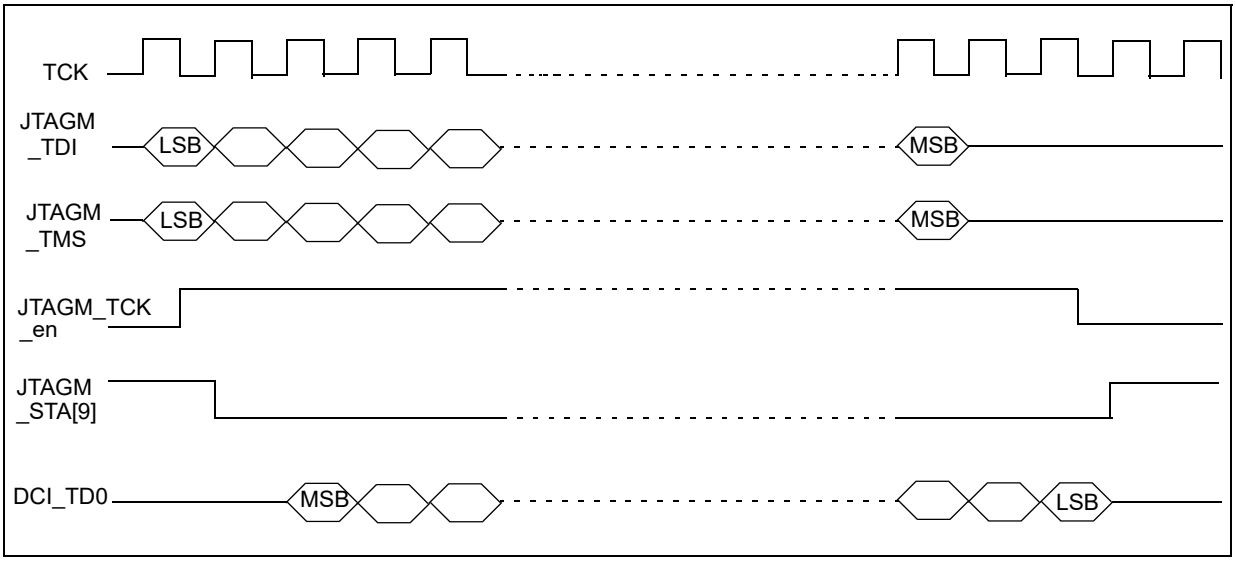
Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.

72.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 72.2.5.1: Status register*

ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written
- 32-bit value to be written to the configuration register
- 24-bit mask of which bits within the status register should be written
- 8 bits of zero-padding
- 24 bits of data to be written to the status register
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data)



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

72.2.8 JTAGM to DCI serial interface

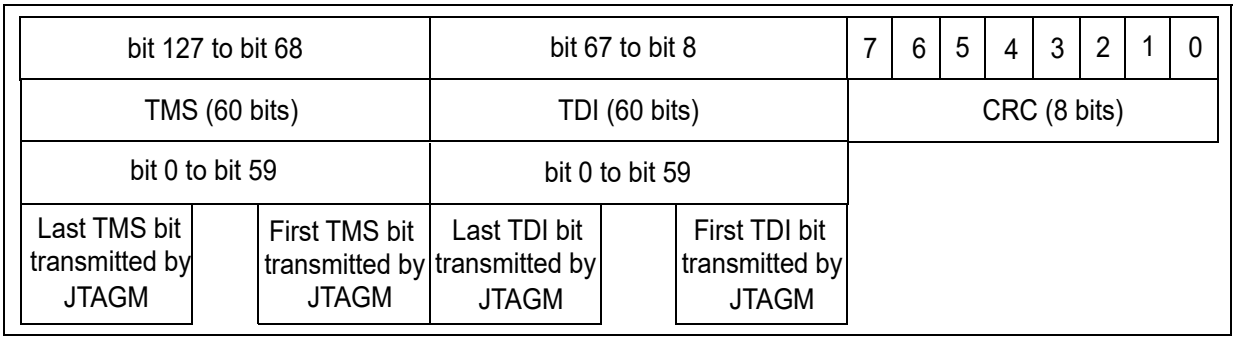
Figure 1992 shows the data transfer timings between JTAGM and DCI.

Figure 1992. JTAGM to DCI serial interface diagram

72.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 1993 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 1993. Bit ordering for LFAST to JTAGM transfer



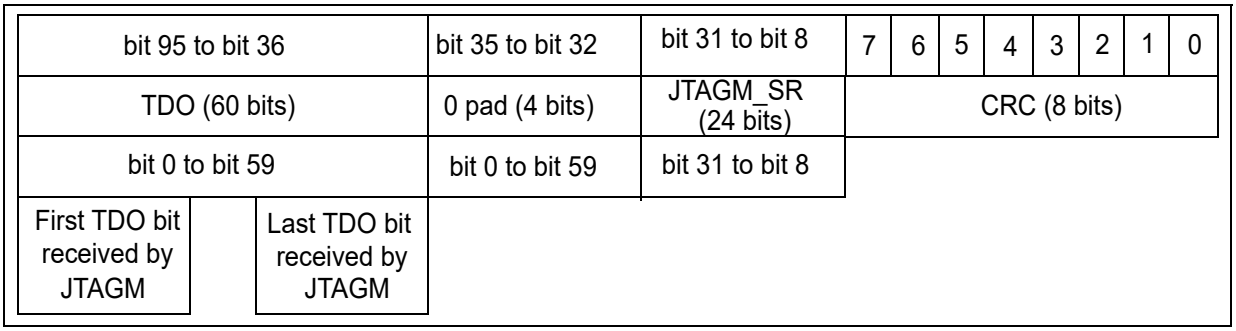


Figure 1994 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 1994. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 1994*).

72.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

72.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

72.4 Memory map and register definition

Table 1923 contains the memory map of the JTAGM registers.

Table 1923. Memory map

Offset	Register	Location
0x00	Module Configuration Register (JTAGM_MCR)	*Section 72.4.1.1*

Figure 1997. JTAGM_SR register in SW mode

The JTAGM_SR register is described in *Table 1925*.

Table 1925. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO0}}$ 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO0}}$

Table 1925. JTAGM_SR register field descriptions (continued)

Field	Description
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to ‘1’ when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode(when DTM =0) , this bit has no effect and acts as a “dont care” . This bit should not be used by the application in the LFAST mode
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

0:27 TDO_HIGH	Higher word of data received on TDO, bits 32–59

73 Debug Zipwire

73.1 Overview

The Debug SIPI and Debug LFAST modules work together as a single unit called Debug Zipwire. The Debug LFAST portion of the two modules allows for high speed debugging capabilities.

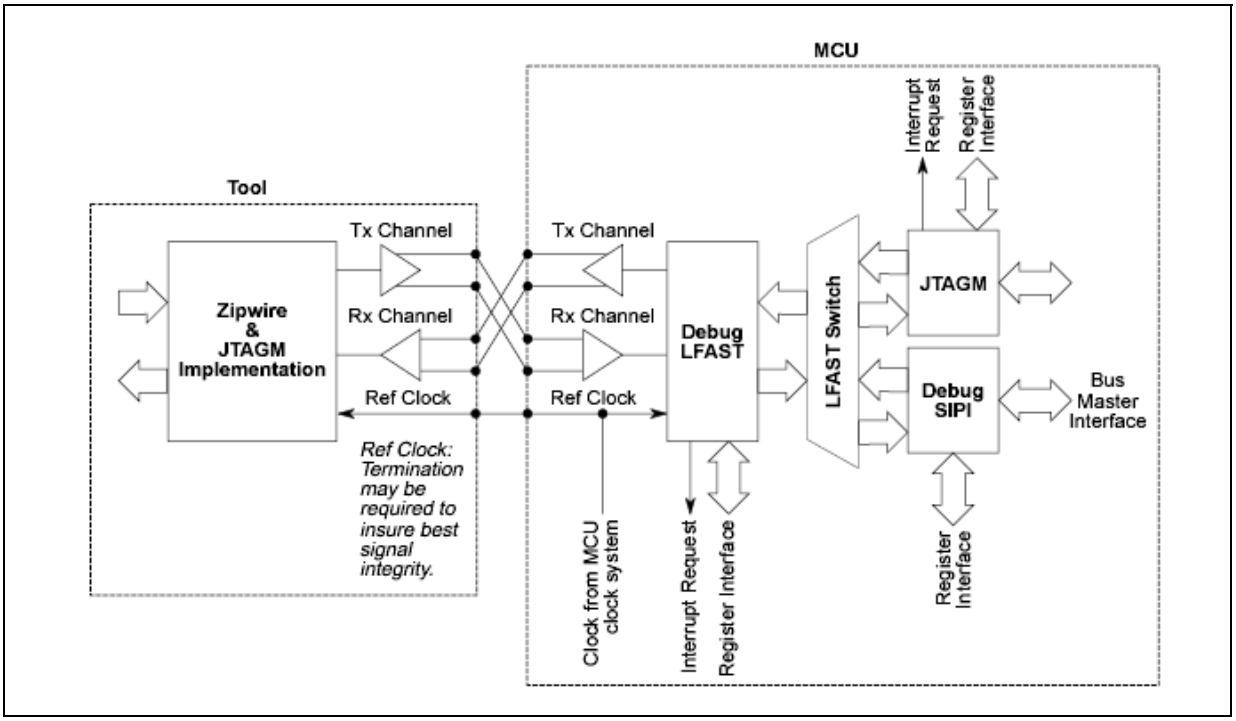
The Debug LFAST operates in slave mode configuration. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

73.2 Debug Zipwire Overview

Dedicated Zipwire functionality is available for debug use allowing support for increased bandwidth read/write operations to the chip memory space performed over the debug interface. This Debug Zipwire function is available on both production and ED devices. The modules used to support Debug Zipwire are the Debug SIPI module, the Debug LFAST module and the LFAST Switch. The Debug Zipwire functionality does not use the LFAST or SIPI modules which support the Zipwire interprocessor bus. The only resource shared between the Debug and interprocessor bus Zipwire interfaces is the use of a single shared LFAST PLL on the Production Device (PD).

The Debug Zipwire interface allows a connected tool to perform 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address in the microcontroller. The Zipwire architecture is fully pipelined and supports multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.The Debug Zipwire interface does not support streaming mode commands.



For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

73.3 Debug Zipwire Block Diagram

Figure 2005 shows a tool connected to the MCU via five wires. These five pins are shared with the standard JTAG pins, but for simplicity this is not shown in the diagram. The MCU Debug Zipwire only supports the Target mode of Zipwire. The Debug SIPI Bus Master Interface is used for all Target Mode transactions. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST Reference clock coming from the MCU clock system.

Figure 2005. Debug Zipwire connection diagram

73.4 Architecture

Debug Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200 mV swing.The pads are shared with JTAG signals.

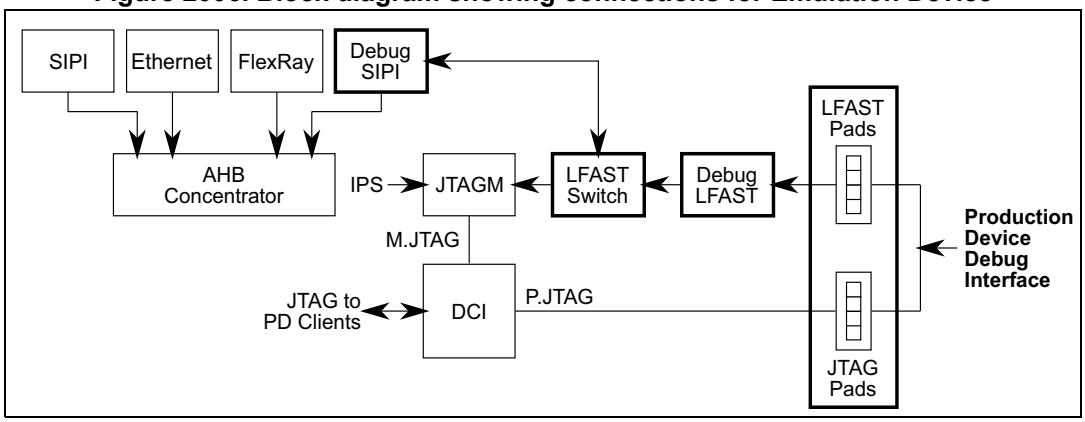
The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). Debug SIPI runs on top of Debug LFAST and is fully encapsulated within the Debug LFAST payload. Debug SIPI uses three fixed sizes of Debug LFAST payload in Debug Zipwire:

- 32-bit
- 64-bit
- 96-bit

The SIPI protocol implements a suite of commands initiated by a tool, for reading and writing any 32-bit address location in a connected MCU. Only the tool can initiate commands. The MCU only responds to commands initiated by the tool and never creates any unsolicited messages.



For Debug Zipwire, a reduced version of the SIPI module called Debug SIPI is used. The Debug SIPI module implements only the recipient part of the SIPI protocol (called Target

mode). The Debug SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating tool, Debug SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

73.5 Debug Zipwire implementation

Figure 2006 shows the modules on the production device which support the Debug Zipwire function, along with their interconnections to the debug interface signals.

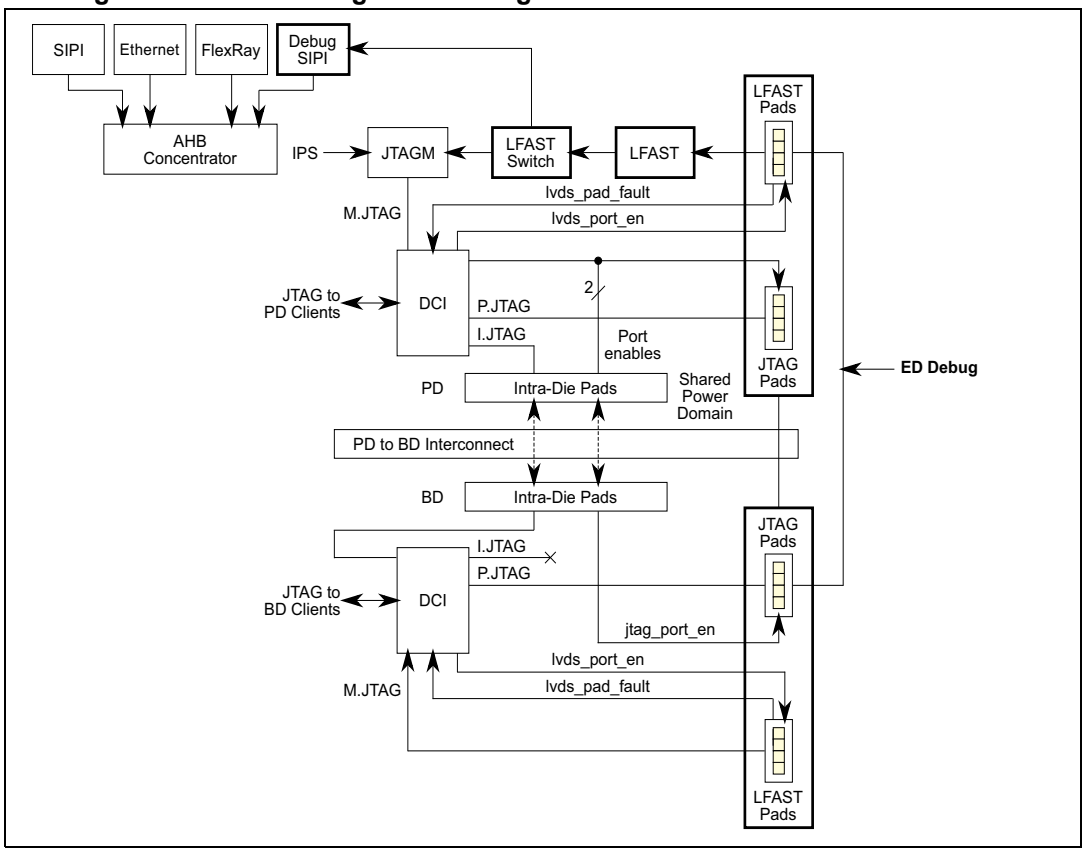


Figure 2006. Block diagram showing connections for Emulation Device

Internal connections to other debug modules which are used to support other debug interface protocols such as JTAG and JTAG over LFAST are also shown. The Debug SIPI module is connected to the Debug LFAST module via an LFAST switch module, which controls routing of debug LFAST traffic to either the Debug SIPI or the JTAGM module.

Figure 2007 shows the equivalent connections for ED devices utilizing the LFAST switch.

Figure 2007. Block diagram showing connections for the Emulation Device

73.6 LFAST clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data. This PLL is used to support both interprocessor bus Zipwire and Debug Zipwire so care must be taken to ensure that any tool configuration of this resource is compatible with application usage of Interprocessor Bus Zipwire. The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to as the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

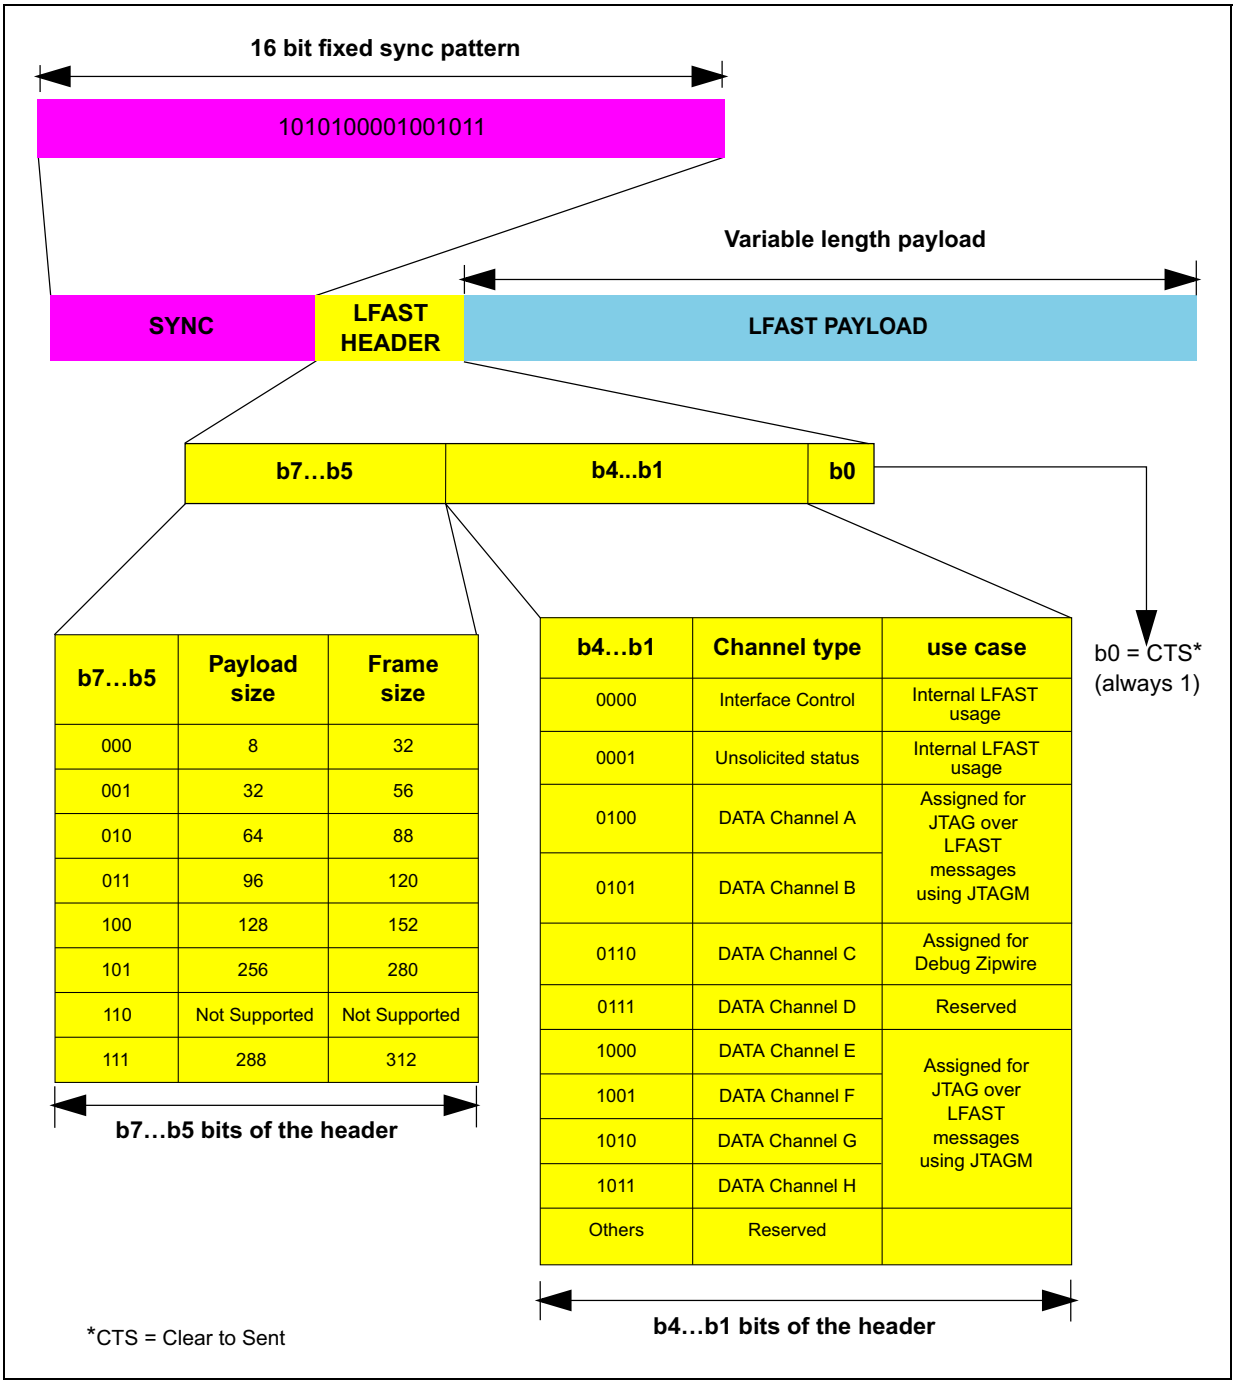
- XOSC
- Output of PLL0 (PLL0:PHI)
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator (XOSC) from one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.



73.7 LFAST switch

Incoming messages on the Debug LFAST interface can be either for JTAG over LFAST use through the JTAGM or debug Zipwire messages. Differentiation of these messages is via use of LFAST channel number. DATA channel C is used to identify high speed Debug SIPI accesses, while JTAG over LFAST messages are supported using LFAST channels A, B, E, F, G, H as shown in *Figure 2008*

The LFAST SWITCH module is used to direct LFAST messages based on the above scheme, with JTAG over LFAST messages being routed to the JTAGM IP block and debug Zipwire messages being routed to the Debug SIPI block.

The LFAST switch has no accessible registers and requires no user configuration.

Figure 2008. LFAST channel allocation

b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	Not Supported	Not Supported
111	288	312

b4…b1	Channel type	use case
0000	Interface Control	Internal LFAST usage
0001	Unsolicited status	Internal LFAST usage
0100	DATA Channel A	Assigned for JTAG over LFAST messages using JTAGM
0101	DATA Channel B	
0110	DATA Channel C	Assigned for Debug Zipwire
0111	DATA Channel D	Reserved
1000	DATA Channel E	Assigned for JTAG over LFAST messages using JTAGM
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

73.8 Debug SIPI module

The debug SIPI module is used to support high bandwidth read/write accesses over the LFAST debug interface. It is dedicated for debug use and is entirely separate from the SIPI module used to support interprocessor bus zipwire interface.

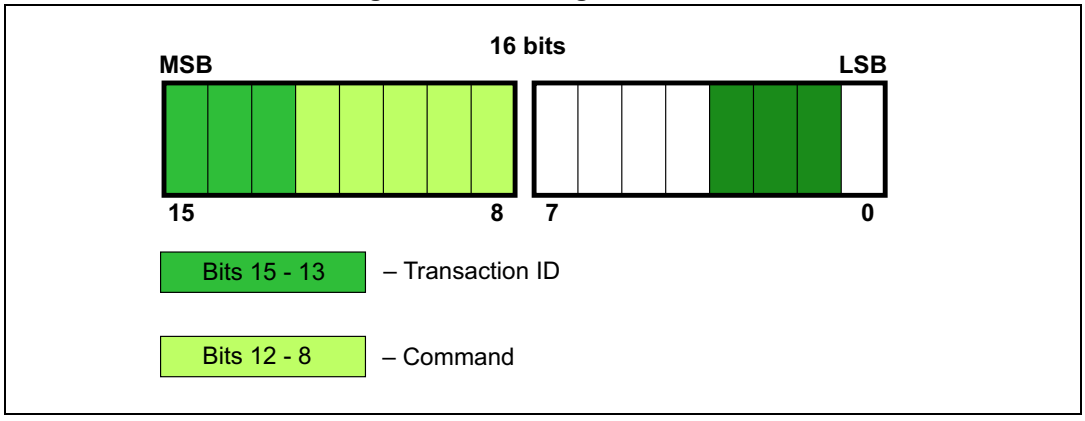
The debug SIPI characteristics are shown in *Table 1933*.

Table 1933. Debug SIPI feature set

Feature	Debug implementation
Number of channels supported	1
Initiator support	No
Target support	Yes
Block transfer support	No
Chip XBAR connection	M1 on XBAR_1

The debug SIPI module issues read and write accesses via the AHB concentrator connected to physical master port 2 on XBAR_1, which is shared with the ethernet, FlexRay and Zipwire SIPI bus masters.

The debug SIPI memory mapped registers are accessible via PBRIDGE_0 (off platform - slot 10) with base address FFFD_4000h.



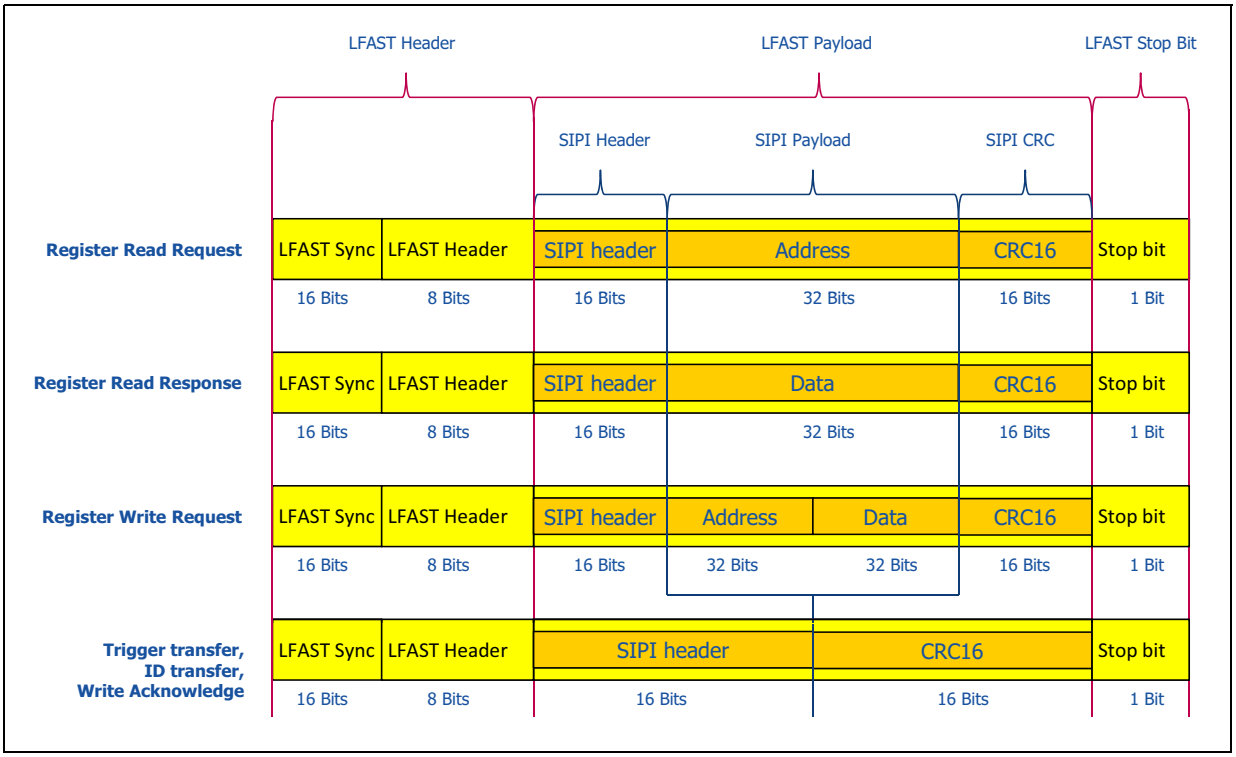
The debug SIPI has Logical Bus Master Assignment of 6 for SMPU0 and SMPU1, an NXMC trace source ID (SRC) of 1101b and a trace master ID (MASTER) = 1011b.

The debug SIPI supports only target mode SIPI operations on a single channel with a reduced command set. Commands supported include read (8/16/32 bits) and write (8/16/32 bits) along with the appropriate responses. Other SIPI commands are unimplemented as noted in *Table 1934*.

The debug SIPI will be capable of:

- receiving a 64-bit command on LFAST channel C and responding with either a 64-bit response or 32-bit error response on LFAST channel C.
- receiving a 96-bit command on LFAST channel C and responding with either a 32-bit acknowledge or 32-bit error response on LFAST channel C.

Figure 2009. Debug SIPI header



Note: See Figure 2008 for the description of bits[7:0]

Table 1934. SIPI header command coding

Bits[12:8] (hex)	Command	Payload Size	Message Direction at chip (SIPI Target)
00	Read 8 bits (Received by SIPI from LFAST)	64	Rx
01	Read 16 bits (Received by SIPI from LFAST)	64	Rx
02	Read 32 Bits (Received by SIPI from LFAST)	64	Rx
03	Reserved	—	—
04	Write 8 bits with ACK (Received by SIPI from LFAST)	96	Rx
05	Write 16 bits with ACK (Received by SIPI from LFAST)	96	Rx
06	Write 32 bits with ACK (Received by SIPI from LFAST)	96	Rx
07	Reserved	—	—
08	ACK – OK (Issued to LFAST from SIPI)	32	Tx
09	ACK – Fault (Issued to LFAST from SIPI)(1)	32	Tx
0A	Read Answer – OK (Issued to LFAST from SIPI)	64	Tx
0B	Reserved	—	—
0C	Unimplemented – Trigger comm and with ACK	32	—
0D	Reserved	—	—
…	…	…	…
11	Reserved	—	—
12	ID Register Read Request	32	Rx
13	Reserved	—	—
…	…	…	…
16	Reserved	—	—
17	Unimplemented – Stream Data with ACK (32 bytes)	288	—
18	Reserved	—	—
…	…	…	…
1F	Reserved	—	—

1. ACK – Fault is also referred to as “NACK” and “ACK Error” in the HSSL/SIPI Interprocessor Bus Protocol Specification.

Figure 2010. Zipwire message format

Note: Identification Register Read is the same as the Register Read response format.

73.8.1 ED power supply constraints

For ED devices the following power domain user constraints must be observed:

- The Vdd_hv_jtag_osc and Vdd_hv_io_bd supplies need to be connected on the application PCB.
- For cold start operation where a tool must be able to communicate via JTAG and read/write ED RAM contents, Vdd_lv_stby, Vdd_hv_jtag_osc and Vdd_hv_io_bd must remain powered.
- For cold start operation where only ED RAM contents have to be maintained, only Vdd_lv_stby must remain powered.

73.9 Debug Zipwire interconnections

Debug LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Connected to the LFAST Switch. This allows LFAST data to be dynamically routed to/from either Debug SIPI for Debug Zipwire operation or JTAGM for JTAG over LFAST operation.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

LFAST Switch has the following connections:

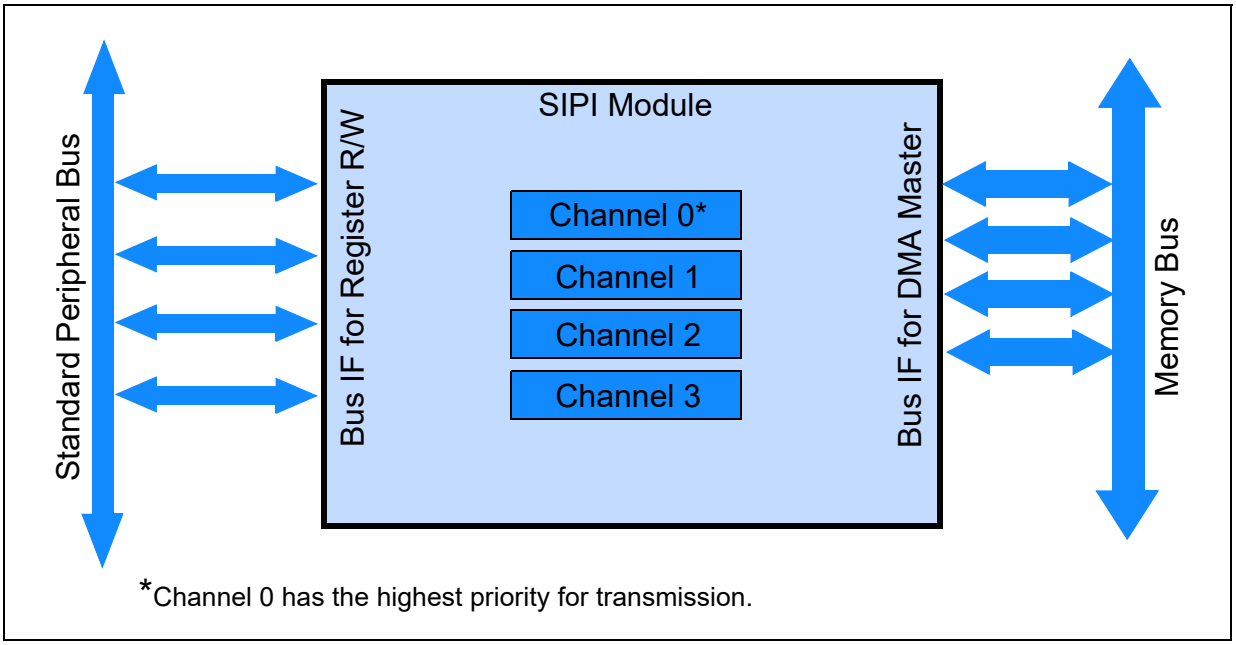
- Tx Data Port/Rx Data port directly connected to Debug SIPI.
- Tx Data Port/Rx Data port directly connected to JTAGM.
- Tx Data Port/Rx Data port directly connected to Debug LFAST.
- LFAST switch has no IPS interface; no registers; no interrupts.

Debug SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers. For the Debug SIPI, a restricted set of registers is implemented. In use, no configuration of these registers is needed from either s/w or a connected tool, as the default settings should be usable for typical operation.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.

74 Debug Serial Interprocessor Interface (SIPI)

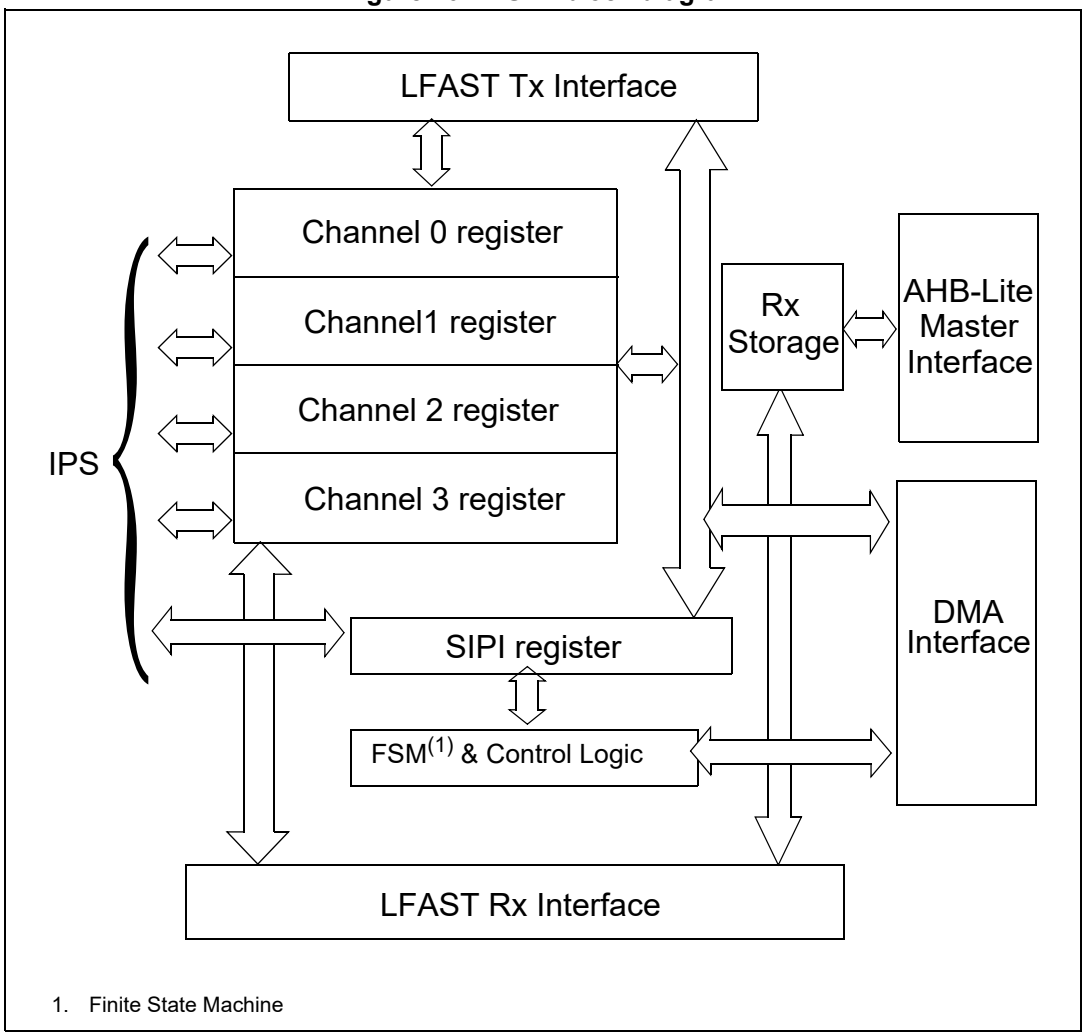
74.1 Introduction



The Debug Serial Interprocessor Interface (SIPI) is an application layer protocol that runs on top of the LFAST module. It is used by the local device to access the shared memory of a remote device. Debug SIPI defines point-to-point full duplex communication between two nodes, where LFAST works as a physical medium of communication between both the devices.

Debug SIPI implements the Target mode of a communication protocol in hardware. Debug SIPI can interpret 'read' and 'write' commands received from an LFAST module and convert them into bus accesses to local memory; then send back to the LFAST module either read data or a write acknowledge response. This provides a mechanism for an external device, such as an external tool, to read and write the address map of the local MCU. The bandwidth of these read/write commands is approximately 10 MBytes/second when accessing random addresses using 32-bit transfers.

74.2 Overview



Debug SIPI can access memory mapped resources directly through its AHB master interface. Debug SIPI has four channels, 0, 1, 2, 3. Payload width for all channels is 32 bits.

Figure 2011. SIPI module

74.3 Debug SIPI block diagram

Figure 2012. SIPI block diagram

1. Finite State Machine

74.4 Feature description

This section describes the features of the Debug SIPI module.

74.4.1 Main features

- Supports 8, 16 and 32-bit read and write commands
- Command/response includes a 16-bit CRC to ensure data integrity
- Command/response include a 2-bit tag to allow tracking of data to commands in a pipelined system
- Command/response include a 3-bit channel identifier to allow multiple Initiators to send commands to a single target node
- Command/response includes a 16-bit header that defines, the function, channel and tag
- Every command generates a response to allow a 'sliding window' flow control protocol to be implemented
- AHB master interface that is used by target node to access memory mapped resources

74.4.2 Standard features

- IPS bus interface
- AHB master interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

74.5 Debug SIPI operation from reset

When the Debug SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

74.6 Functional description

74.6.1 External signals

The Debug SIPI has no chip external signals.

74.6.2 Frame format

All frames have the same general format:

- 16-bit header
- Address, address and data, or nothing
- 16-bit CRC

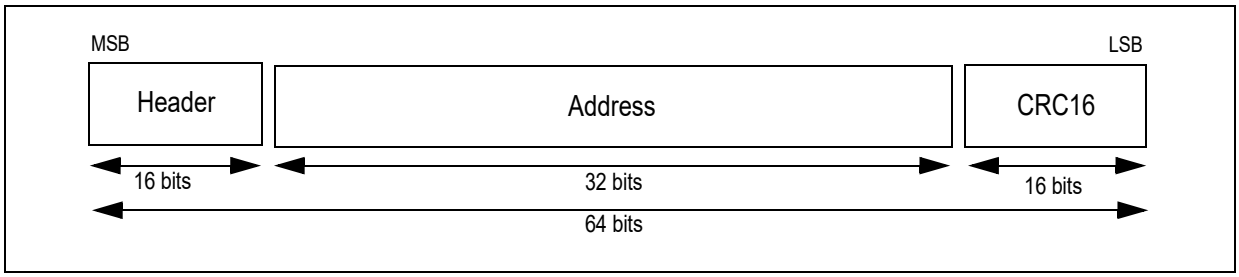
There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

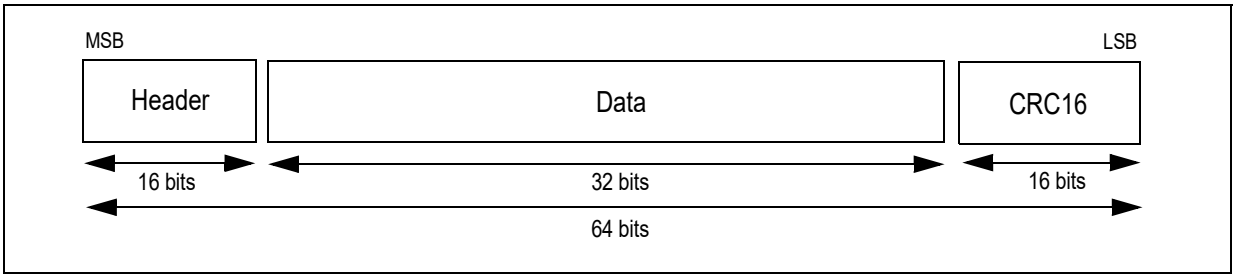
There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID.



The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

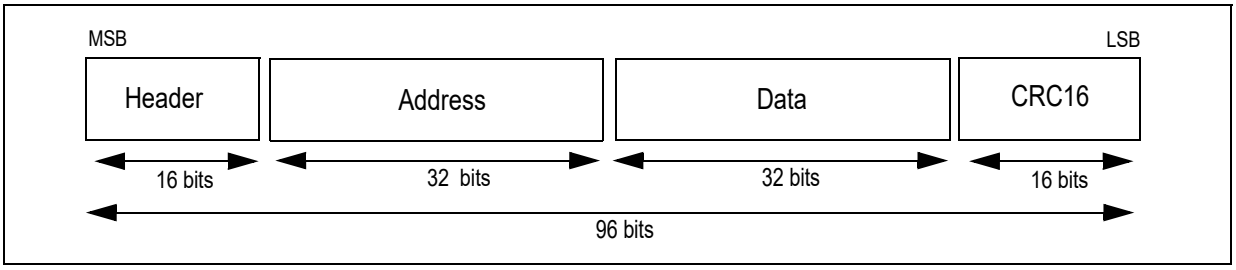
The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

Note: SIPI module architecture is always big endian but the storage in host memory depends on endianness architecture of host memory.



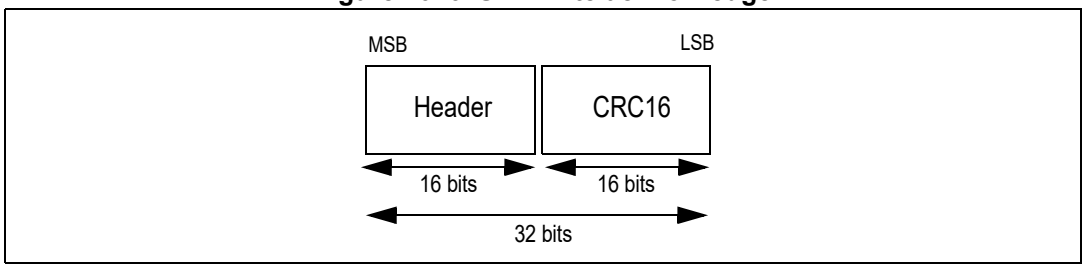
74.6.2.1 Register read request

Figure 2013. SIPI register read request



74.6.2.2 Register read response, ID request response

Figure 2014. SIPI read response



74.6.2.3 Register write request

Figure 2015. SIPI register write request

74.6.2.4 ID transfer, write acknowledge

Figure 2016. SIPI write acknowledge

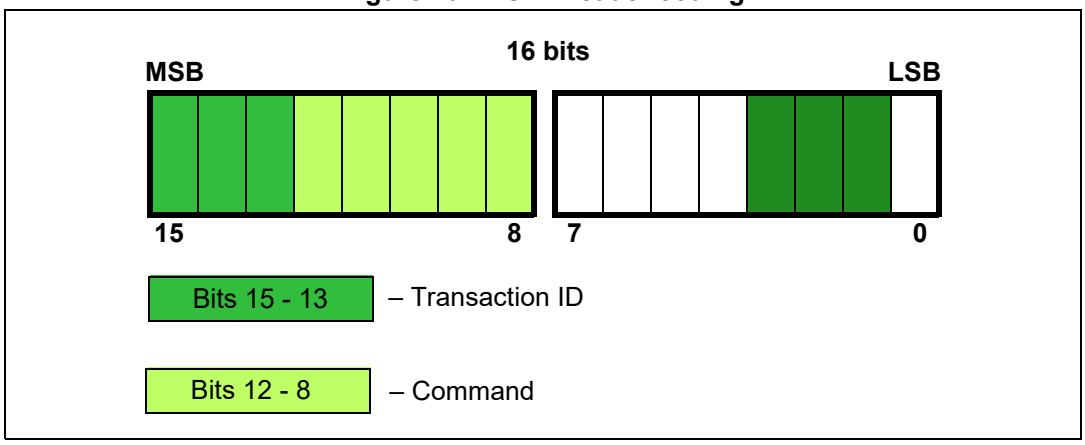
74.6.2.5 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

74.6.2.5.1 Debug SIPI header coding

Figure 2017, *Table 1935*, and *Figure 2018* show how the Debug SIPI header bits are coded.

Figure 2017. SIPI header coding



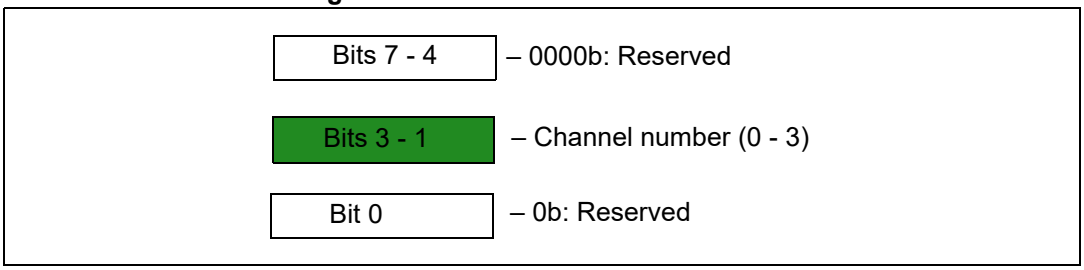


Table 1935 shows the command coding for the bits[12:8] of the header.

Table 1935. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
0x00	Read 8 bits	64
0x01	Read 16 bits	64
0x02	Read 32 Bits	64
0x03	Reserved	—
0x04	Write 8 bits with ACK	96
0x05	Write 16 bits with ACK	96
0x06	Write 32 bits with ACK	96
0x07	Reserved	—

Figure 2018 shows the content of bits[7:0] in the SIPI header.

Figure 2018. SIPI header channel field

74.6.2.6 Address field

The address field is 32 bits wide with the MSB transmitted first.

74.6.2.7 Payload field

Table 1936 shows the payload sizes of LFAST frames.

Table 1936. Payload size of LFAST channel frame

LFAST code for payload size	Debug SIPI Code	LFAST payload size (bits)(1)	LFAST payload size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16
101b	101b	256	32
111b	111b	288	36

1. Only 32, 64, 96 and 288 bits sizes are used for SIPI.

Table 1937 shows the coding of LFAST channel for a given Debug SIPI channel code.

Table 1937. Converted coding of LFAST channel code for Debug SIPI headers

LFAST channel code	Debug SIPI channel code	Data channel(1)
0100b	100b	Data channel A
0101b	101b	Data channel B
0110b	110b	Data channel C
0111b	111b	Data channel D
1000b	000b	Data channel E (not used by Debug SIPI)
1001b	001b	Data channel F (not used by Debug SIPI)
1010b	010b	Data channel G (not used by Debug SIPI)
1011b	011b	Data channel H (not used by Debug SIPI)

1. Debug SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
Debug SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
Debug SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
Debug SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

74.6.2.8 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). The data stream is transmitted with the MSB sent first.

74.6.2.8.1 CRC examples

Example 1 – 32-bit write

- Header = 0x260A
- Address = 0x1122_3344
- Data = 0xCCDD_EEFF
- CRC = 0xBF7D

Example 2 – 32-bit read

- Header = 0x420C
- Address = 0x89AB_CDEF
- CRC = 0x6B80

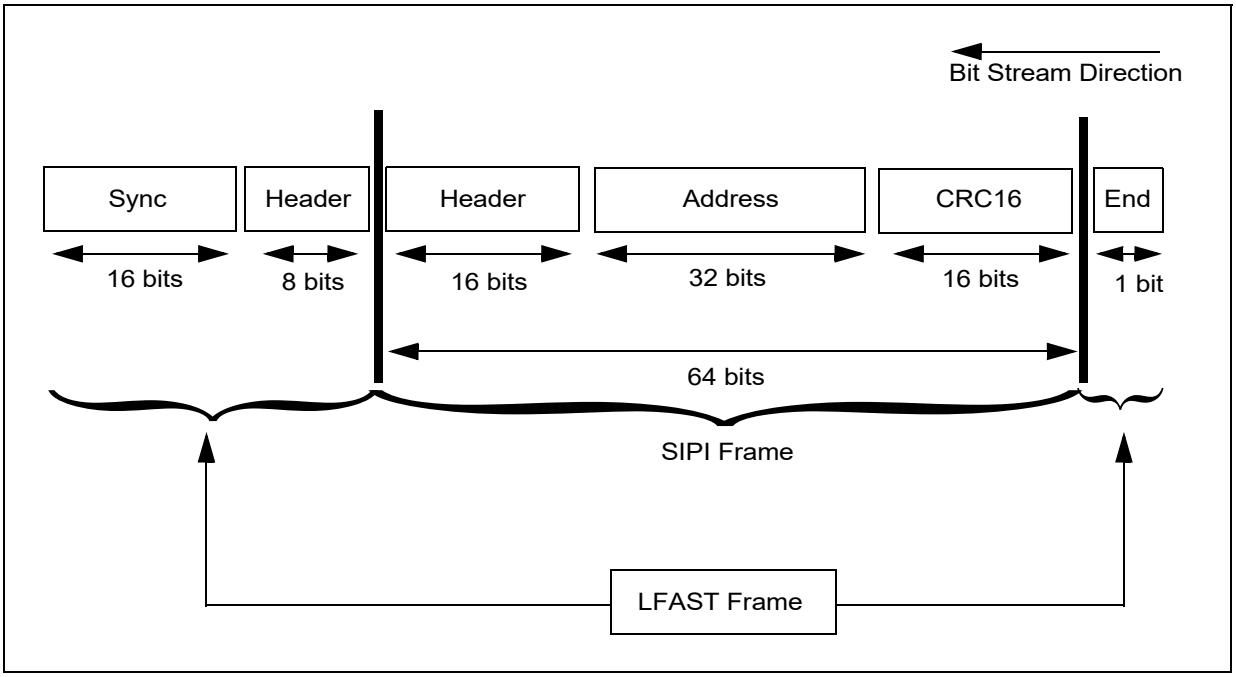
Example 3 – Event command

- Header = 0x6C0E
- CRC = 0xB286

74.7 Transfer types

This section describes the available transfer types of the Debug SIPI module. The Debug SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

74.7.1 Read transfer



A Read transfer can be of two types:

- Read request transfer (at initiator node)
- Read response transfer (at target node)

74.7.1.1 Register read request transfer

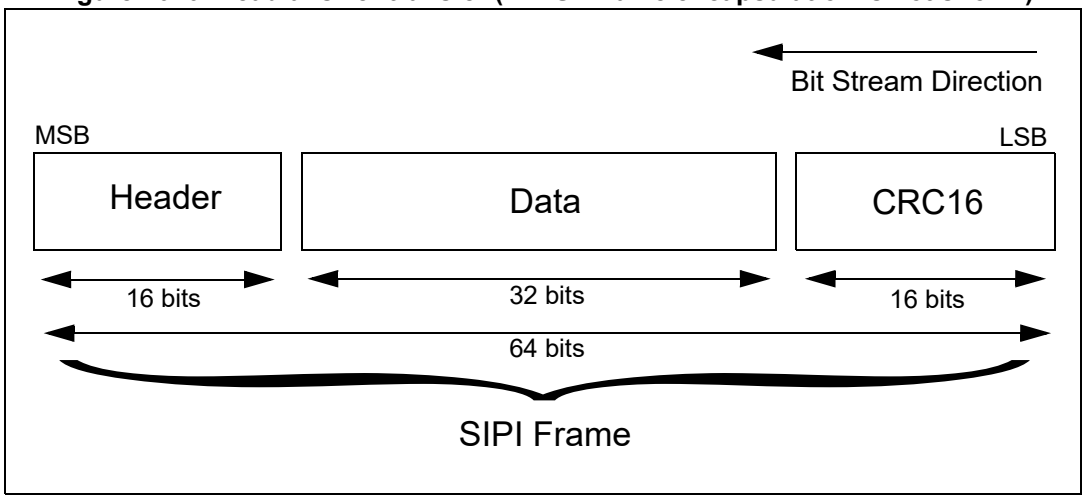
If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in *Figure 2019*.

Figure 2019. Read request transfer (showing LFAST frame encapsulation)

74.7.2 Register read answer transfer

In response to a read request, Debug SIPI sends header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (refer to *Figure 2020*). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (refer to *Figure 2021*).

Figure 2020. Read answer transfer (LFAST frame encapsulation is not shown)



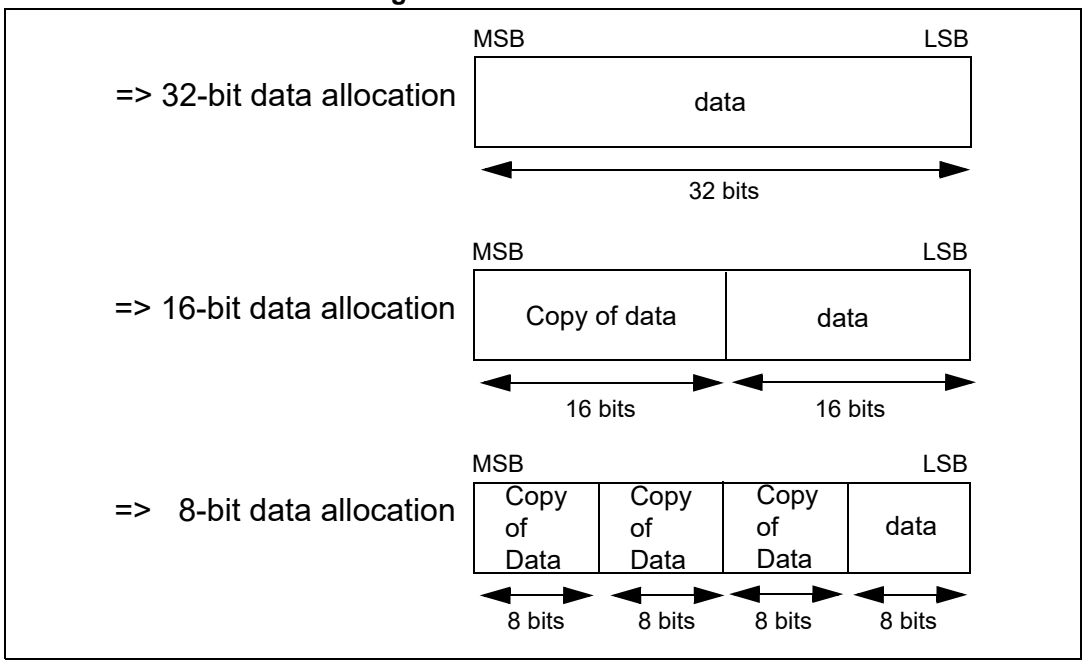


Figure 2021. Data allocation

Note: For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables (big endian):

Bits[1:0]:

- *00: Byte 3 enabled (MSB)*
- *01: Byte 2 enabled*
- *10: Byte 1 enabled*
- *11: Byte 0 enabled (LSB)*

For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable (big endian).

Bit[0]:

- *0: Half-word 1 enabled (MSB)*
- *1: Half-word 0 enabled (LSB)*

Note: Byte Ordering depends from address written in CAR and transfer width:
Example:

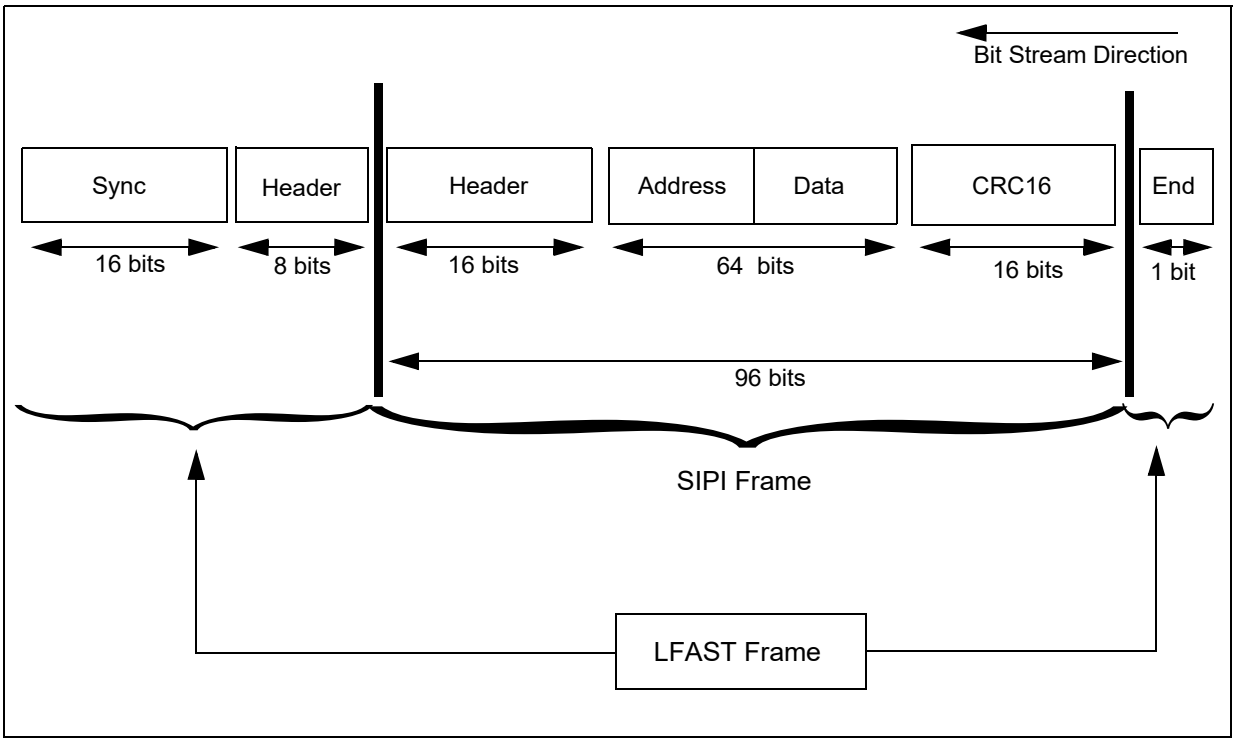
- *CDR content: 0x12345678*
- *CAR content: see table columns*

Table 1938. Target Memory content dependent from CAR content

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
32-bit transfer	0x02040	12	12	12	12
	0x02041	34	34	34	34
	0x02042	56	56	56	56
	0x02043	78	78	78	78

Table 1938. Target Memory content dependent from CAR content (continued)

	Target Memory Byte Address	CAR = 0x02040	CAR = 0x02041	CAR = 0x02042	CAR = 0x02043
16-bit transfer	0x02040	12	56	xx	xx
	0x02041	34	78	xx	xx
	0x02042	xx	xx	12	56
	0x02043	xx	xx	34	78
8-bit transfer	0x02040	12	xx	xx	xx
	0x02041	xx	34	xx	xx
	0x02042	xx	xx	56	xx
	0x02043	xx	xx	xx	78



74.7.3 Register write transfer

Register write transfer can be of type:

- Normal write transfer – channels 0, 1, 2 and 3

A Register write transfer can be done through Normal write transfer - channels 0, 1, 2 and 3 (refer to *Section 74.7.3.1: Normal write transfer*) as shown in *Figure 2022*.

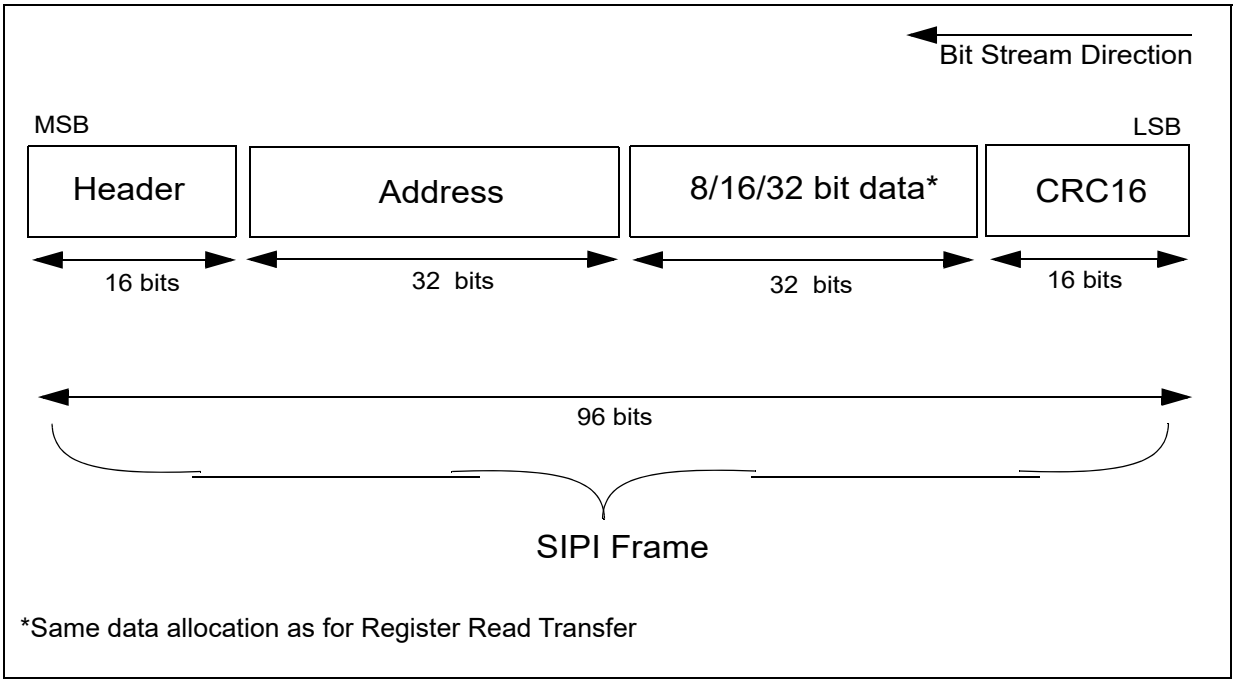


Figure 2022. Register write transfer (showing LFAST frame encapsulation)

74.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and 16-bit CRC as shown in *Figure 2023*.

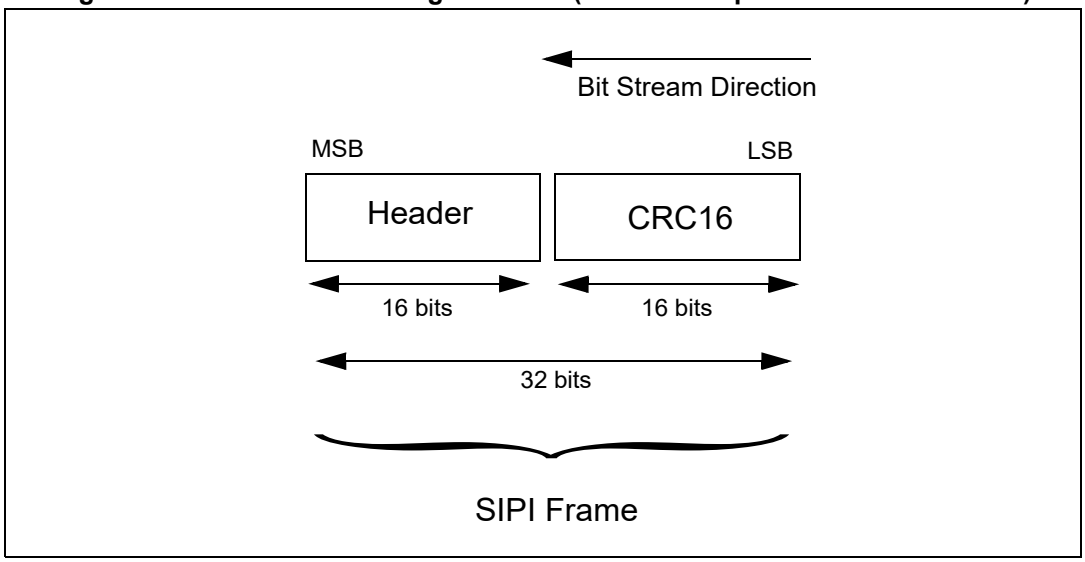
Figure 2023. Write transfer (LFAST frame encapsulation is not shown)

Note: In the case of an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as a byte enable:

Bits[1:0]:

- *00 – byte 3 enabled (MSB)*
- *01 – byte 2 enabled*
- *10 – byte 1 enabled*
- *11 – byte 0 enabled (LSB)*

In the case of a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as a half-word enable:



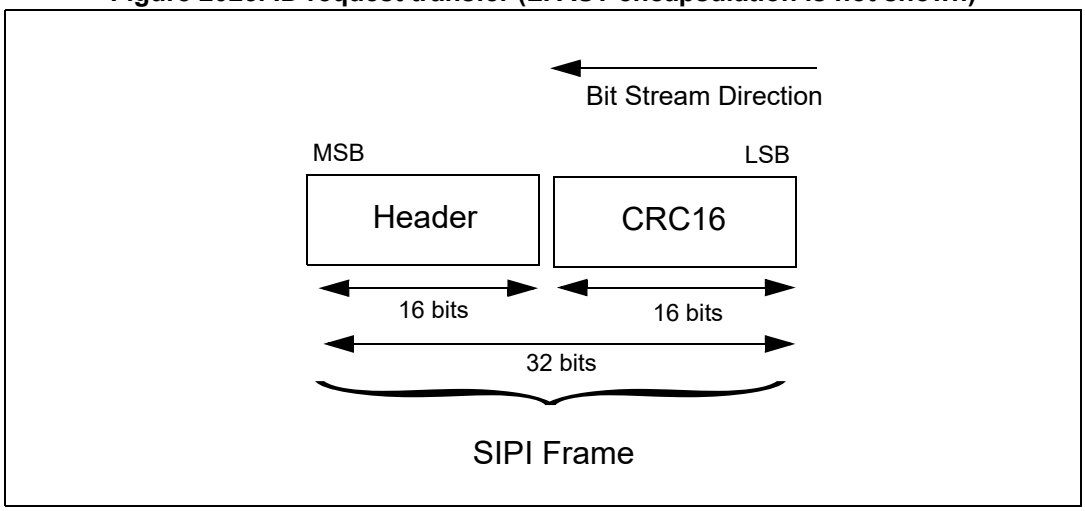
Bit[0]:

- *0 – half-word 1 enabled (MSB)*
- *1 – half-word 0 enabled (LSB)*

74.7.4 Write acknowledge transfer

A write acknowledge transfer contains only header and CRC bits (refer to *Figure 2024*). The CRC bits are calculated on the header field.

Figure 2024. Write acknowledge transfer (LFAST encapsulation is not shown)



74.7.5 ID request response

74.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in *Figure 2025*.

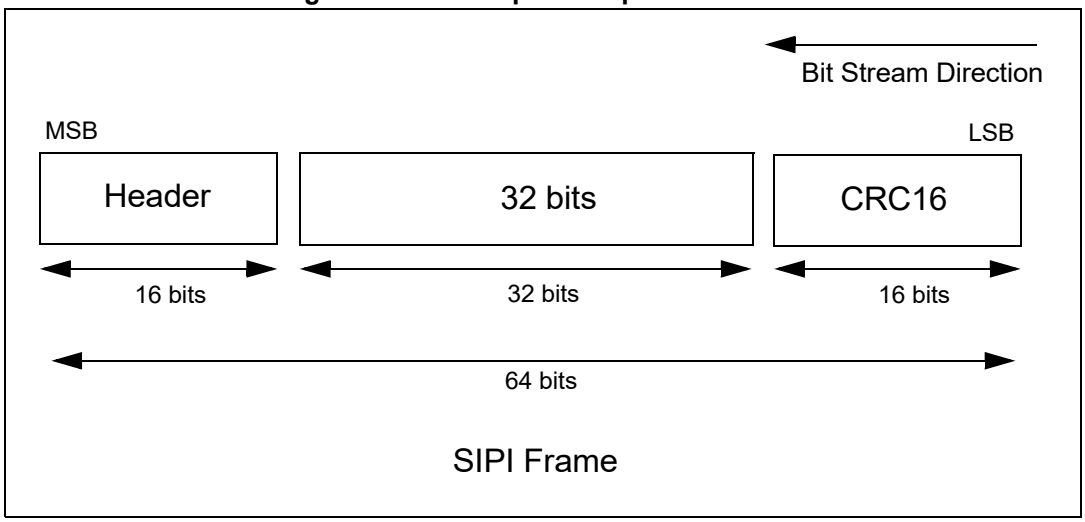


Figure 2025. ID request transfer (LFAST encapsulation is not shown)

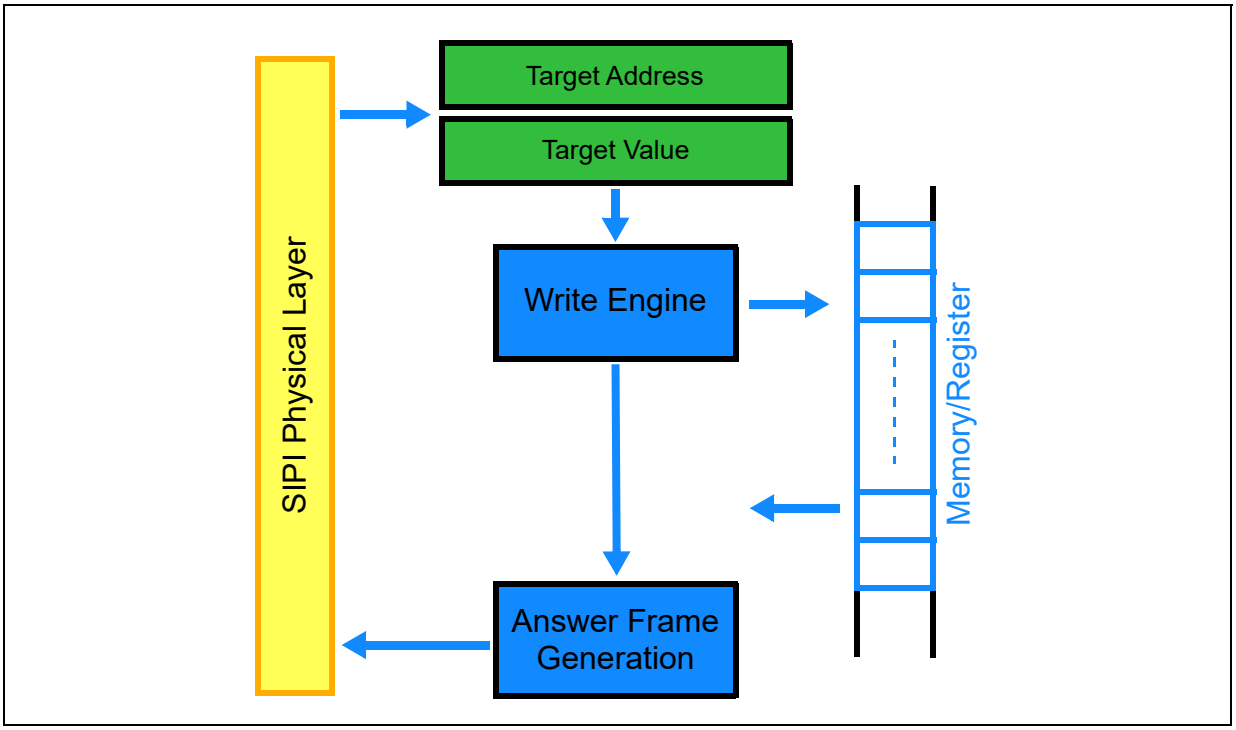
74.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in *Figure 2026*.

Figure 2026. ID request response transfer



Note: The ID request response contains the value of the CHIP ID in place of data.

74.8 Transfer API and flow charts

On a single write transfer request reception (refer to *Figure 2027*):

1. Debug SIPI will place the address, data and control information on its AHB master interface.
2. When the process in completed, the Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

Figure 2027. SIPI single register write API – Flow chart

On multiple write transfer request reception:

1. Debug SIPI will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

On single read transfer request reception:

1. Debug SIPI will place the address and control information on its AHB Master Interface.
2. When the process in completed, Debug SIPI will send read response back to LFAST.

On multiple read transfer request reception:

1. Debug SIPI then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

74.9 CRC calculation

Example 1

If header is 0xAABB, address is 0x1122_3344 and data is 0xCCDD_EEFF. Then CRC calculation will take place as follows:

1. The CRC seed is initialized by 0xFFFF_FFFF.
2. All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
3. So the header will be sent as 0xDD55_0000, byte_enable = 0xC.
4. Address will be sent as 0x22CC_4488, byte_enable = 0xF.
5. Data will be sent as 0xFF77_BB33, byte enable = 0xF.

74.10 Memory map and register description

Table 1939. SIPI memory map

Figure 2028. SIPI Module Configuration Register (SIPI_MCR)

Table 1940. SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. 0 No Freeze mode request. 1 Enters Freeze mode if FRZ bit is asserted.
29 INIT	Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits cannot be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete. Statical configuration, data and address registers remain unchanged.

74.10.1.2 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Offset: 0x00A0 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

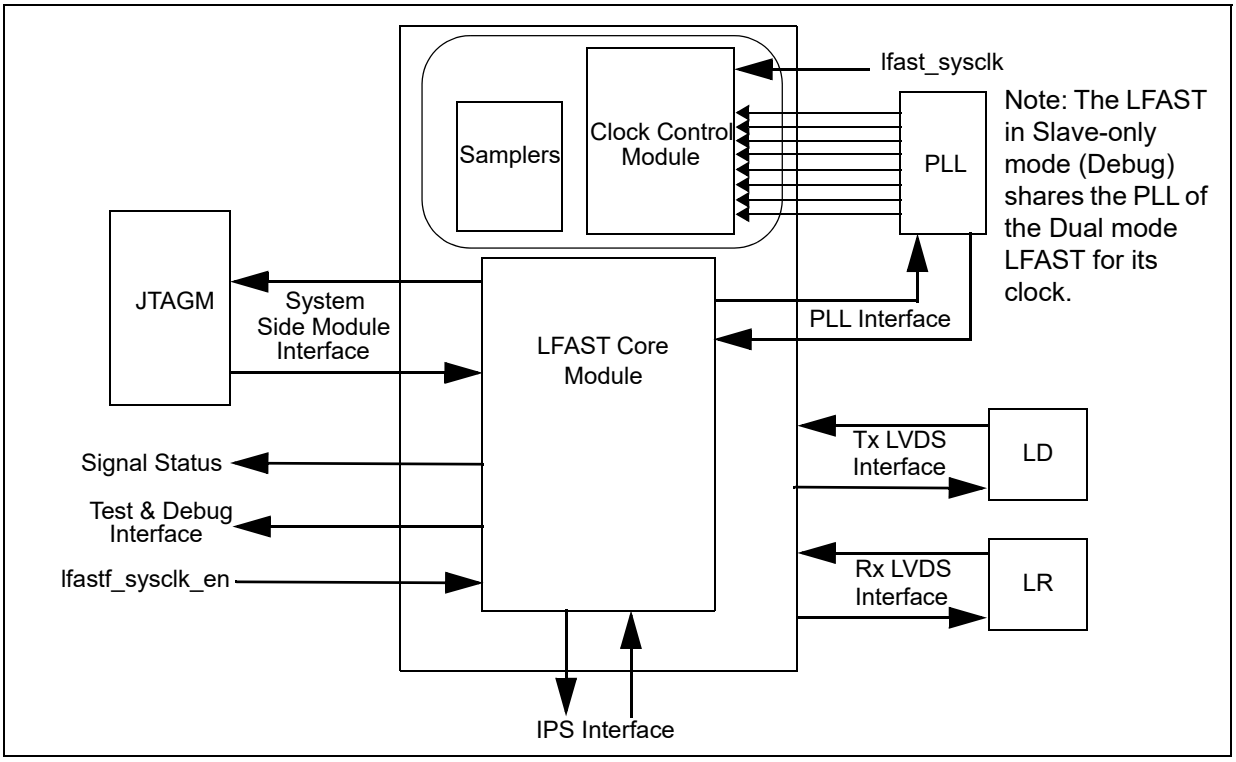
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2029. SIPI Status Register (SIPI_SR)

Table 1941. SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI not in any low power modes 1 SIPI is in Disable mode

75 LVDS Fast Asynchronous Serial Transmission – High Speed Debug



75.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

75.2 Block diagram

Figure 2030 depicts LFAST interaction with other modules on the device.

Figure 2030. LFAST block diagram

75.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
  - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

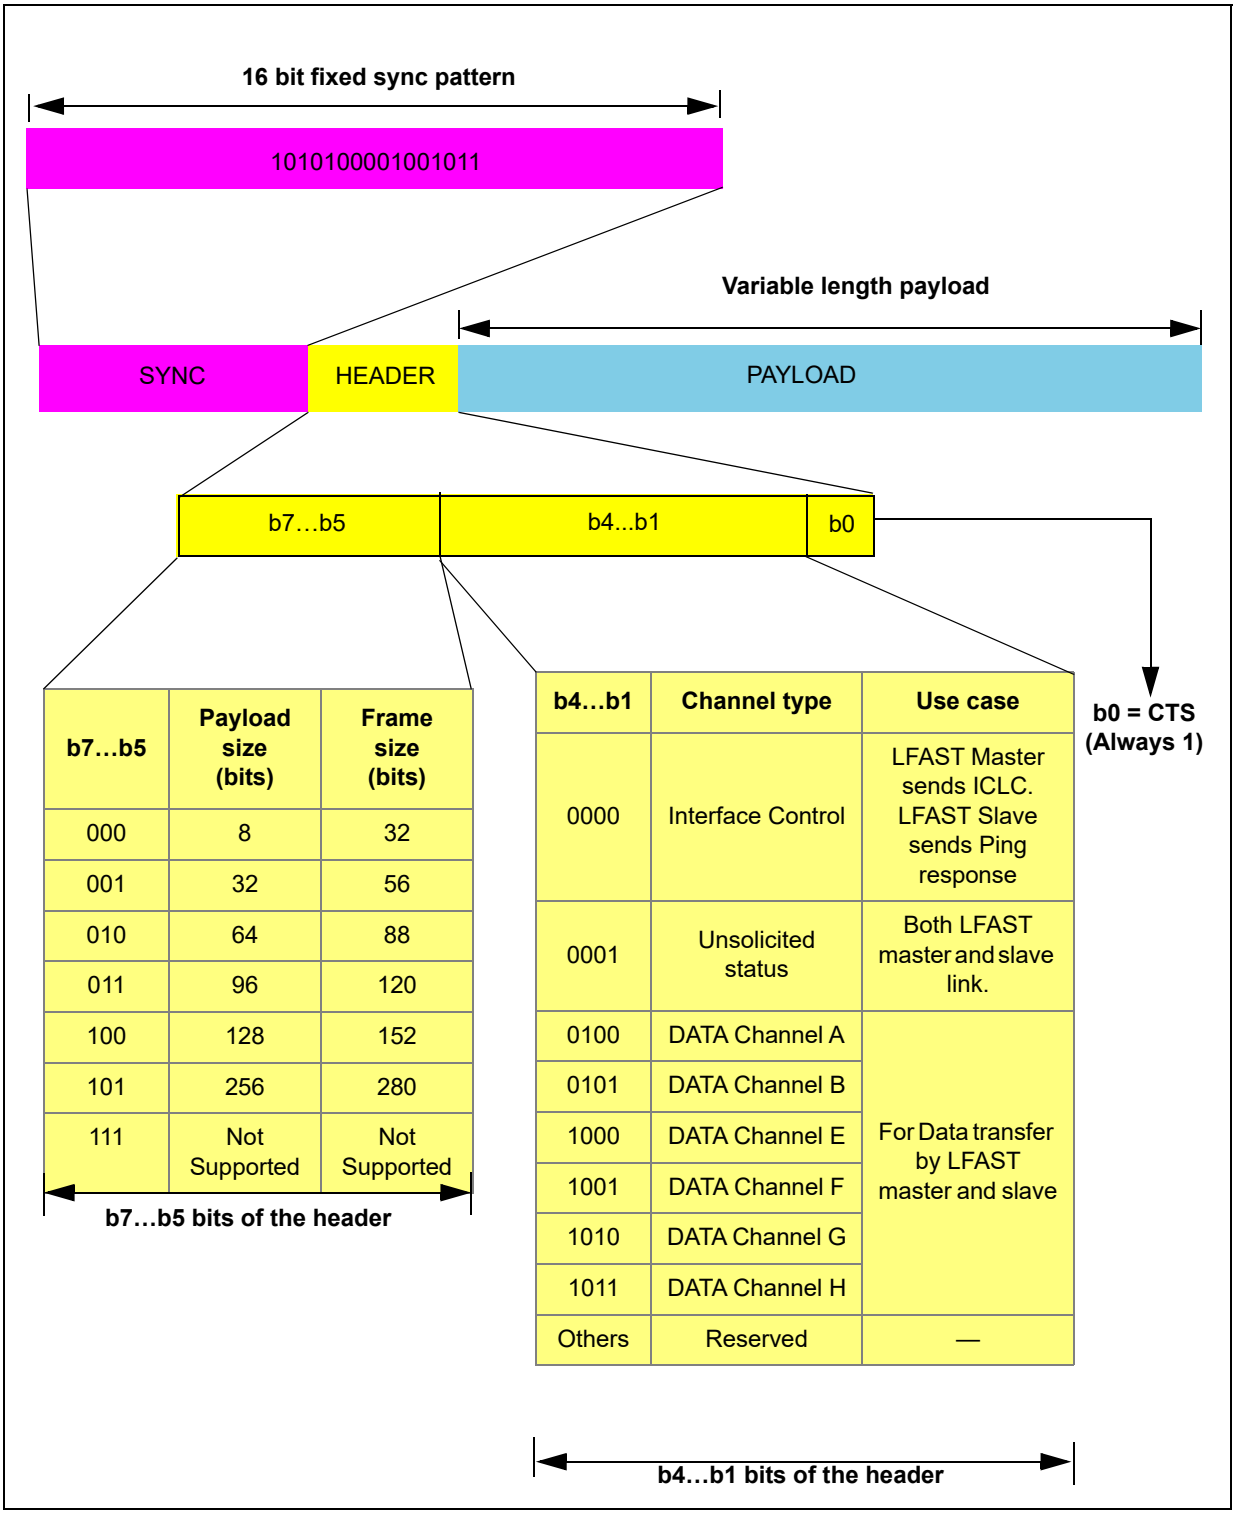
LFAST interface is an asynchronous high speed LVDS interface.

75.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

75.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.



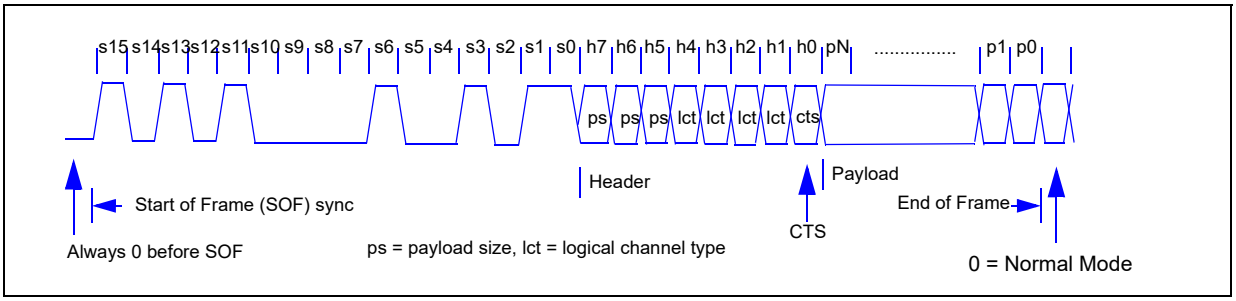
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See *Figure 2031* for details of the LFAST frame.

Figure 2031. LFAST frame structure



b7…b5	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported

b4…b1	Channel type	Use case
0000	Interface Control	LFAST Master sends ICLC. LFAST Slave sends Ping response
0001	Unsolicited status	Both LFAST master and slave link.
0100	DATA Channel A	For Data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	—

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 2032. Serial frame structure

The frame structure is shown in *Figure 2032* and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto-correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to *Table 1942*.

Table 1942. Header payload sizes

b7-b5 (bin)	Payload size (bits)	Frame size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

75.5 Features

- Supports slave only mode
- Supports asynchronous data transfer rates up to the maximum data rated shown in the product Datasheet
- Transmits and receives data and unsolicited frames
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes
- Supports flow control using sliding window protocol
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits
- Supports PLL configuration (such as feedback loop divider) through registers
- Supports LVDS configuration through registers
- Supports multiple loopback modes for checking the physical interface
- Supports automatic ping response generation
- Supports for detection of unsupported channel number and unsupported payload size

75.6 Memory map and register definition

All registers are 32-bit wide.

75.6.1 Memory map

Table 1943. LFAST memory map

Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Writable only once after the asynchronous reset.
2. Only writable when MCR[DRFEN] = 0.
3. Set by user software and cleared by system hardware.

Figure 2033. Mode Configuration Register (MCR)

Table 1944. MCR field descriptions

Field	Description
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode Refer to *Section 75.10.2: Slow speed clock* for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.

Table 1944. MCR field descriptions (continued)

Field	Description
17 RXEN	LFAST Receiver Enable This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave hardware on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
27 TXARBD	Tx Arbiter Disable This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
30 DRFRST	LFAST Soft Reset This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

75.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

1. Only writable when MCR[DRFEN] = 0.

Figure 2034. Speed Control Register (SCR)

Table 1945. SCR field descriptions

Field	Description
15 DRMD	Data Rate Controller mode Defines the mode set for LFAST slave device by the software or the LFAST master. This bit should not be modified by the software and left as SCR[DRMD] =1.
23 RDR	Receiver Data Rate This bit defines the receiver data rate. This bit should not be modified by the software.
31 TDR	Transmit Data Rate This bit defines the transmitter data rate. This bit should not be modified by the software.

75.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Offset: 0x0008 Access: User read/write

1. Only writable only when MCR[RXEN] = 0.

Figure 2035. Correlator Control Register (COCR)

Table 1946. COCR field descriptions

Field	Description
0:7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection) Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 0x00 Sampler Data Path selected by correlator 0x01 Sampler Data Path 0 selected 0x02 Sampler Data Path 1 selected 0x04 Sampler Data Path 2 selected 0x08 Sampler Data Path 3 selected 0x10 Sampler Data Path 4 selected 0x20 Sampler Data Path 5 selected 0x40 Sampler Data Path 6 selected others Sampler Data Path 7 selected
28:30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation …. 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 0 8 phases 1 4 phases

75.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Offset: 0x000C Access: User read/write

1. Writable only when TMCR[LPON] = 0.

Figure 2036. Test Mode Control Register (TMCR)

Table 1947. TMCR field descriptions

Field	Description
6 CLKTST	Clock Test mode The software can define when the clock test mode is enabled. This bit can also be set and cleared by hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable The software can define when the loopback logic is enabled. This bit can also be written by LFAST slave hardware on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled. 0 Loopback mode is disabled.
13:15 LPMOD	Loopback mode Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by the software)
16:31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0x0000: Reserved (Not to be used) 0x0001: Check 1 frame have correct sync, header and payload. … 0xFFFE: Check 65534 frames have correct sync, header and payload. 0xFFFF: Check 65535 frames have correct sync, header and payload.

Figure 2039. Wakeup Delay Control Register (SLCR)

Table 1950. SLCR field descriptions

Field	Description
0:7 HSCNT	High Speed Sleep mode Exit Time Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. 0x00: cycle 0x01: 1 cycle … 0x12: 18 cycles (200 ns + 8 cycles of High speed clock) … 0xFE: 254 cycles 0xFF: 255 cycles
12:15 LSCNT	Low Speed Sleep mode Exit Time Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. 0x0: 0 cycle 0x1: 1 cycle (200ns + 1 cycle of Low speed clock) … 0xE: 14 cycles 0xF: 15 cycles
16:23 HWKCNT	Wake Up time for the LD Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. 0x00: 0 cycles 0x01: 1 cycle … 0x5F: 95 cycles (1.18 us) … 0xFF: 255 cycles Maximum
28:31 LWKCNT	Wake Up time for the LD Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. 0x0: 0 cycle 0x1: 1 cycle 0x2: 2 cycles (1.18 us) … 0xE: 14 cycles 0xF: 15 cycles

Figure 2041. LVDS Control Register (LCR)

Table 1952. LCR field description

Field	Description
8 SWWKLD	Software signal to take LVDS LD out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep).
9 SWSLPLD	Software signal to put LVDS LD into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep.
10 SWWKLR	Software signal to take LVDS LR out of Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep).
11 SWSLPLR	Software signal to put LVDS LR into Sleep mode This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up).
12 SWOFFLD	Software signal to turn OFF the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.

Table 1952. LCR field description (continued)

Field	Description
13 SWONLD	Software signal to turn ON the LVDS LD This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
14 SWOFFLR	Software signal to turn OFF the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
15 SWONLR	Software signal to turn ON the LVDS LR This bit can be changed only when DRFEN is high. This bit should not be modified by the software.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode.
17 LVTXOE	LVDS LD output buffer enable 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad.
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only). 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only). 0 Use for LFAST receiver baud rates less than maximum baud rate 1 Required for LFAST receiver maximum baud rate
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection 0 Micro-Second Bus selection 1 LFAST Bus selection

Table 1952. LCR field description (continued)

Field	Description
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 Normal clock used to sample the LVDS data 1 Adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

75.6.2.10 Unsolicited Tx Control Register (UNSTCR)

Field	Description
0:31 UNRXD	Unsolicited Receive Data This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288-bit payload.

75.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements (Refer to the “Functional safety” chapter for register classification details. All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

75.7 Functional description

75.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

75.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCR are programmed according to the LVDS parameter in the device datasheet.
2. The PLLCR[(w)] is programmed with the configuration parameters of the PLL.
3. The LCR is programmed with the configuration parameters of the LVDS.
4. MCR[DATAEN] fields is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 0x31 is received the hardware writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 0x00 frame is received and the hardware writes RIISR[ICPRF] = 1.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 0x02 is received and the hardware writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 0x80 is received and the hardware writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 0x10 is received and the hardware writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 0x00 is received and the hardware writes RIISR[ICPRF] = 1.

75.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

LFAST interface enable (lfast_sysclk_en) negation:

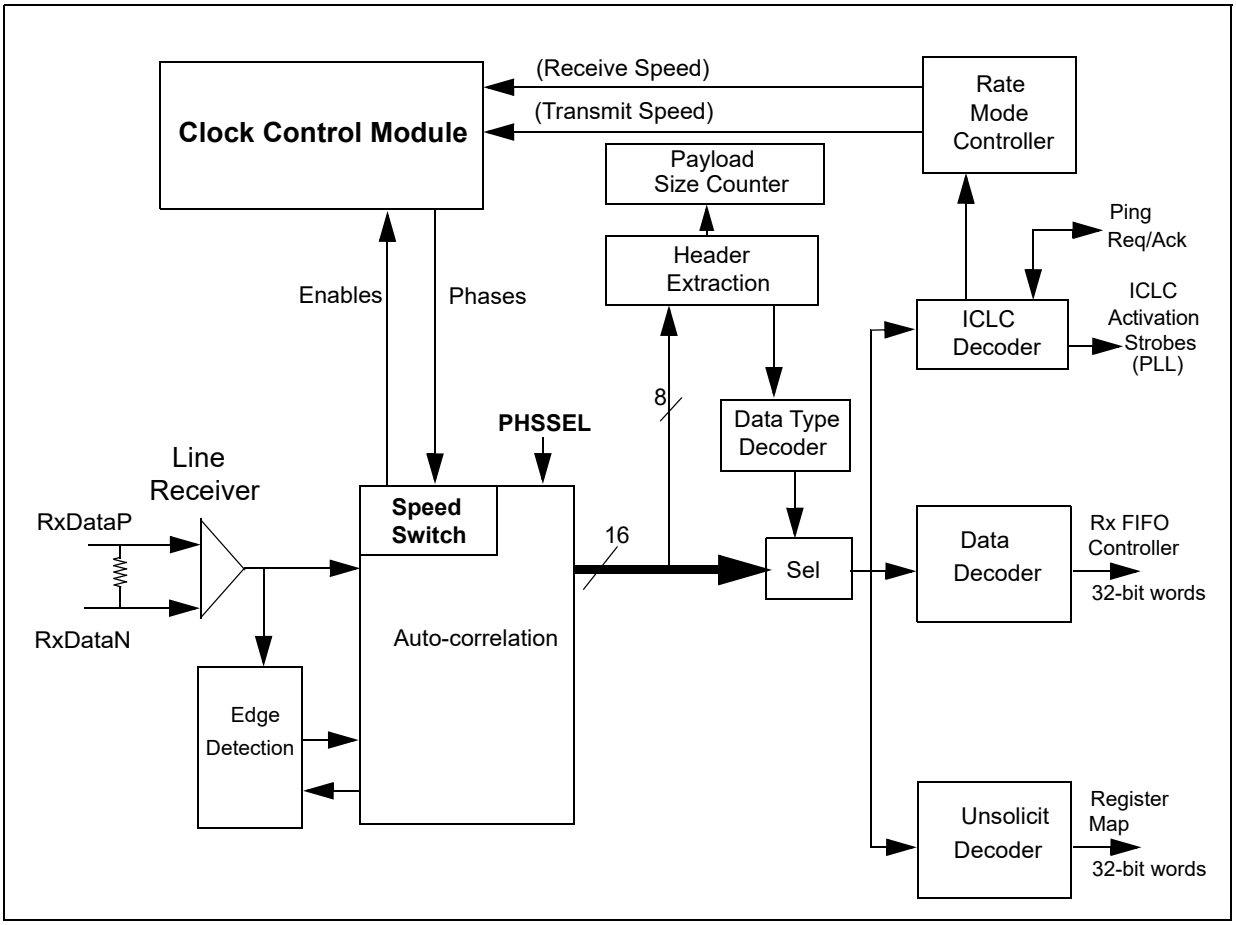
1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then the software writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

w. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

1. The LD LVDS pad is power up, if all conditions are met:
   – LCR[SWOFFLD] = 0.
   – LCR[SWONLD] = 1.
   – MCR[TXEN] = 1.
   – When frame ICR[ICLCPLD] = 0x31 is received.
2. LR LVDS pad is powered up if all conditions are met:
   – LCR[SWOFFLR] = 0.
   – LCR[SWONLR] = 1.
   – MCR[RXEN] = 1.

75.7.3 Line Receiver (LR)



75.7.3.1 Introduction

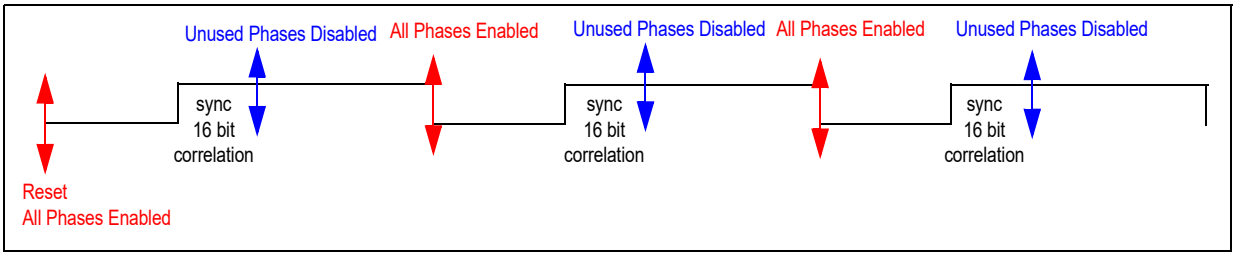
The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto-correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 2052 shows the block diagram of Uplink controller.

Figure 2052. Top level receive controller

75.7.3.2 Edge-detection and auto-correlation



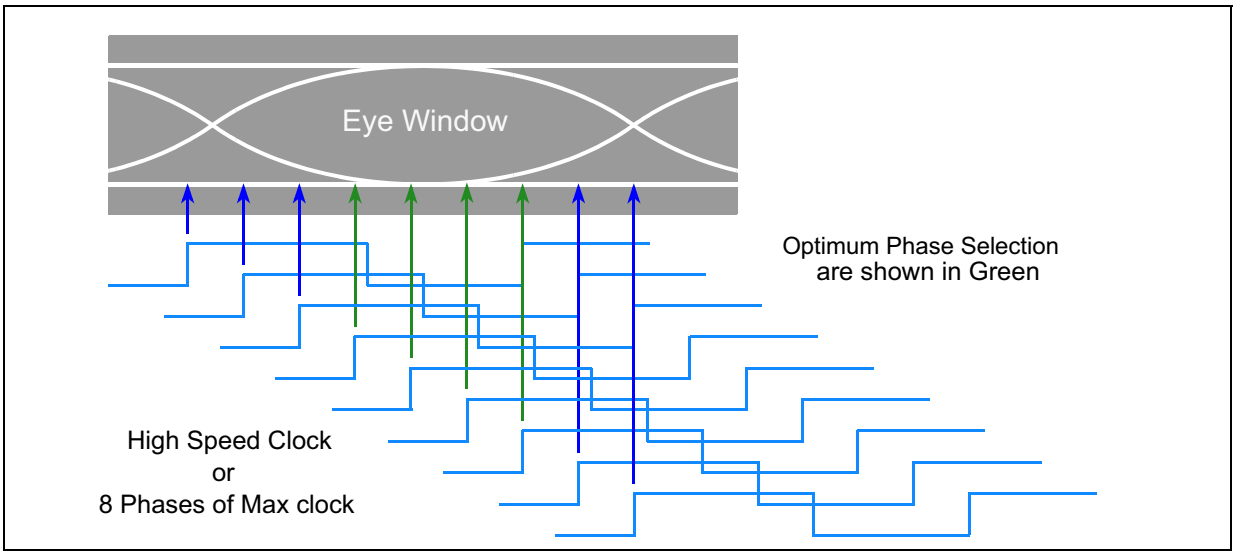
The edge-detection and auto-correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

75.7.3.2.1 Auto-correlation modes

75.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

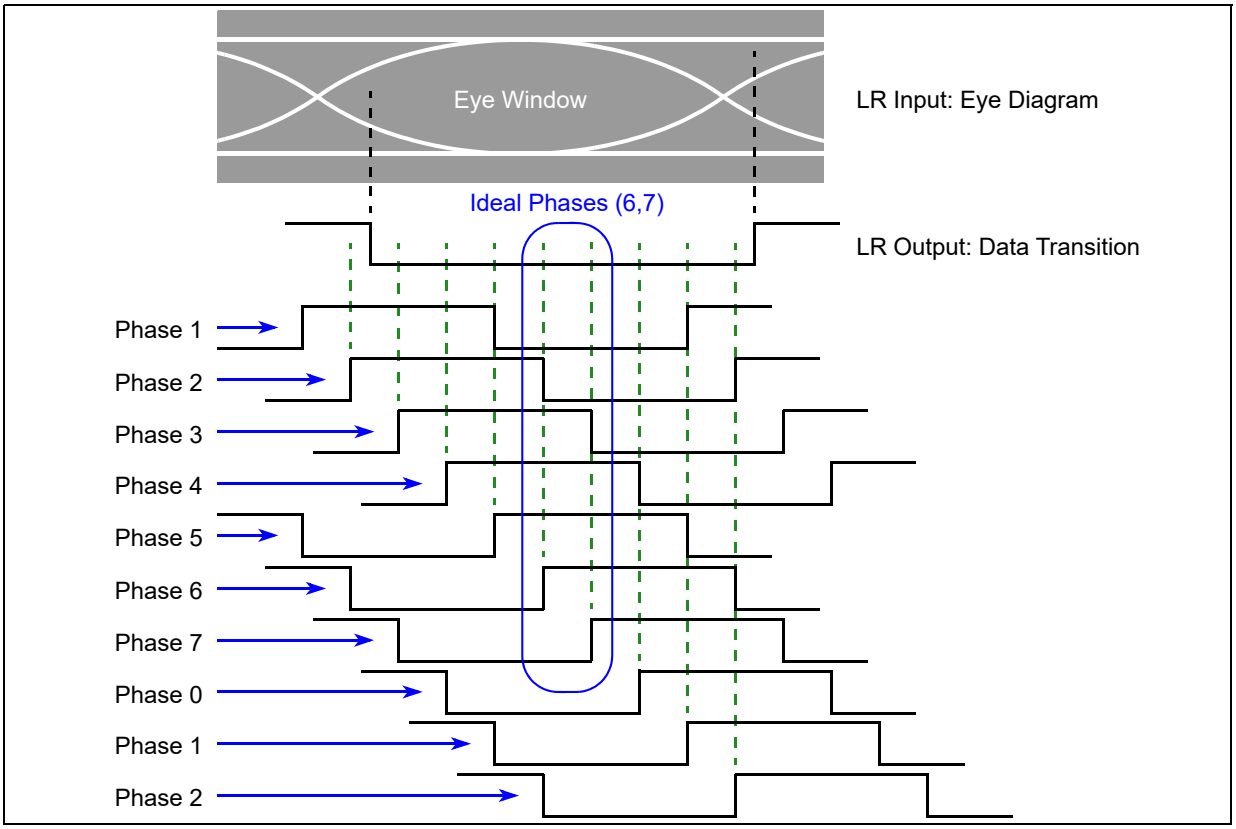
Figure 2053. Hunt correlation mode



75.7.3.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

75.7.3.2.3 Auto-correlation



The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto-correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in *Figure 2054*.

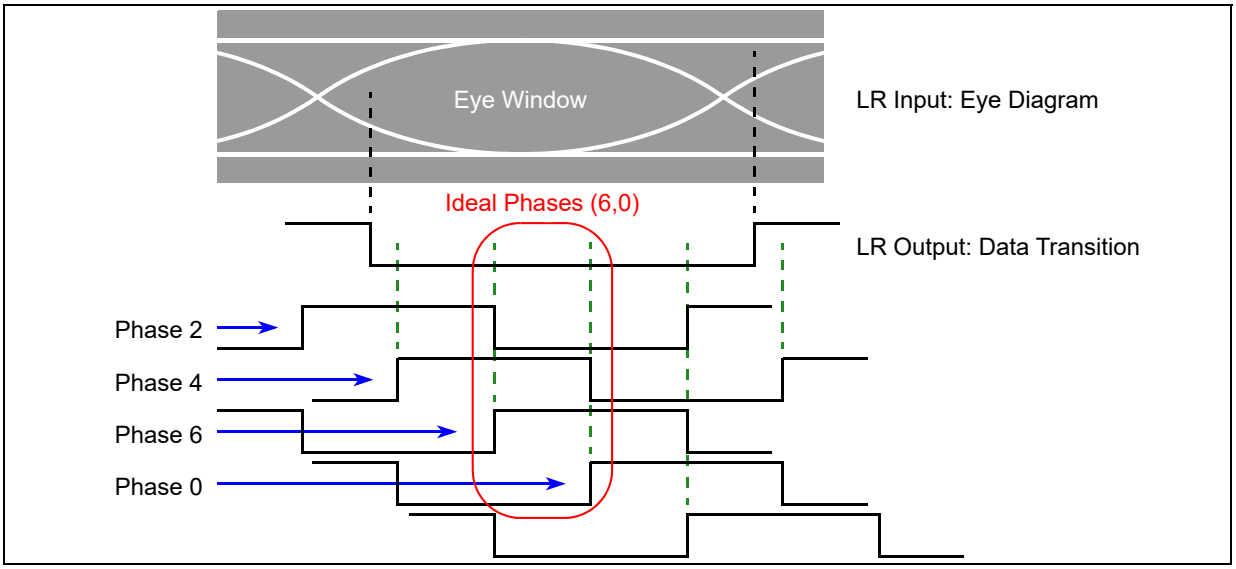
Figure 2054. High speed 8 phase selection

The objective of the auto-correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in *Figure 2055*.

Figure 2055. High speed 8 phase clock alignment example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in *Figure 2056* and *Figure 2057*.

Figure 2056. High speed 4 phase clock alignment example



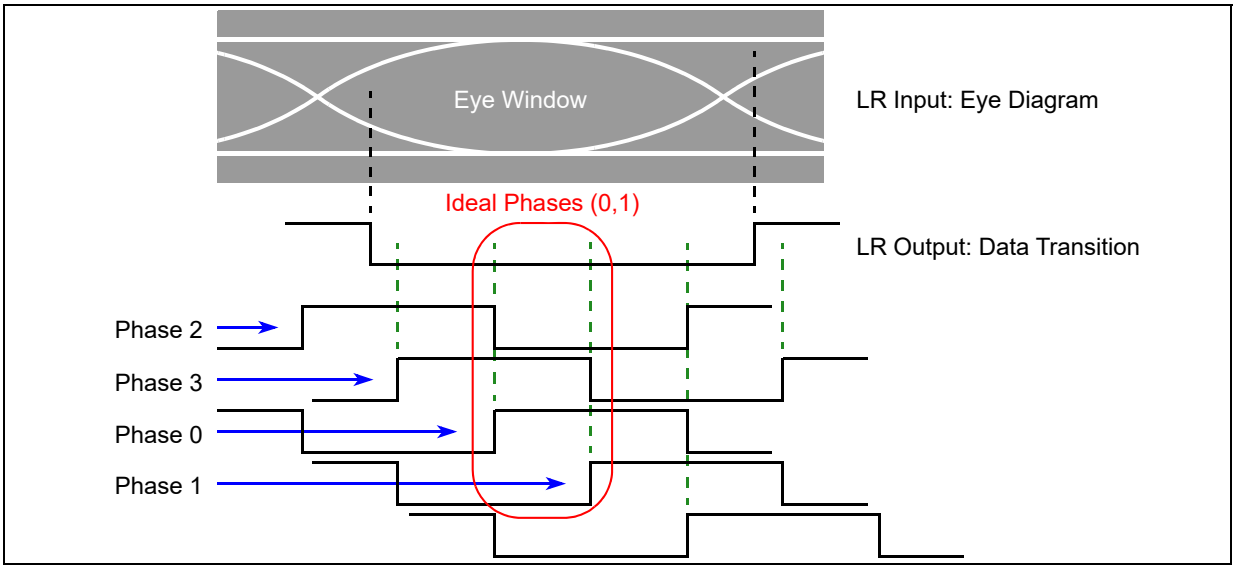


Figure 2057. Low speed 4 phase clock alignment example

The auto-correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to an intermediate phase as shown in *Table 1963*, *Table 1964*, and *Table 1965* before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 1963. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 1964. High speed 4 phase selection - sampling procedure

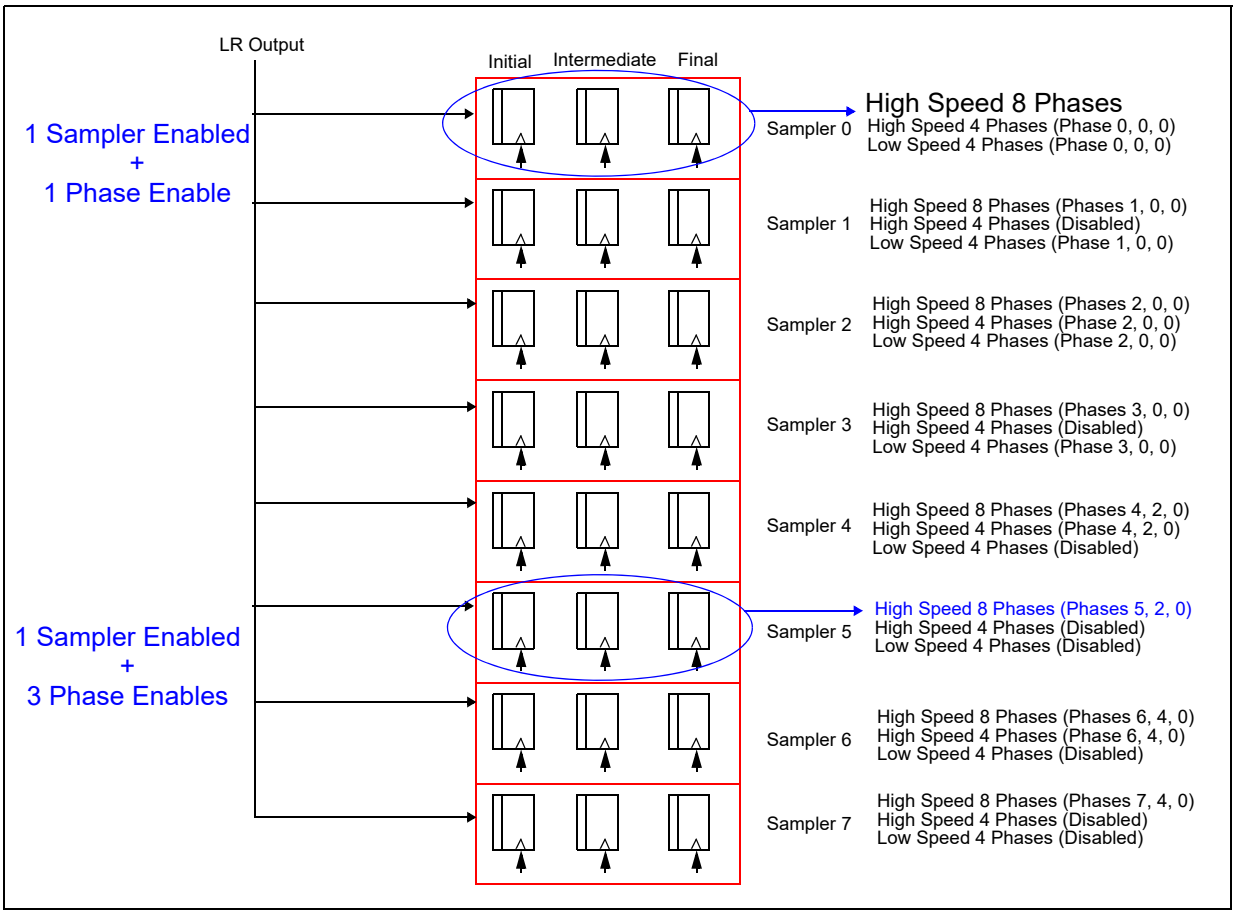
Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See *Table 1964*, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 1965. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See *Table 1965*, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.



75.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto-correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in *Figure 2058*.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for instance Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

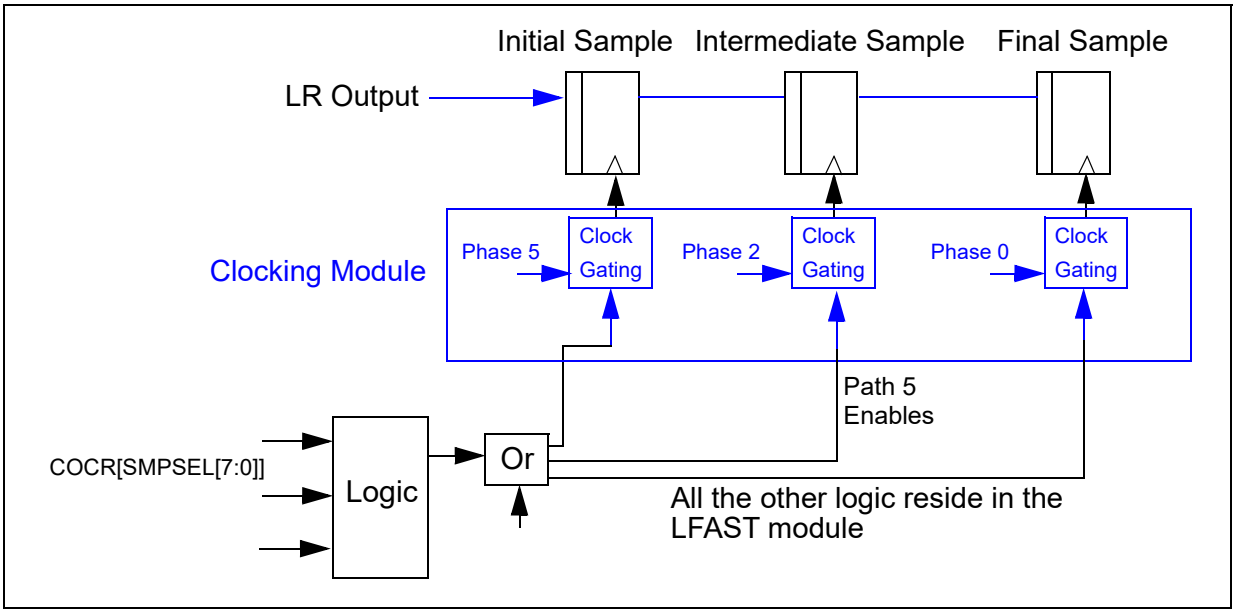


Figure 2058. Samplers, each sampler has 3 registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in *Figure 2059*.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

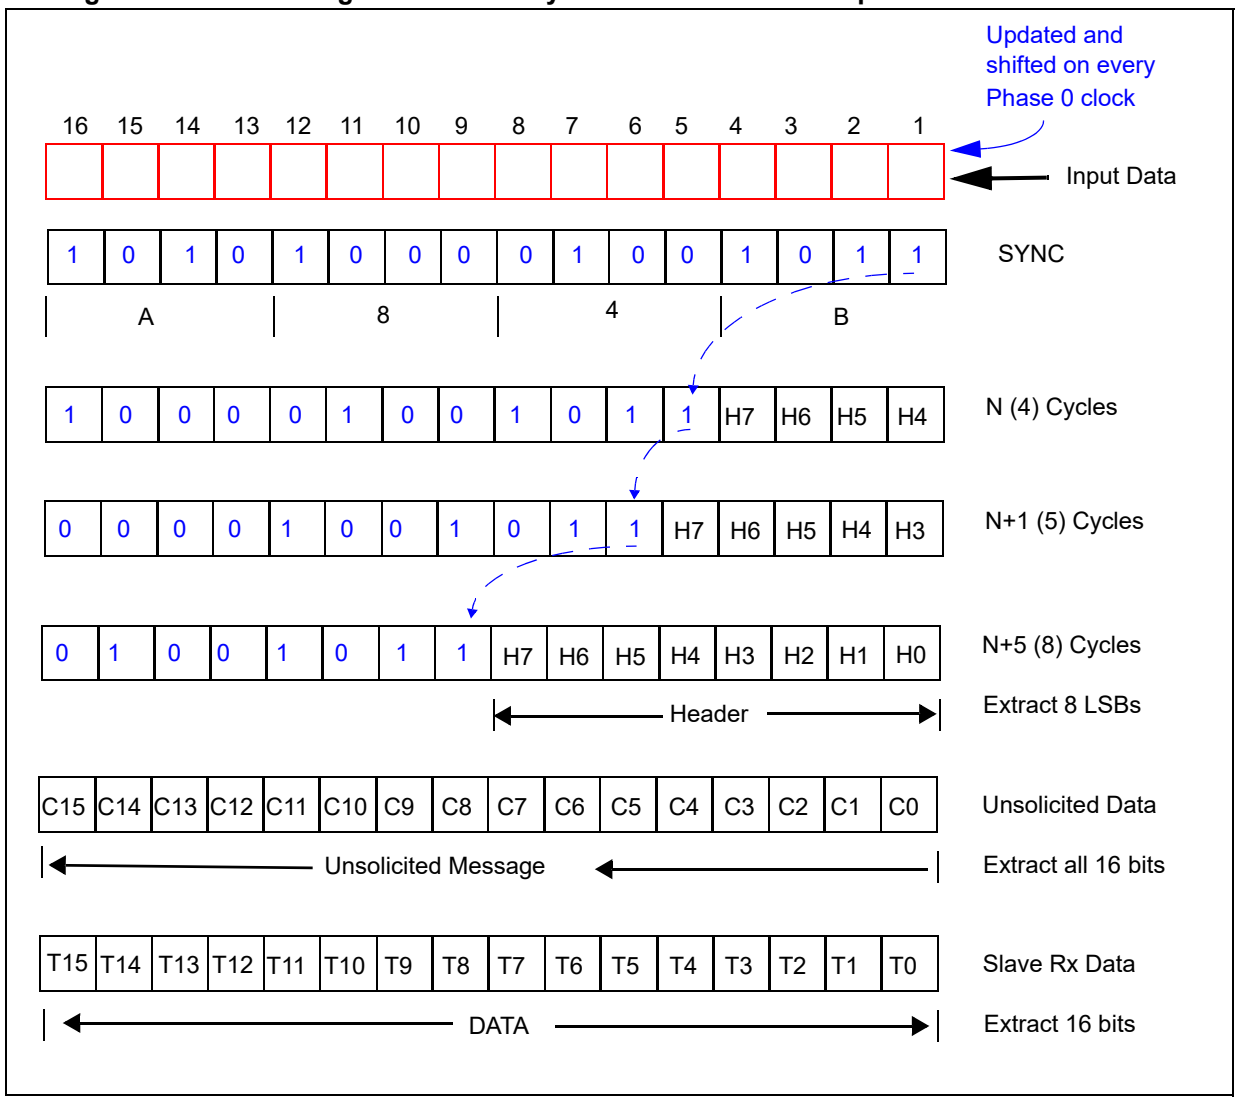

Figure 2059. Sampler 5 Logic

75.7.3.3 Header and Payload extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16-bit word, bit shifted every Phase 0 clock as shown in *Figure 2060*.

Figure 2060. Extracting Header and Payload from the 16-bit output from Auto-correlation

75.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown
  The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep
  The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- Normal
  In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 1966. Line Receiver state

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

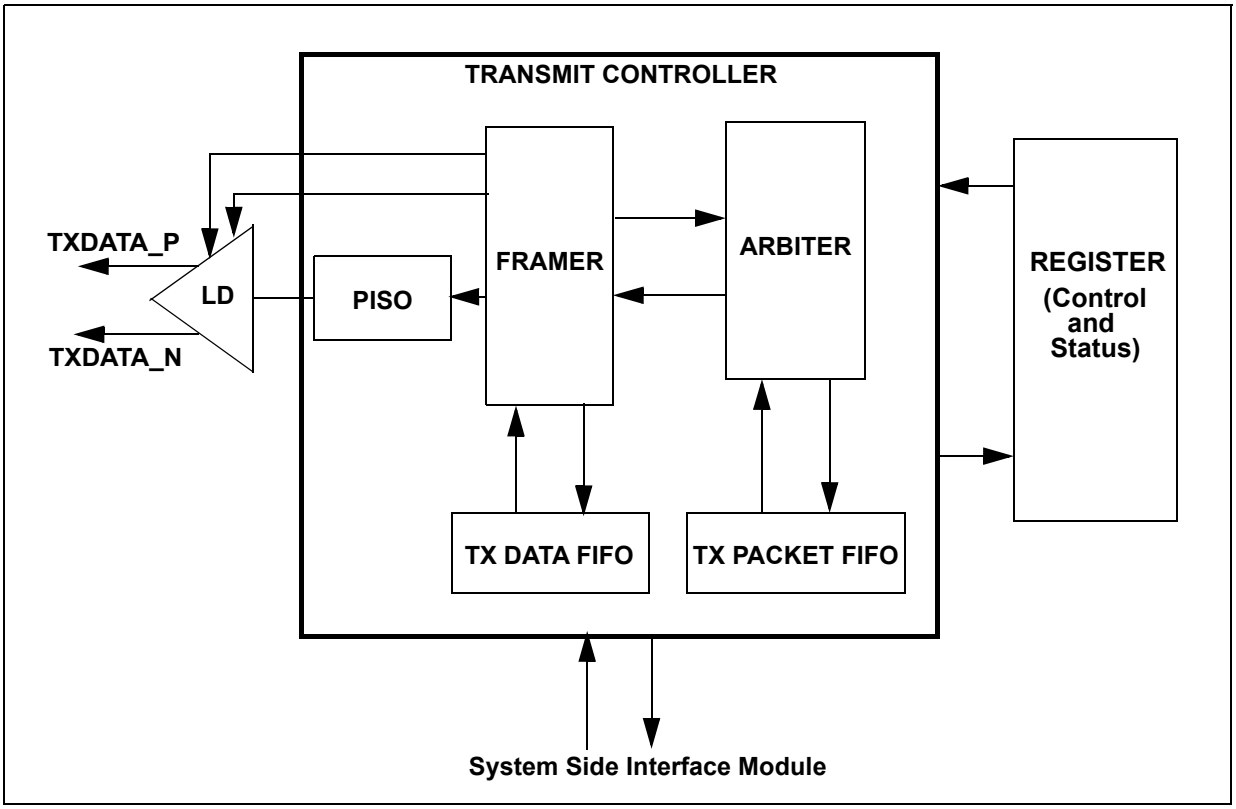
75.7.4 Transmit controller

75.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, such as unsolicited, ICLC, ping. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:



- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in *Figure 2061*.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 2061. Transmit controller connections

75.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- Software programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in *Table 1967*.

Table 1967. Priority levels for the Transmit controller

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 1967. Priority levels for the Transmit controller (continued)

Request	LFAST slave priority	Triggering conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

Table 1968. Line driver states

LD state	LFAST slave triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

75.7.5 Frames supported

Table 1969 provides the frames supported and their permissible payload sizes

Table 1969. Frames supported by LFAST interfaces

Frame type	LCT code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload size (bits)
Data frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited frame	0001b	YES	YES	8, 32, 64, 96, 128, 256, 288
ICLC frame	0000b	YES	NO(1)	8
CTS frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

75.7.6 Frame flow

The following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

75.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

75.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

75.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.

75.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

75.7.6.2 Unsolicited flow

75.7.6.2.1 Unsolicited frame transmit flow

The software is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

75.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the *Mode Configuration Register (MCR)* to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1.
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

75.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

75.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

75.7.6.3.1 .ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

75.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The software can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame.The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

75.7.6.3.1.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

75.7.6.3.1.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

75.7.6.3.1.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or software programs MCR[TXEN] = 1.

75.7.6.3.1.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

75.7.6.3.1.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

75.7.6.3.1.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

75.7.7 Test and debug support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

75.7.7.1 Loopback test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for software should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

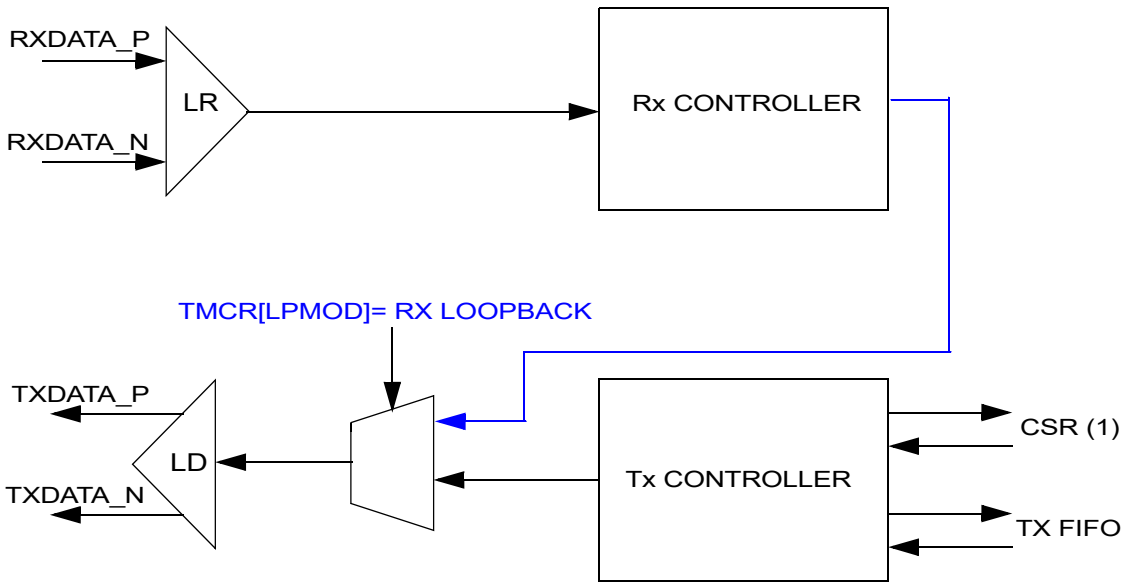
Table 1970. Loopback modes

LPMOD[2:0]	Mode selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation

Table 1970. Loopback modes (continued)

LPMOD[2:0]	Mode selected
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by the software, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.



In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

75.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

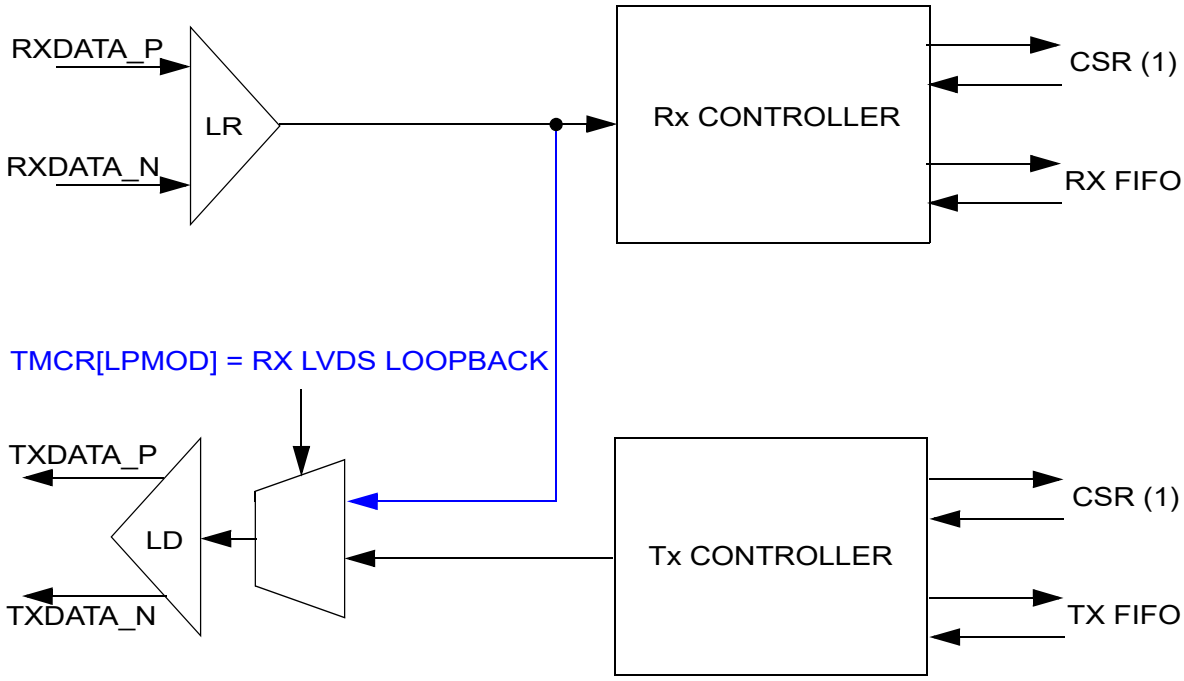
Figure 2062. Rx Loopback mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx Loopback mode:

1. Software programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: - Reception of ICLC Frame with Payload 0xFF (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:



- Software programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 0x38 (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

75.7.7.1.2 Rx LVDS Loopback mode

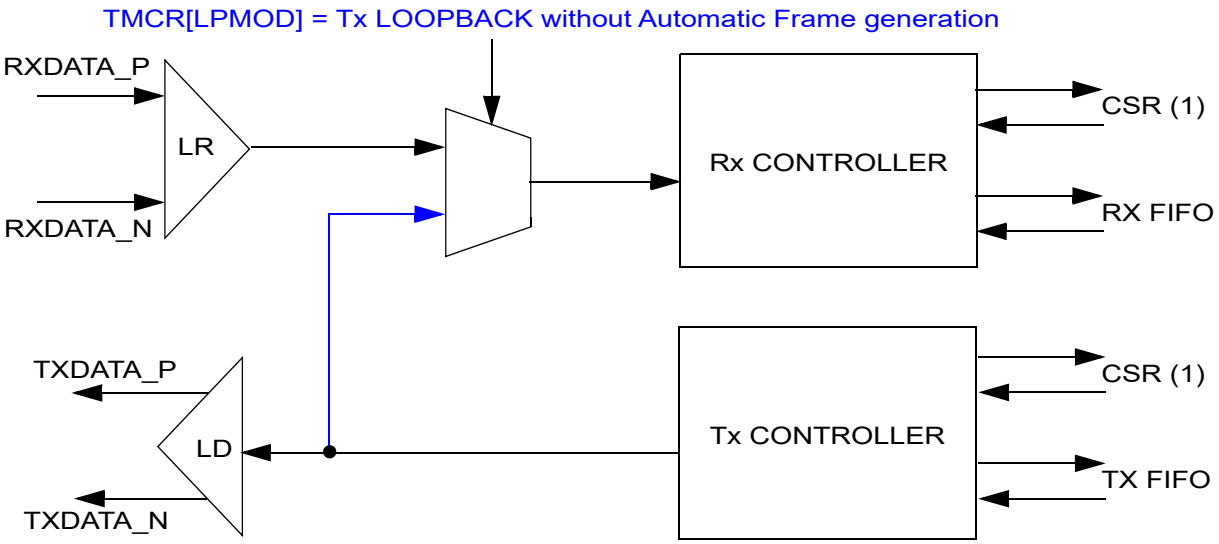
This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 2063. Rx LVDS LoopBack mode

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Rx LVDS Loopback mode:

1. Software programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   - The software writes TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload = 0xFF (Loopback mode ON), from LFAST Master.



Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 0x38 (Test mode off), from LFAST Master.
  - Deassertion of the LFAST interface enable (lfast_sysclk_en).

75.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 2064. Tx LoopBack mode without automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback without Automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - Software programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from LFAST Master

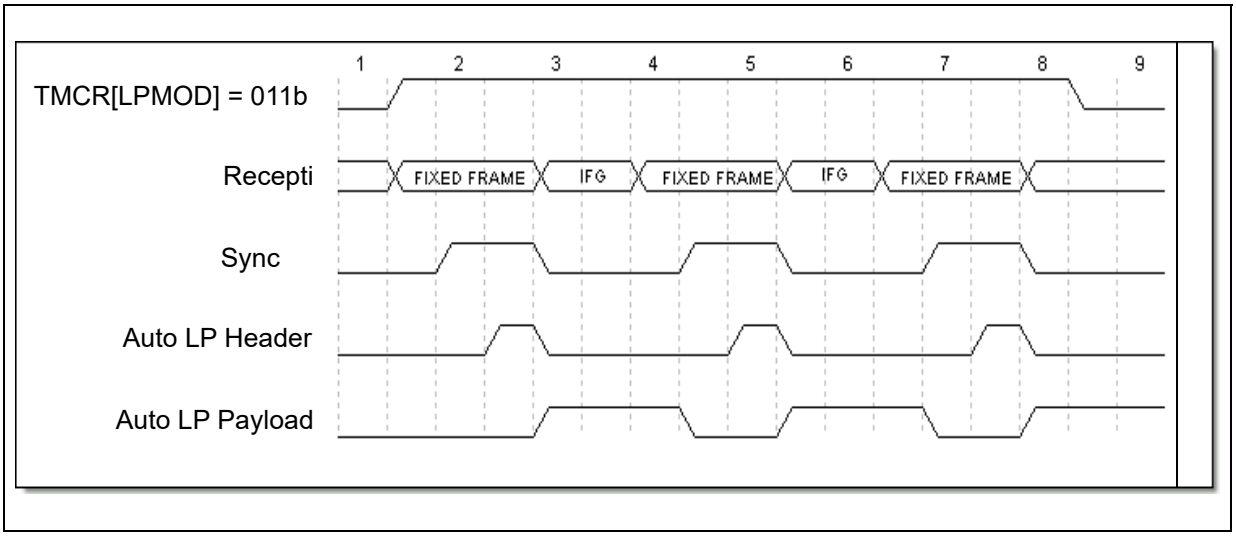
Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

75.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal software intervention.



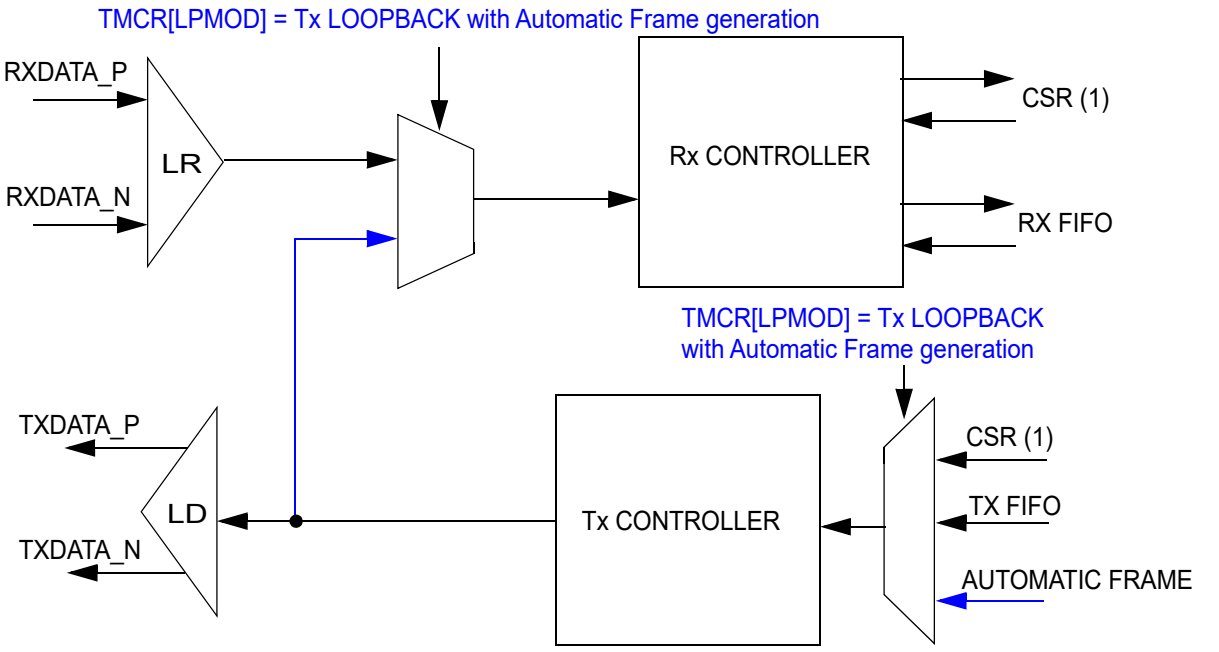
The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 0x13 received.
- GSR[LPCPDV]: Frame with Payload of 0xCB received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 2065. Automatic Loopback test status signal timings



The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

75.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

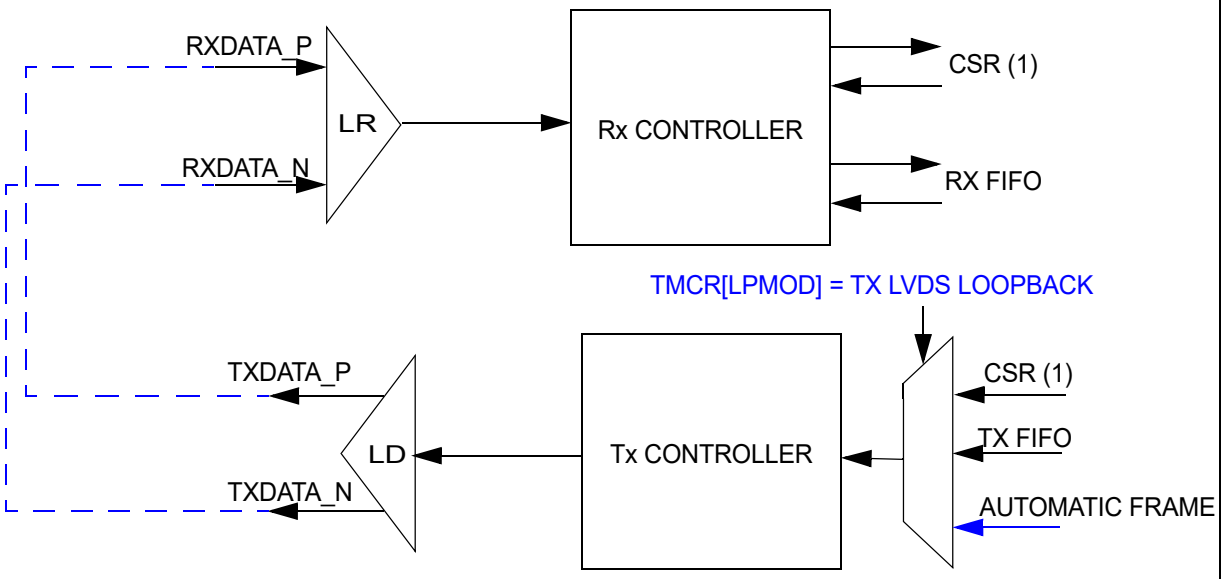
When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the software. The frames generated have fixed header of 0x13 and payload of 0xCB. The successful reception of this frame is indicated by the status signals and registers.

Figure 2066. Tx LoopBack mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx Loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on), from the LFAST Master.



Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

75.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 2067. Tx LVDS Loopback (external) mode with automatic frame generation

1. CSR stands for Control and Status Registers (used to configure and indicate the status of the Tx/Rx controller).

Entry to Tx LVDS loopback with automatic frame generation mode:

1. Software programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   – Software programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload 0xFF (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- Software programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

75.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- Software programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 0x34 (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be canceled by any of the following methods:

- Software programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 0x38 (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

75.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 1971. Frames supported by LFAST interfaces

Frame type	Tx buffer (in bits)	Rx buffer (in bits)	Memory type
Data frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC frame	N/A	1 × 8 max 1 packet(1)	Registers PICR[PNGPYLD]
CTS frame	N/A	N/A	N/A

1. Ping response packet.

75.9 Resets

The various blocks in LFAST are reset as described in *Table 1972*.

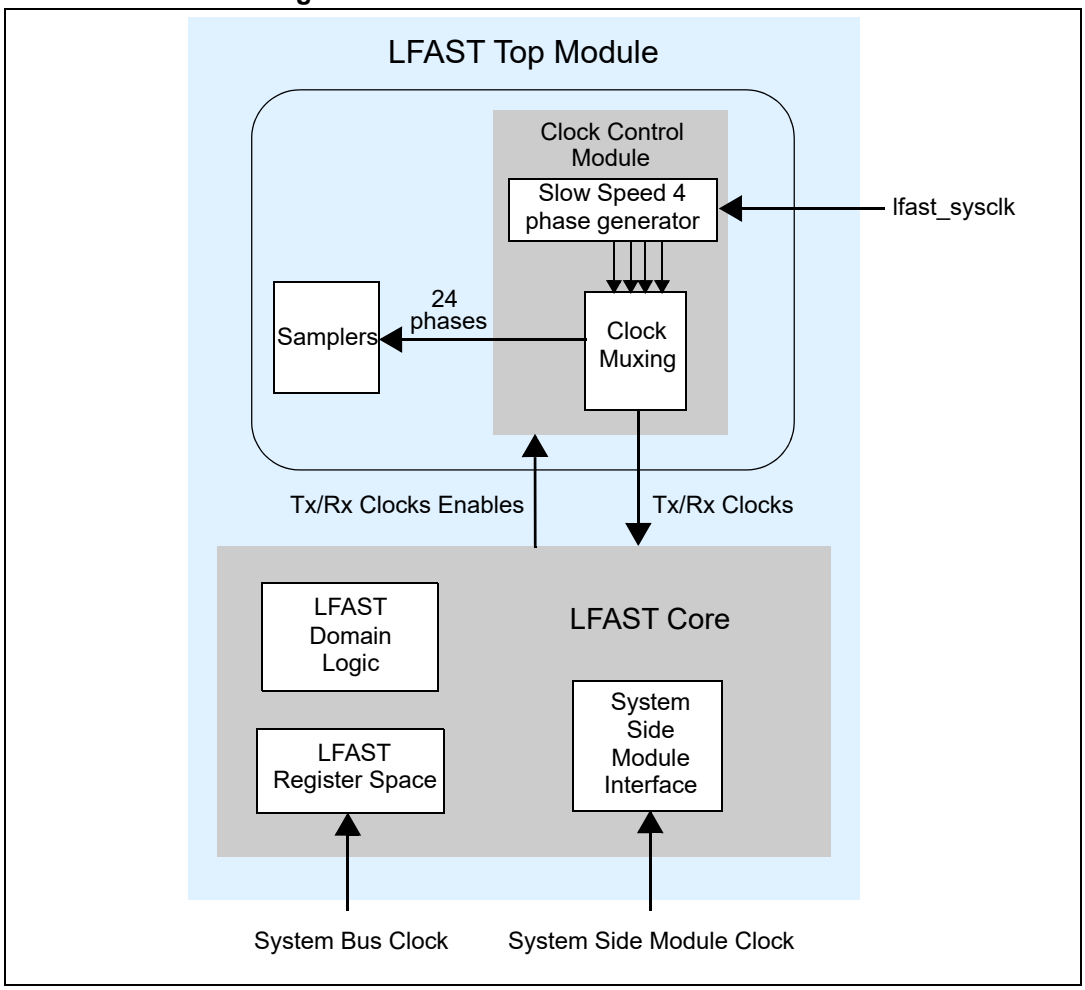
Table 1972. Recommended receive exception handling mechanism

Reset	Blocks reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of *Mode Configuration Register (MCR)*	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space

Table 1972. Recommended receive exception handling mechanism (continued)

Reset	Blocks reset
DRFEN bit of *Mode Configuration Register (MCR)*	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits do not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

75.10 Clocks



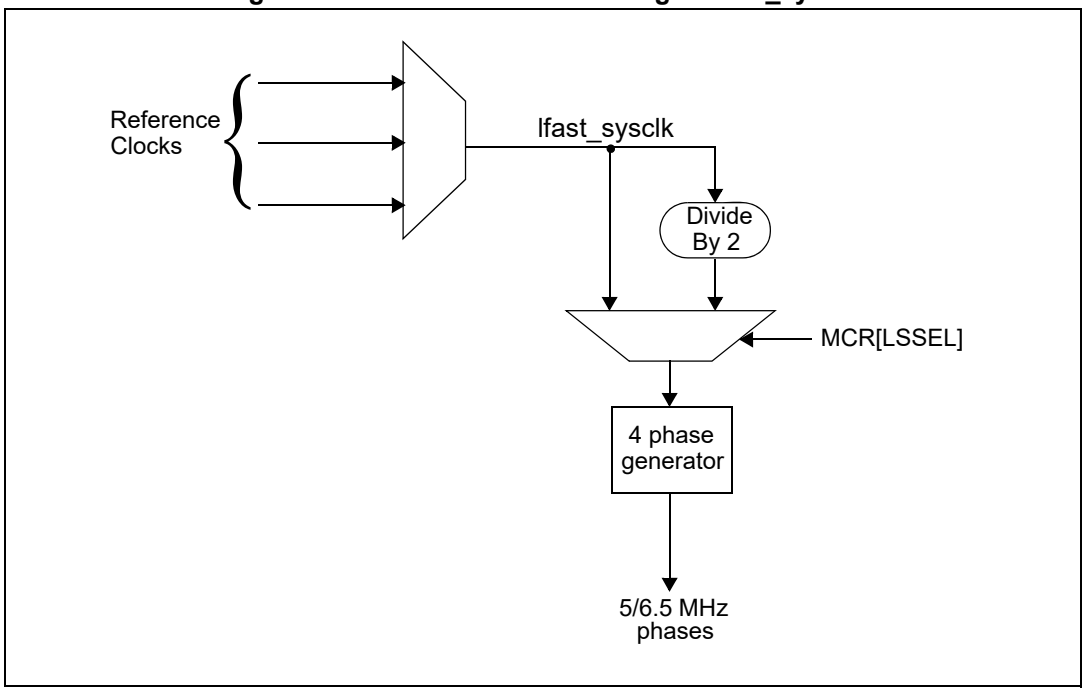
The LFAST mainly works on two clocks:

- System Bus Clock, used to program the registers.
- System Side Module clock, which is synchronous to the System Bus clock.

75.10.1 Clocking strategy

Figure 2068 shows the clock domain in which each module functions. The Clock Module will generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 2068. LFAST module clock domains



75.10.2 Slow speed clock

75.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in *Figure 2069*, *Figure 2070* and *Figure 2071*.

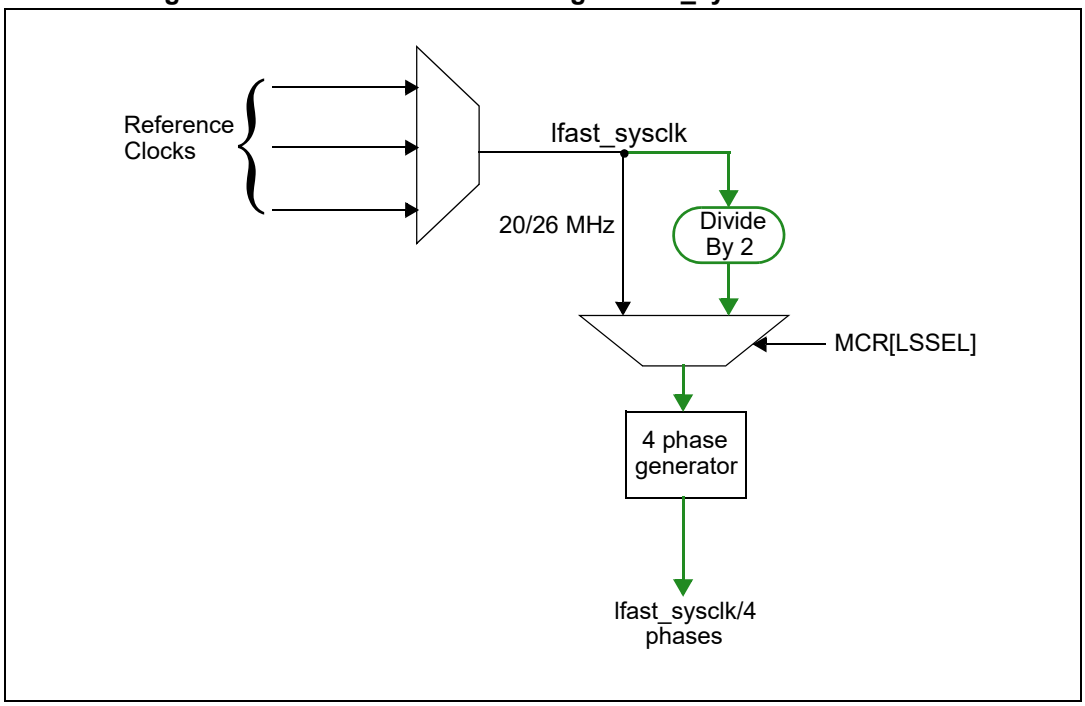


Figure 2069. External clock muxing of lfast_sysclk

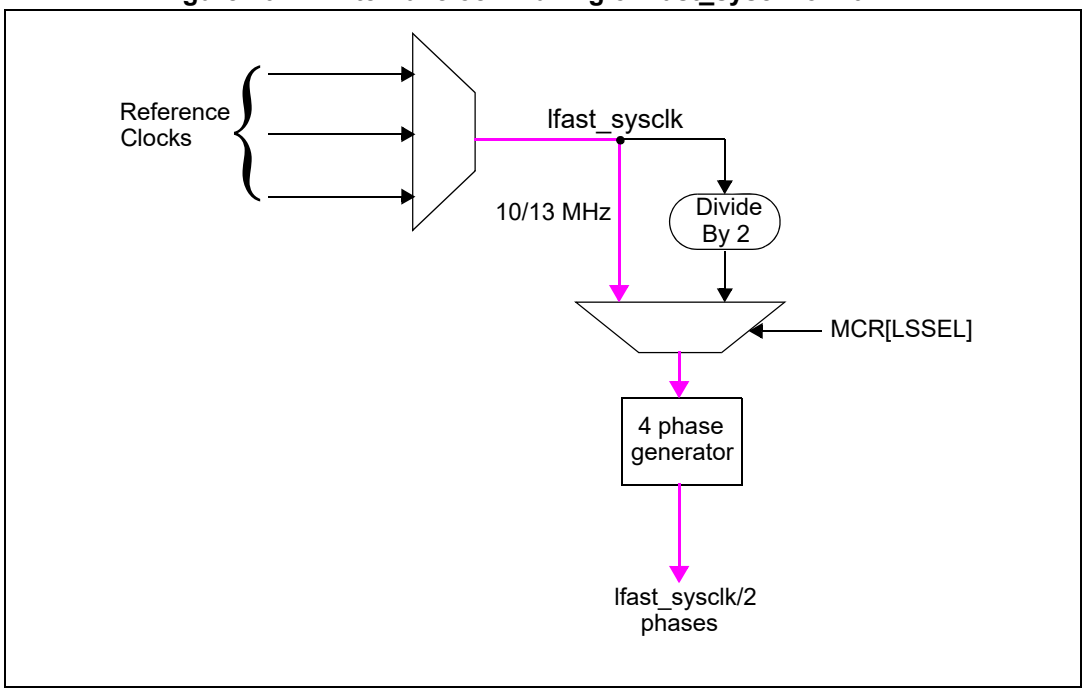
All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in *Figure 2069*.



The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2070* (selected clock path shown in green).

Figure 2070. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2071* (selected clock path selected shown in magenta).

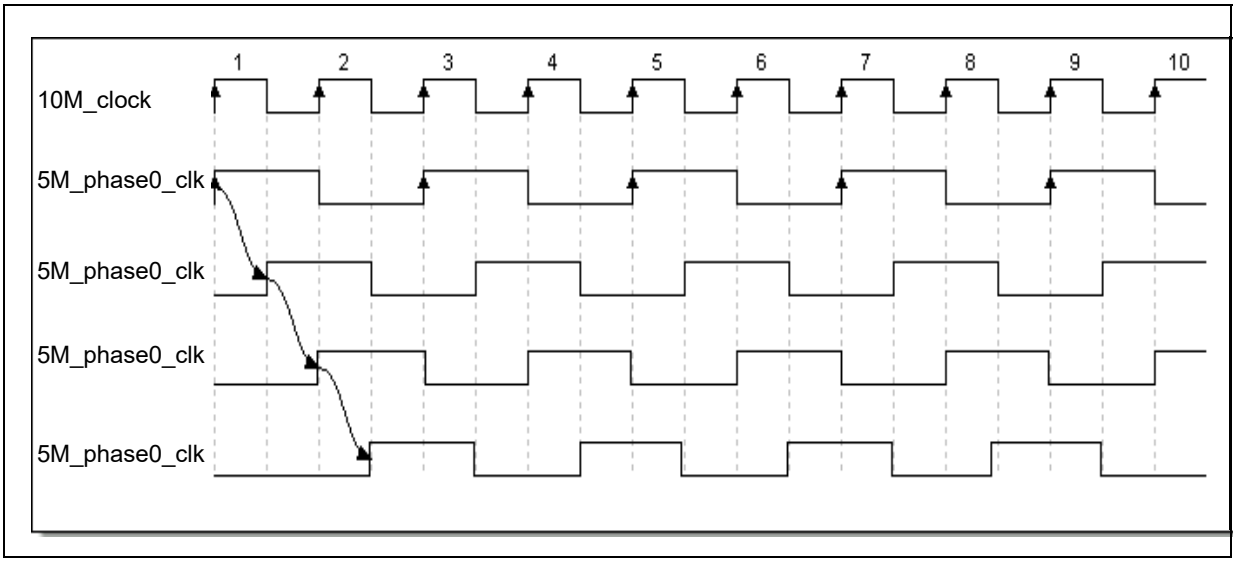


Figure 2071. External clock muxing of lfast_sysclk of 10 MHz

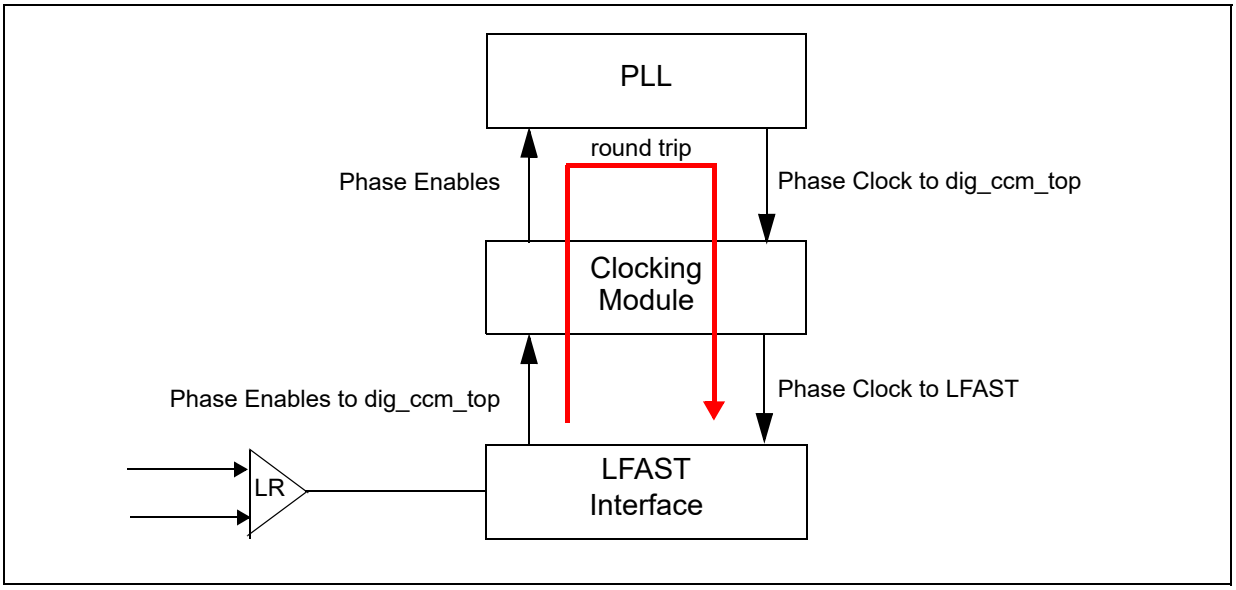
75.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. *Figure 2072* Shows 4 phases getting generated using lfast_sysclk.

Figure 2072. Slow speed 4 phases generation



75.10.3 Rx controller clocks

75.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in *Figure 2073*.

Figure 2073. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

75.10.3.2 Clock module requirements for low speed phases

75.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

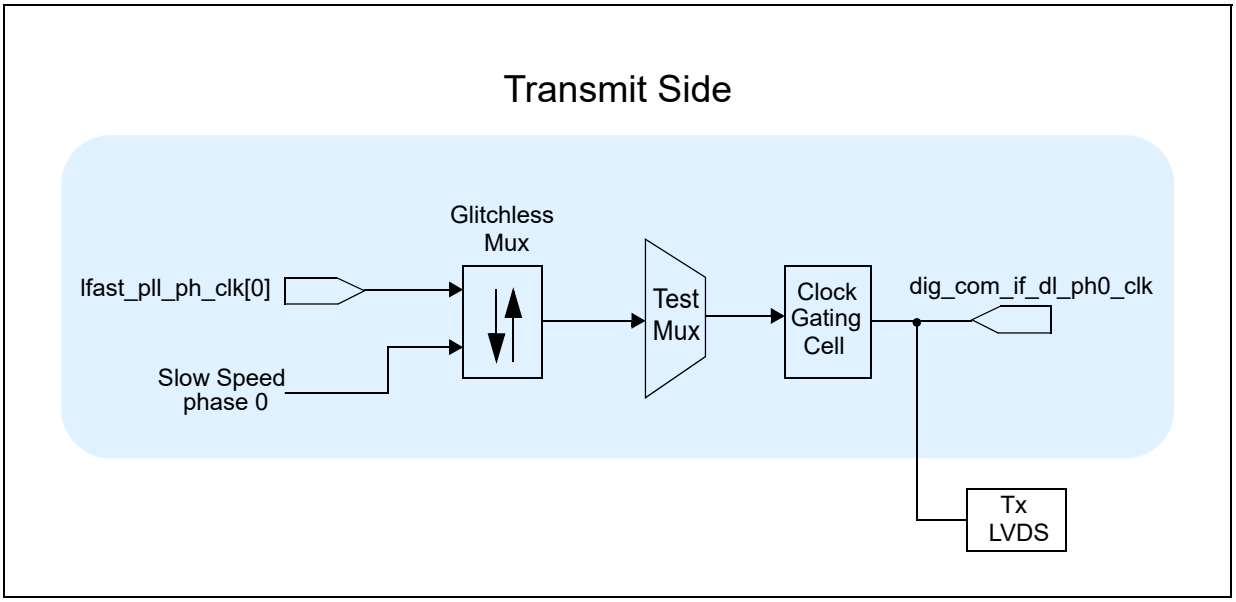
Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 1973. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

75.10.4 Tx controller clocks

75.10.4.1 Clocking module requirements for speed phases



The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See *Table 1974*.

Table 1974. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

75.10.4.2 Transmit clock muxing

Figure 2074. Transmit clocks muxing

75.10.4.3 Tx request clock control

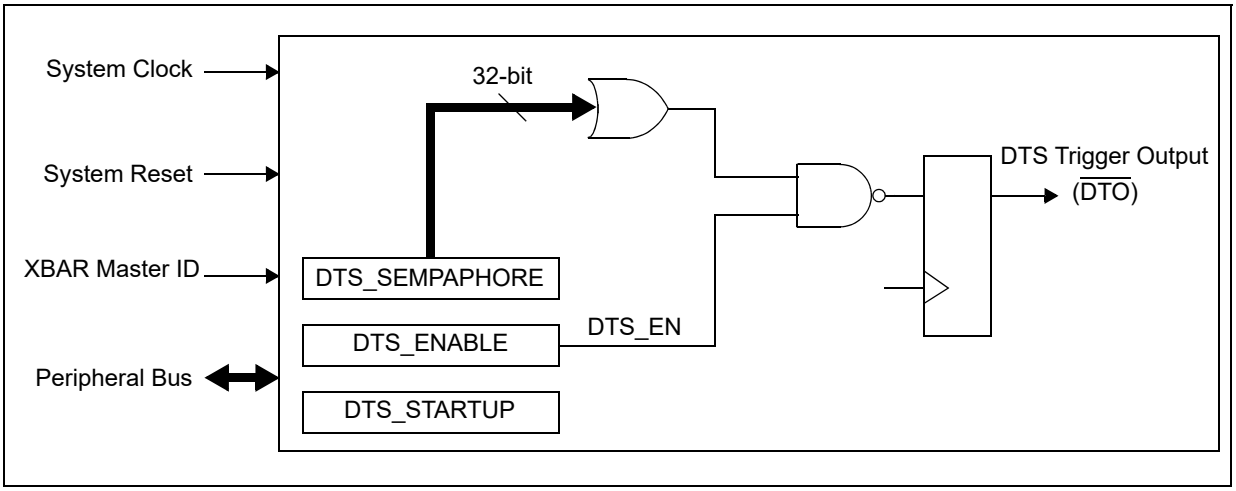
The Tx phase 0 clock is enabled when all the resets are negated.

76 Development Trigger Semaphore (DTS)

76.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.



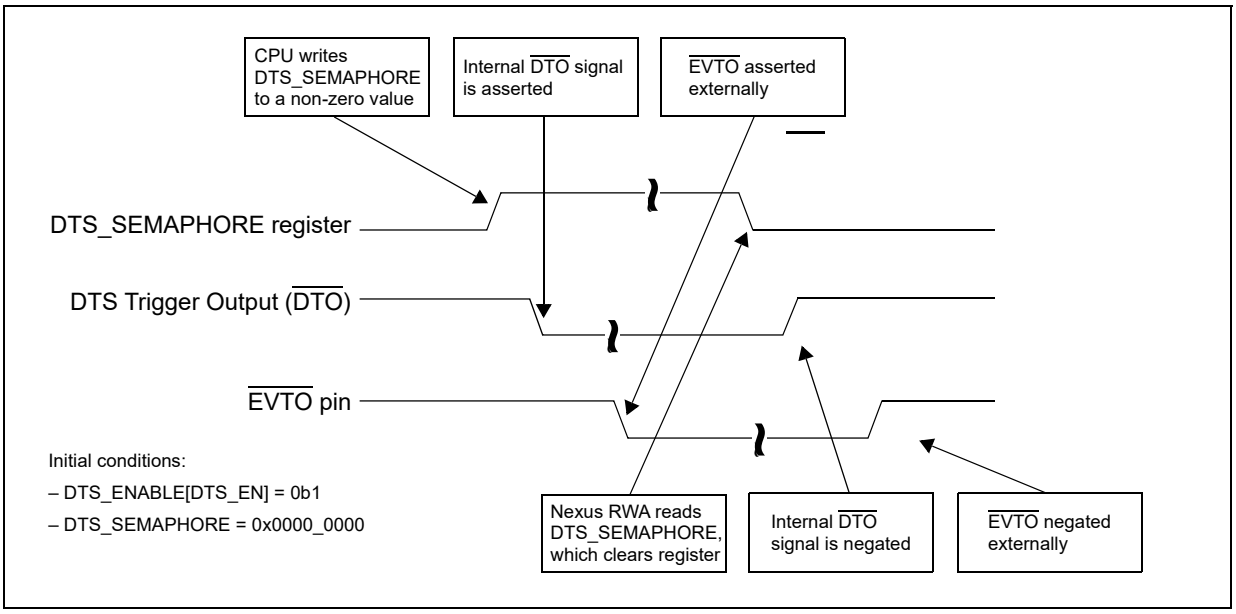
76.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal, DTS Trigger Output ($\overline{\text{DTO}}$). The registers are as follows:

- DTS_SEMAPHORE register: Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_STARTUP register: This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register: This register provides an enable/disable capability for the DTS feature.

The architecture is shown in *Figure 2075*.

Figure 2075. DTS block diagram



The DTS Trigger Output ($\overline{\text{DTO}}$) signal is connected to one of the $\overline{\text{EVTO}}$ inputs of the Debug and Calibration Interface (DCI). The other $\overline{\text{EVTO}}$ inputs are connected to the other Nexus modules in the device. $\overline{\text{DTO}}$ is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and $\overline{\text{EVTO}}$ becomes the $\overline{\text{DTO}}$. Unlike the $\overline{\text{EVTO}}$ function that only asserts for one clock, the $\overline{\text{DTO}}$ function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 2076 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

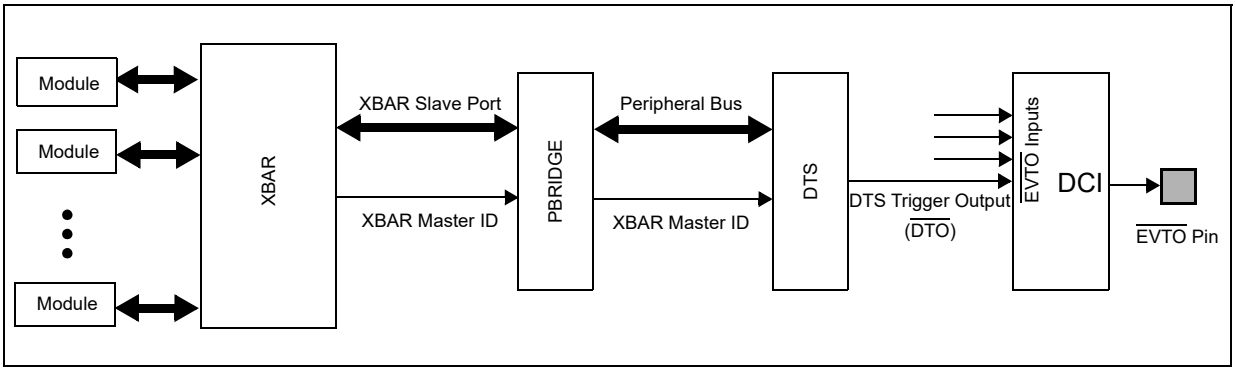


Figure 2076. $\overline{\text{DTO}}$ event sequence example

76.3 DTS device connections

Figure 2077 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 2077. DTS device connections

The registers have limited access as described in *Section 76.3.1: DTS register access*. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore register is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool or debug Zipwire can clear bits in the semaphore register (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access or debug Zipwire.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

76.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in *Table 1975*. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 1975. DTS register access effects

Register	32-bit read				32-bit write			
	RWA(1)	Core	eDMA	Other crossbar masters	RWA(1)	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear(2)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore register by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: The XBAR Master ID should not be confused with the Master Port number of the XBAR. See Chapter 16: Crossbar switch (XBAR), for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core or debug Zipwire. External tool accesses through either core appear as if the access is

via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

76.4 Memory map and register definition

Table 1976 shows the memory map of the DTS module registers.

Table 1976. DTS memory map

Offset address	Register name	Access	Reset Value	Location
0x0000	DTS Output Enable register (DTS_ENABLE)	Restricted R/W(1)	0x0000_0000	*Section 76.4.1.1*
0x0004	DTS Startup register (DTS_STARTUP)	Restricted R/W(1)	0x0000_0000	*Section 76.4.1.2*
0x0008	DTS Semaphore Register (DTS_SEMAPHORE)	Restricted R/W(1)	0xFFFF_FFFF	*Section 76.4.1.3*
0x000C	DTS Semaphore Extension (DTS_SEMAPHORE_B)	Restricted R/W(1)	0xFFFF_FFFF	*Section 76.4.1.4*

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

76.4.1 Register descriptions

76.4.1.1 DTS output enable register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. *Figure 2078* shows the format of the DTS_ENABLE register. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA) or debug Zipwire.

Note: Access to the DTS_SEMAPHORE and DTS_STARTUP registers are unaffected by the state of this register.

Offset 0x0000 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

Figure 2078. DTS output enable register (DTS_ENABLE)

Table 1977. DTS_ENABLE field descriptions

Field	Description
31 DTS_EN	DTS Enable Controls whether the DTO signal is routed to the EVTO pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external RESET or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal (DTO).

76.4.1.2 DTS startup register (DTS_STARTUP)

Figure 2079 shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA modules and other crossbar masters but can only be updated by a Nexus Read Write Access (RWA) or debug Zipwire.

Offset 0x0004 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	AD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	AD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The DTS_STARTUP register can be read by the cores, the eDMA module and Nexusbut can only be updated by a Nexus Read Write Access (RWA).

Figure 2079. DTS startup register (DTS_STARTUP)

Table 1978. DTS_STARTUP field descriptions

Field	Description
0:31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access or debug Zipwire to update the contents of this register. **Note:** A device reset (either from the RESET pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

76.4.1.3 DTS semaphore register (DTS_SEMAPHORE)

Figure 2080 shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the DTO signal on the device EVTO pin. A one in any

bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Offset 0x08 Access: Restricted R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2080. DTS semaphore register (DTS_SEMAPHORE)

Table 1979. DTS_SEMAPHORE field descriptions

Field	Description
0:31 ST	Semaphore Trigger. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

76.4.1.4 DTS semaphore extension (DTS_SEMAPHORE_B)

Figure 2081 shows the format of the DTS_SEMAPHORE_B register. The DTS_SEMAPHORE_B register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

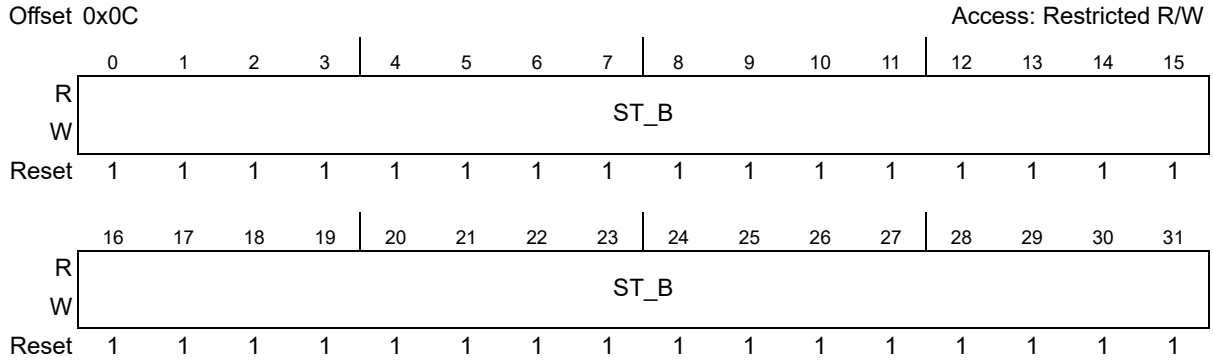

Figure 2081. DTS Semaphore extension register (DTS_SEMAPHORE_B)

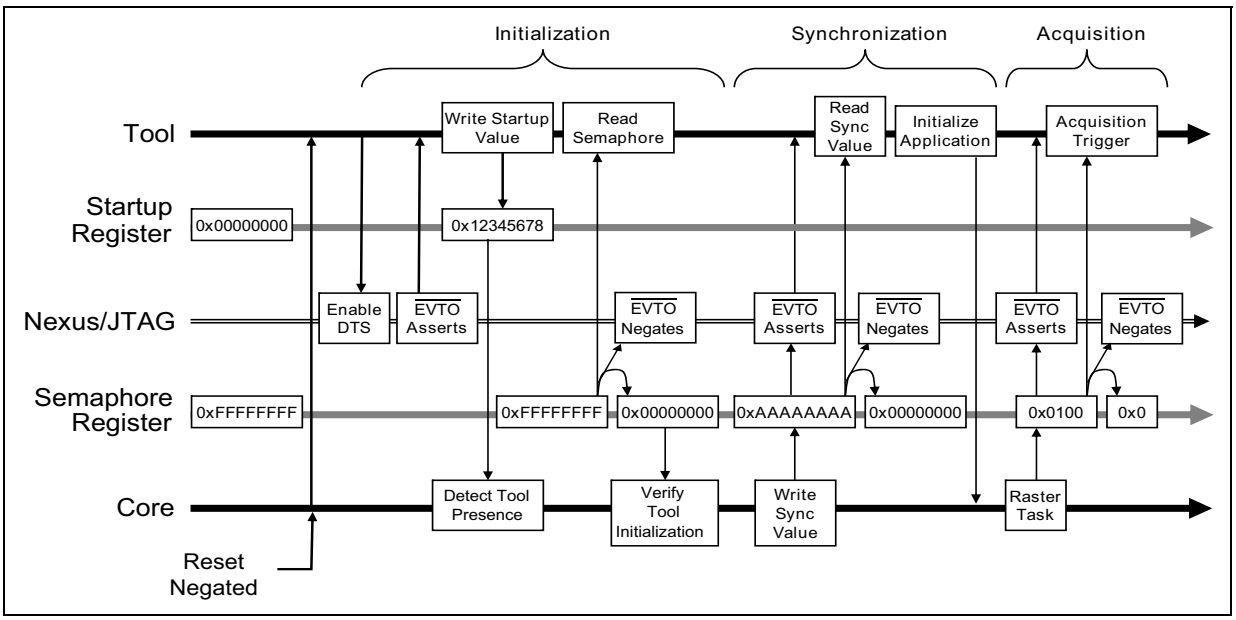
Table 1980. DTS_SEMAPHORE_B field descriptions

Field	Description
0:31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

76.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.



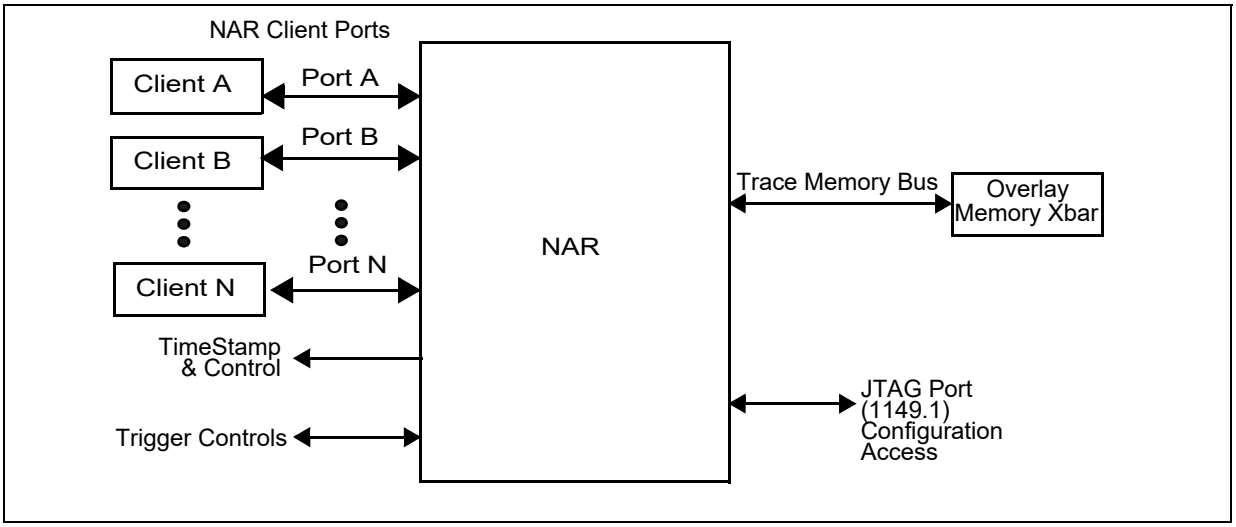
In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note: It is the user’s responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

Figure 2082 shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA, all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 2082. DTS startup sequence example



77 Nexus Aurora Router (NAR)

77.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 2083*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 2083. NAR top level diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

77.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port or the Trace port, or both. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

77.3 Features

The NAR supports the following features:

- Connects 10 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domians.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

77.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 1981. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	on page 3459
NAR_ST—NAR Status Register	R	1	on page 3461
NAR_SFR—Source Filter Register	R/W	2	on page 3463

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2084. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 1982. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 77.5.2.2: Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). *Note: Some clients may only support timestamps on every message.* 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 Reserved 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9	Reserved and must be written with 0s.

Table 1982. NAR_CR field descriptions (continued)

Field	Description
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 Aurora out is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2	Reserved and must be written with 0.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

77.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 2085. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 1983. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 1997* for coding
23–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)

77.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 77.5.6: Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

77.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

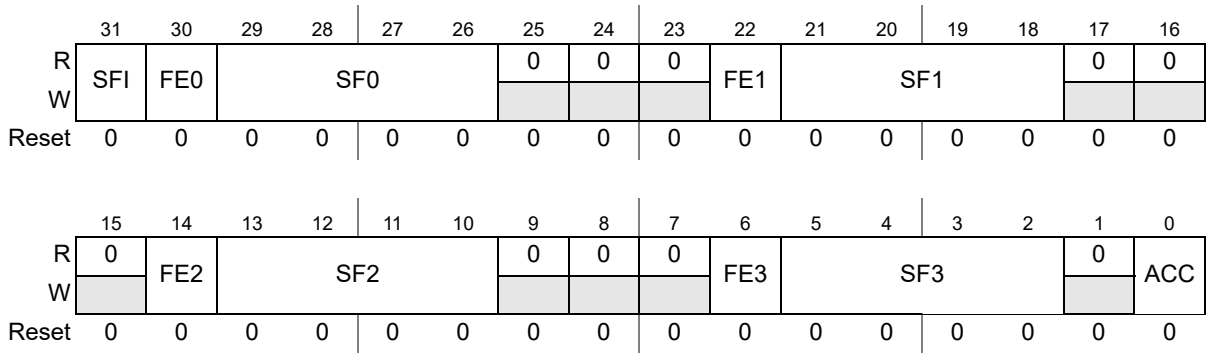

Figure 2086. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1984. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2

Table 1984. NAR_SFR field descriptions (continued)

13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

77.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

Figure 2087. Message type filter register (NAR_TFR)

The NAR_TFR is described in the following table.

Table 1985. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See *Section 77.5.6: Output arbitration* for an example.

Table 1985. NAR_TFR field descriptions (continued)

23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 77.5.6: Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 77.5.6: Output arbitration* for an example.

77.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

77.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

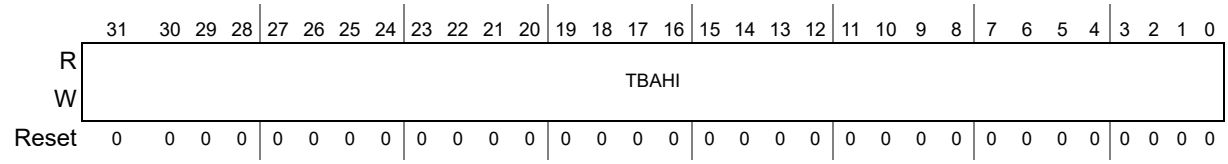

Figure 2088. Trace memory base address register NAR_TBAHI

Register index: 4

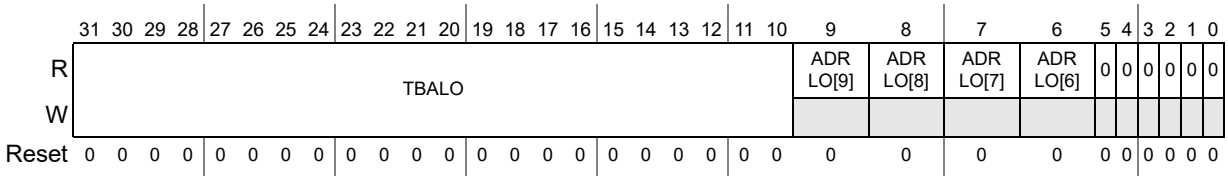

Figure 2089. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 1986. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 1987. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

77.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is

specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

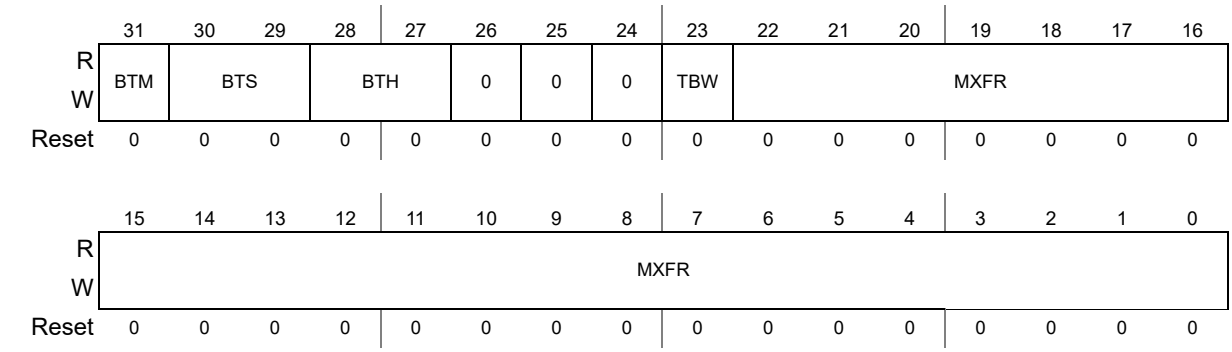

Figure 2090. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 1988. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

77.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 77.5.4: Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to

suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

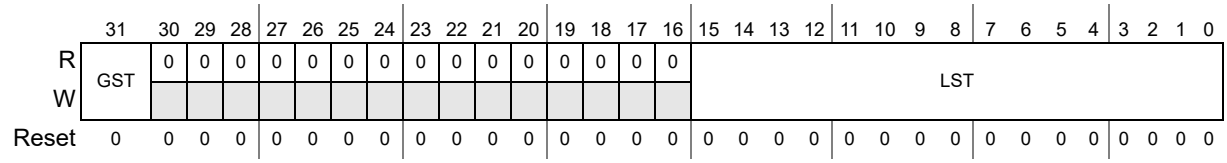

Figure 2091. Suppress trigger control registers (NAR_STCR1–4)

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1989. NAR_STCR field descriptions

Field	Description

77.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–0	Reserved

77.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Register index: C

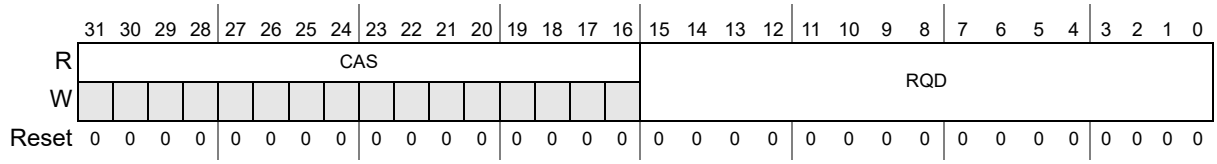

Figure 2093. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1991. NAR_CDR field descriptions

Figure 2094. Trace memory fill level and partition configuration register (NAR_AHFPAR)

The NAR_AHFPAR is described in the following table.

Table 1992. NAR_AHFPAR field description

Field	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 77.5.12: Overlay and internal trace memory full status generation* **Note:** This is used in PD as it has memory ranges from 1K to 15K

77.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

77.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 77.5.4: Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

77.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 1993. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

77.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

77.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

77.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

77.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

77.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 1994. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8×32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8×32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.

Table 1994. NAR transmit operations (continued)

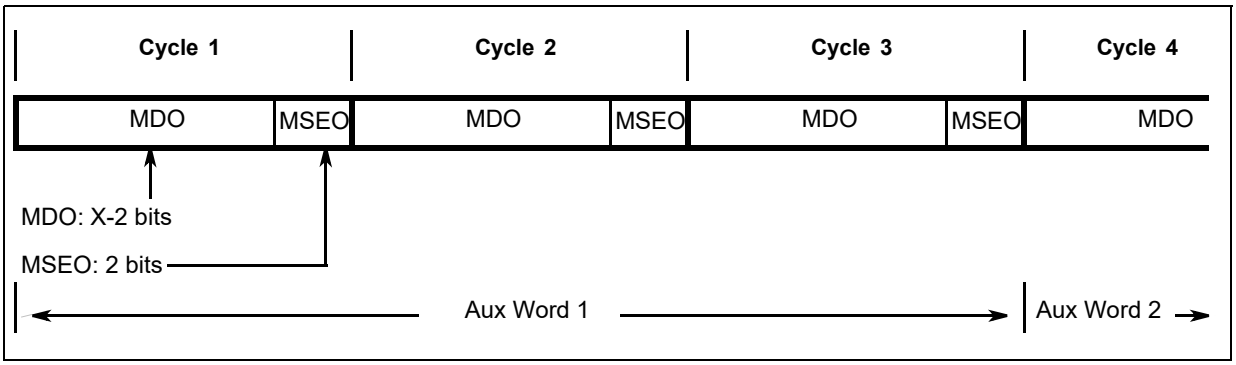
Operation	Description
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

77.5.3 Data reception and arbitration

The NAR supports 10 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn $\times$ 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment.

Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2095. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

77.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only

supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

77.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

77.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type or messages from a particular client, or both, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types or four sources, or both.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0)

or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

77.5.7 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

77.5.7.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

77.5.7.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data

interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

77.5.8 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

77.5.9 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (that is unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 $\times$ 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

77.5.10 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 1998*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 1995. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 1996*
	12	12	fixed	ECODE	See *Table 1997*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC(2)	NAR source ID
	6	6	fixed	WPHIT	See *Table 1998*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

77.5.10.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 1996. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 1997*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 1997*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 1997*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 1997. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

77.5.10.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

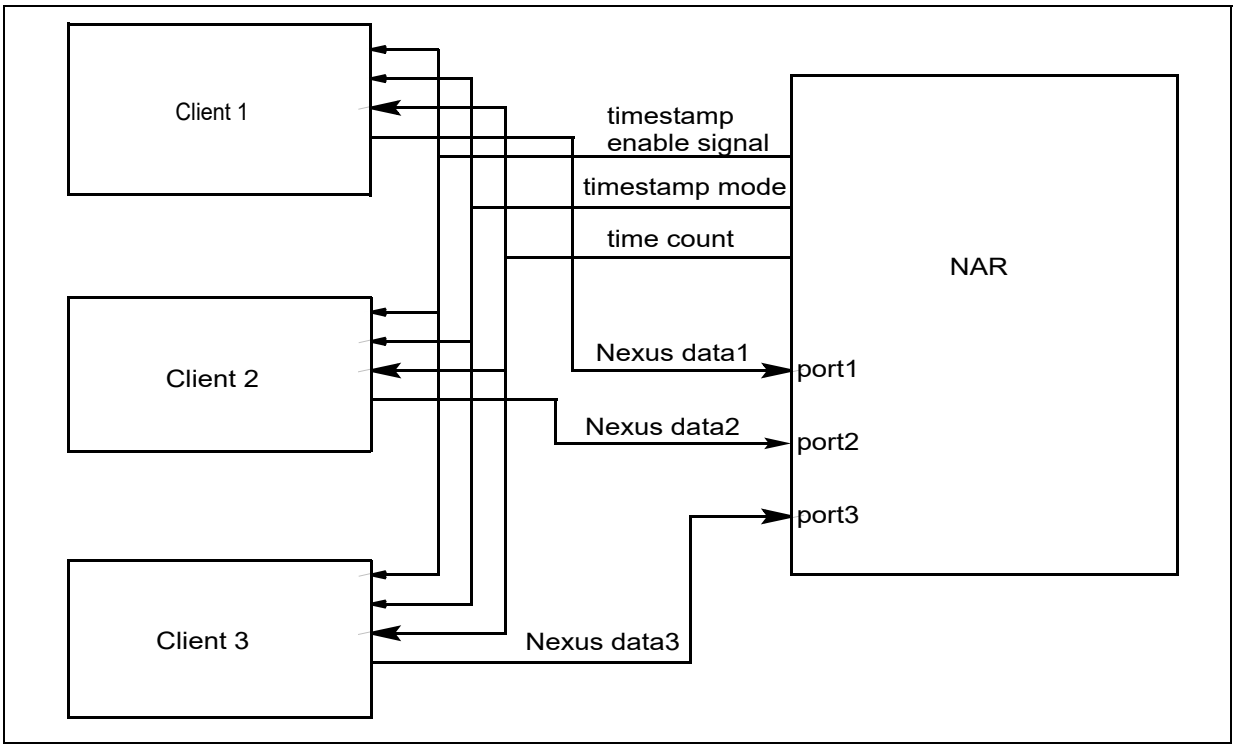


Table 1998. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

77.5.11 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 2096*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2096. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

77.5.12 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

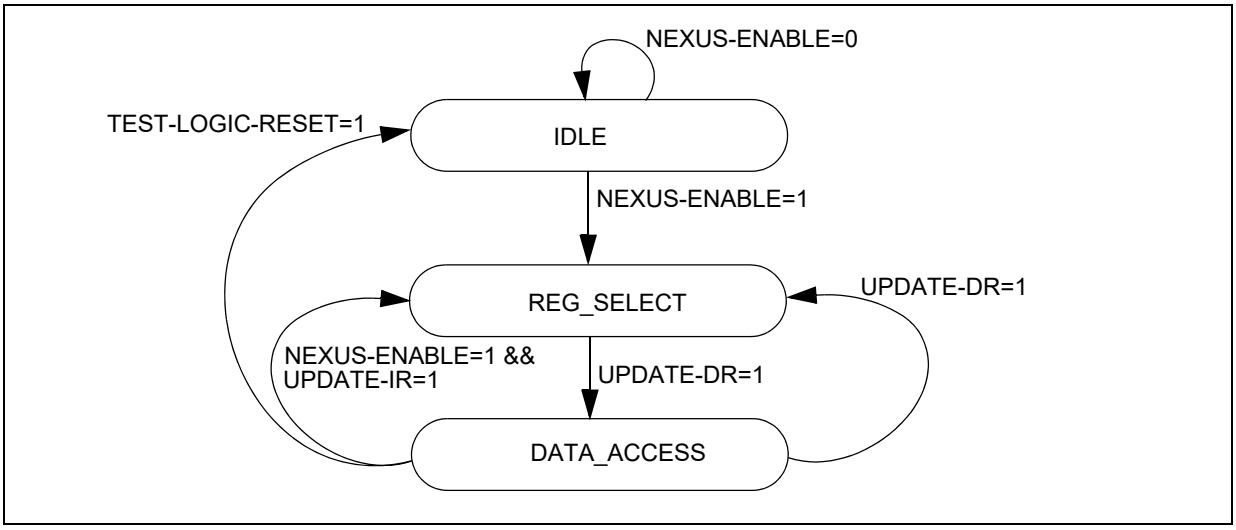
77.5.13 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 1999*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2097. Nexus controller state machine



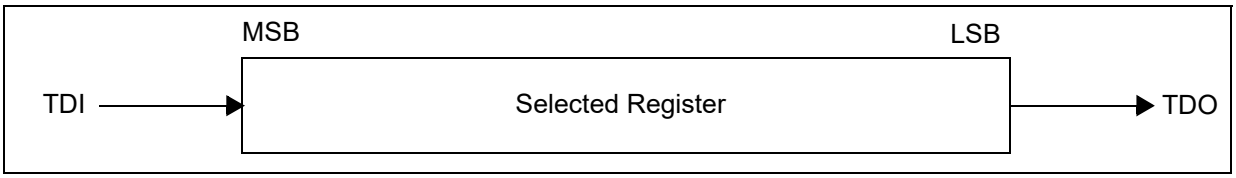


Table 1999. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2098. Shifting data into register

77.5.13.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

77.5.13.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2097*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 2000. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

77.5.13.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2099*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 1981*.

Figure 2099. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 2001. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

77.5.14 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

77.5.14.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

77.5.14.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

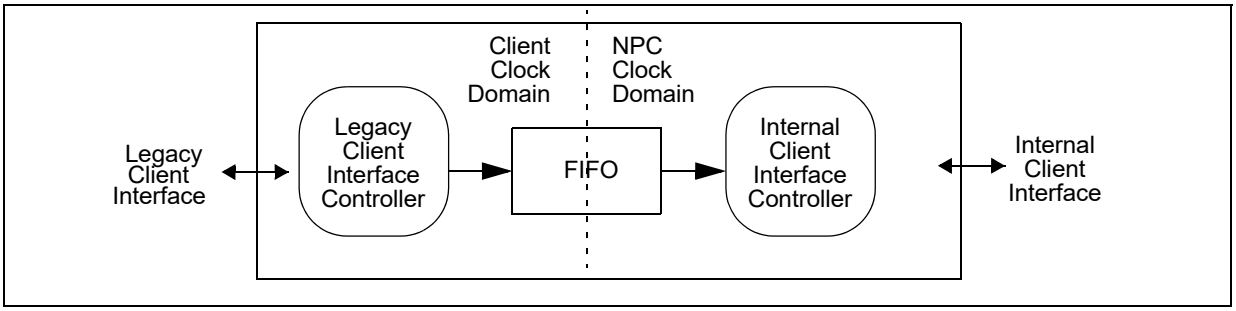
77.5.14.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

77.5.15 Legacy client interface controller



This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in *Figure 2100*.

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of paramaterizeable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

Figure 2100. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how may spaces are freed in receive queue.

77.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 77.5.2.1: Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

77.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 77.5.6: Output arbitration*.

78 e200z4256 Nexus 3 Module

The e200z4256 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

78.1 Introduction

78.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

78.1.2 Terms and Definitions

Table 2002 contains a set of terms and definitions associated with the Nexus 3 module.

Table 2002. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 2002. Terms and Definitions (continued)

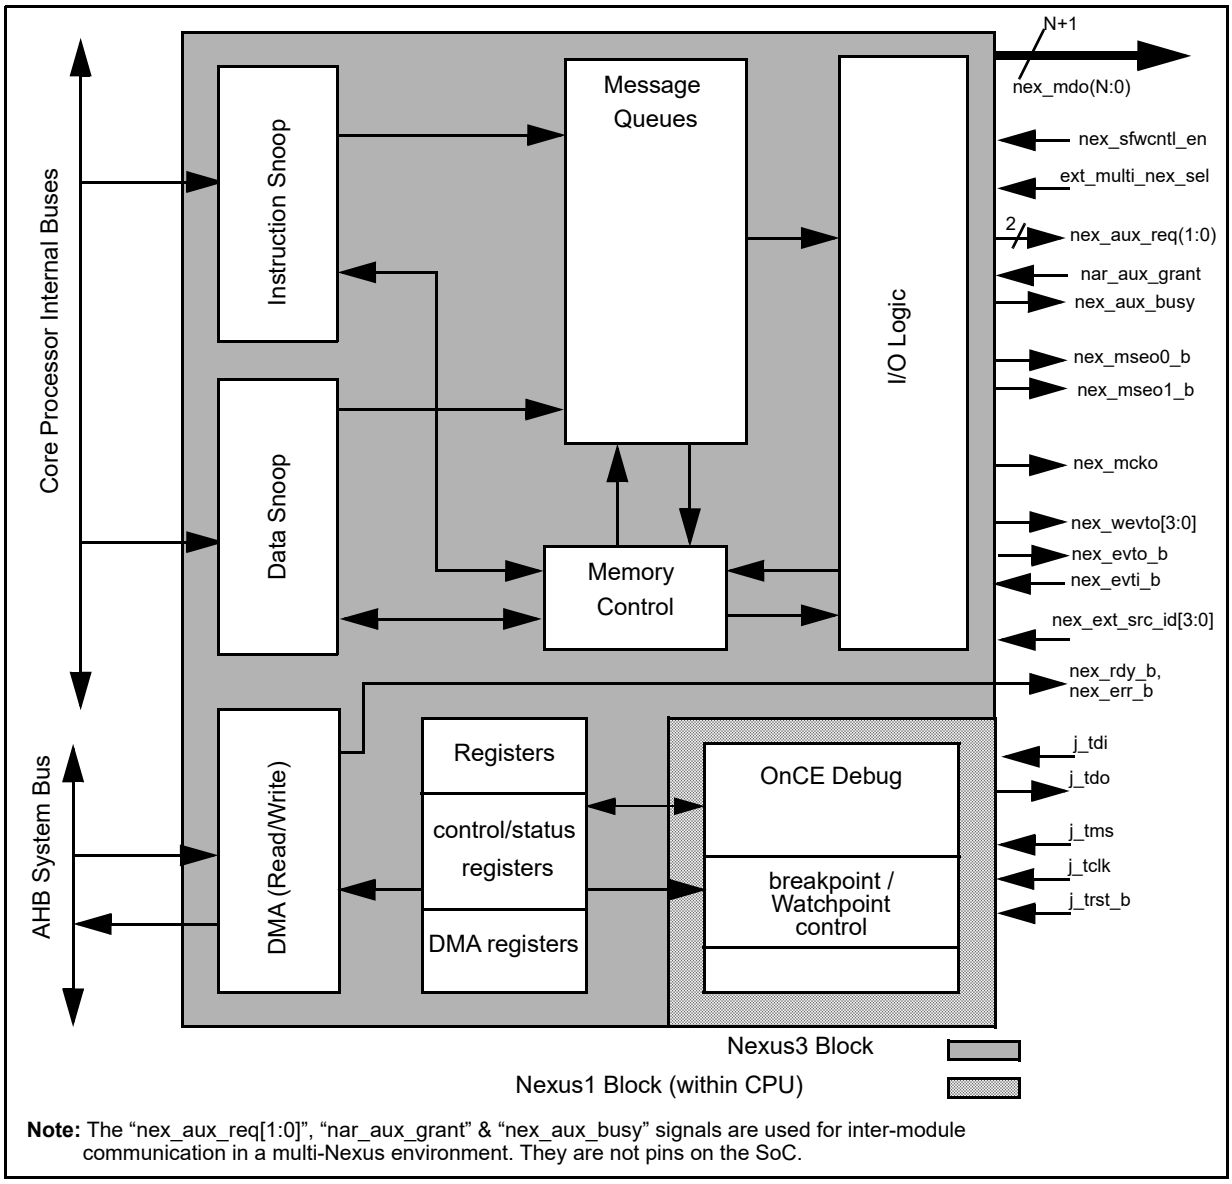
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

78.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (such as direct and indirect branches, exceptions), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

78.1.4 Functional Block Diagram

Figure 2101. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

78.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (NEXUS3-ACCESS) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

78.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

78.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 2003*.

Table 2003. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2008*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2003. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2008*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2003. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2008*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2008*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 2006*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See *Section 78.12.4: Resource Full Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2003. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 78.12.1: Branch Trace Messaging types*)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See *Section 78.12.1: Branch Trace Messaging types*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to *Table 2007*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See *Section 78.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See *Section 78.12.5: Program Correlation Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 78.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 2004 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 2004. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (such as Debug Status messages)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 2005 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 2005. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 2006 shows the encodings used for resource codes for certain messages.

Table 2006. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 2007 shows the event code encodings used for certain messages.

Table 2007. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 2008 shows the data trace size encodings used for certain messages.

Table 2008. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

78.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 78.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 78.6: Nexus 3 Register Access via Software* for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 2009 details the register map for the Nexus 3 module.

Table 2009. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.

2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

78.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Reserved				CS			
7	6	5	4	3	2	1	0

Nexus Reg# 0x1; Read-only; Reset: 0x0

Table 2010. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

78.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

OPC	0	MCK_EN	MCK_DIV	0
31	30	29	28 27 26	25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit	Name	Description
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

78.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 2104* and its fields are described in *Table 2012*.

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enabled for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 78.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 78.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

78.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 2105* and its fields are described in *Table 2013*.

1. Refer to *Table 2007* for implemented EVCODEs.

78.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

Figure 2108. Development Status (DS) register

25:0	—	Reserved for future functionality (read as 0)

78.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allow the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between

enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

78.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0

Nexus Reg# 0x15; DCR: 408; Read/Write; Reset: 0x0

Figure 2124. Data Trace End Address 4 register

Table 2025 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2025. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings

indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (that is when the instruction prefetch is discarded).

78.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 2027*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Figure 2125. Read/Write Access Control/Status (RWCS) register

1. ERR and DV are read-only

Table 2026. RWCS field descriptions

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access
RWCS[30]	RW	Read/Write Select 0 Read access 1 Write access
RWCS[29:27]	SZ	Word Size 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 64-bit (doubleword, requires two passes through RWD) 1*xx* Reserved (default to word)
RWCS[26:24]	MAP	MAP Select 000 Primary memory map All other values are reserved

Table 2026. RWCS field descriptions (continued)

Bits	Name	Description
RWCS[23:22]	PR(1)	Read/Write Access Priority 00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority
RWCS[21:18]	ATTR	Access Attributes 0xxx Reserved 1xxx Reserved x0xx **p_d_hprot[4]** driven to 0 for accesses x1xx **p_d_hprot[4]** driven to 1 for accesses xx0x **p_d_hprot[3]** driven to 0 for accesses xx1x **p_d_hprot[3]** driven to 1 for accesses xxx0 **p_d_hprot[2]** driven to 0 for accesses xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR(2)	Read/Write Access Error (see *Table 2027*)
RWCS[0]	DV(2)	Read/Write Access Data Valid (see *Table 2027*)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 2027. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

78.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 2126. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 2028* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 2028. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data) second RWD pass (high order data)	0 0 0	0 1 1	X X	X X	X X	X X

Table Notes:
"X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 2029 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 2029. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]
Byte @001	0 0 1	—	—	—	AHB[15:8]
Byte @010	0 1 0	—	—	—	AHB[23:16]
Byte @011	0 1 1	—	—	—	AHB[31:24]

Table 2029. RWD byte lane mapping (continued)

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:
"—" indicates byte lanes that will contain unused data.

78.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 2127. Read/Write Access Address (RWA) register

78.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 2009*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 78.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 2009*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 2128. JTAG DR format

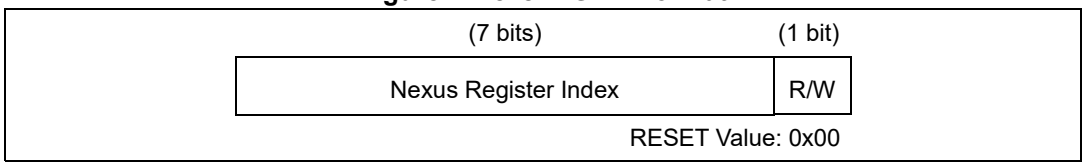

Table 2030. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 2009*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

78.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these accesses only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 2009* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

78.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

78.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

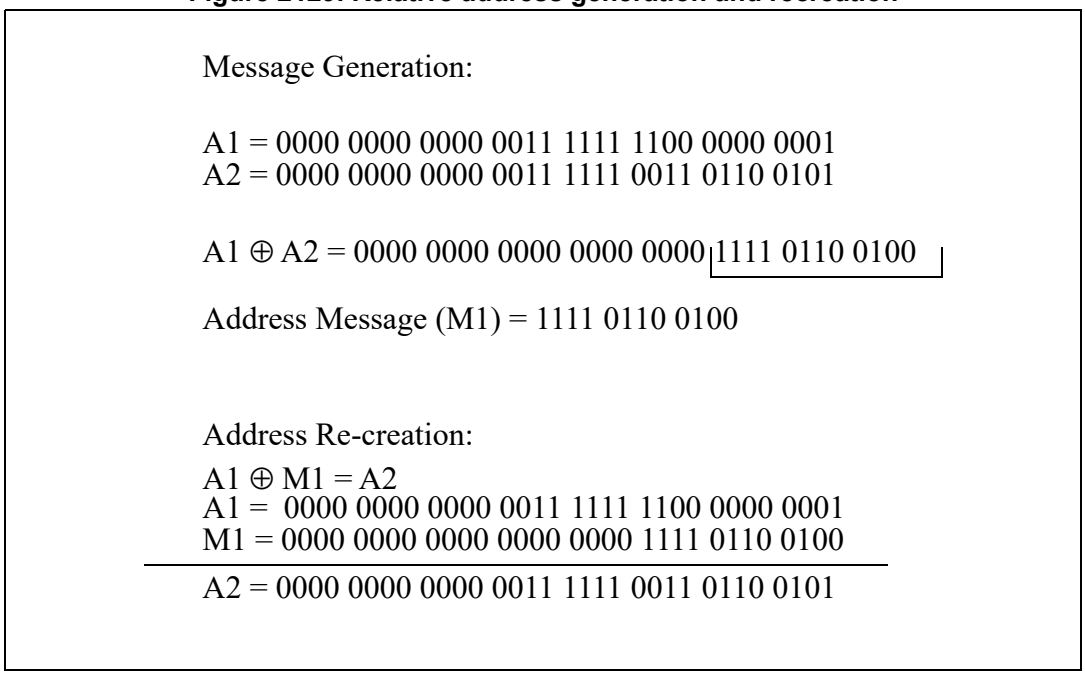
78.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

78.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 2129. Relative address generation and recreation

78.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization

messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

78.7.5 Timestamp Field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the **nex_tsen** input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of **nex_tsmode[0:1]** and the timestamp value is based on the **nex_timebase[0:29]** inputs. These signals are first synchronized to the **nex_clk** clock domain, and for **nex_timebase[0:29]**, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they enter the message queues. Leading zeros in the timestamp value are removed. *Table 2031: nex_tsmode[0:1] Timestamp mode encoding* shows the **nex_tsmode[0:1]** encodings used for the timestamp mode.

Table 2031. nex_tsmode[0:1] Timestamp mode encoding

nex_tsmode[0:1]	Timestamp mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

78.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

78.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming

messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

78.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 78.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

78.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 78.8.1: Message Queue Overrun*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

78.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstance:

More than three messages are generated in the same cycle

Table 2032 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 2032*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 2032. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

78.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

78.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

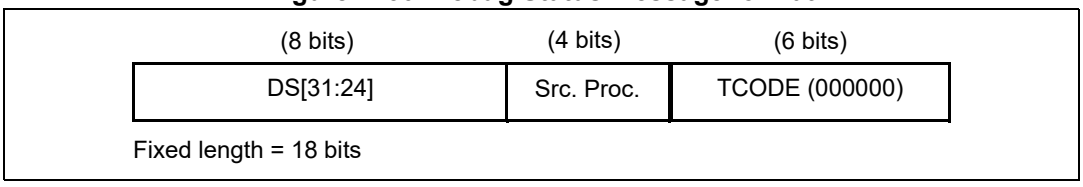
78.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

78.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



78.8.9 Data Trace Message Priority Loss Response

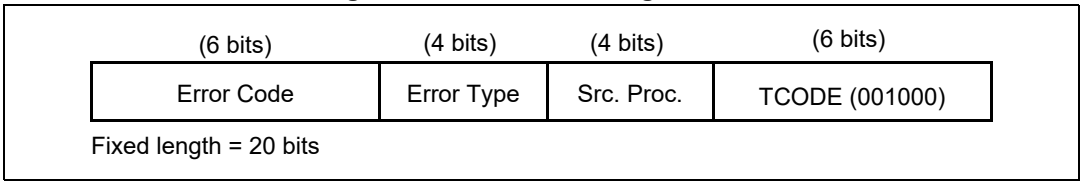
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

78.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 2130. Debug Status message format

78.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

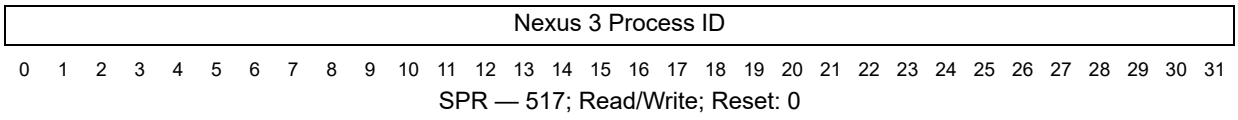
Error information is messaged out in the following format (also see *Table 2004* and *Table 2005*):

Figure 2131. Error message format

78.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

78.11.1 Overview



Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

78.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z420n3) processors contain a *PowerISA 2.06* defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

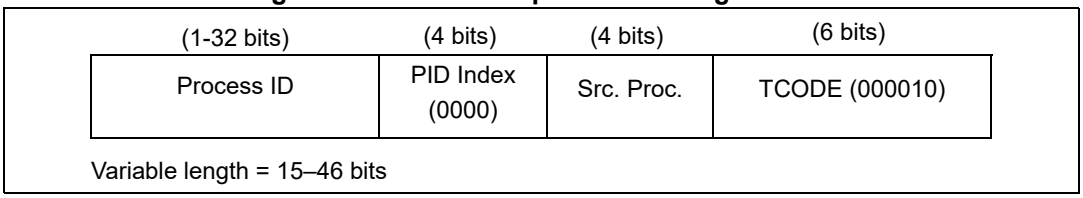
Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

SPR — 517; Read/Write; Reset: 0

Figure 2132. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.



The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 2133. Ownership Trace Message format

78.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z4256 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z420n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

78.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction,

taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

78.12.1.1 Indirect Branch Message instructions

Table 2033 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 2033. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfci, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

78.12.1.2 Direct Branch Message Instructions

Table 2034 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 2034. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

78.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

78.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

78.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

78.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to ‘1’, indirect branch information is messaged out in the following format:

Figure 2134. Indirect branch message (history) format

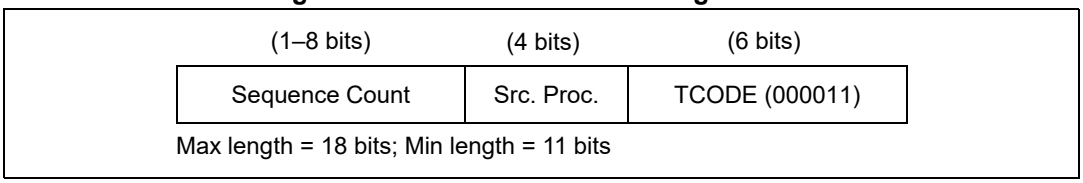
(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

78.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to ‘0’, indirect branch information is messaged out in the following format:

Figure 2135. Indirect branch message format



(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

78.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 2136. Direct branch message format

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

78.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

78.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

78.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 2035. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

78.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the reconstructed address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

78.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 2137. Resource Full Message format

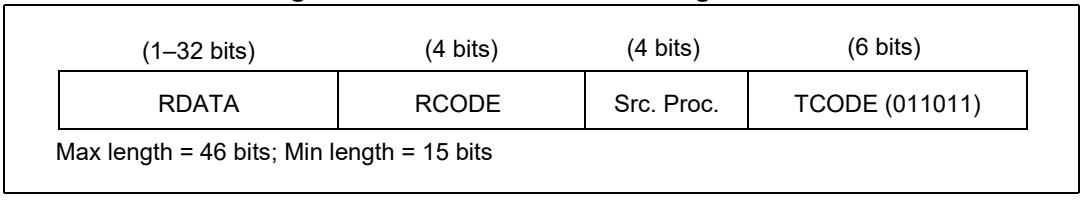


Table 2036 shows the RCODE encodings and RDATA information used for Resource Full Messages.

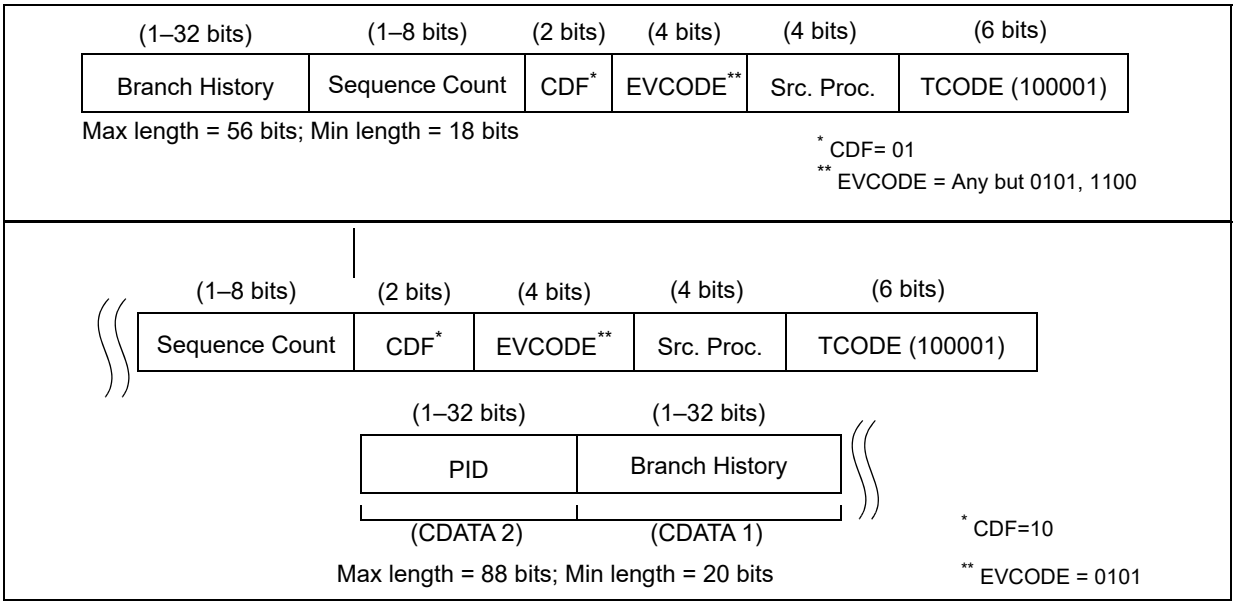
Table 2036. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

78.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 2007* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 2138. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

78.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

78.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

78.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via

the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 2037*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 2139. .Program Trace Synchronization message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in *Table 2037*.

Table 2037. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

78.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 2037*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 2140. Direct/Indirect Branch with Sync message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 2141. Indirect Branch History w/ Sync message format

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 2038*.

Table 2038. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

78.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of the three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

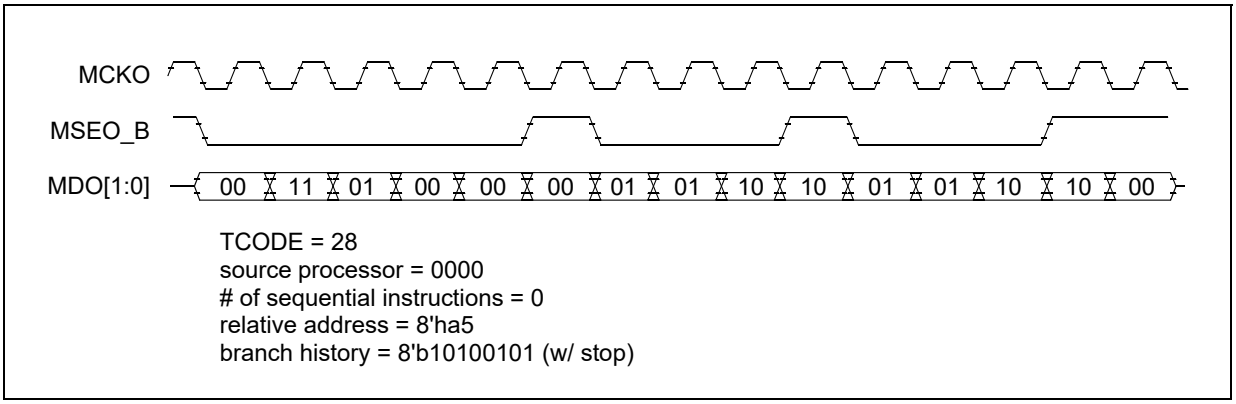

Figure 2144. Program Trace — Direct Branch (traditional) & Error messages

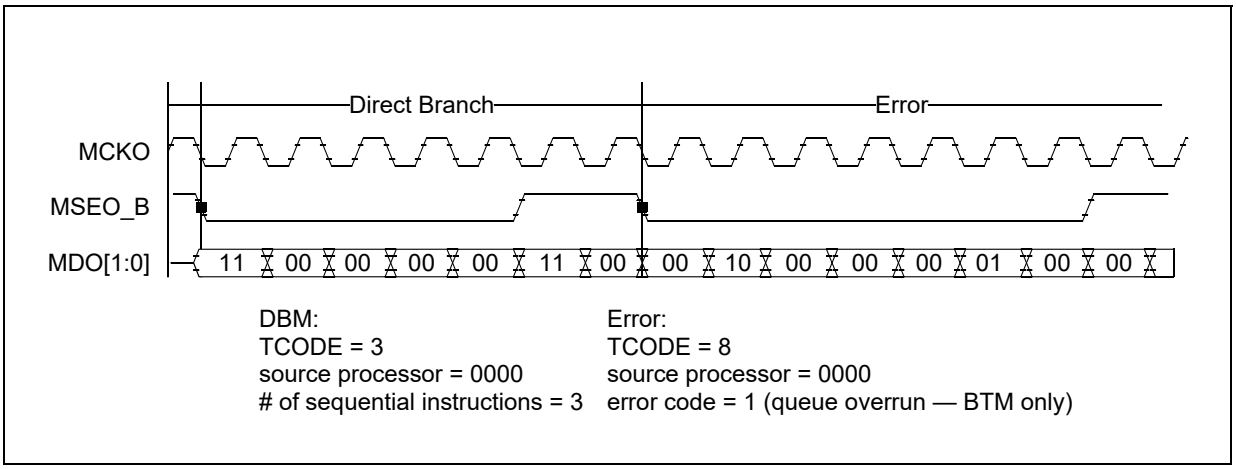

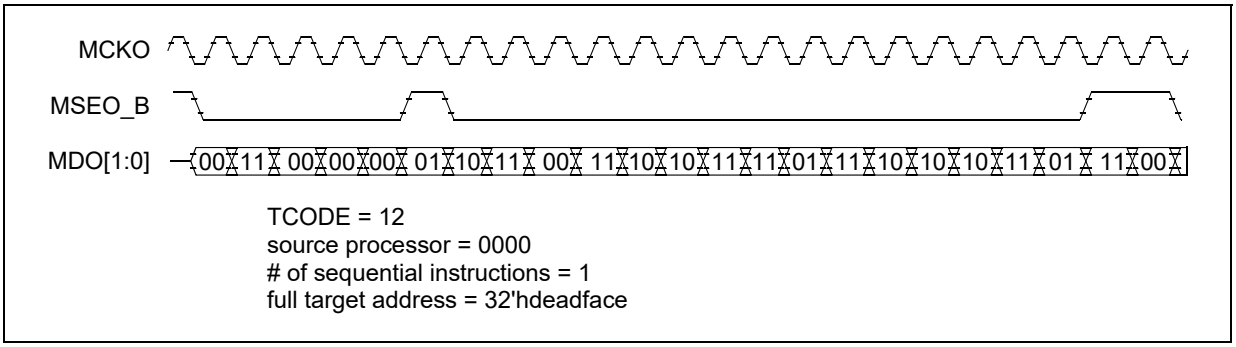

Figure 2145. Program Trace — Indirect Branch w/ Sync message

78.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

78.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z420n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

78.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

78.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 2146. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

78.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 2147. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

*Note: Core (e200z420n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the*

Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

*For Core (e200z420n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.

78.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 2039*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 2148. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in *Table 2039*.

Table 2039. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

78.13.3 DTM operation

78.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

78.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

78.13.3.3 Data Trace filtering

Data Trace filtering is available based on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

78.13.3.4 Bus cycle special cases

Table 2040. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error(1)	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

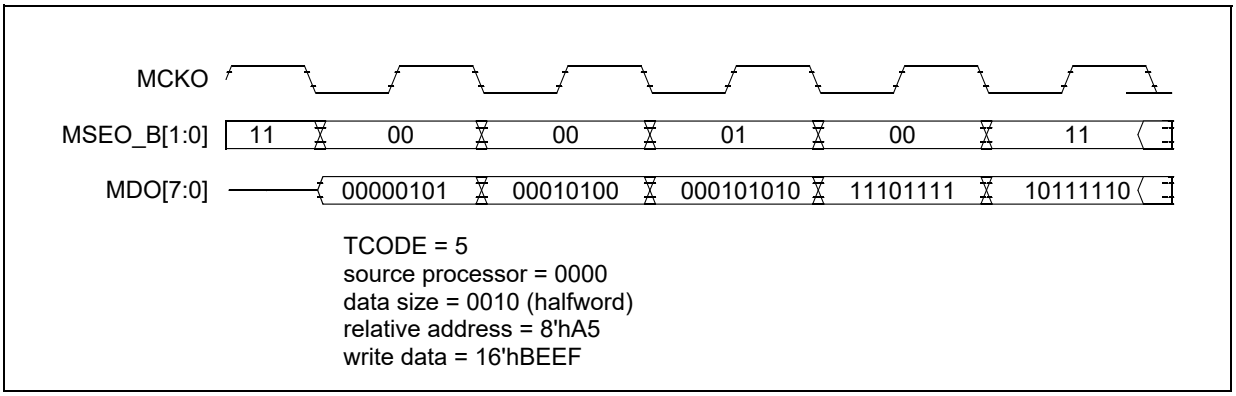
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z420n3) Core Debug Support chapter.)

Note: A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

78.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 2149. Data Trace — Data Write message



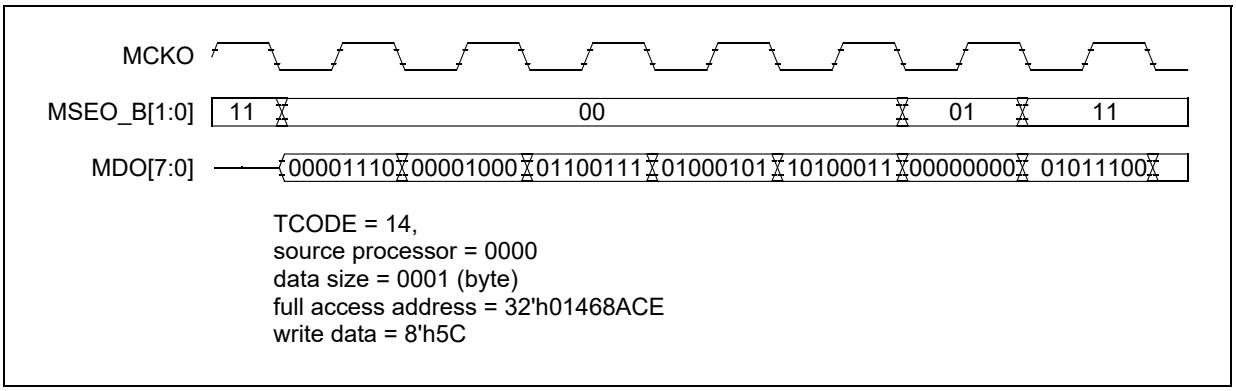


Figure 2150. Data Trace — Data Read w/ Sync message

78.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

78.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

78.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

78.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z420n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Table 2041. .Data Acquisition message format

(1–32 bits)	(8 bits)	(4 bits)	(6 bits)
DQDATA	DQTAG	Src. Proc.	TCODE (011011)

Max length = 50 bits; Min length = 19 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

78.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z420n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 2045* for details on **nex_evto_b**.

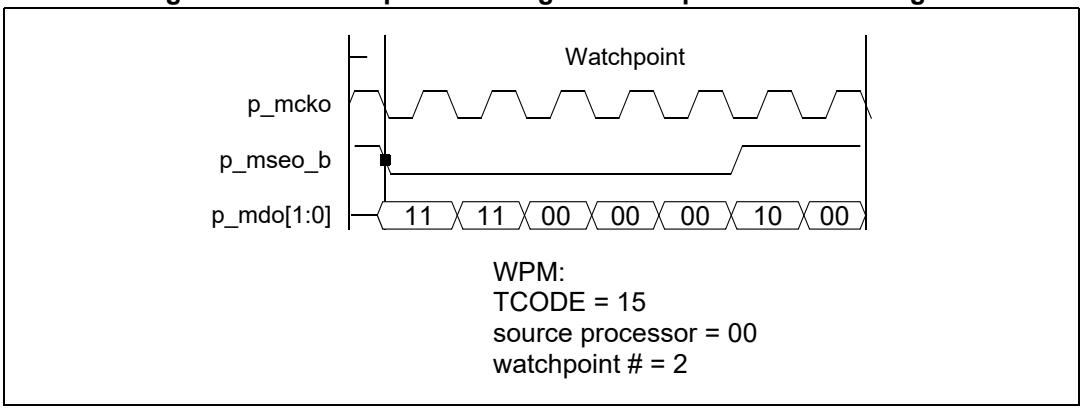
Watchpoint information is messaged out in the following format:

Figure 2151. Watchpoint message format

(1–30 bits)	(4 bits)	(6 bits)
Watchpoint Source	Src. Proc.	TCODE (001111)

Variable length = 11–40 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 2042. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1	Watchpoint #0 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*x*	Watchpoint #1 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxxx*1*xx*	Watchpoint #2 enabled for WTM
*xxxxxxxxxxxxxxxxxxxxxxxxxxx*1*xxx*	Watchpoint #3 enabled for WTM

Figure 2152. Watchpoint Message & Watchpoint Error message

78.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 2043* details the external hardware trigger signals.

Table 2043. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 2043. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

78.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

78.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 2045* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note: Only the **nex_ahb_start, nex_rdy_b, and nex_err_b** *pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

78.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 78.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 78.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

78.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 2045* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*.

Note: Only the **nex_ahb_start, nex_rdy_b,** *and* **nex_err_b** *pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

78.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 78.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see *Table 2045* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 2045* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 78.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 78.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (that is doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

78.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

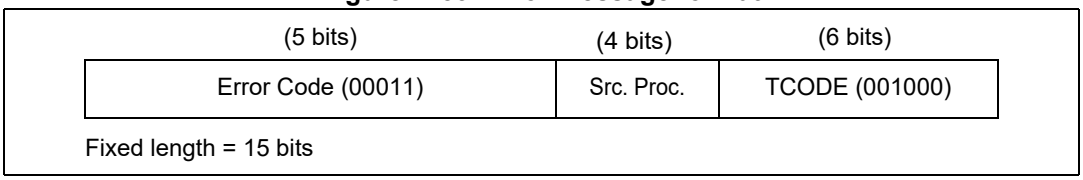
78.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

78.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

78.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 2153. Error message format

78.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

78.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 2045*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 78.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z420n3) Core Debug Support chapter.

Table 2044. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 2045*.

Table 2045. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted

Table 2045. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 78.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

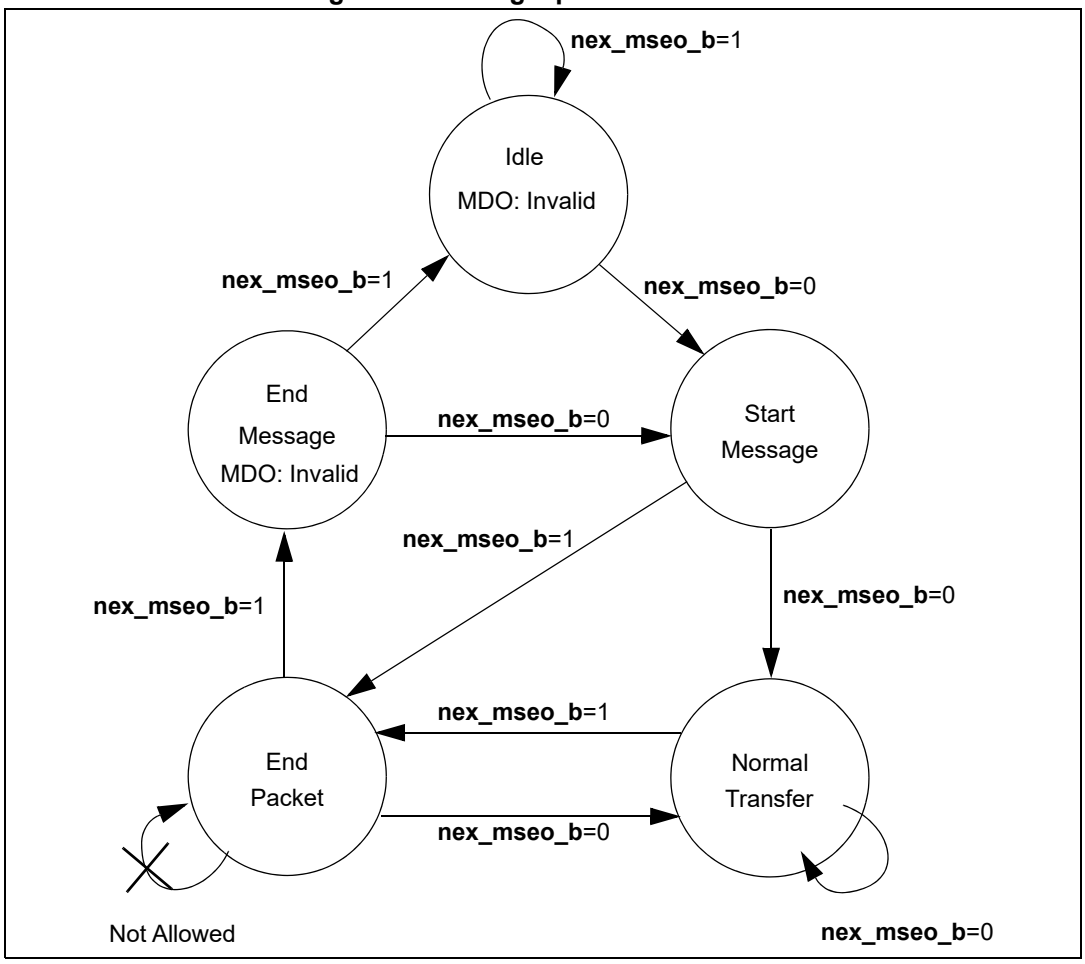
Table 2046. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 2048*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

78.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 2047*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



Single pin MSEO is not supported on the SPC58xNx.

Table 2047. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 2154 illustrates the state diagram for single pin MSEO transfers.

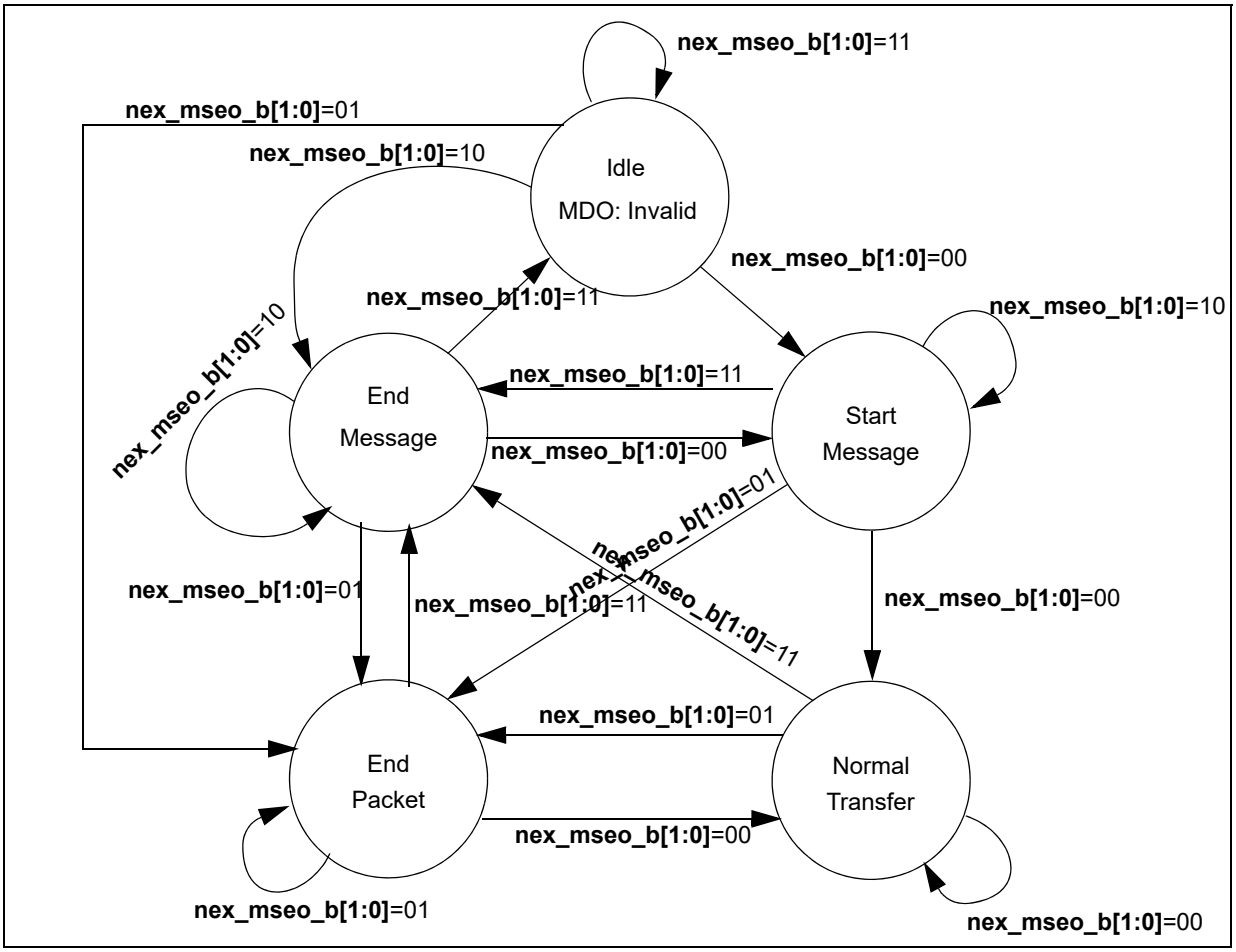


Figure 2154. Single pin MSE transfers

Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 2155 illustrates the state diagram for dual pin MSEO transfers.

Figure 2155. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

78.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-

order bit so that it can end on a port boundary.

For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

78.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 2048* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 78.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the "End Message" state.

Table 2048. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

78.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 2049 illustrates an example of Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 2050* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 2049. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 2050. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2051 and *Table 2052* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 2051. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 2052. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2053 illustrates an example of Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 2054* illustrates the same DWM with 8 MDO / 2 MSEO configuration.

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 2053. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 2054. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

78.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC58xNx Data Sheet.

78.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

78.23.1 JTAG sequence for accessing internal Nexus registers

Table 2055. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

78.23.2 JTAG sequence for read access of memory-mapped resources

Table 2056. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

78.23.3 JTAG sequence for write access of memory-mapped resources

Table 2057. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

79 Nexus Crossbar Multi-Master Client (NXMC)

79.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA AHB, and CPU Data Bus AHB start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.This also provides the capability of sending user defined messages for the peripherals attached to it.

79.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to (selected) internal memory resources
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

79.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 2059*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (refer to *Section 79.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 2058* describes the JTAG pins.

Table 2058. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 2059. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (refer to *Section 79.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

79.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 2060*. The SRC

and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 2060. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2061*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2061*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (refer to *Table 2062*)
	14	14	ECODE	fixed	Error code (refer to *Table 2063*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2061*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2060. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2061*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (refer to *Table 2075*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2061. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 2062. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved

Table 2062. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 2063. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved
Source (SRC) n = peripheral index		
CKSRCn	XXXXXXX1	Reserved
CKSRCn	XXXXXX1X	Reserved
CKSRCn	XXXXX1XX	Reserved
CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

79.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. Refer to *Section 79.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 2064*.

Table 2064. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	0x2	R/W	0x04	0x05
Development Control 2 (DC2)	0x3	R/W	0x06	0x07
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B
Data Trace Start Address1 (DTSA1)	0xE	R/W	0x1C	0x1D
Data Trace Start Address2 (DTSA2)	0xF	R/W	0x1E	0x1F
Data Trace End Address1 (DTEA1)	0x12	R/W	0x24	0x25
Data Trace End Address2 (DTEA2)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register1 (BWC1)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register2 (BWC2)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register1 (BWA1)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register2 (BWA2)	0x1F	R/W	0x3E	0x3F

79.4.1 Register definitions

Detailed register definitions for the current NXMC implementation are described in the following sections.

79.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. *Figure 2156* shows the format of the DC1.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0(1)	0(1)	0(1)	EOC		0	0	WEN	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	EIC		TM		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 2156. Development control register 1 (DC1)

The DC1 is described in *Table 2065*.

Table 2065. DC1 register field description

Field	Description
3:4 EOC	$\overline{\text{EVTO}}$ Control. 00 $\overline{\text{EVTO}}$ upon occurrence of watchpoint (internal or external) 01 $\overline{\text{EVTO}}$ upon entry into system-level Debug Mode 1x Reserved
7 WEN	Watchpoint Trace Enable. 0 Watchpoint Messaging disabled 1 Watchpoint Messaging enabled
27:28 EIC	$\overline{\text{EVTI}}$ Control 00 $\overline{\text{EVTI}}$ for synchronization (Data Trace) 01 Reserved 10 $\overline{\text{EVTI}}$ disabled 11 Reserved
29:31 TM	Trace Mode 000 No Trace 1xx Reserved x1x Data Trace enabled xx1 Reserved

79.4.1.2 Development control register 2 (DC2)

The Development Control Registers control the basic development features of the NXMC module. *Figure 2157* shows the format of the DC2.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EWC								0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PME0(1)
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 2157. Development control register 2 (DC2)

The DC2 is described in *Table 2066*.

Table 2066. DC2 register field description

Field	Description
0:7 EWC	$\overline{\text{EVTO}}$ Watchpoint Configuration(1). 00000000 No Watchpoints trigger $\overline{\text{EVTO}}$ 1XXXXXXX External Watchpoint #1 triggers $\overline{\text{EVTO}}$ X1XXXXXX External Watchpoint #2 triggers $\overline{\text{EVTO}}$ XX1XXXXX Reserved(2) XXX1XXXX Reserved(2) XXXX1XXX Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$ XXXXX1XX Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$ XXXXXX1X Reserved(2) XXXXXXX1 Reserved(2)
31 PME0	Peripheral Messaging Enable for the In-Circuit Trace (ICT) feature.(3) 0 Peripheral Interface disabled 1 Peripheral Interface enabled

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. Writing bits 2,3,6,7 has no impact and read value will be 0 for these bits.
3. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

79.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 2158* shows the format of the WT register.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	DTS		DTE				0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2158. Watchpoint trigger register (WT)

The WT register is described in *Table 2067*.

Table 2067. WT register field description

Field	Description(1)
6;8 DTS	Data Trace Start Control. 000 Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved
9;11 DTE	Data Trace End Control. 000Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

79.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. *Figure 2159* shows the format of the DTC register.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RWT1		RWT2		0	0	0	MME	0	0			MID

Figure 2159. Data trace control (DTC) register

The DTC register is described in *Table 2068*.

Table 2068. DTC field description

Field	Description
0:1 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x nable data write trace
2:3 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
7 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
12:15 MID	ID of the system bus Master to be traced(1)
24 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
25 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

79.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 2160* shows the format of the DTSA1 and DTSA2 registers.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2160. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

79.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. *Figure 2161* shows the format of the DTEA1 and DTEA2 registers.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2161. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 2069 illustrates the ranges that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2069. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range – no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

79.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. *Figure 2162* shows the format of the BWC1 register.

Address: refer to *Table 2064* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2164. Breakpoint /watchpoint address registers 1 and 2 (BWA1 and BWA2)

79.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 2064*. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

79.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of TRST and system reset de-assertion, after the JTAG ID register has been read by the tool after negation of TRST and should be programmed before deassertion of system reset.

79.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 79.5.4: NXMC register access via JTAG*.

79.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the TRST pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

79.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the TRST pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set.

79.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 2064*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to *Table 2064*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 2165* and *Table 2072*.

Figure 2165. JTAG DR for Nexus register access

Table 2072. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 2064*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

79.6 Functional description

79.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

79.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

79.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

79.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in *Figure 2166*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

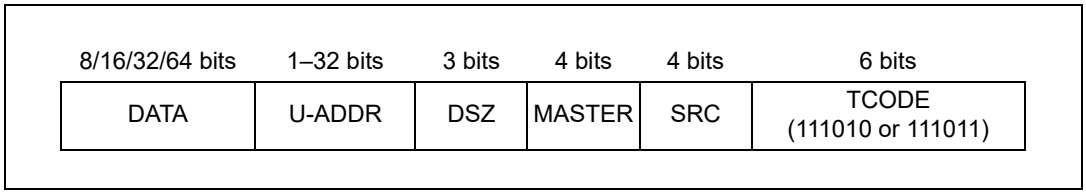

Figure 2166. DTM message format for DATA width = 64 bits

TSTAMP is another optional field which is inserted based on the controls received from the NAR, refer to *Section 79.6.4: Timestamping feature*.

79.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

79.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 2167*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

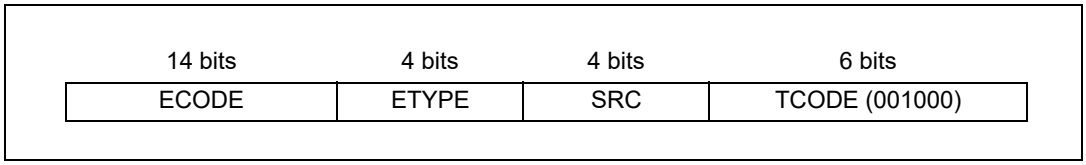

Figure 2167. DTM error message format (fixed length = 48 bits)

79.6.1.2.3.1 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to *Table 2073*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message
- Upon returning from a low power state, the first data trace message is a synchronization message
- Upon returning from debug mode, the first data trace message is a synchronization message
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 2168*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Figure 2168. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 2073*.

Table 2073. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table 2073. Data trace exception summary (continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

79.6.1.3 DTM operation

79.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

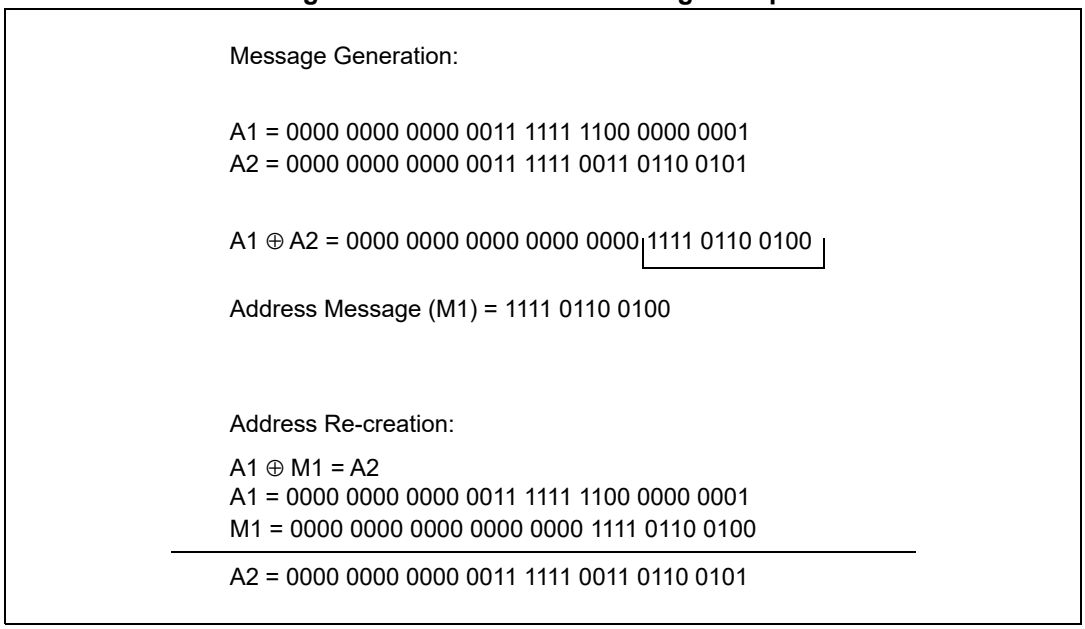
- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (that is DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure the correct DTM functionality.

79.6.1.3.2 DTM queuing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).



79.6.1.3.3 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address

transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 2169*.

Figure 2169. Relative addressing example

79.6.1.3.4 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

79.6.1.3.5 System bus cycle special cases

The system bus cycle special cases are shown in *Table 2074*.

Table 2074. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

79.6.1.3.6 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (refer to figure in *Section 79.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

79.6.1.3.7 HSM master filtering

For security reasons certain HSM masters need to be disabled or filtered from data tracing operations.

79.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

79.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (that are BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints: Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 79.6.1.3.6: System bus multi-master tracing*).
- External watchpoints: The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level.The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (that is on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 2170* and *Table 2075*.

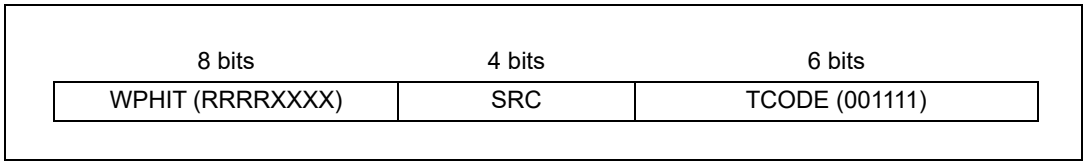


Figure 2170. Watchpoint message format (fixed length = 18 bits)

Table 2075. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

79.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 2171*.

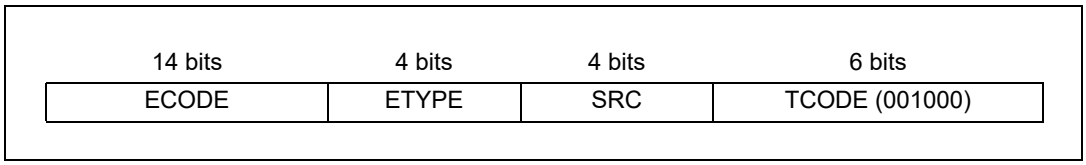

Figure 2171. Error message format (fixed length = 28 bits)

79.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

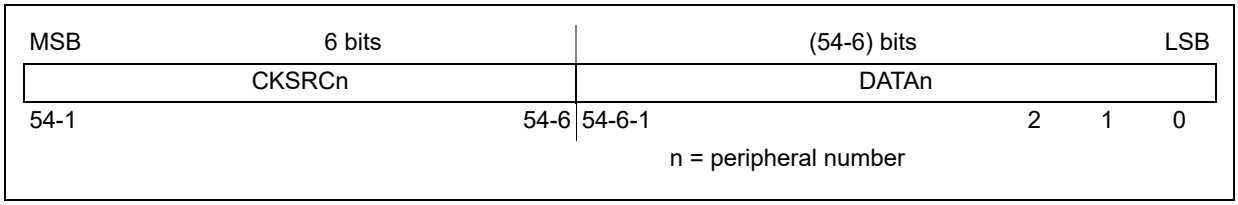

Figure 2172. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

79.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in *Figure 2173*. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

1–44 bits	6 bits	4 bits	6 bits
CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 2173. Peripheral message format (max length = 60 bits, min length = 17 bits)

79.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in *Figure 2174*.

14 bits	4 bits	4 bits	6 bits
ECODE(CKSRCn,ErrCODE)	ETYPE	SRC	TCODE (001000)

Figure 2174. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in *Table 2062* and *Table 2063*.

79.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. *Figure 2175* shows an example of ICTM message with a TSTAMP field.

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 2175. Message with TSTAMP field example

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via such as TM, PME0 control bits)

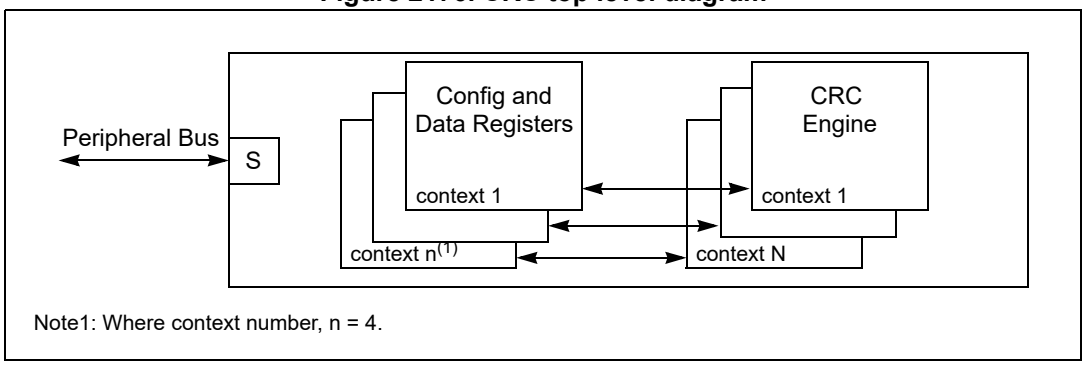
80 Cyclic Redundancy Check (CRC) Unit

80.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

80.2 Main features

- 4 contexts for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 4 hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
  - Support for byte, halfword, or word width of the input data stream



80.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

80.3 Block diagram

The top level diagram of the CRC module is given in *Figure 2176*.

Figure 2176. CRC top level diagram

80.4 Signal description

The CRC module does not generate any external signals.

80.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

80.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

80.5.1 Register description

Table 2076 shows the memory map for the CRC registers.

Table 2076. CRC unit memory map

Offset	Register	Location
CRC registers per context (n=0 to CRC_CNTX_NUM - 1 with CRC_CNTX_NUM = 4)		
0x000 + *n**0x10	CRC Configuration Register *n* (CRC_CFG*n*)	*Section 80.5.1.1*

Table 2077. CRC_CFG*n* field descriptions

Field	Description
26 SWAP_BYTEWISE	SWAP_BYTEWISE 0 No swap 1 Byte wise (MSB to LSB, LSB to MSB) bytes swap performed on CRC_INP input data internally for CRC-32 polynomial calculations **Note:** INV and SWAP bits are set to ‘1’ for CRC-32 polynomial calculations.
27 SWAP_BITWISE	SWAP_BITWISE 0 No swap 1 Bit wise (MSB to LSB, LSB to MSB) bits swap performed on CRC_INP input data internally for CRC-16 polynomial calculations

Table 2077. CRC_CFG*n* field descriptions (continued)

Field	Description
28:29 POLYG	Polynomial selection 00 CRC-CCITT polynomial 01 CRC-32 polynomial 10 CRC-8 polynomial 11 CRC-8H2F Autosar polynomial This bit can be read and written by software. **Note:** This bit can be written only during the configuration phase.
30 SWAP	SWAP selection 0 No swap selection applied on the CRC_OUTP content 1 Swap selection (MSB to LSB, LSB to MSB) applied on the CRC_OUTP content. The swap operation is a bit-by-bit rotation of the content. In case of CRC-CCITT polynomial, the swap operation is applied on the 16 LSB bits. This bit can be read and written by software. **Note:** This bit can be written only during the configuration phase.
31 INV	INV selection 0 No inversion selection applied on the CRC_OUTP content 1 Inversion selection (bit x bit) applied on the CRC_OUTP content. The inversion operation is a complement or negation of the content. In case of CRC-CCITT polynomial the inversion operation is applied on the 16 LSB bits. This bit can be read and written by software. **Note:** This bit can be written only during the configuration phase.

80.5.1.2 CRC Input Register *n* (CRC_INP*n*)

Offset: 0x004 + *n* * 0x10 (*n* = 0 to CRC_CNTX_NUM - 1) Access: User read/write

Figure 2180. CRC Output Register *n* (CRC_OUTP*n*)

Table 2080. CRC_OUTP*n* field descriptions

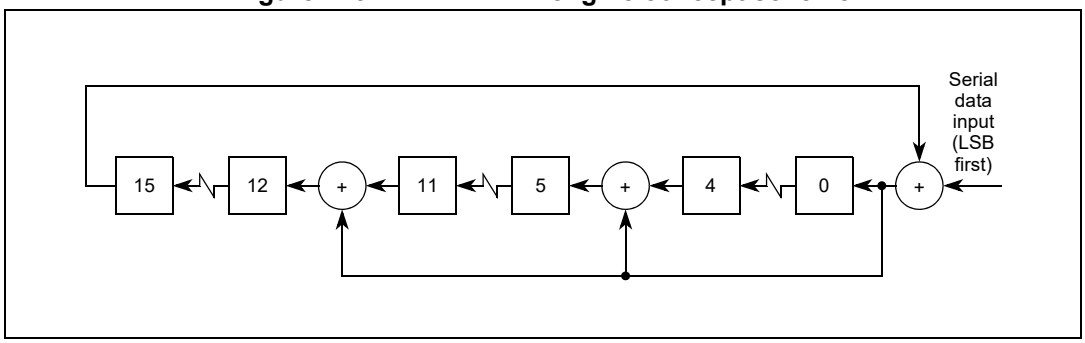
Field	Description
0:31 OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

80.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 95*, *Equation 96* and *Equation 97* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.



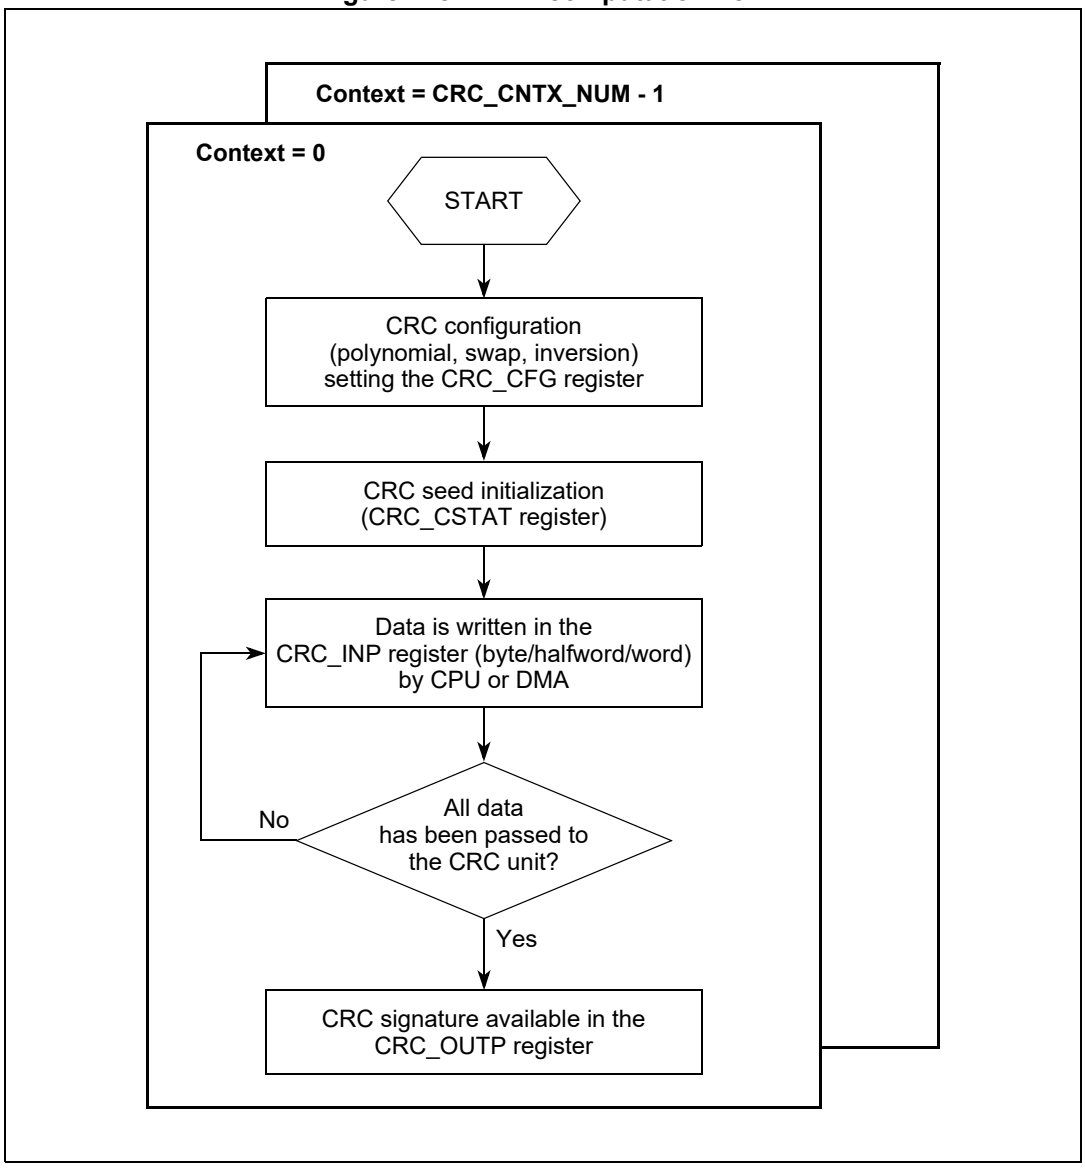
Equation 95 CRC8 VDA CAN:
$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 96 CRC-CCITT (x.25 protocol):
$$x^{16} + x^{12} + x^5 + 1$$

Equation 97 CRC-32 (Ethernet protocol):
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 98 CRC-8-H2F (Autosar 4.0 protocol):
$$x^8 + x^5 + x^3 + x^2 + x + 1$$

Figure 2181. CRC-CCITT engine concept scheme



The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 2181* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (such as SPI), a bit swap (MSB → LSB, LSB → MSB) or bit inversion of the final CRC signature, or both can be applied (CRC_OUTP register) before transmitting the CRC.

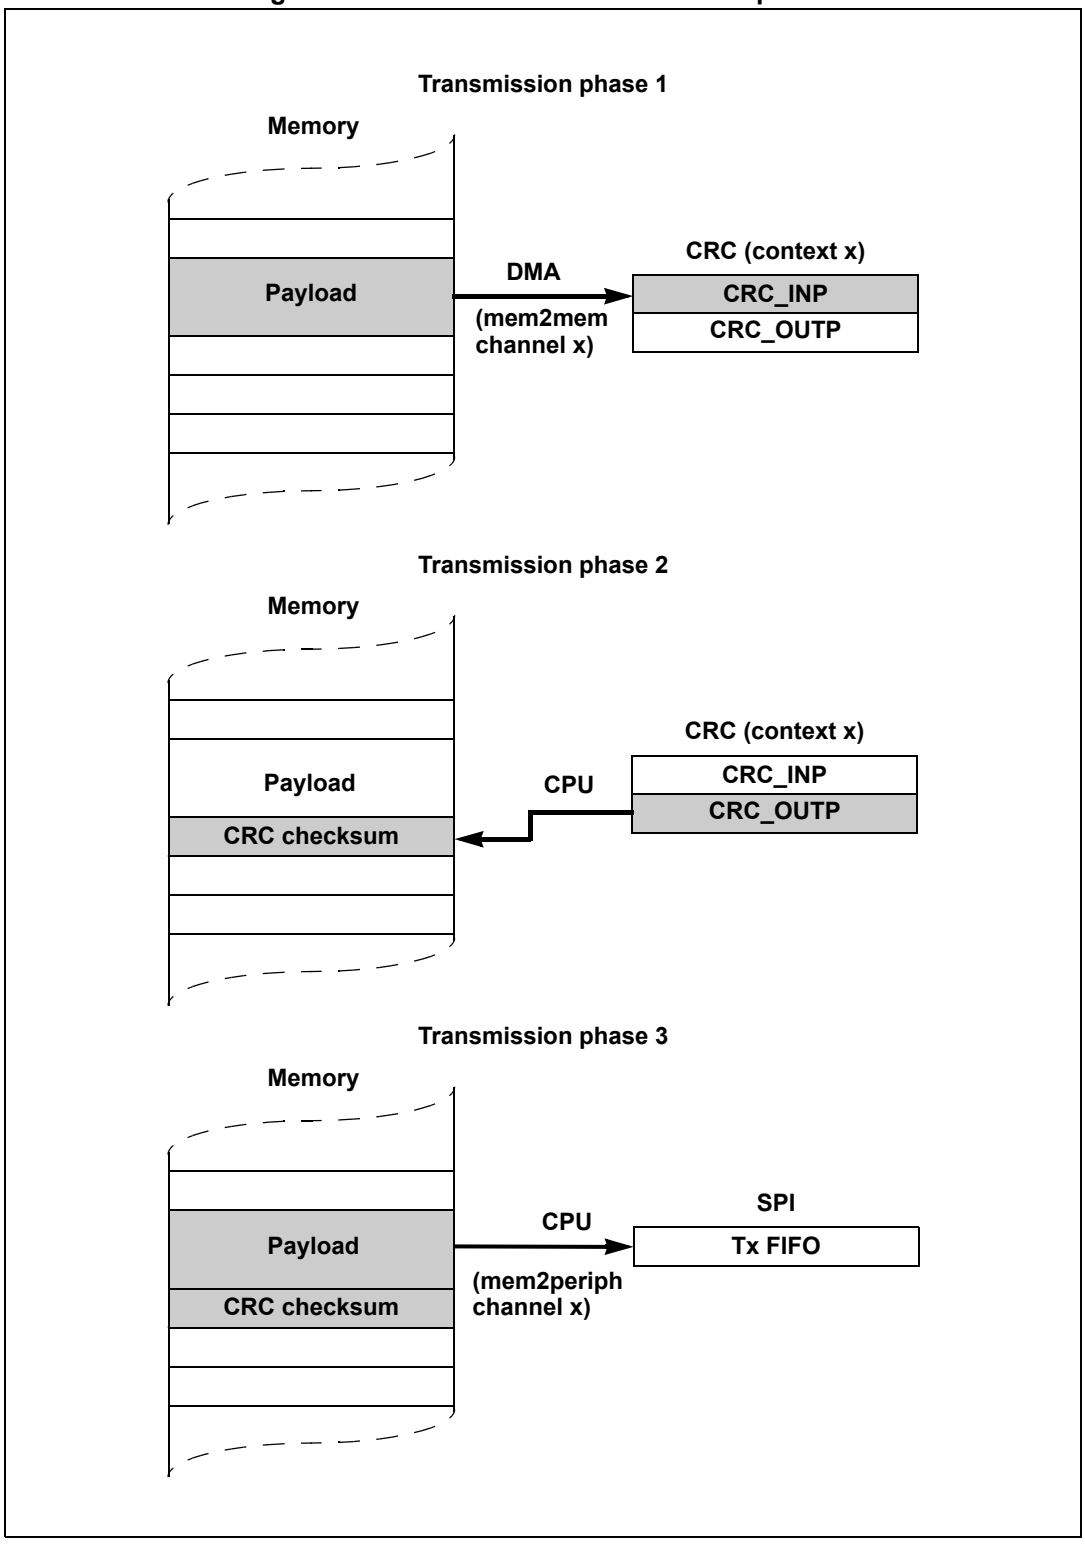
Use of the CRC module is summarized in the flow chart given in *Figure 2182*.

Figure 2182. CRC computation flow

80.7 Use cases

80.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:



- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer: mem2mem, periph2mem, mem2periph; then this sequence, as shown in *Figure 2183*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 2183. DMA-CRC transmission sequence

80.7.2 Register programming

- INV or SWAP, or both (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

81 Memory Error Management Unit (MEMU)

81.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- SRAM
- Peripheral RAM
- Flash memory.

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single/Double bit error in the data part that is detected via ECC for flash memory. Reporting of single/double bit error as correctable error depends on CTRL.FLASH_ERR_SELECT configuration.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Double/Multiple(more than two) bit error that is detected via ECC for Flash Memory. Reporting of double bit error as uncorrectable error depends on CTRL.FLASH_ERR_SELECTION configuration.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

When multiple errors are indicated from various sources at the same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

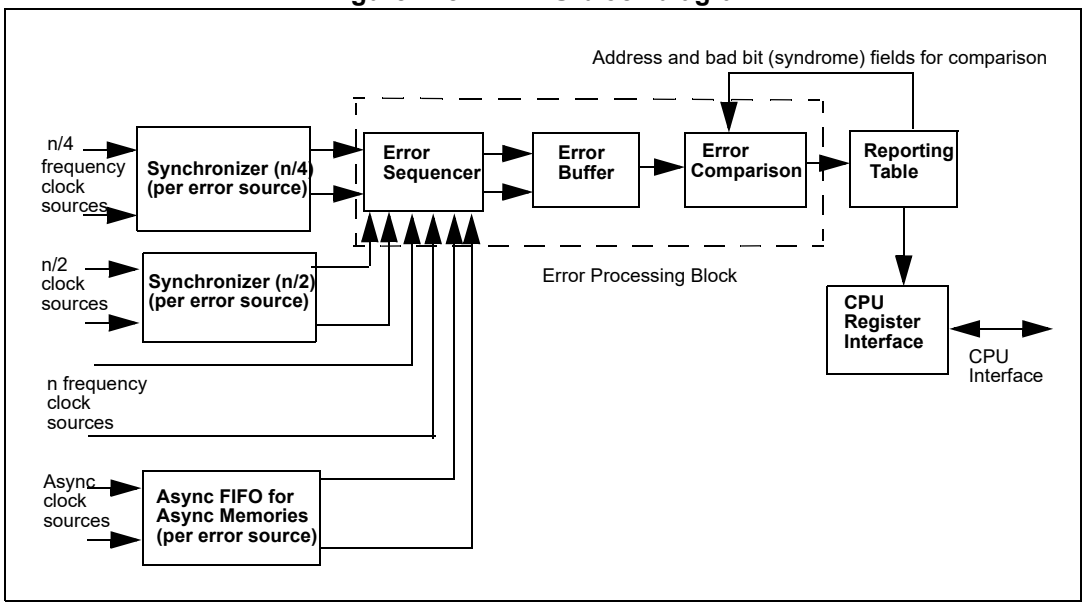
MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral SRAM ECC
- Flash memory ECC.

Each instance has two reporting tables–Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 81.4: Design overview* for the reporting block details.



81.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral SRAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

81.3 Block diagram

Figure 2184. MEMU block diagram

81.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 81.7.3: Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set, else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error (Correctable Error: CE or Uncorrectable Error: UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with

the error buffer, if the type of errors (CE and UCE) differ they are treated as unique.

– Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable).
– Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (*System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

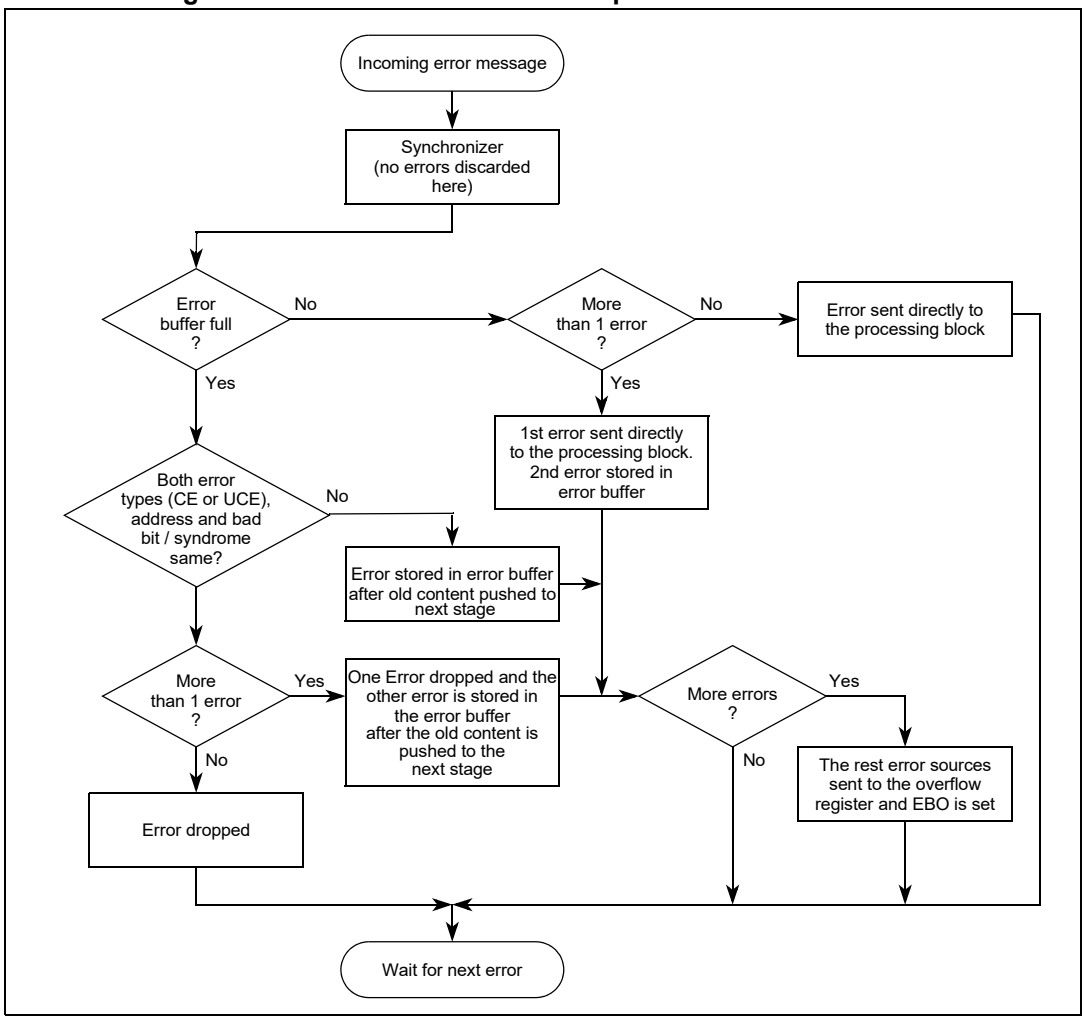
4. Register block

The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 2185. MEMU error buffer uniqueness check flow chart



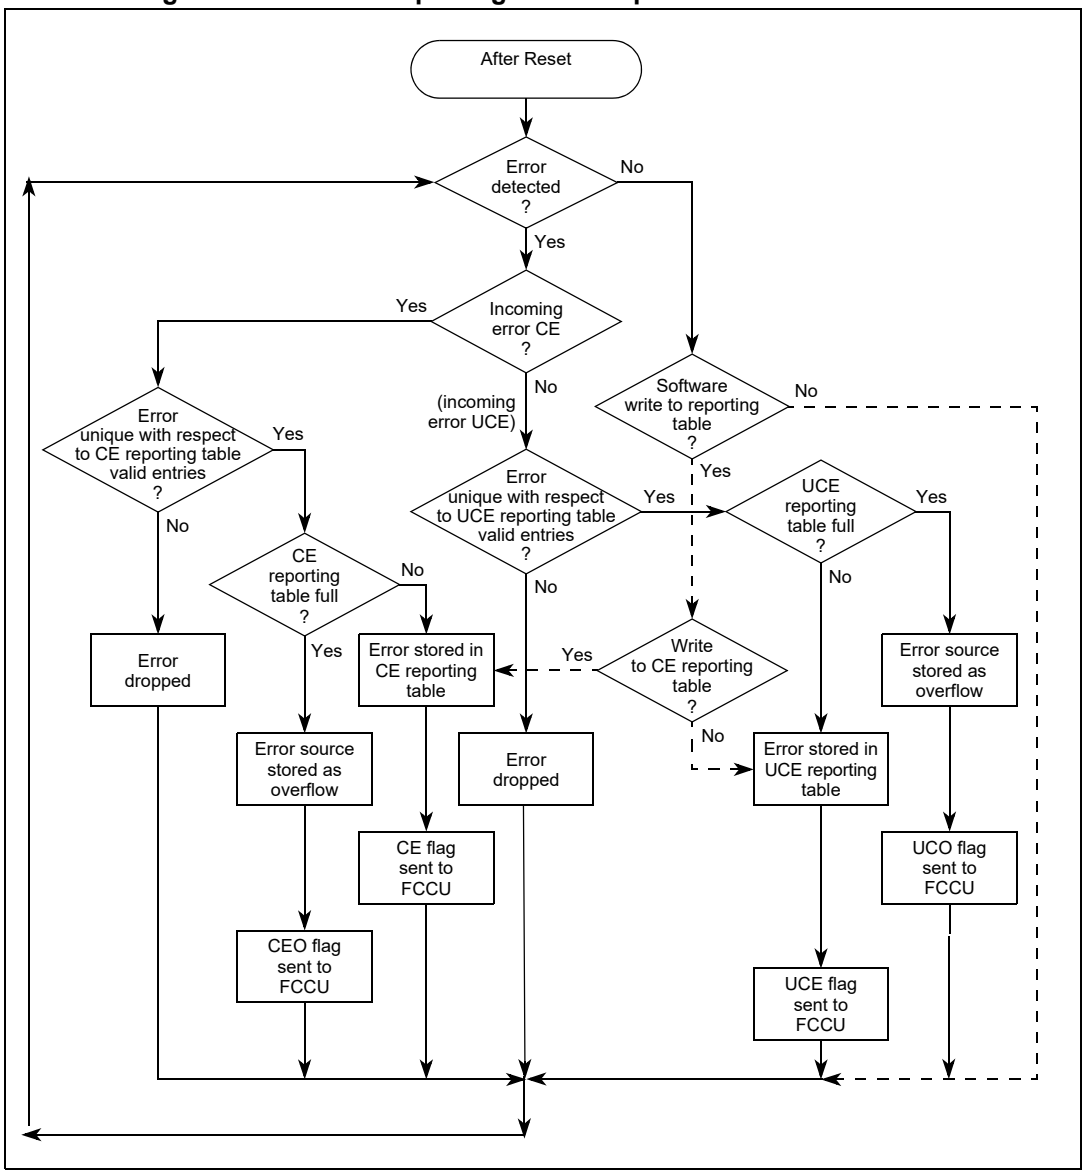


Figure 2186. MEMU reporting table uniqueness check flow chart

81.5 External signal description

MEMU has no external signals.

81.6 Memory map and register definition

81.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see Chapter 7: Device configuration that describes how modules are configured and connected.

Flash Single-bit or Double-bit error corrections, both are stored as correctable errors. 10 Store 20xSEC. Flash Single-bit error corrections only are stored as correctable errors 11 Reserved

81.6.2.2 Error Flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a ‘1’. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 2188. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 2083. ERR_FLAG field descriptions

Field	Description
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table 2083. ERR_FLAG field descriptions (continued)

Field	Description
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.

Table 2083. ERR_FLAG field descriptions (continued)

Field	Description
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to '1' if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

81.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

1. In this calculation, round any fractional result of the division to the next highest integer. For example, if the division is 94 ÷ 32 = 2.9375 or 66 ÷ 32 = 2.0625, round the result to 3.

Figure 2204. Flash memory concurrent overflow registers (FLASH_OFLWn)

Table 2099. FLASH_OFLWn field descriptions

Field	Description
0:31 OFLW	Overflow Bit Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 81.7.3: Handling overflows (Multiple error reporting)* occurs.

81.7 Functional description

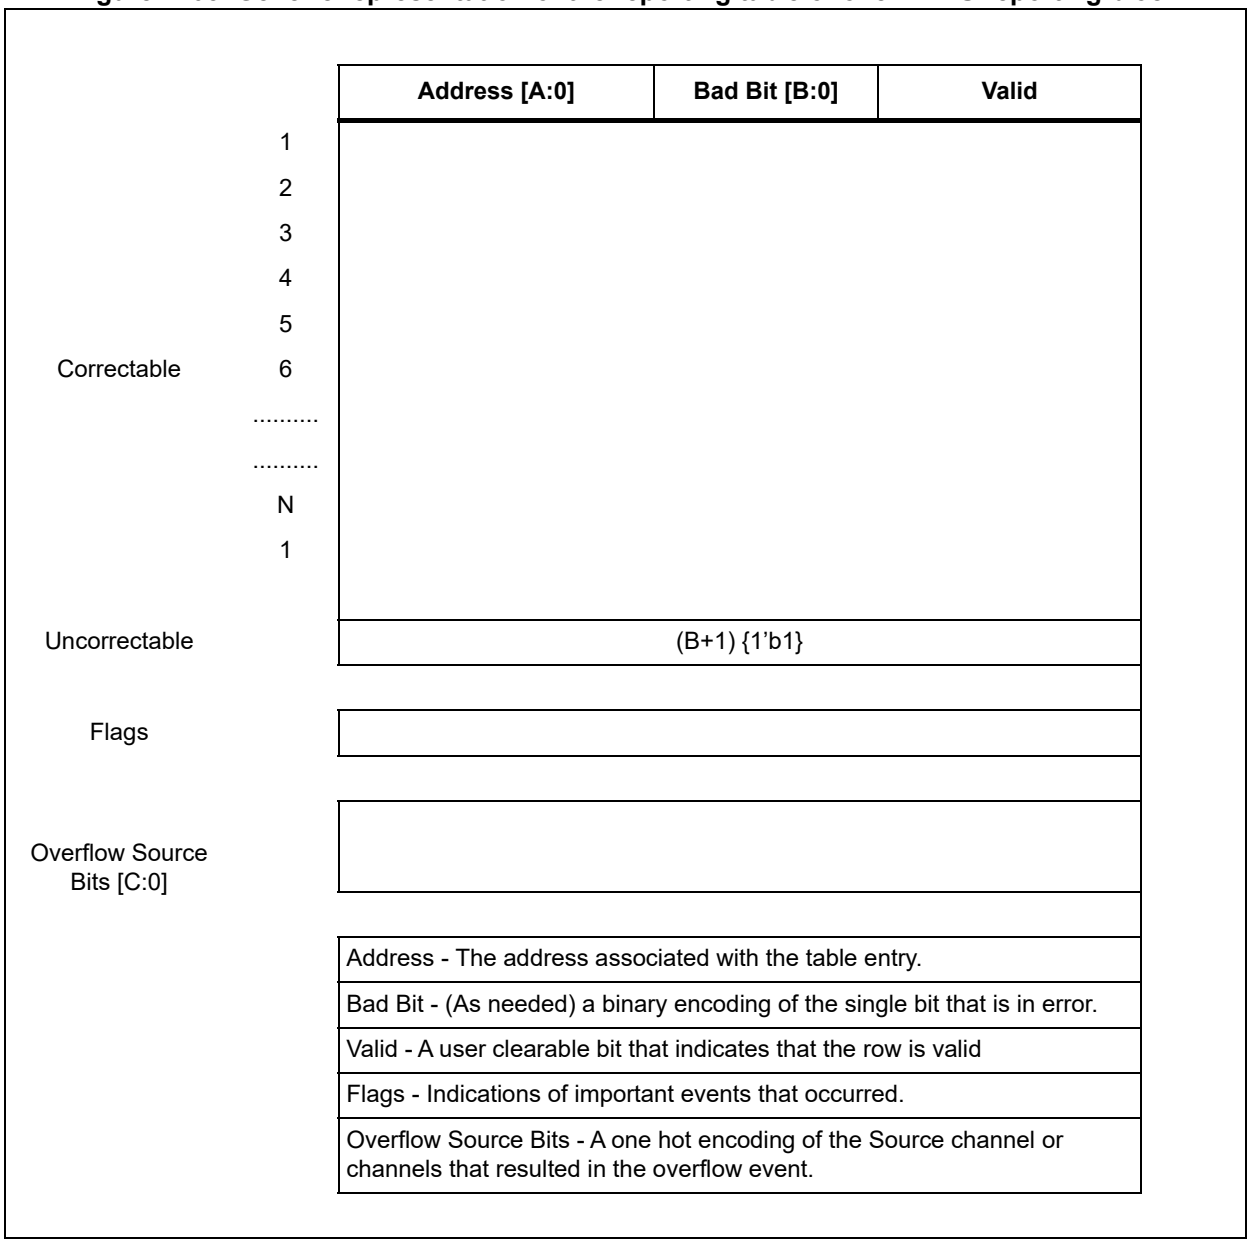
In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

81.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address.The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:



1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (duplicate entries).

81.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 2205. Generic representation of the reporting table of one MEMU reporting block

81.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table through the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
   – More than 2 errors detected at the same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
   – An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order which means that if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

82 Indirect Memory Access (IMA)

82.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading or modifying data, or both, including ECC check bits. This capability is useful for test activities, for example, verifying ECC functionality.

The SPC58xNx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays.
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. Refer to the Device Configuration chapter for details.

82.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no backdoors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed: I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

82.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control register (CDACNTL)
- Cache Debug Access Data register (CDADATA)

These registers are summarized in the following sections.

82.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

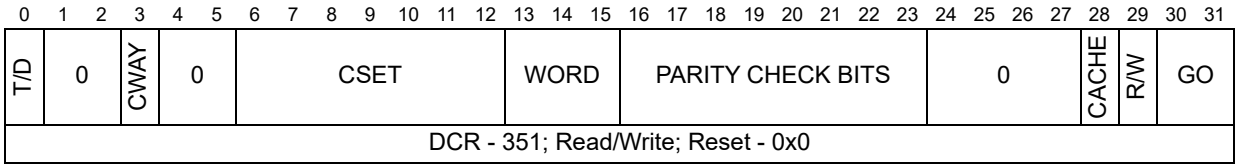


Figure 2206. Cache Debug Access Control register (CDACNTL)

The CDACNTL bits are described in *Table 2100*.

Table 2100. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1:2	—	Reserved - read as zeros.
3	CWAY	Cache Way: Specifies the cache way to be selected.
4:5	—	Reserved - read as zeros.
6:12	CSET	Cache Set: Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13:15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set.
16:23	PARITY CHECK BITS	Parity check bits (I or D-cache): D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24:27	—	Reserved - read as zeros.
28	CACHE	Cache Select: Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30:31	GO	GO command bits: 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

82.2.1.2 Cache Debug Access Data register (CDADATA)

The Cache Debug Access Data register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

TAG or DATA																															
DCR - 350; Read/Write; Reset - Undefined/Unaffected																															

Figure 2207. Cache Debug Access Data register (CDADATA)

The CDADATA bits are described in *Table 2101*.

Table 2101. CDADATA field descriptions

Bits	Name	Description
0:31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1- Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23 byte 2 24–31 byte 3

82.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

82.2.2.1 e2eECC Error Control/Status register 0 (E2EECSR0)

The e2eECC Error Control/Status register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31
0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
DCR - 511; Read/Write; Reset - 0x0; Privileged						

Figure 2208. e2eECC Error Control/Status register 0 (E2EECSR0)

The E2EECSR0 bits are described in *Table 2102*.

Table 2102. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros.
4:11	RCHKBIT	Read Checkbits: This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12:15	—	Reserved - read as zeros.
16:17	WRC	Write Control: 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control: 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection

Table 2102. E2EECSR0 field descriptions (continued)

Bits	Name	Description
20:23	—	Reserved - read as zeros.
24:31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask: This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

82.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Note the following restrictions on memory access via IMA:

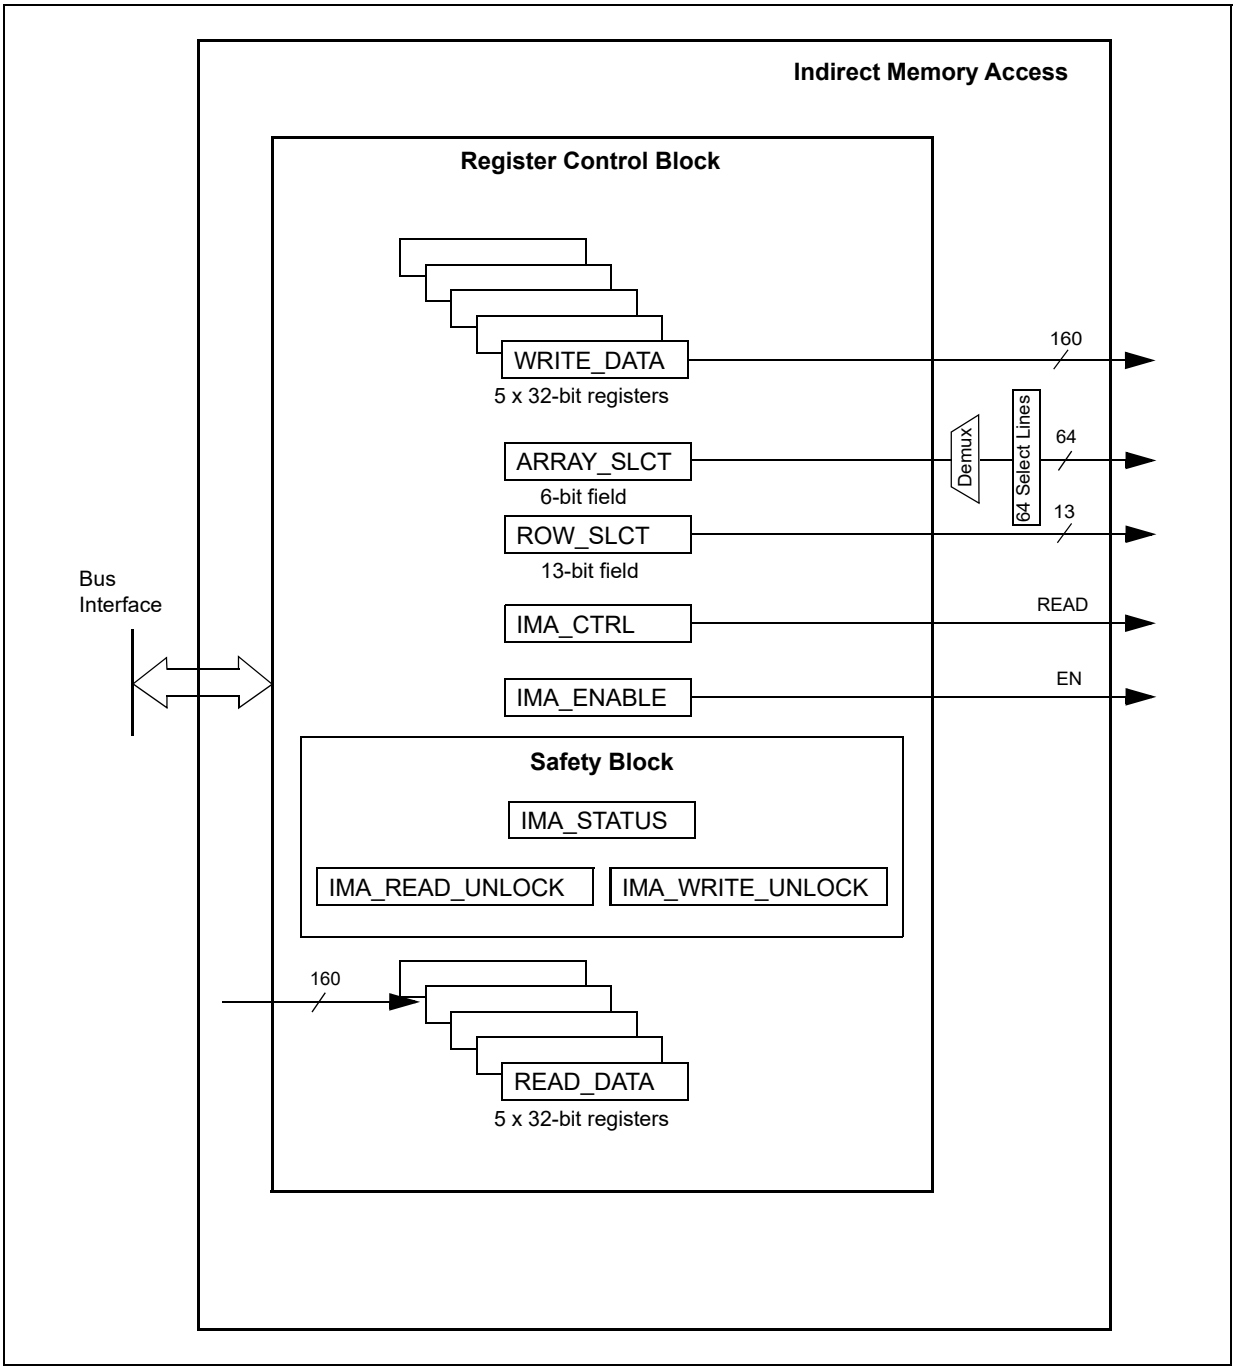
- When a bus master performs an IMA access, no other bus master shall perform an access to the same memory.Before any IMA access, the user shall disable the FCCU fault related to the IMA. If not, the FCCU triggers a fault.
- The IMA must be unlocked for reads.

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

82.3.1 Features



The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads.
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data
  - Writes have no effect
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

82.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it too.

Figure 2209. IMA block diagram

82.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 2103. IMA memory map

0x005C	IMA RAM Read Data register 0 (IMA_READ_DATA_0)	*Section 82.3.3.8*

82.3.3.1 IMA Control register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Offset: 0x00 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 2104. IMA_CTRL field descriptions

Field	Description
31 READ	IMA Read This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

82.3.3.2 IMA Enable Access register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: Back to back writes to the enable bit is not valid. It will still generate a two-clock enable pulse and will be considered as a single access initiation.

Offset: 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2212. IMA Status register (IMA_STATUS)

Table 2106. IMA_STATUS field descriptions

Field	Description
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed. 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

82.3.3.4 IMA RAM Select register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, such as accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. Refer to the Device Configuration chapter for details.

Offset: 0x0C Access: User read/write

Field	Description
3:15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is 32 KB RAM.
26:31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

82.3.3.5 IMA Write Unlock register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

Table 2109. IMA_READ_UNLOCK field descriptions

Field	Description
0:31 READ_KEY	Key to unlock the IMA Read Access to RAMs. – 0xF06AB5BC is the first key that has to be written to start the unlock process. – 0x14081B56 is the second key that has to be written to unlock the IMA.

82.3.3.7 IMA RAM Write Data register n (IMA_WRITE_DATA_*n*)

The IMA_WRITE_DATA_*n* registers hold the data values to be written to the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

0x2C (WRITE_DATA_4)
0x30 (WRITE_DATA_3)
Offset: 0x34 (WRITE_DATA_2) Access: User read/write

Table 2110. IMA_WRITE_DATA_*n* field descriptions

Field	Description
0:31 WRITE	Contains data to be written to RAM. – WRITE_DATA_4[WRITE] contains write data bits[159:128] – WRITE_DATA_3[WRITE] contains write data bits[127:96] – WRITE_DATA_2[WRITE] contains write data bits[95:64] – WRITE_DATA_1[WRITE] contains write data bits[63:32] – WRITE_DATA_0[WRITE] contains write data bits[31:0]

82.3.3.8 IMA RAM Read Data register n (IMA_READ_DATA_*n*)

The IMA_READ_DATA_*n* registers hold the data values read from the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_*n* registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Offset: 0x4C (READ_DATA_4), 0x50 (READ_DATA_3), 0x54 (READ_DATA_2), 0x58 (READ_DATA_1), 0x5C (READ_DATA_0)

Field	Description
0:31 READ	Contains data to be written to RAM. – READ_DATA_4[READ] contains read data bits[159:128] – READ_DATA_3[READ] contains read data bits[127:96] – READ_DATA_2[READ] contains read data bits[95:64] – READ_DATA_1[READ] contains read data bits[63:32] – READ_DATA_0[READ] contains read data bits[31:0]

82.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

82.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

82.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

82.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Refer to the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

82.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

82.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY.
2. Write 0x14081B56 to READ_KEY.

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY.

82.3.4.3.3 Unlocking writes

The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY.
2. Write 0xE4A9EBF7 to WRITE_KEY.

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY.
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

82.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

82.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections show the different accesses that are available depending on the options.

82.3.4.5.1 Read access

Read Accesses are expected to follow the sequence below:

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register.
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

82.3.4.5.2 Write access

Write Accesses are expected to follow the sequence below:

1. Unlock Write Access by performing appropriate consecutive writes to WRITE_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

82.3.5 Application information

Caution: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

83 Fault Collection and Control Unit (FCCU)

83.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a systematic approach to fault detection and control. The FCCU provides a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

83.2 Features

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

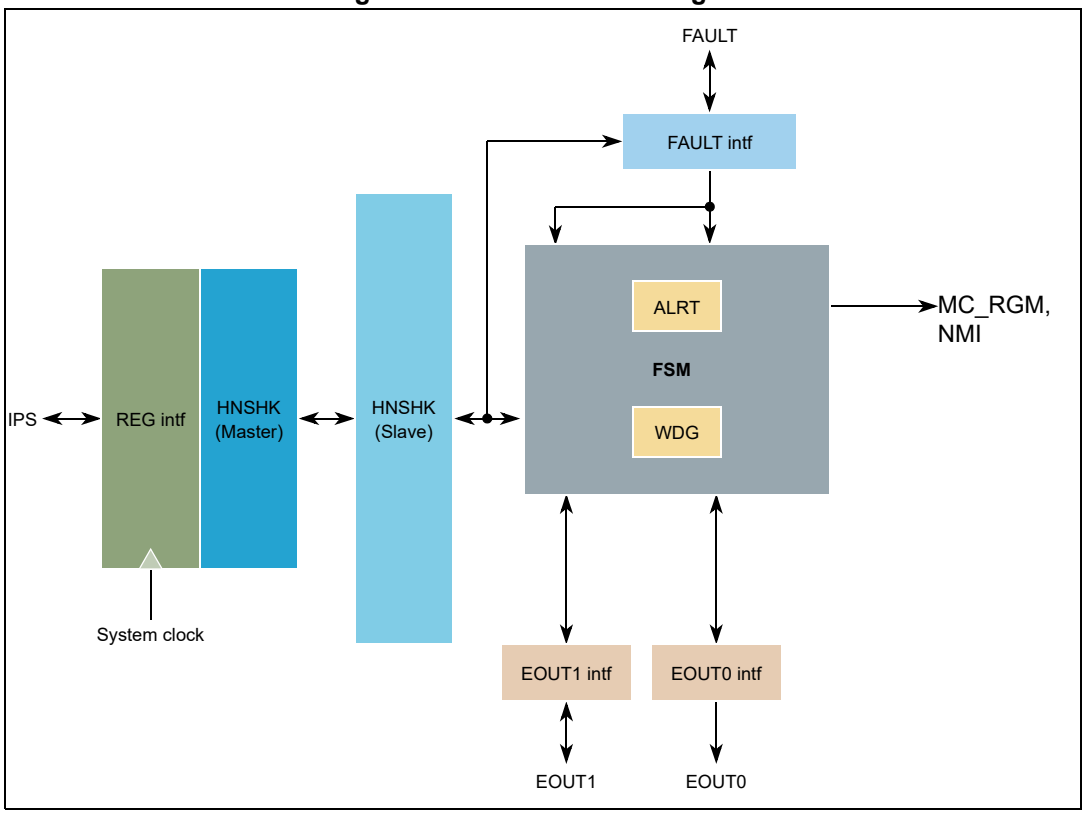
- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; refer to the implementation-specific details)
- Bi-stable, Dual Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Redundant collection of hardware checker (for example RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal (SoC) reactions
  - ALARM state: interrupt request
  - FAULT state: long functional reset request pulse, short functional reset request pulse, NMI
- Internal reactions (independently configurable for each RF)
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU
- Configuration lock: The FCCU’s configuration is lockable in two ways
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into

FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register

- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol that is dual rail and time switching
- After power-on the error out pins have high impedance(x). FCCU goes to operational state only on software request
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms
- The overall error detection, processing and indication time is less than 10 ms
- The actual maximum time is five safe (IRCOSC) clock cycles

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster than the IRC clock.

83.2.1 Standard features



- IPS (slave bus signals) bus interface

83.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 2218*.

x. Actual value depends on the SoC settings at pad level.

Figure 2218. FCCU block diagram

The FCCU module includes the submodules listed in *Table 2112*.

Table 2112. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of two asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: Watchdog timer (WDG) Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

83.4 Signal description

83.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 83.5.9: EOUT interface*.

For the availability of these signals on a chip, refer to the device configuration chapter.

83.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers.
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0] data write/read operations to any registers.
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (for example FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2121: FCCU memory map*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode.

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

83.5 Functional description

83.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization.
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization.
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

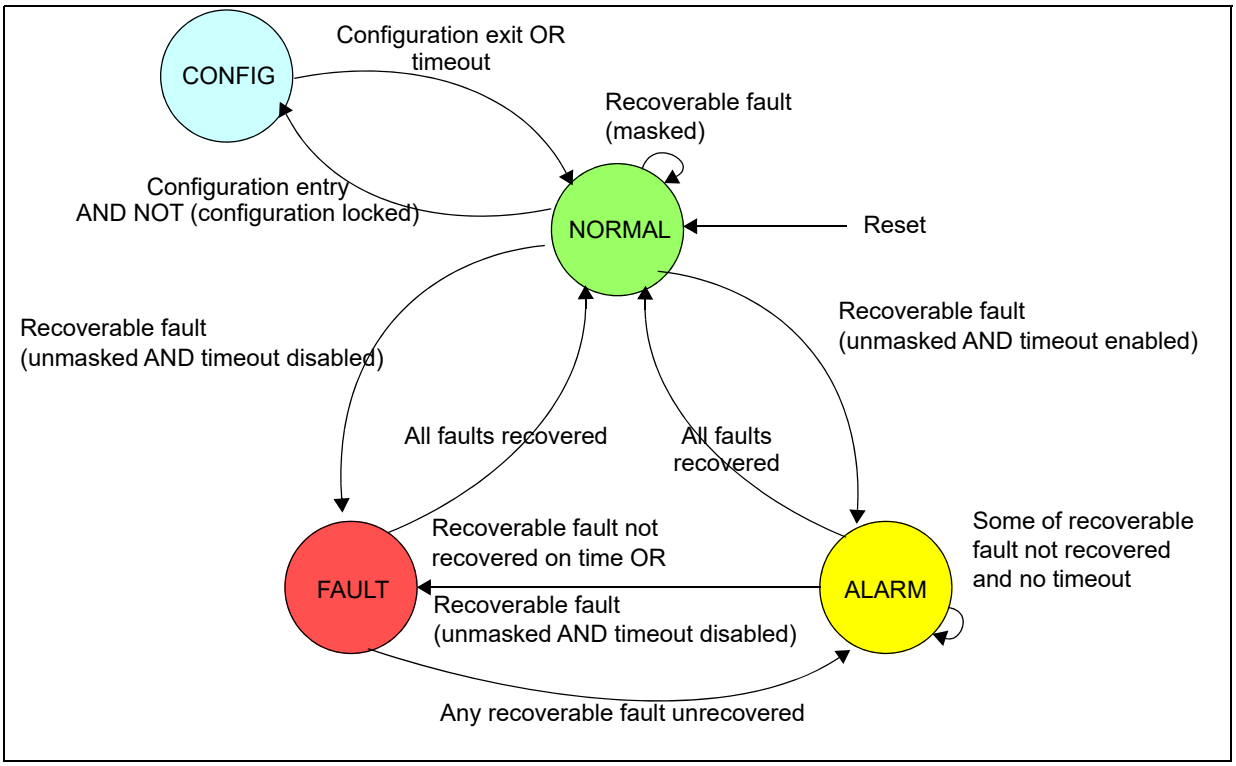
83.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 2219*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Succeeding one of the following events:
  - unmasked recoverable faults with the timeout disabled → the FCCU moves to the FAULT state.
  - unmasked recoverable faults with the timeout enabled → the FCCU moves to the ALARM state.
  - masked recoverable faults → the FCCU stays in NORMAL state.
- ALARM: the FCCU moves into the ALARM state when an unmasked recoverable fault occurs and the timeout is enabled. The transition to the ALARM state goes along with an interrupt request (ALARM state), if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the

FAULT state. The timeout is re-initialized if the FCCU state moves to the NORMAL state. The timeout restarts following the recovery from the FAULT state.



- FAULT: the FCCU moves into the FAULT state when one of the following conditions occurs:
  - timeout related to a recoverable fault when the FCCU is in the ALARM state.
  - unmasked recoverable faults with the timeout disabled.

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional).
- EOUT signaling (optional).
- SW option: Soft reaction (Short functional reset request pulse if configured).
- SW option: Hard reaction (Long functional reset request pulse if configured).

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 2219. FCCU state diagram

83.5.3 Reset interface

The FCCU has two input resets, as described in *Table 2113* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 2114* for each type of fault reaction (hard, soft or self-checking), the respective output reset (Long functional reset, Short functional reset) is activated. In *Table 2115* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit generates the corresponding input reset as described in *Table 2113*.

Table 2113. Input reset

Input reset	Description
System reset	Global reset of the FCCU synchronous to the system clock.
System reset (RC oscillator)	Global reset of the FCCU synchronous to the IRCOSC.

Table 2114 and *Table 2115* describe a typical reset strategy at system level.

Table 2114. Reset reactions

FAULT reaction	Active reset	System reset signal
Hard	Long functional reset	disabled
Soft	Short functional reset	disabled

Table 2115 shows the Reset sources.

Table 2115. Reset sources

Reset source	System reset signal
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 2116 summarizes the MC actions corresponding to each reset generated by FCCU.

Table 2116. MC actions

Active reset	MC action
Long functional reset	Reset Flash and digital modules excluded FCCU, STCU
Short functional reset	Reset digital modules excluded FCCU, STCU

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for two IRCOSC clock periods.

83.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (possible for RFs only) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a RF (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any RF is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the RF that causes an ALARM to FAULT state transition. In this case the alarm timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

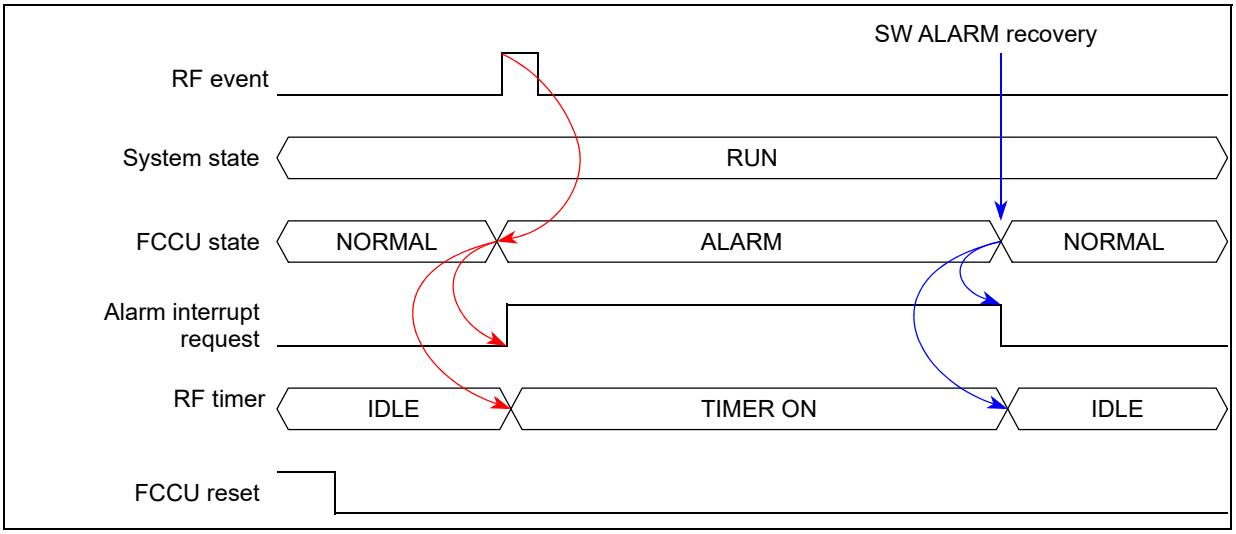
83.5.5 Fault recovery

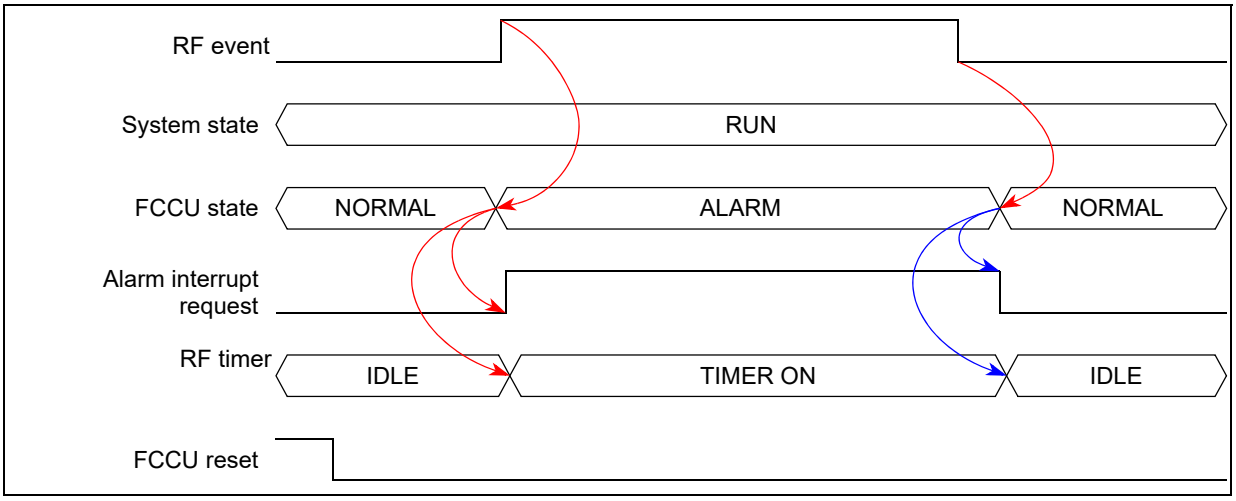
The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a RF management (ALARM state), refer to *Figure 2220* and *Figure 2221*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if configured)
  - Timeout running
- System state: RUN
- Alarm interrupt management: FAULT recovery (by SW): FCCU state transition ALARM → NORMAL

Figure 2220. RF (ALARM state) recovery (a)





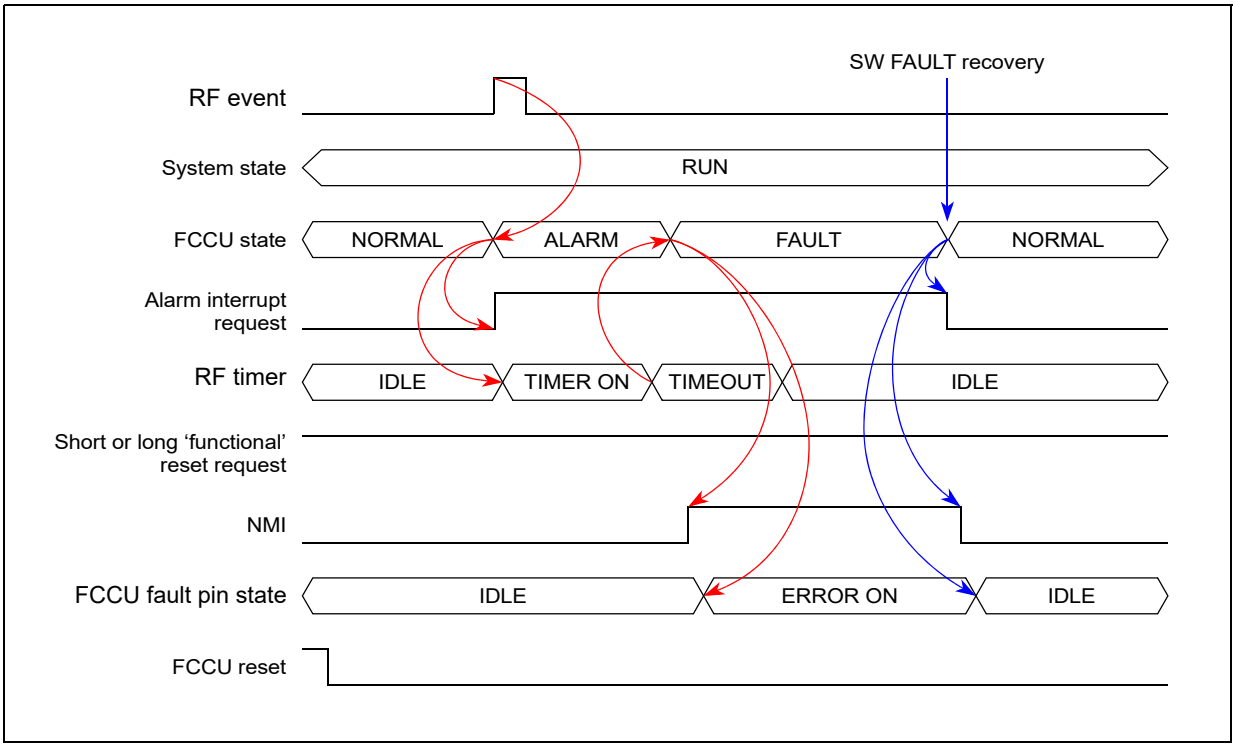


Figure 2221. RF (ALARM state) recovery (b)

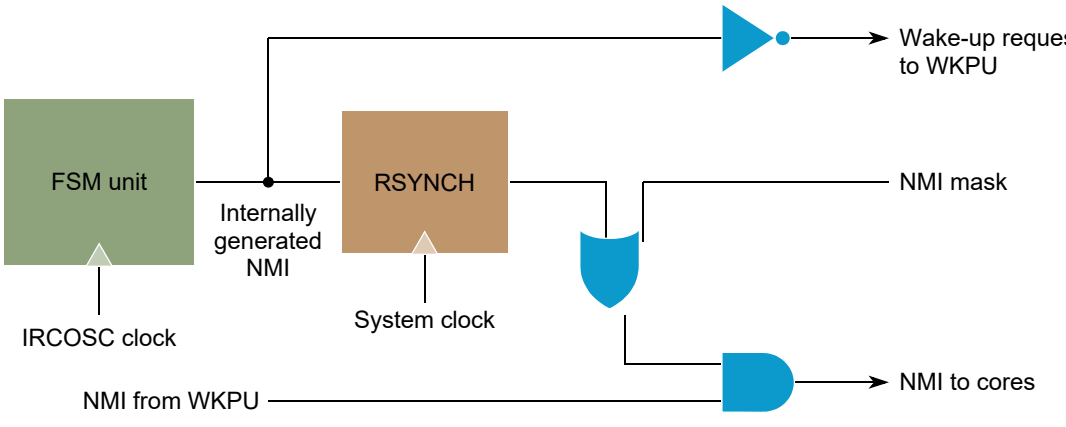
A typical sequence related to a RF management (ALARM → FAULT state), refer to *Figure 2222*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if enabled)
  - Timeout running
- FCCU state transition (following the timeout trigger): ALARM → FAULT: NMI assertion (if enabled)
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL

Figure 2222. RF(ALARM -> FAULT state) recovery

83.5.6 NMI/WKPU interface



The wake-up interface includes Non-maskable interrupt: NMI interrupt source generated by the WKPU. It is synchronous with the system clock and active low. A logical AND interconnects the NMI sources (internally generated by FCCU and by WKPU) in order to provide a single NMI output.

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (MC state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (MC mode SW change request = 1).

Figure 2223. NMI/WKUP scheme

Note: All NMI signals are shown active-low.

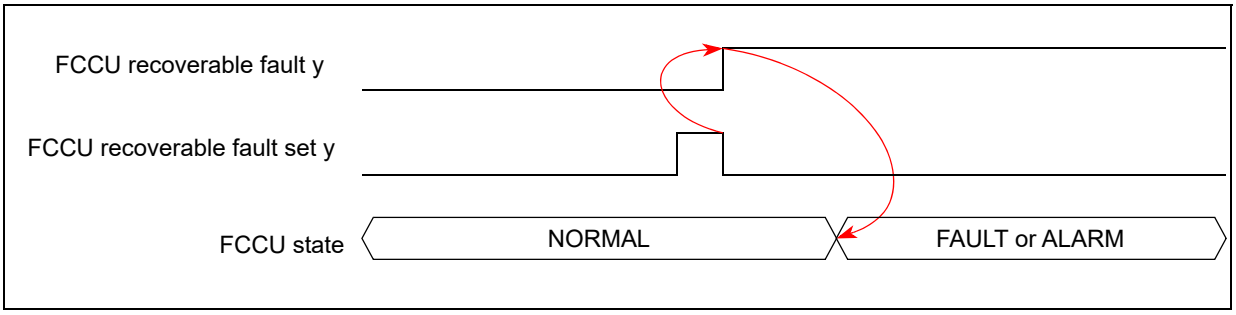
83.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple, programmable edge-sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2224*. The fault injection is executed by a write operation in the FCCU_RFF register.The reaction following a fake RF cannot be masked. The fault injection mechanism is optional; refer to the implementation-specific details. Refer to “FCCU failure inputs” table in Functional Safety chapter, for more details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (FCCU recoverable faults clear) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2225*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_S*n*. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 2224. FAULT injection



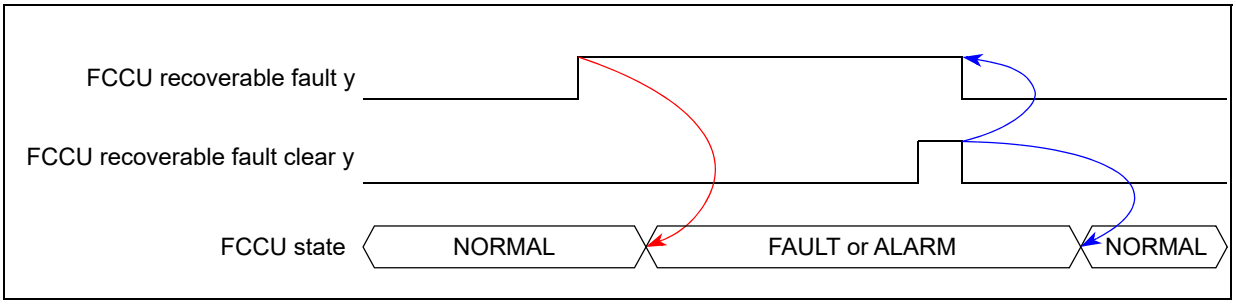


Figure 2225. FAULT clearing

83.5.8 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the following FCCU fault:
  - Recoverable
- The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- A mask (EOUT mask[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible for providing a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible for providing the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 2226. STCU-FCCU (case a)

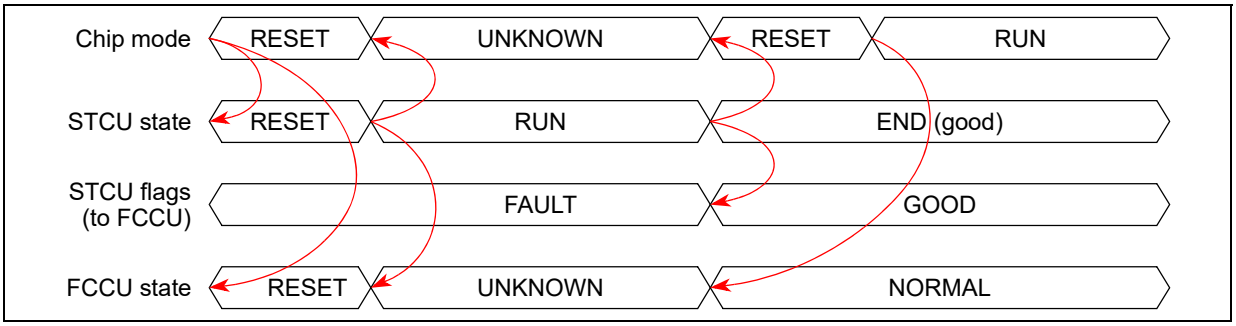

Figure 2227. STCU-FCCU (case b)

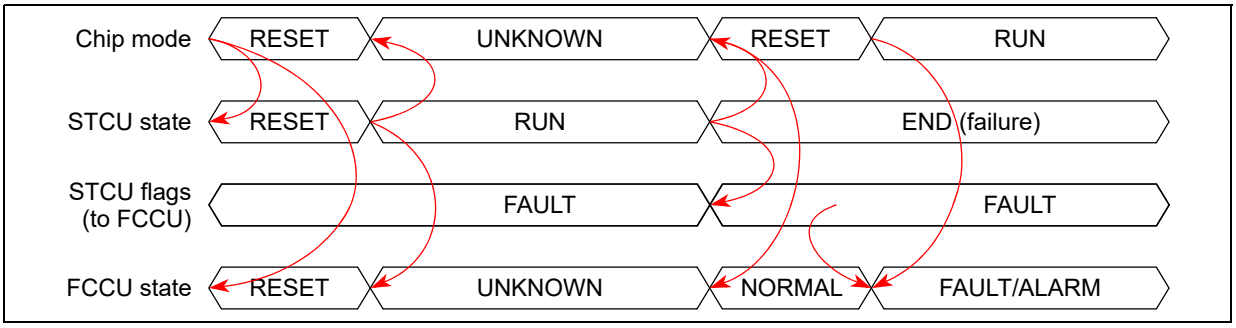

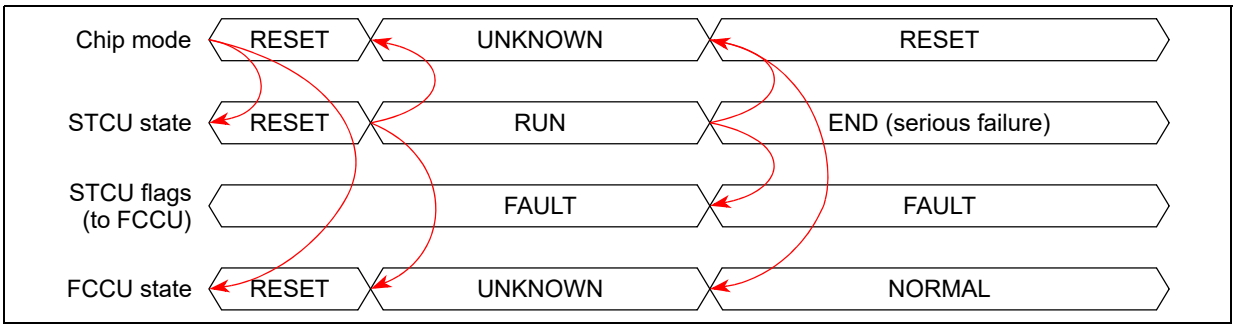

Figure 2228. STCU-FCCU (case c)

83.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (refer to table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS field in the FCCU_CFG register. For example, for PS = 0, FCCU Error output[0] = 0 and FCCU Error output[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual rail or time switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL). The EOUT protocol

transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.

- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occur in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18}. With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual rail or time switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, that is an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset, and software bit FCCU_RST in RGM_PRST5) should not influence the state of the failure indication, pins.

Note: The transition from FAULT to CONFIG state is not possible but is shown to display the behavior in all four states: RESET, NORMAL, FAULT and CONFIG.

Table 2117. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state with Fault disabled | enabled			NORMAL+CONFIG states			Transition from NORMAL to ALARM state with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written FCCU_SET_AFTER_RESET bit to 1.

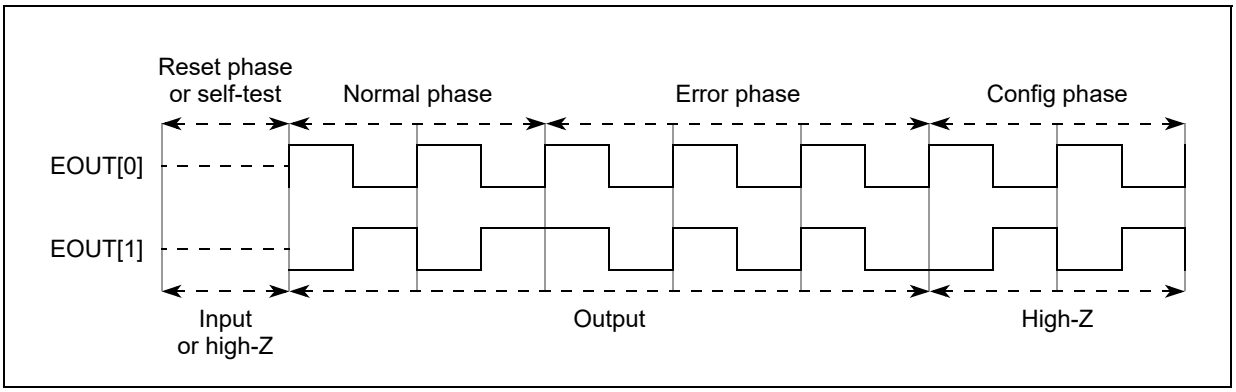
Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

83.5.9.1 Dual rail protocol

Dual rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual rail encoded circuits use two wires to carry each bit. The encoding scheme is given in *Table 2118* and the related timing diagram is given in *Figure 2229* and *Figure 2230*.

Table 2118. Dual rail encoding

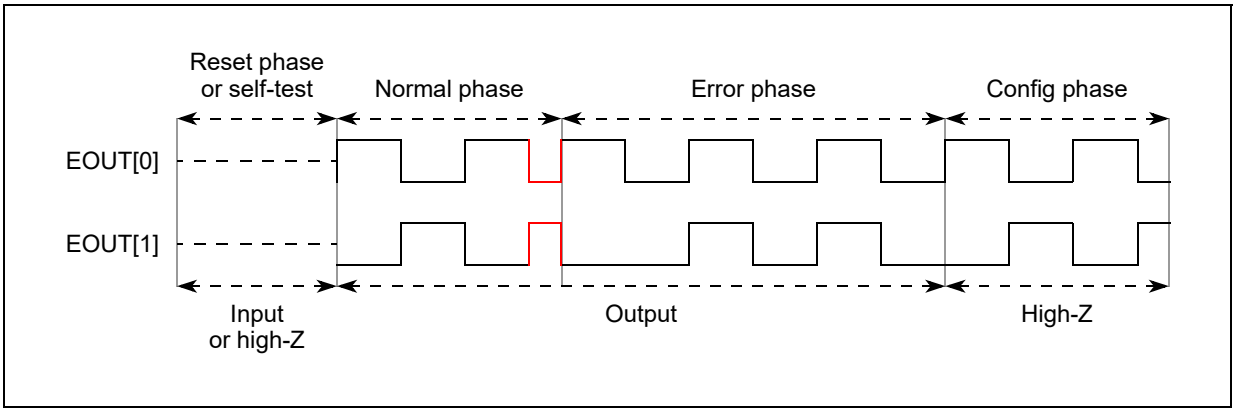
Logical state	Dual rail encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	00	toggling
faulty	11	
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling



1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the RESET phase the output pins are set as “high impedance”(y).



Note: Figure 2229 and Figure 2230 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 2229. Dual rail protocol (slow switching mode)

y. Actual value depends on the SOC settings at pad level.

Figure 2230. Dual rail protocol (fast switching mode)

83.5.9.2 Time switching protocol

The encoding scheme is given in *Table 2119* and the related timing diagram is given in *Figure 2231*.

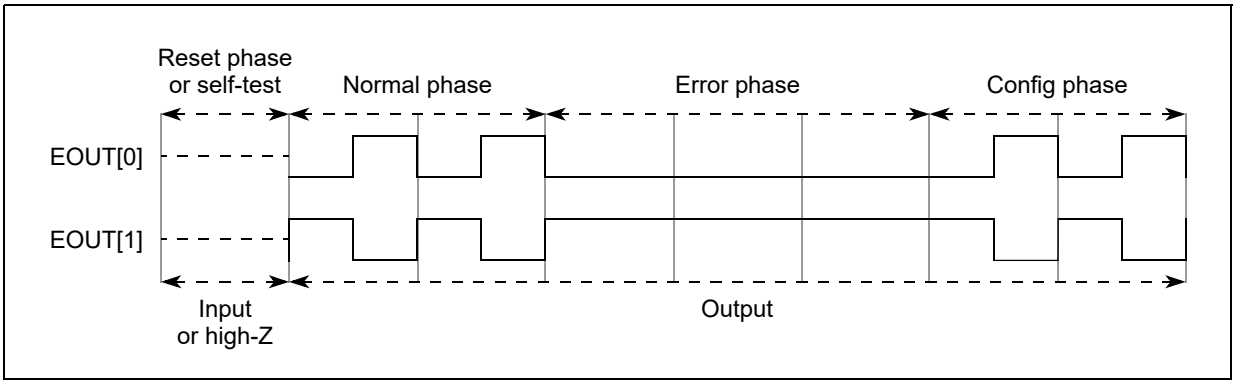
Table 2119. Time switching encoding

Logical state	Time switching encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the FAULT state, the output pin FCCU Error output pin[0] is set as low.



In Time Switching mode the second output (FCCU Error output pin[1]) is the inverted signal of first output (FCCU Error output pin[0]).

In the RESET phase the output pins are set as “high impedance”(z).

Note: Figure 2231 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

z. Actual value depends on the SOC settings at pad level.

Figure 2231. Time switching protocol

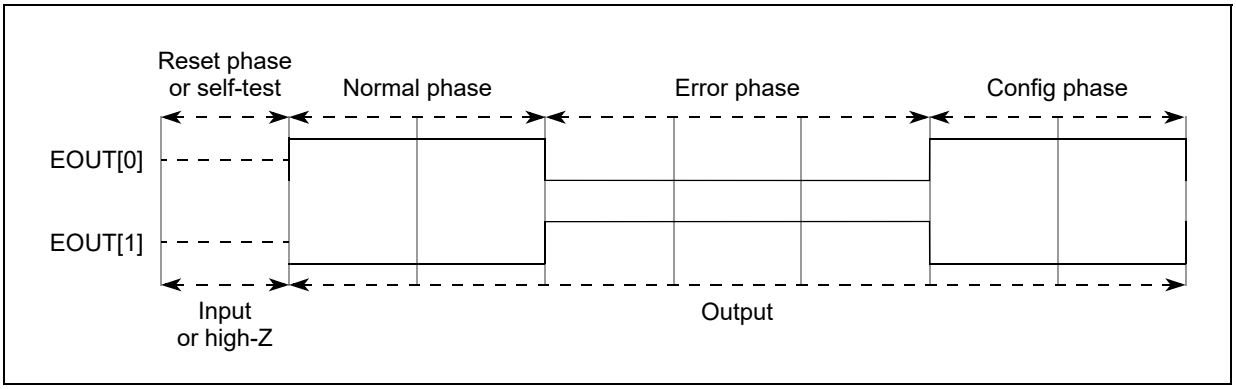
83.5.9.3 Bi-stable protocol

The encoding scheme is given in *Table 2120* and the related timing diagram is given in *Figure 2232*.

Table 2120. Bi-stable encoding

Logical state	Bi-stable encoding (FCCU Error output pins [1:0])	Note
nonfaulty	01	no toggling
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	no toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.



In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (FCCU Error output[1]) is the inverted signal of first output (FCCU Error output[0]).

In the RESET phase the output pins are set as “high impedance”(aa).

Note: Figure 2232 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

aa. Actual value depends on the SOC settings at pad level.

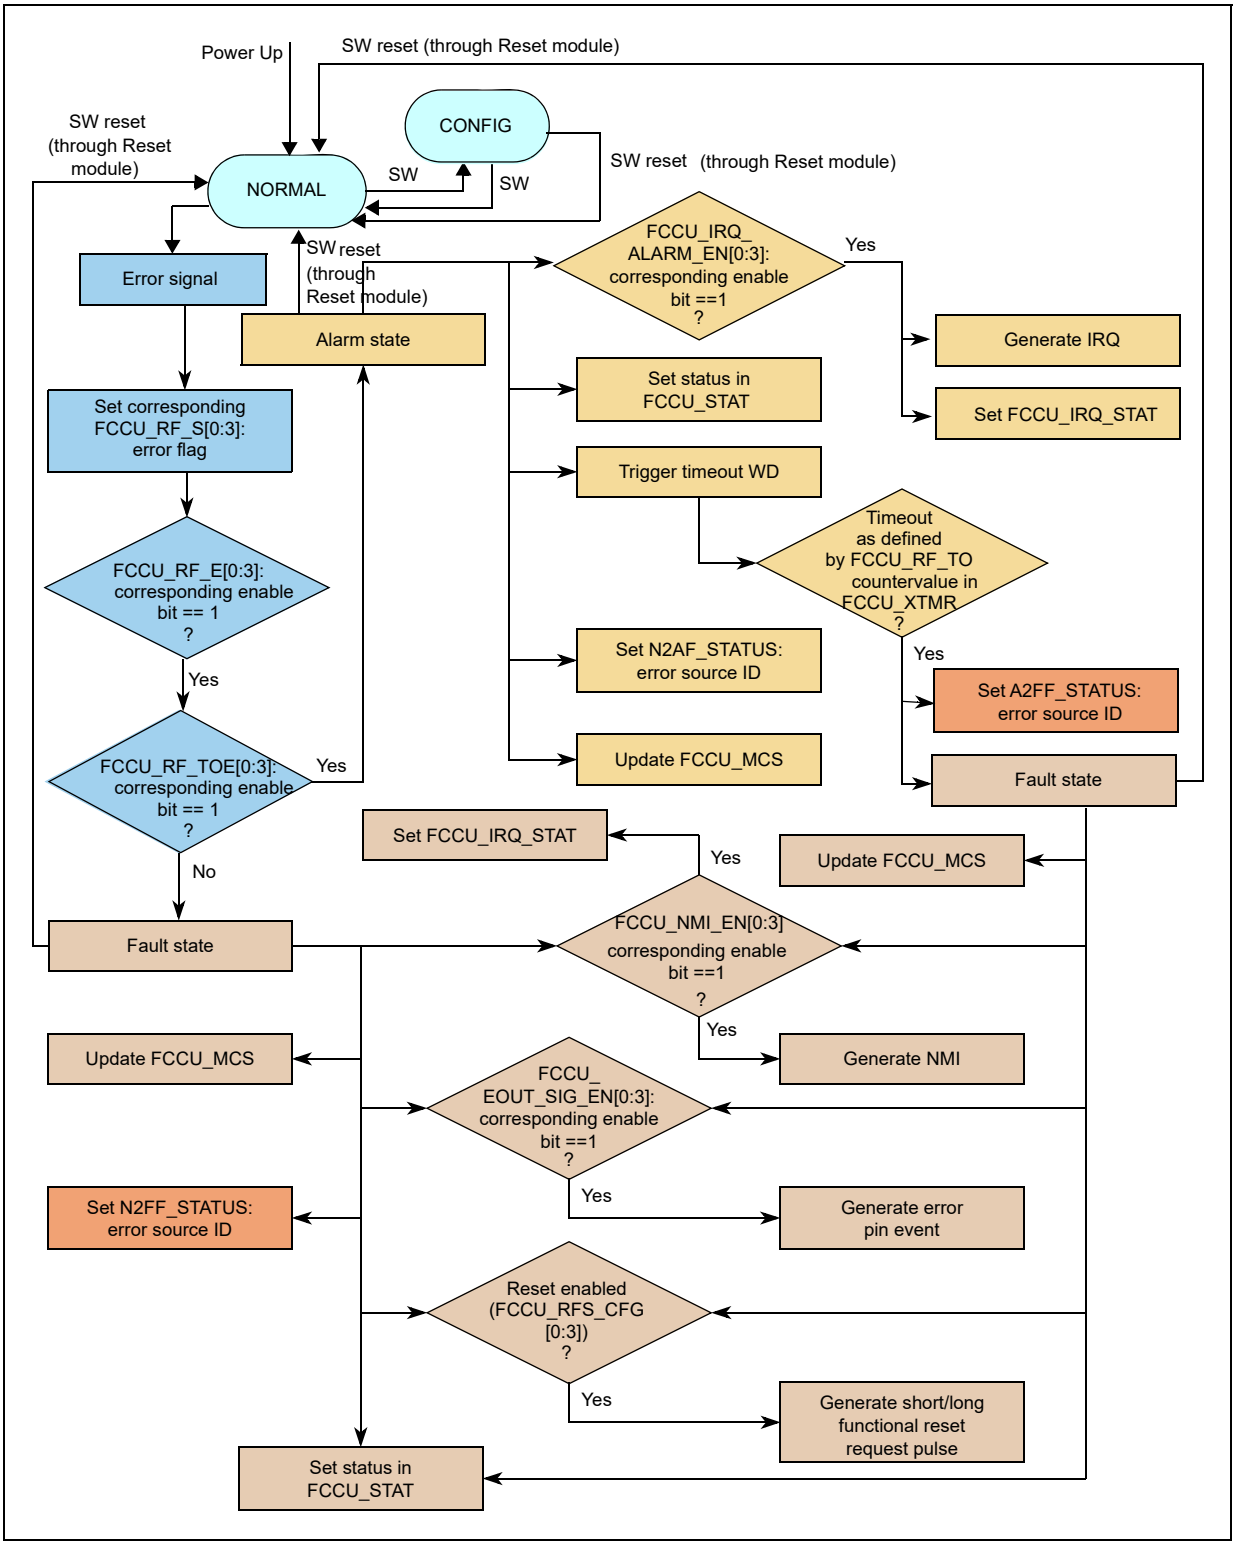


Figure 2232. Bi-stable protocol

83.5.10 Error signal flow for RF case

On Power up, FCCU moves to NORMAL state. SW can configure it by moving it to CONFIG and back again. SW reset leads to movement back to NORMAL. On reaching ALARM state, depending on ALARM being enabled, FCCU generates IRQ (alarm) and the FCCU_IRQ_STAT's alarm status is also set. FSM status is set in FCCU_STAT along with N2AF_STATUS. If Error is enabled (FCCU_RF_E) and timeout disabled (FCCU_RF_TOE), FCCU moves straight to FAULT state and depending on FCCU_NMI_EN or FCCU_SIG_EN, or both, being set, it generates a NMI or signals error, or both, out to the external world. FCCU FSM status is also captured in FCCU_STAT.

Figure 2233. Error signal flow

83.6 Register description

The FCCU registers are listed in *Table 2121*. Any address offset not explicitly mentioned in *Table 2121* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 2121*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

1. In this column, R/W = read/write, R = read-only, and W = write-only.

83.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state.
- moving the FCCU state from the CONFIG state into the NORMAL state.
- reading or to clear the RF status register.
- reading the FCCU FSM status register.
- reading or to clear the FCCU freeze registers.
- reading the ALARM timer.
- reading the Watchdog timer.
- configure the glitch filter present on EIN0 input (FCCU failure input #96).

Some critical operations require a key as defined in the FCCU_CTRLK register.

The Glitch filter, filters out pulses of widths up to 50/75/100 µs, as governed by FCCU_CTRL[FILTER_WIDTH]. It becomes active as soon as FCCU_CTRL[FILTER_BYPASS] is de-asserted (default value).

The implementation is as follows:

1. Fault line assertion - If a Fault is asserted, then the output of the filter is asserted after the delay, equal to the programmed glitch width time. If the fault is de-asserted before

the programmed glitch width time, then the output of the filter is not asserted and stays at the deactivated level (after having rejected the spurious glitch).

2. Fault line de-assertion - If a Fault, which was kept asserted for a time greater than the programmed pulse width is de-asserted (and glitch filter output is at asserted level now), then the output of the filter is de-asserted only after the delay equal to the programmed glitch width time. If the fault is again asserted before the programmed glitch width time, then the output of the filter is not de-asserted and stays at the active level (after having rejected the spurious glitch).

The output of the filter becomes the effective fault input fed to the FCCU error management engine. Since there is an inherent latency involved, SW must either wait for the programmed delay value before trying to clear the fault status flag, FCCU failure input #96 or first set FCCU_CTRL[FILTER_BYPASS] to one and then try to clear the fault status flag. This bit should not be made '1' again, till the filter width time elapses, else fault status will be latched again.

Offset: 0x000 Access: User read/write

1:2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs for 20 MHz IRC clock 11 filters glitches up to 100 µs for 20 MHz IRC clock Make sure that the filter width does not cross the FOSU timeout value else unintended reset may occur.

Table 2122. FCCU_CTRL field descriptions (continued)

Field	Description
22 DEBUG	Debug mode entry 0 Normal operation 1 Put FCCU into debug mode When Debug pin signal is asserted and this bit is set, FCCU moves into debug state and suspend the transition of the FSM by suspending timer elapse time effect.
24:25 OPS	Operation status 00 Idle 01 In progress 10 Aborted 11 Successful These bits can be read and cleared (via OP15 operation) by the software.

Table 2122. FCCU_CTRL field descriptions (continued)

Field	Description
27:31 OPR	Operation run 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (refer to the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (refer to the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (refer to the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (refer to the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (refer to the F2A_STATUS register) [OP7] 01000 Reserved 01001 Reserved 01010 Read the RF status register (refer to the FCCU_RF_S register) [OP10] 01011 Reserved 01100 RF status clear operation in progress (refer to the FCCU_RF_S register) [OP12] 01101 Clear the freeze status registers (refer to the freeze registers) [OP13] 01110 CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111 Clear the operation status (OPS=Idle) [OP15] 10000 Reserved 10001 Read the ALARM timer (refer to the FCCU_XTMR register) [OP17] 10010 RESERVED 10011 Read the CFG timer (refer to the FCCU_XTMR register) [OP19] 10100 Read the Error Pin low counter value (refer to *Section 83.6.21: FCCU XTMR Register (FCCU_XTMR)*) [OP20] 10101 Reserved ... 11111 Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution The max timing needed for ABORT/SUCCESS response is 15 IRC cycles

83.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There shall not be any other operation in between the above steps and the 32 bits need to be written in one cycle. So, store FCCU_CTRLK, merge with OP1 or OP2 then send it.

The FCCU_CTRLK register is not readable, a 0x0000_0000 value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0(2)	0	0	0

1. Writable only in the CONFIG state.
2. After powerup, reset value will be 0. If configuration timeout occurs then default value will be changed to 1.

Figure 2236. FCCU Configuration Register (FCCU_CFG)

Table 2124. FCCU_CFG field descriptions

Field	Description
7 FCCU_SET_AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0 FCCU's Error indication stops functioning and error pins are in HI-Z state(1). 1 write to start FCCU functioning. After power-on the error out pins shall be in high impedance(1). They will go to normal state only on software request, this bit is set to 1. It is Software responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
8:9 FCCU_SET_CLEAR	Error pin state can be controlled by these bits 01 Error Pin driven to logic 0. 11 Error Pin driven to logic 1 (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault). 00 FCCU acts independent of above SW control. 10 FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z(1). Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state. This bit feature may not work with toggling protocols for example say EOUT pins are set high by SW using this bit followed by switching to a toggling protocol after returning control to FCCU FSM via setting this bit to 00 or 10, the user may find that EOUT pins do not toggle as was being expected.

Table 2124. FCCU_CFG field descriptions (continued)

Field	Description
19 OD	Open Drain Mechanism to select between Push-pull and Open drain (OD) mode for the error indicating pin(s). 0 push-pull 1 OD
21 SM	Switching mode 0 EOUT protocol (dual rail, time switching) slow switching mode. 1 EOUT protocol (dual rail, time switching) fast switching mode. SM has no effect on the bi-stable protocol.
22 PS	Polarity selection 0 FCCU Error output[1] active high, FCCU Error output[0] active low. 1 FCCU Error output[1] active low, FCCU Error output[0] active high. This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non toggling in Error phase.
23:25 FOM	Fault Output Mode selection 000 Dual Rail (default state) [FCCU Error output[1:0]= outputs] 001 Time Switching [FCCU Error output[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [FCCU Error output[0]= input, FCCU Error output[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= input] **Note:** In Test mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.

1. Actual value depends on the SOC settings at pad level.

83.6.4 FCCU RF Configuration Register *n* (FCCU_RF_CFG*n*)

The FCCU_RF_CFG*n* registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

83.6.5 FCCU RFS Configuration Register *n* (FCCU_RFS_CFG*n*)

The FCCU_RFS_CFG*n* registers contain the configuration of each recoverable fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

These registers are writable only in the CONFIG state.

Offset: 0x04C +*n**0x4 (*n* = 0 to 7) Access: User read/write(1)

83.6.6 FCCU RF Status register *n* (FCCU_RF_S*n*)

The FCCU_RF_S*n* register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_S*n* register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field
3. Wait for the completion of the operation (FCCU_CTRL.OPS field)
4. Read the FCCU_RF_S*n* register in order to verify the effective deletion and in case of failure to repeat the sequence

As a result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (refer to *Section 83.5.7: FAULT interface*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_S*n* read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_RF_S*n* register

In case of reconfiguration of the FCCU (CONFIG state), before returning in NORMAL state the pending status bits into the FCCU_RF_S*n* must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

83.6.7 FCCU RF Key register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_S*n* register.

The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx

The key must be written for each FCCU_RF_S*n* clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0x0000_0000 value is always returned in case of read operation.

83.6.8 FCCU RF Enable Register *n* (FCCU_RF_E*n*)

The FCCU_RF_E*n* registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_S*n* register is anyway set, only the reaction is masked.

These registers are writable only in the CONFIG state.

83.6.9 FCCU RF Timeout Enable Register *n* (FCCU_RF_TOE*n*)

The FCCU_RF_TOE*n* registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective timeout is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

83.6.10 FCCU RF Timeout Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state. The alarm timeouts value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU timeout.

This register is writable only in the CONFIG state.

Field	Description
0:31 TO	Recoverable fault timeout Timeout = (TO) x $T_{RC16MHz}$

83.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2121: FCCU memory map*. The watchdog timeout is clocked with the RC oscillator clock (16 MHz). The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

83.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the FCCU Error output pin[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the FCCU Error output pin[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the FCCU Error inputs level

Table 2138: Bi-stable encoding shows Bi-stable encoding.

Table 2138. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

31 EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => FCCU Error output[0] configured in output mode) 0 force FCCU Error output[0] = 0 1 force FCCU Error output[0] = 1 The EOUT0 set/clear the respective FCCU Error output[0] signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a “do not care” value.

83.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status. The FCCU finite state machine (FSM) operates by the RC oscillator clock asynchronous with the System clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization

sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Field	Description
26:27 PhysicErrorPin	Physical Error Pin state PhysicErrorPin[26] corresponds to error pin 0, PhysicErrorPin[27] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0 Error Pin is at logical 0 1 Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. **Note:** This field indicates the real time status of the Error pin as driven by FCCU (at FCCU boundary) to the pad and not what is seen at/from the pad, which is based on different IPs (such as SIUL2) configurations of the SoC.
28 ESTAT	Current Error Pin Status SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in nonfaulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state.This state is taken from the FCCU Eout logic (That is, as late as possible).
29:31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state Other: UNKNOWN state

83.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the recoverable source (FCCU recoverable fault x) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

83.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

83.6.16 FCCU NF Freeze Status Register (N2FF_STATUS)

The N2FF_STATUS register contains a unique code to identify the recoverable fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

83.6.17 FCCU FA Freeze Status Register (F2A_STATUS)

The F2A_STATUS register contains a unique code to identify the recoverable fault source (recoverable fault x) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the F2A_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the N2FF_STATUS register

The SW application executes the F2A_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

83.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recoverable fault in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 83.5.7: FAULT interface*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

83.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The external interrupt line (Interrupt request) is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

83.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The external interrupt line “Interrupt request (miscellaneous conditions)” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

83.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

EOUTMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it loads (a value corresponding to T_min = 250 µs + value programmed in FCCU_DELTA_T register) and then starts down-counting and becomes 0 on the expiry of T_min window. It reloads on occurrence of another fault event which has EOUT signaling enabled. T_min feature is available only in Bi-Stable

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   a) OP17
   b) OP19
   c) OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

Table 2149: Timer state/value shows Timer state/value.

83.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

0x128	FCCU_EOUT_SIG_EN3	EOUTEN[127:96]

83.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (that is FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

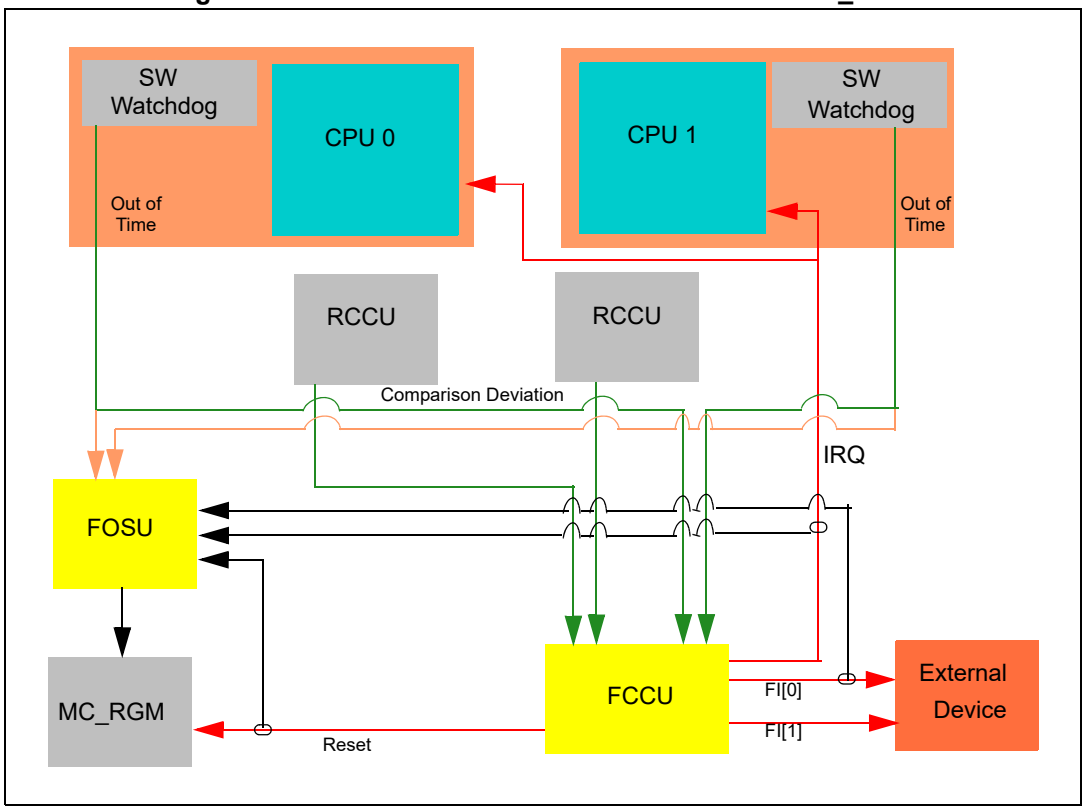
There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a “static” input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state.The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC.The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset.
- IRQ: NMI or Alarm.
- Error out triggered (by FCCU or by SW).

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is de-asserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.
The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as it is used by the FCCU (System reset), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is de-asserted.

The following conditions show a use case of the FOSU:



1. The user configures the channel x of the FCCU to react with a functional reset, either long or short.
2. The user sets the EOUTEN[x] flag of EOUT_SIG_EN register to 0.
3. The software does not clear the FCCU status flag related to the fault x after its first occurrence.
4. The fault x triggers again after the functional reset. Under these circumstances, the FOSU triggers a destructive reset after the FOSU timeout.

The rationale behind is that the functional reset is not able to clear the source of the fault. If the software can't react to the second occurrence of the fault before the FOSU timeout expires, the FOSU triggers a destructive reset.

If the users want to increase the availability of the system by avoiding the destructive reset, they can set the EOUTEN[x] flag of EOUT_SIG_EN register to 1. In such a case, the FOSU does not trigger the destructive reset.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 2262. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

83.8 Use cases and limitations

83.8.1 Mis-configurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.

Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.

4. Software reset is optional.
5. The user must program the FCCU for a higher timeout value than the value hard-coded for FOSU. In this way FCCU reacts later than FOSU expects and as a result, FOSU generates a destructive reset request on its timeout, if a fault occurred when the FCCU was in CONFIG state.

83.8.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, the following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status.
   b) Verify FCCU is in NORMAL state, else repeat step (a) above.
   c) Configure FCCU.
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire.
   b) Check and clear fault status.
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires.
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state.
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU.
   f) Check and clear any new pending fault status until FCCU is in NORMAL state.
   g) Reconfigure FCCU.

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

84 Self-Test Control Unit (STCU2)

84.1 Introduction

The self-test control unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the offline or online, or both, conditions. The hardware can manage the logic built-in self-test (LBIST) and the Memory (SRAM or ROM) built-in self-test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the self-test parameters (LBIST or MBIST scheduling activity, LBIST setup, unrecoverable faults (UF) or recoverable faults (RF) management, CRC and MISR expected values, PLL management, and so on) from Flash memory during the offline self-test phase. This interface is only able to write the configuration parameters and start the self-test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the offline self-test and to load or check the execution of the online self-test.

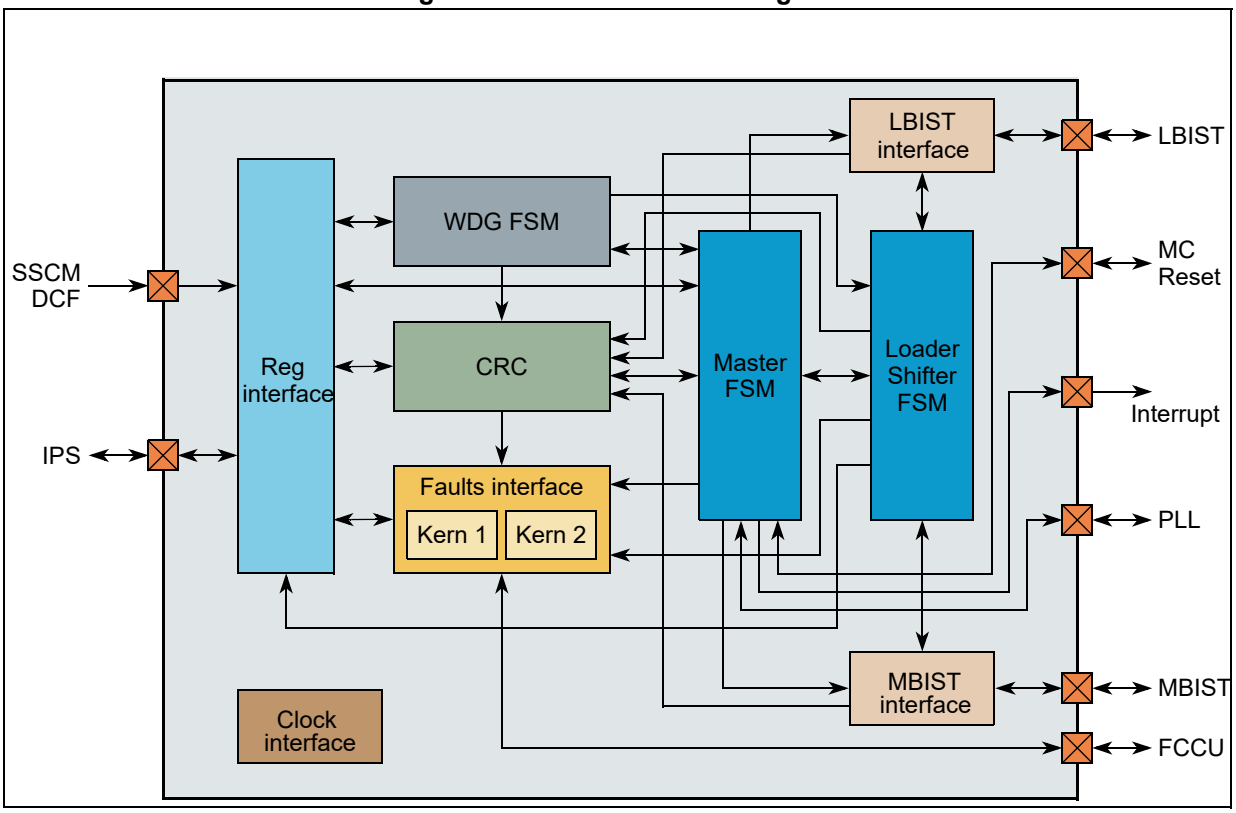
The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the self-test run to increase the STCU2's self-checking capability.
- A programmable watchdog timer (WDG) to check the LBIST and MBIST self-test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before watchdog timeout.
- Direct PLL control during the offline self-test sequence.
- Two interrupt lines enabled only during the online self-test to simplify the software handling of self-test execution end.
- Two sets of registers to separately collect the LBIST or MBIST results during offline and online self-test.

To increase the security of this module, a different security key sequence is also required during offline and online self-test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after self-test sequence is completed.
- The register ITF clock when the WDG timeout is detected after a double security key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

84.2 Main features



- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG[WRP] bit) register interface.
- Programmable scheduler for LBIST or MBIST execution.
- LBIST concurrent/sequential execution.
- MBIST concurrent/sequential execution.
- Programmable LBIST delayed concurrent start.

- 32-bit CRC for STCU2 self-checking capability (enabled by STCU_CFG[CRCEN] bit).
- Online hardware self-test sequence abort capability.
- Programmable internal clock prescaler to reduce internal and MBIST or LBIST TCK clocks.
- Programmable PLL direct control during offline self-test sequence.
- PLL lock signal monitoring during offline and online self-test.
- MBIST dedicated online interrupt source generation.
- Programmable WDG timer for self-check MBIST or LBIST time execution.
- Hard-coded WDG timeout to flag offline initialization errors.
- Hard-coded WDG timeout to auto-lock STCU2 write access after double key sequence.
- LBIST and SRAM or ROM MBIST offline status flags.
- STCU2 internal errors offline status flag.
- LBIST and SRAM or ROM MBIST online status flags.
- STCU2 internal errors online status flag.
- Online hardware abort status flag.
- LBIST and SRAM or ROM MBIST offline or online programmable failure severity (UF/RF).
- STCU2 internal errors offline or online programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software.
- LBIST MISRE registers access to perform redundant software checks.
- Self-test bypass capability.
- Protection mechanism of the global write register based on double security key.
- STCU2 global auto power-saving when:
  - Self-test is completed.
  - bypass mode is selected.
  - WDG timeout is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).
- STCU2 ITF/WDG auto power-saving when hard-coded WDG timeout is detected after software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).

84.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 2263*.

Figure 2263. STCU2 block diagram

The STCU2 module includes the following submodules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface.
- **CRC**: This module is the core of the self-checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface:** This module collects the error conditions respective to LBIST or MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the set or clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- **Clock Block:** This module manages the internal and the LBIST or MBIST TCK clock prescaler, the internal clock gating power saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different watchdogs:
  - A hard-coded Watchdog used to auto-lock the STCU2 access, forcing a reset condition on the double security key registers.
  - A dual function watchdog:

    - After a reset event initializes the STCU2, it is used as a hard-coded watchdog timeout.

    - During LBIST or MBIST runs, it is used as a programmable watchdog timer to check the LBIST or MBIST have completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the self-test sequence.

- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the LBIST or MBIST registers and read back the data to be checked at the end of each self-test operation.
- **LBIST interface**: This module includes the interface between the LBIST engines and the STCU2 controllers of the device.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

84.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The self-test sequence parameters are loaded before offline self-test is executed.
- The IPS access on some specific registers (see *Section 84.5: Register description*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following R/W bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register.
- Any write operation on double security key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the double security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed offline on registers where writes are only allowed during the online self-test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on read only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 84.5: Register description*.

84.4 Functional description

84.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the self-test operations and the other state machines.
- Loader/Shifter State Machine: used to program the MBIST and the LBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the master state machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and LBIST and the timeouts in case of incorrect STCU2 programming.

84.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the offline self-test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the self-test execution phase depends on the self-test conditions and on the content of the STCU_LBRMSW register reported in the following subsections.

In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the associated MC_RGM module.

84.4.2.1 Offline reset generation

At the end of the offline self-test execution, the STCU2 raises the global functional reset. In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module.

84.4.2.2 Online reset generation (only MBIST)

The online execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences respective to the write operations performed by the MBIST execution other than prevent any read/write operation during the self-test execution. If necessary, the software must also restore the memory content (only for RAM) at the end of the self-test execution.

84.4.2.3 Online Reset generation (LBIST enabled)

At the end of the execution, the online execution of the LBIST generates two possible types of reset depending on the status of the STCU_LBRMSW register. See *Section 84.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*.

If all the selected LBISTs do not require the global functional reset, only the partitions subjected to LBIST are cleaned up applying a pulse on the dedicated reset line. If at least one of the selected LBISTs requires the global functional reset, the global functional reset is raised at the end of the online self-test execution.

Note: If an ABORT condition is detected by STCU2 during the online self-test execution, regardless of the value of the STCU_LBRMSW register, only the respective reset line is pulsed to prevent any potential dangerous system level operations

84.4.3 LBIST and MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST or LBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 84.6.4: Design implementation information*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first LBIST is mapped on 0x00, the second on 0x01, and so on. The first MBIST is mapped at the address 0x10, the second on 0x11 and so on. The additional pointers are in the bitfield STCU_LB_CTRL*x*[PTR] for LBIST*x* (where *x* is the selected LBIST) and STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_LB_CTRL[CSM] and STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the LBIST or MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 84.5.33: STCU2 LBIST Control n Register (STCU_LB_CTRLn)* and *Section 84.5.45: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*.

84.4.4 ABORT management

The STCU2 module provides online self-test execution abort. When the abort is detected, the online self-test operation stops running and the status of the currently running MBIST or LBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run. For an LBIST run, see *Section 84.4.2: Reset management*, regarding reset specific management when abort is detected.

84.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a functional reset that requires the self-test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the online self-test execution run.

84.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the offline self-test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 84.5.2: STCU2 Run Software Register (STCU_RUNSW)*.

When STCU_RUN[RUN] is set to start the offline self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configuration parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end of the MBIST run, the clock source reverts to the original one.

The same behavior applies when STCU_RUN[LBPLLEN] is active and LBIST is currently selected.

84.4.6 Interrupt interface

There are two interrupt sources:

- One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1).
- One triggered by LBIST (enabled by programming STCU_RUNSW[LBIE] = 1).

As described in *Section 84.5.2: STCU2 Run Software Register (STCU_RUNSW)*, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential runs in the same session, the number of interrupts generated is equivalent to the number of sequential sessions, thus providing fine granularity with respect to the completed run.

The MBIFLG bit in the *STCU2 Interrupt Flag Register (STCU_INT_FLG)* registers flag interrupt condition and allows the clearing of interrupt requests. Interrupt bit to be cleared by writing the respective bit to 1 to enable the next interrupt request.

84.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an unrecoverable failure (UF) or a recoverable failure (RF) during the self-test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

84.4.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished on time.

84.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the self-test sequence (safety mode).
- Bypass the self-test sequence by setting the STCU_RUN[BYP] bit. If Bypass bit is configured/set by DCF it cannot be anymore changed on the device even though STCU_RUN register itself is not Write once.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded watchdog timeout flags the incorrect behavior. See *Section 84.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* for more details.

84.4.8.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time is configured as described in *Chapter 84.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* to account for the overall execution time of the self-test sequence. If the selected LBISTs or MBISTs are not yet completed:

- During an offline self-test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBE1/2/3 or STCU_LBE registers.
- During an online self-test, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBE1SW/2SW/3SW or STCU_LBESW.

In case of multiple sequential runs in the same online or offline session and the timeout occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 84.4.2: Reset management*.

84.4.8.3 Write access timeout

The access on the STCU2 registers during the self-test configuration phase (both online or offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software self-test configuration as the software application may enable write access to the STCU2 registers.

84.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomy to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the self-test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

84.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

84.5 Register description

The STCU2 registers are listed in *Table 2160*.

Note: n and k are variables representing the repeated register blocks of the multiple LBISTs and MBISTs: n ranges from 0 up to 6, k ranges from 0 up to 91.

84.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the offline self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Offset: 0x0000 Access: User read/write

Figure 2264. STCU2 Run Register (STCU_RUN)

Table 2161. STCU_RUN field descriptions

Field	Description
21 BYP	Bypass mode 0 Offline self-test is active. If the STCU_RUN[RUN] bit is not set before the hard-coded WDG timeout, the WDTO error is generated in the STCU_ERR_STAT register. 1 Offline self-test is bypassed and access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
22 MBPLLEN	Offline MBIST with PLL0 Enabled 0 Offline MBIST is executed without using the on-chip PLL0. 1 Offline MBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
23 LBPLLEN	Offline LBIST with PLL0 Enabled 0 Offline LBIST is executed without using the on-chip PLL0. 1 Offline LBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
31 RUN	RUN The RUN bit is automatically cleared by the STCU2 when the offline self-test procedure has been completed. 0 Idle 1 Offline self-test procedure is running

84.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the online self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- Online self-test phase is active. The online condition starts when the offline condition finishes. In this condition, the system is alive and the SW can program the STCU.

Figure 2265. STCU2 Run Software Register (STCU_RUNSW)

Table 2162. STCU_RUNSW field descriptions

Field	Description
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories, the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are concluded. If there is a sequence of concurrent runs in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[MBIFG] bit in between.
21 LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST, the STCU2 forces an interrupt request to notify LBIST of the concurrent selected partitions are concluded. If there is a sequence of concurrent run in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[LBIFG] bit in between.
22 MBSWPLLEN	Online MBIST with PLL1 Enabled 0 Online MBIST is executed without waiting for PLL1 lock. 1 Online MBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.

Table 2162. STCU_RUNSW field descriptions (continued)

Field	Description
23 LBSWPLLEN	Online LBIST with PLL1 Enabled 0 Online LBIST is executed without waiting for PLL1 lock. 1 Online LBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take the PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the online self-test procedure has been completed. 0 Idle. 1 Online self-test procedure is running.

84.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2 asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the offline or online test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: Note that after the self-test sequence has been completed or the bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.

In case of invalid access or sequence (Keys1 and 2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG timeout, STCU2 write access is locked and the WDG and register ITF clocks are switched off. Also in this case the correct sequence must be applied in order to re-enable write access to the STCU2 and the WDG and register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG timeout expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 0x00000000.

84.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the offline and online test steps.

Access to this register is described in *Figure 2267*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the online self-test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Offset: 0x000C Access: User read/write

Reset	The reset value is chip-specific; see the chapter that describes how modules are configured and connected.															

1. You can always read this field. In the offline self-test phase, you can always write to this field. In the online self-test phase, you can write to this field only when WRP = 0.

Figure 2267. STCU2 Configuration Register (STCU_CFG)

Table 2164. STCU_CFG field descriptions

Field	Description
0:7 PTR	LBIST or MBIST pointer. PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0, then the LBIST0 is initially scheduled. (0x00 to LBIST - 1) – pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution.
8:15 LB_DELAY	Delay LBIST run. LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. 0x00 No delay 0x01 1 × 16 STCU2 Core clock cycles 0x02 2 × 16 STCU2 Core clock cycles 0x03 3 × 16 STCU2 Core clock cycles … 0xFD 253 × 16 STCU2 Core clock cycles 0xFE 254 × 16 STCU2 Core clock cycles 0xFF 255 × 16 STCU2 Core clock cycles **Note:** STCU2 is being clocked from PBRIDGE Clock. Refer to Clocking chapter for PBRIDGE clock frequency value.
23 WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after offline self-test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after offline self-test sequence has completed, thus preventing any user application write operation.

Table 2164. STCU_CFG field descriptions (continued)

Field	Description
26 CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values. 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS test is not enabled 1 MBIST PMOS test is enabled
28 MBU	MBIST MBU Test Enabled. 0 MBIST full algorithm or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified multi-bit upset algorithm is used to check the RAM. If a ROM is selected, the applied algorithm will be standard one without PMOS test. ***This bit overwrites the PMOSEN feature***.
29:31 CLK_CFG	Logic, memory BIST and STCU2 core clock configuration. CLK_CFG defines the ratio between the STCU2 core clock and the TCK used to program the LBIST, the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 PBRIDGE_CLK 001 PBRIDGE_CLK/2 010 PBRIDGE_CLK/3 011 PBRIDGE_CLK/4 100 PBRIDGE_CLK/5 101 PBRIDGE_CLK/6 110 PBRIDGE_CLK/7 111 PBRIDGE_CLK/8 **Note:** refer to Clocking chapter for PBRIDGE_CLK clock frequency value.

84.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the offline LBISTs or MBISTs are performed and STCU_RUN[MBPLLEN] = 1 or STCU_RUN[LBPLLEN] = 1.

In the online state, these bits are not effective. It is also possible to set the PLL during active online mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is active.

Figure 2268. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Note: f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.

Table 2165. STCU_PLL_CFG field descriptions

Field	Description
2:7 PLLODF	PLL Output Division Factor. The value of this field drives the output division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the respective PLL's output division factor.
13:15 PLLIDF	PLL Input Division Factor. The value of this field drives the input division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the respective PLL's input division factor.
25:31 PLLLDF	PLL Loop Division Factor. The value of this field drives the loop division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the respective PLL's loop division factor.

84.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for LBIST and MBIST execution, providing protection against dead-locks or infinite loop conditions during the self-test procedure. When the offline self-test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15 to 0 define the timeout before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the offline or online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active
- Online self-test phase is active and STCU_CFG[WRP] = 0

Offset: 0x0014 Access: User read/write

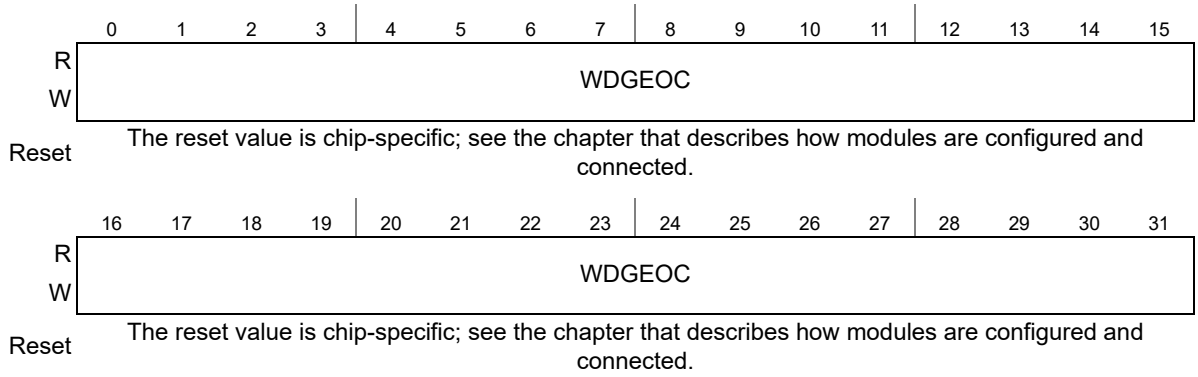

Figure 2269. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 2166. STCU_WDG field descriptions

Field	Description
0:31 WDGEOC	Watchdog End of Count Timer. This value must be set in order to define the time budget respective to the offline and online self-test execution and check that everything is working correctly in this timeslot. The allowed time delays are: 0x00000000 1*k*STCU2 core clock cycles 0x00000001 2*k*STCU2 core clock cycles 0x00000002 3*k*STCU2 core clock cycles … 0xFFFFFFFD 4294967294*k*STCU2 core clock cycles 0xFFFFFFFE 4294967295*k*STCU2 core clock cycles 0xFFFFFFFF 4294967296*k*16 STCU2 core clock cycles where k is: – ‘1’ for offline self-test – ‘16’ for online self-test **Note:** STCU2 core clock is specified through STCU_CFG[CLK_CFG] field.

84.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST and LBIST interrupt pending bits. These bits are effective only during the online self-test phase and managed only when the respective control bit in the STCU_RUNSW register (MBIE and LBIE) enabled.

Offset: 0x0018 Access: User read/write

Table 2167. STCU_INT_FLG field descriptions

Field	Description
30 MBIFLG	MBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled MBIST is completed is pending. Write 1 to clear the bit.
31 LBIFLG	LBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled LBIST is completed is pending. Write 1 to clear the bit.

84.5.8 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the self check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

CRC-32 (ethernet protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

84.5.9 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the offline and online self-test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

84.5.10 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the online and offline self-test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 84.6.4: Design implementation information*.

Access to this register is described in *Figure 2273* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

Offset: 0x0024 Access: User read/write

Figure 2273. STCU2 Error Register (STCU_ERR_STAT)

Table 2170. STCU_ERR_STAT field descriptions

Field	Description
6 ABORTHW	Online hardware abort flag. 0 No hardware abort was requested during the online self-test sequence 1 A hardware abort was detected during the online self-test sequence
11 LOCKESW	Online LOCK Error. 0 If PLL is enabled, it is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the online self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW[LBSWPLLEN] is set or during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1, or during both.
12 WDTOSW	Online Watchdog timeout. 0 LBIST and MBIST time slots have completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not completed in the assigned watchdog time or there are internal mismatches in the end of execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 CRCSSW	Online CRC Status. This flag is activated *only* when online self-test is performed and STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to 0) 1 Failed CRC comparison
14 ENGESW	Online Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	Online Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the unrecoverable faults condition 1 There are errors that trigger the unrecoverable faults condition

Table 2170. STCU_ERR_STAT field descriptions (continued)

Field	Description
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the recoverable faults condition 1 There are errors that trigger the recoverable faults condition
27 LOCKE	Offline LOCK Error 0 The PLL is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the offline self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLLEN] = 1 or during the MBIST run when STCU_RUN[MBPLLEN] = 1, or during both.
28 WDTO	Offline Watchdog timeout. 0 LBIST and MBIST time slots have been completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not been completed within the assigned watchdog time or there are internal mismatches among end of execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the watchdog reach the end of count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Offline CRC status. This flag is activated *only* when offline self-test is performed STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
30 ENGE	Offline Engine Error. 0 Valid engine execution 1 Invalid engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Offline Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)

84.5.11 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of Unrecoverable or recoverable faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

84.5.16 STCU2 Online LBIST Reset Management (STCU_LBRMSW)

The STCU_LBRMSW register defines the online reset mapping for each LBIST. Global or specific functional resets can be programmed depending on the online Self Test requirements and top level integration architecture.

The size of the register depends on the number of LBISTs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

84.5.30 STCU2 MBIST 1 Unrecoverable FM Register (STCU_MBUFM1)

The STCU_MBUFM1 register defines the fault mapping, in terms of unrecoverable or recoverable fault, of the MBIST in the range NMCUT = 0 to 31. The size of the register depends on the amount of RAM or ROM subject to BIST.

Note: Refer to Section 7.10.6: STCU2 configuration in Device configuration chapter for the number of NMCUT available in this device.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Table 2190. STCU_MBUFM1 field descriptions

Field	Description
0:31 MBUFM[31:0]	MBIST Unrecoverable Fault Mapping. 0 Recoverable fault mapping 1 Unrecoverable fault mapping

84.5.31 STCU2 MBIST 2 Unrecoverable FM Register (STCU_MBUFM2)

The STCU_MBUFM2 register defines the fault mapping, in terms of unrecoverable or recoverable fault, of the MBIST in the range NMCUT = 32 to 63. The size of the register depends on the amount of RAM or ROM subject to BIST.

Note: Refer to Section 7.10.6: STCU2 configuration in Device configuration chapter for the number of NMCUT available in this device.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

84.5.32 STCU2 MBIST 3 Unrecoverable FM Register (STCU_MBUFM3)

The STCU_MBUFM3 register defines the fault mapping, in terms of unrecoverable or recoverable fault, of the MBIST in the range NMCUT = 64 to 95. The size of the register depends on the amount of RAM or ROM subject to BIST.

Note: Refer to Section 7.10.6: STCU2 configuration in Device configuration chapter for the number of NMCUT available in this device.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

Figure 2296. STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

Table 2193. STCU_LB_CTRL*n* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer, the CSM bit has to be set Sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current LBIST has been completed. (0x0 to NLBIST - 1) pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
13:15 SHS	Shift Speed 000 Shift at full rate (STCU core clock) 001 Shift at 1/2 rate (STCU core clock) 010 Shift at 1/3 rate (STCU core clock) 011 Shift at 1/4 rate (STCU core clock) 100 Shift at 1/5 rate (STCU core clock) 101 Shift at 1/6 rate (STCU core clock) 110 Shift at 1/7 rate (STCU core clock) 111 Shift at 1/8 rate (STCU core clock)

Table 2193. STCU_LB_CTRL*n* field descriptions (continued)

Field	Description
16:19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
20:23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
26 PFT	Past Flush Test The LBIST controller, by default apply 32 flush test patterns. This bit allows to skip/apply the flush test pattern sequence. 0 Apply flush test patterns 1 Skip flush test patterns
27:31 CWS	Capture window size 00000 Controller waits 16 shift cycle for capture to finish. 00001 Controller waits 1 shift cycle for capture to finish. 00010 Controller waits 2 shift cycles for capture to finish. … 00111 Controller waits 7 shift cycles for capture to finish.

84.5.34 STCU2 LBIST PC Stop *n* Register (STCU_LB_PCS*n*)

The STCU_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0104 + n * 0x40 (n = 0 to 6) Access: User read/write

Field	Description
6:31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

84.5.35 STCU2 LBIST PRPG Low *n* Register (STCU_LB_PRPGL*n*)

The STCU_LB_PRPGL register defines the LSB part (31 to 0) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0108 + n * 0x40 (n = 0 to 6) Access: User read/write

Table 2195. STCU_LB_PRPGL*n* field descriptions

Field	Description
0:31 PRPG[31:0]	PRPG LBIST low bits This field defines the low part (31 to 0) of the LBIST PRPG start value.

84.5.36 STCU2 LBIST PRPG High *n* Register (STCU_LB_PRPGH*n*)

The STCU_LB_PRPGH register defines the MSB part (63 to 32) of the PRPG start value of the LBIST controller. The size of the register depends on the number of PRPG bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x010C + n * 0x40 (n = 0 to 6) Access: User read/write

0:31 PRPG[63:32]	PRPG LBIST High Bits This field is the high part (63 to 32) of the LBIST PRPG start value.

84.5.37 STCU2 Offline LBIST MISR Expected Low *n* Register (STCU_LB_MISREL*n*)

The STCU_LB_MISREL register defines the LSB part (31 to 0) of the expected MISR of the offline LBIST controller. The size of the register depends on the number of MISR bits of the respective LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Offset: 0x0110 + n * 0x40 (n = 0 to 6) Access: User read/write

Figure 2306. STCU2 Online LBIST MISR Read Low *n* Register (STCU_LB_MISRRLSW*n*)

Table 2203. STCU_LB_MISRRLSW*n* field descriptions

Field	Description
0:31 MISRRSW[31:0]	Online MISR read low bits. This field is equivalent to the low bits (31 to 0) of the MISR obtained at the end of the offline LBIST execution.

84.5.44 STCU2 Online LBIST MISR Read High *n* Register (STCU_LB_MISRRHSW*n*)

The STCU_LB_MISRRHSW register report the MSB part (63 to 32) of the MISR obtained at the end of each online LBIST controller execution. The size of the register depends on the number of MISR bits of the respective LBIST.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Field	Description
0:31 MISRRSW[63:32]	Online MISR Read high bits. This field is equivalent to the high bits (63 to 32) of the MISR obtained at the end of the offline LBIST execution.

84.5.45 STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

The STCU_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x0600 + k*0x4 (k = 0 to 91) Access: User read/write

Figure 2308. STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

Table 2205. STCU_MB_CTRL*k* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current MBIST has been completed. (0x00 to LBIST - 1) — pointer to LBIST PTR = 0x10 + $MBIST_i$ (Pointer to MBIST) for i = 0 to XX: please refer to the MBIST partitions table for the $MBIST_i$ code. PTR = 0xFF: Pointer to NIL. No additional MBIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode

84.6 Use cases and limitations

The STCU2 module is designed to give high flexibility during the online and offline self-test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Offline self-test sequence after a reset trigger event
- Bypass mode of the self-test sequence after a reset trigger event
- Online self-test sequence

The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.

84.6.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and LBIST or MBIST execution parameters stored in the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the system RAM or ROM according to the system specifications. The sequence is the following:

- Unlock the offline STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFM1/2/3 registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, the STCU_LB_PRPGL/H can also be programmed to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the offline self-test sequence in the STCU_CRCE register.
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.
- Program the RUN bit in the STCU_RUN register to enable the offline self-test execution and the LM/BPLLEN bits to enable the PLL during LBIST or MBIST execution according to STCU_PLL_CFG register content.
- Start the offline self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the self-test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application read the STCU_LBS flag register to check the failed LBIST when UF or RF conditions are detected.

- The software application read the STCU_LBE flag register to check the LBIST still on-going when UF or RF are detected.
- The software application read the STCU_MBS1/2/3 flag registers, depending on the number of memories, to check the failed RAM or ROM memory BIST when UF or RF are detected.
- The software application read the STCU_MBE1/2/3 flag registers, depending on the number of memories, to check the RAM or ROM memory BIST still running when UF or RF are detected.
- The software application read the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- For each LBIST, the software application reads the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

84.6.2 Online self-test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the LBIST or MBIST execution. Since the online operations clean up the content of the respective digital logic (LBIST) or RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the online STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 online self-test registers.
- The LBIST, MBIST and STCU2 internal fault reaction should already be programmed during the offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_LBUFM, STCU_MBUFM1/2/3 and STCU_ERR_FM.
- Program the Reset management during online LBIST execution setting the STCU_LBRMSW register.
- The STCU_LB_CTRL, STCU_LB_PCS should already be programmed during offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.

- Overwrite/Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBISTs are running simultaneously to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the online self-test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the online self-test execution, the L/MBIE to enable the Interrupt requests, and the L/MBSWPLLEN bits to enable the PLL lock signal monitor during LBIST or MBIST execution.
- Start the online self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- If the L/MBIE are enabled, an interrupt is generated at the end of all the LBIST or MBIST runs. The software application has to manage these interrupt signals and clean up the respective flags (L/MBIFLG) in the STCU_INT_FLG register.
- The STCU2 switches off the core clock at the end of the self-test run.
- The activated functional reset is managed by the STCU_LBRMSW.
- If at least one of the selected LBISTs enables the global functional reset, the STCU2 requests a functional reset which restarts the system. If all the selected LBISTs enable their own dedicated functional reset, only these local reset lines are applied and only the respective LBIST partitions are cleaned up.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBESW flag register to check the LBIST is still running when UFs or RFs are detected.
- The software application reads the STCU_MBS1SW/2SW/3S+W flag registers, depending on the number of memories, to check the failed RAM/ROM memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBE1SW/2SW/3SW flag registers, depending on the number of memories, to check the RAM/ROM memory BIST is still running when UFs or RFs are detected.
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.

- For each LBIST, the software application reads the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after online self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

84.6.3 Bypass USER Mode

In this mode, the user application parameters stored in Flash and read by SSCM are written to skip the self-test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the offline Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the self-test sequence is not applied and the system can wake up and start the user application.

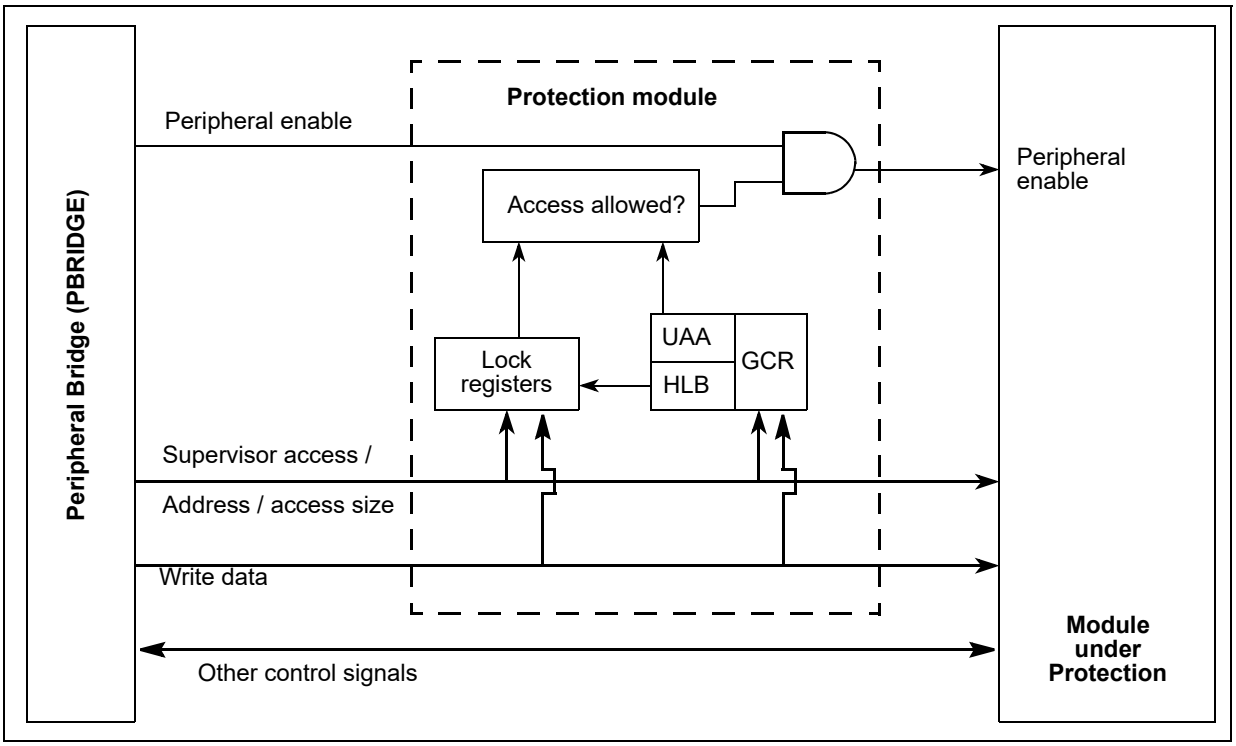
84.6.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the on/offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- As the software has full control of the system while applications are running during the online self-test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

85 Register Protection (REG_PROT)

85.1 Introduction



85.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Refer to the Device configuration chapter for protected registers.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 2309*.

Figure 2309. REG_PROT block diagram

85.1.2 Features

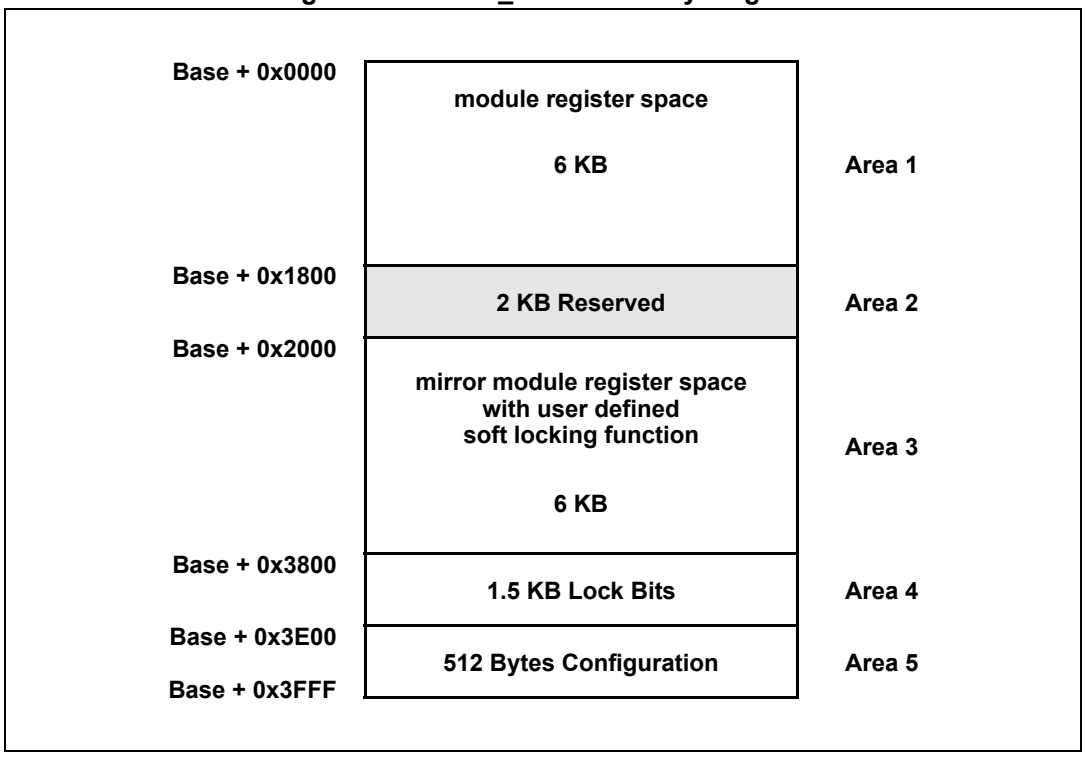
Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set.

85.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.



85.2 External signal description

There are no external signals.

85.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 2310*.

Figure 2310. REG_PROT memory diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

85.3.1 Memory map

Table 2206 shows the memory map for a module which is protected via a REG_PROT module.

Table 2206. REG_PROT memory map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*Section 85.3.2.1*
0x0001	Module Register 1 (MR1)	*Section 85.3.2.1*
0x0002	Module Register 2 (MR2)	*Section 85.3.2.1*
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	*Section 85.3.2.1*
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	*Section 85.3.2.2*
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	*Section 85.3.2.2*
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	*Section 85.3.2.2*
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3	*Section 85.3.2.3*
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	*Section 85.3.2.3*
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	*Section 85.3.2.3*
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	*Section 85.3.2.4*

Note: Reserved registers in area #1 will be handled as specified in the protected module's documentation.

85.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

85.3.2.1 Module registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

85.3.2.2 Module register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 2208*.

85.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 2207. Soft lock bits vs. protected address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

Note: As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3800-0x3DFF

Access: Read always
Supervisor write

Figure 2311. Soft Lock Bit Register (SLBR*n*)

Table 2208. SLBR*n* field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR*n* register: SLB0 can block accesses to MR[*n* *4 + 0] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[*n* *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[*n* *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[*n* *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable

85.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3FFC

Access: Read Always

Figure 2312. Global Configuration Register (GCR)

Table 2209. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register cannot be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and cannot be modified 0 All SLB bits are accessible and can be modified.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

85.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

85.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size is device and module specific, please refer to *Chapter 7: Device configuration for details.*

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

85.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

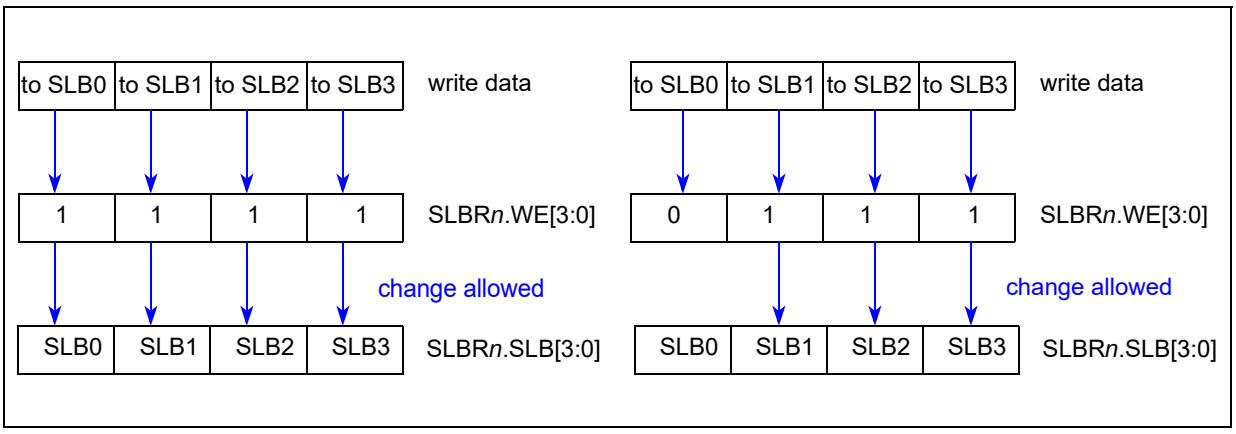
Both methods are explained in the following sections.

85.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 2313 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 2313. Change lock settings directly via Area #4



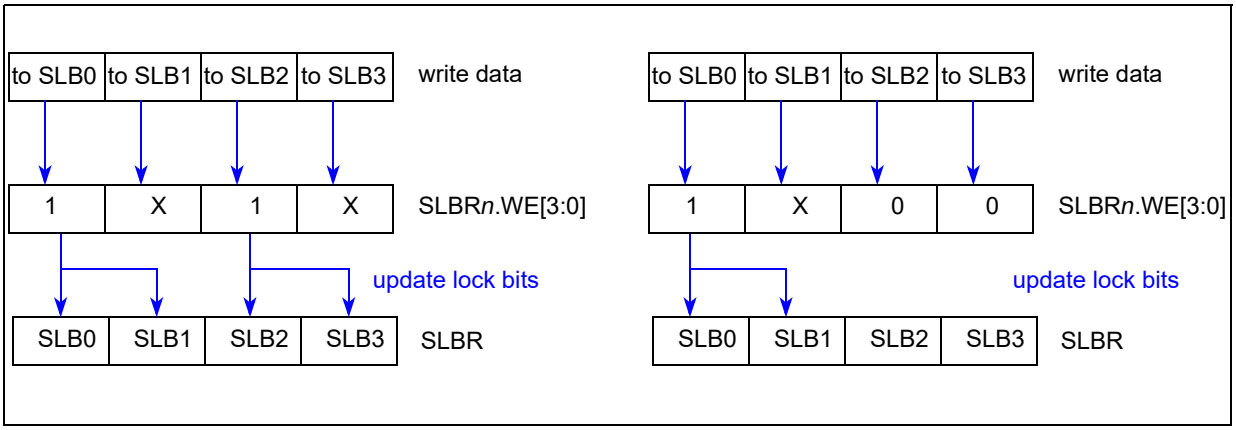


Figure 2313 shows four registers that can be protected 8-bit wise. In *Figure 2314* registers with 16-bit protection and in *Figure 2315* registers with 32-bit protection are shown:

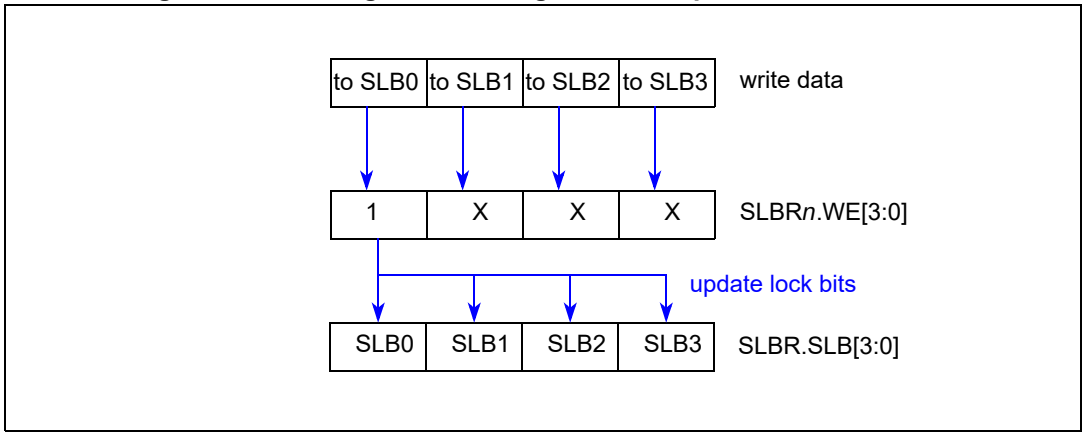
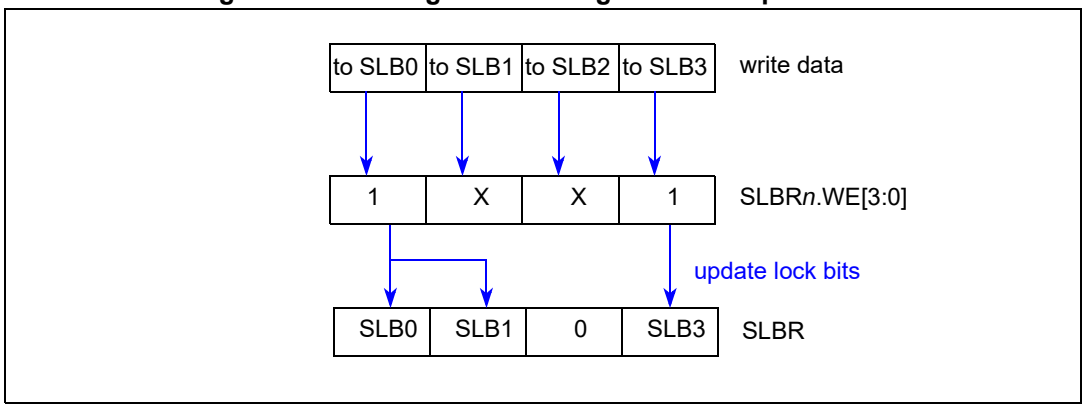
Figure 2314. Change lock settings for 16-bit protected addresses



On the right side of *Figure 2314* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 2314* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

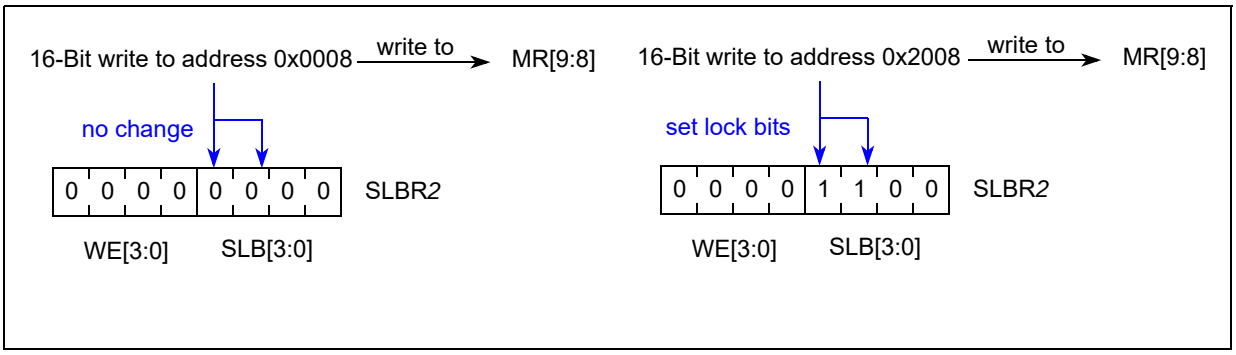


In *Figure 2315* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 2315. Change lock settings for 32-bit protected addresses

In *Figure 2316* an example is shown which has a mixed protection size configuration:

Figure 2316. Change lock settings for mixed protection

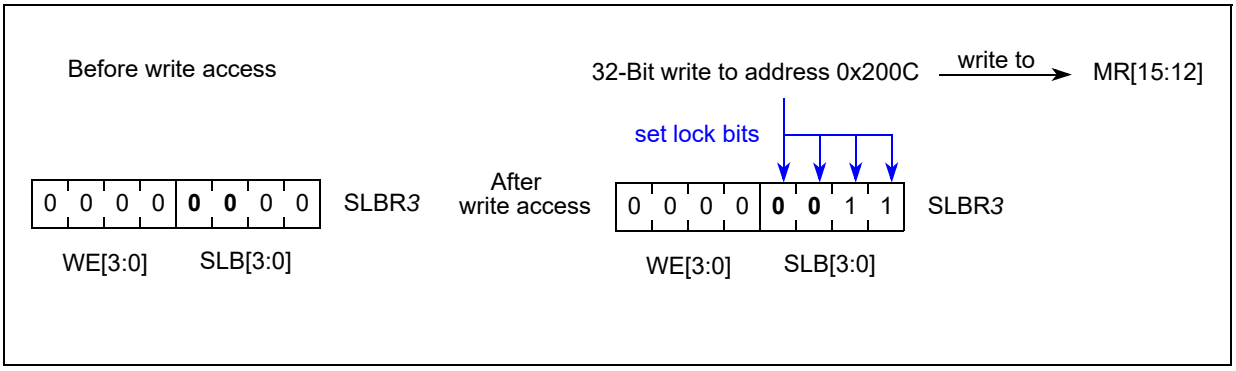


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

85.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 2317* shows one example:

Figure 2317. Enable Locking Via Mirror Module Space (Area #3)



When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 2314*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 2314*).

Figure 2318 shows an example where some addresses are protected and some are not:

Figure 2318. Enable locking for protected and unprotected addresses

In the example in *Figure 2318* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

85.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 85.4.2.1: Change lock settings directly via Area #4* and *Section 85.4.2.2: Enable locking via mirror module space (Area #3)* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

85.4.3 Access errors

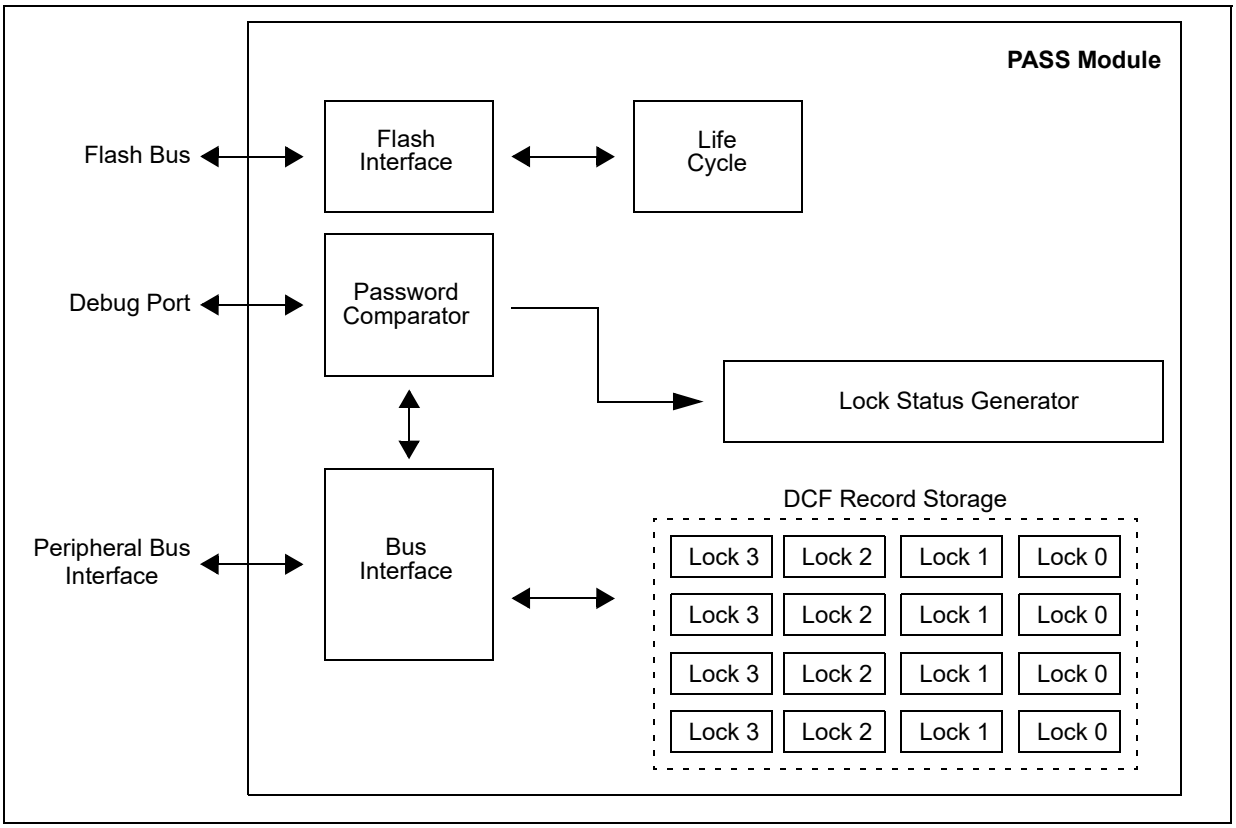
The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 2310*.

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set.

85.5 Initialization/application information

85.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 85.3.2*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.



86 Password and Device Security Module (PASS)

86.1 Introduction

86.1.1 Overview

The Password and Device Security (PASS) module shown in *Figure 2319* receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 2319. PASS module block diagram

86.1.2 Features

The PASS includes these distinctive features:

- Lifecycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Fuse Bypass Configuration and Password Comparison

86.1.3 Modes of operation

The PASS operates identically in all system modes.

86.2 External signal description

The PASS has 1 external pin that is used for Production Disable control (Refer to *Section 86.4.2: Production Disable*).

86.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 86.4: DCF clients*.)

Table 2210 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

Do not write to address 0x00D0 with bit value 0.

Table 2210. PASS memory map

Offset	Register	Access	Reset Value	DCF Client Address(1) (ADDR[14:0])	Section

0x013C	Lock 3 Status Register (LOCK3_PG3)	R/W	0xXFXXXXXX[2]	0x013C	*Section 86.3.1.9*

1. DCF Client Address column shows what is the DCF used to preload the register value during reset. If the column value is “None”, it means that the register value at reset is fixed in hardware.
2. Reset value depends on password group lock state.

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

86.3.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

86.3.1.1 Lifecycle Status register (LCSTAT)

The Lifecycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device lifecycle forward), but never to revert the lifecycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external lifecycle management module (like SSCM). It is a 3-bit lifecycle. This register simply displays the lifecycle input from external blocks.

Offset: 0x0000 Access: Software Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	FBE	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	x(1)	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	0	0	0	0	0	0	0	0	0	0	0	0	LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

1. Reset value depends on the Censorship DCF client.

Figure 2320. Lifecycle Status register (LCSTAT)

PASS_LCSTAT register functions are as shown in *Table 2211*.

Table 2211. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the state of the Censorship DCF Client. The bit can be set (or cleared) via DCF Record in UTEST Flash. Refer to *Section 86.6.3: Censoring and uncensoring the device*. 0 Device is uncensored 1 Device is censored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit. **Note:** Refer to the SPC58xNx Microcontroller Security Reference Manual for details.

Table 2211. LCSTAT register field descriptions (continued)

Field	Description
2 FBE	Fuse Bypass enable This field indicates whether the Fuse Bypass DCF Client is set to Fuse Bypass Enable. 0 No Fuse Bypass 1 Fuse Bypass Enable **Note:** Refer to *Section 86.4.3* for details.
29:31 LIFE	The lifecycle setting is manipulated externally (SSCM). Pass displays a 3-bit input lifecycle. 000 Failure Analysis mode 001 Reserved 010 OEM Production 011 Customer Delivery 110 ST Production 111 In Field

86.3.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.

The ID of the accessing master sets the CMST field of the Challenge Status register.

Offset: 0x0008 Access: Software Read/Write

Figure 2323. Challenge Input register (CIN*n*)

CIN register functions are as shown in *Table 2214*.

Table 2214. CIN*n* register field descriptions

Field	Description
0:31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

86.3.1.5 Clock Jitter Enable (CJE)

Software accessible one time writable register. This register stores the jitter enable status for the Pseudo Random Clock Divider Module (PRCD). The default value of this register if '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial communications modules includes large amounts of pseudo random clock edge jitter, making the serial communications modules unusable. For details about which serial communications modules are affected, refer to the clocking section of the Reference Manual.

For more information on Production disable, refer to *Section 86.5.5: Production Disable*

Debug access is blocked when Production disable bit[0] (Gated Debug Enable) is asserted, the Chip is *In Field* and Clock Jitter is not enabled.

Offset: 0x00D0 Access: Software Read/Write

Table 2215. CJE field descriptions

Field	Description
31 CJE	Clock Jitter Enable 0 Clock Jitter is enabled. The baud rate clock to Serial communications modules includes large amounts of pseudo random clock edge jitter. 1 Clock Jitter is disabled. The baud rate clocks function normally.

86.3.1.6 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the lifecycle has matured to *OEM Production* or older.

Offset: 0x0100 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MIDLOCK															
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 2325. Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

LOCK0_PG*n* register functions are as shown in *Table 2216*.

Table 2216. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTEST NVM Lock. This bit is used to lock the UTEST NVM block from programs on the alternate interface (erase protection not needed since UTEST NVM is OTP and not erasable).
2:15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16:31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, indicating that a block is locked.

Warning: **When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.**
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

When Production Disable register bit[1](BAF PLock Hardware Interlock enable) is asserted and lifecycle is *In Field*, then the external signal is ORed with BAF_plock(low_lock[0]) of LOCK0_PGx.

86.3.1.7 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x0104 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2326. Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

LOCK1_PG*n* register functions are as shown in *Table 2217*.

Table 2217. LOCK1_PG*n* register field descriptions

Field	Description
16:31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is '1', which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

86.3.1.8 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle is matured to *OEM Production* or older.

Offset: 0x0108 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit resets to ‘1’.

Figure 2327. Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 2218*.

Table 2218. LOCK2_PG*n* register field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

86.3.1.9 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x010C + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. Not all devices include this field. Refer to the device reference manual's chip configuration chapter for details.
2. Reset value depends on lifecycle. If lifecycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2328. Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

LOCK3_PG*n* register functions are as shown in *Table 2219*.

Table 2219. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally (if lifecycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked).
1 DBL	Debug Interface Lock The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM). 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked.

Table 2219. LOCK3_PG*n* register field descriptions (continued)

Field	Description
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared. 1 Only the Master which unlocked the passgroup can change the passgroup settings.
4:7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
11 RL4	Read Lock Region 4 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
12 RL3	Read Lock Region 3 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
13 RL2	Read Lock Region 2 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
14 RL1	Read Lock Region 1 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
15 RL0	Read Lock Region 0 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
16:31 A256KLOCK	256K address space block lock A256KLOCK[47:32] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to *Section 86.5.3: Flash Memory Read Protection*.

Once a censored device enters the *Failure Analysis* lifecycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash UTest region controlled by LOCK3[0]is read unlocked in Failure Analysis lifecycle.

86.4 DCF clients

Where a DCF client is listed, the reset value of that register may automatically be preloaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

86.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Censorship DCF client defines whether the MCU is censored or not (Refer to *Table 2210*).

DCF Client Address: 0x00B0 Censorship Access: DCF Record Write

Table 2220. Censorship register field descriptions

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored. If this value is anything other that 0x55AA, the MCU is censored.

86.4.2 Production Disable

Note: Production Disable is a DCF client that is not accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable and Hardware Interlock aspects of the Production Disable feature (refer to Table 2210).

Note: The DCF client implements 2 bits with a default value of '0'. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, refer to *Section 86.5.5: Production Disable*

DCF Client Address: 0x00C0 Production Disable — Access: DCF Record Write Once Only

Figure 2330. Production Disable DCF client

Table 2221. Production Disable DCF Client field descriptions

Field	Description
HI	Hardware Interlock 0 BAF Flash block programming is controlled by PASS_LOCK0[BAF] bits. 1 BAF Flash block is locked for programming while external hardware pin is asserted '0'.
DD	Debug disable 0 Debug Interface is Enabled and Disabled using Censorship, JTAG password & PASS_LOCK3[DBL] bit as described elsewhere. 1 Debug Interface is disabled while Clock Jitter is NOT enabled .

86.4.2.1 Debug Disable (DD)

Note: Debug Disable is an optional feature that, once the Lifecycle is In Field or beyond, overrides all other debug controls and disables the debug interface (refer to Table 2224).

86.4.2.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the lifecycle is In Field or beyond, prevents programming of the BAF Flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

86.4.3 Fuse Bypass DCF Client

This DCF client is used to configure the password protected Fuse bypass feature. Refer to *Section 86.5.6: Fuse Bypass* for details.

The Fuse Bypass DCF Client is not directly readable in software, but the state of the Fuse Bypass bit can be read in the LCSTAT register (refer to *Lifecycle Status register (LCSTAT)*).

The DCF client is written during Destructive Reset Phase 3 and compared during Functional Reset Phase 3; if this compare does not match the data already written, the logic will decode No fuse bypass.

DCF Client Address: 0x00E0 Fuse Bypass — Access: DCF Record Write Once Only

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 2331. Fuse Bypass DCF Client

Table 2222. Fuse Bypass register field descriptions

Field	Description
31 FB	Fuse Bypass enable 0 The Fuse can NOT be Bypassed 1 Bypass of the fuse is possible with a password

86.4.4 Password Slot Access

Password Slot Access is a write-once DCF client. The DCF controls access for both read and write starting from Lifecycle = OEM Production. If the bit is 1, the slot is still accessible when Life Cycle = OEM Production (and blocked starting from Life Cycle = In Field). Otherwise if the bit is set to 0, the slot is blocked starting from Life Cycle = OEM Production.

DCF Client Address: : 0x00B4 Password Slot Access — Access: DCF Record Write Once

Figure 2332. Password Slot Access DCF Client

Table 2223. Password Slot Access DCF Client field descriptions

Field	Description
28:31	Password Slot Access per password group

86.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

86.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (refer to *Section 86.4.1: Censorship*).

86.5.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (refer to *86.3.1.9: Password Group n - Lock 3 status register (LOCK3_PGn)*). Both of these debug enabling options are further conditioned by lifecycle and Production Disable.

The following table describes all options for enabling/blocking Debug Interface access.

Table 2224. Debug Interface Enable Truth table

Input Conditions						Outcome
Lifecycle	**Production Disable mode**	**Clock Jitter Enable**	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
In Field	Disabled	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Disabled
	Enabled	Jitter enabled	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not matched	Disabled
		Jitter disabled		Don't Care	Don't Care	Disabled
Failure Analysis	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled

The HSM can also block Debug Interface Access, even if it enabled by PASS. This allows HSM to granted Debug Interface Access after an encrypted secure challenge/response protocol with an external tool (refer to the SPC58xNx Microcontroller Security Reference Manual).

86.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

86.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 2225: Flash Memory Read Protection truth table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The Flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (refer to *Chapter 7: Device configuration*, *Section 7.11.1: Password and Device Security Module (PASS) configuration*).

Table 2225. Flash Memory Read Protection truth table

INPUTS				OUTPUTS	
Lifecycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
STMicroelectronics Production / Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable

86.5.4 UTEST protection

During the *Customer Delivery* lifecycle, the user must program a valid password or a DCF record that writes LOCKm_PGn registers to unprotect the UTest for each password group in order to prevent permanent and irreversible locking of Flash blocks.

86.5.5 Production Disable

Production disable activation protocol and implementation is described in *Chapter 61: Boot Assist Flash (BAF)*, *Section 61.3.6: Production disable activation protocol and implementation*.

86.5.5.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

Note: Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (CAN and FlexRay). This jitter means those serial communications modules are not able to communicate on the network.
As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted (refer to Section 86.4.2: Production Disable for details).

86.5.5.2 Enabling

Note: The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. Bit 1 enables the Hardware Interlock pin.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

Note: If no DCF Record writes to this client, the default state of both features is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature cannot be Enabled accidentally.

86.5.5.3 Clock jitter activation

The BAF code copies the ‘Clock Jitter Activation’ constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (refer to *Section 86.3.1.5: Clock Jitter Enable (CJE)* for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF Flash is 0xFFFF_FFFF (erased state).

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF Flash should be programmed to make the most significant bit ‘0’. After the next reset, the BAF copies this updated value to the Clock Jitter Register and the feature is activated.

86.5.5.4 Clock Jitter Truth table

Table 2226 shows the relationship between Lifecycle, Production Disable & Clock Jitter enable input conditions versus the state of the Baud Rate Clock.

Table 2226. Clock Jitter Truth Table

Lifecycle	Production Disable [Debug Disable]	Clock Jitter Enable	Baud Rate Clock State
STMicroelectronics_ Production Customer_Delivery In_Field	Don’t Care	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
Failure_Analysis	Off[0]	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
	On[1]	Don’t Care	Jitter

86.5.6 Fuse Bypass

86.5.6.1 Fuse

Some devices include an additional security feature, whereby a silicon fuse is used to gate access to Flash Test Mode when the device is in Failure_Analysis lifecycle. The fuse must be blown, creating physical damage to the silicon, before access is granted to Flash Test Mode. The PASS implements a configurable feature to bypass the requirement to blow the fuse to enter flash test mode, by entering a password instead. This feature is called Fuse Bypass.

86.5.6.1.1 Use Case: No Fuse Bypass

Customers who want no alternative to the Fuse to enter Flash Test Mode in FA lifecycle:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 0.
- And as a back-up, during customer assembly, the customer could program the Fuse Bypass Password to a random value.

86.5.6.1.2 Use Case: Fuse Bypass Password

Customers who require a password to enter Flash Test Mode in FA lifecycle, but do not require the added sophistication of blowing a fuse:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 1.
- During customer assembly, the customer programs the Fuse Bypass Password into Flash.
- The customer maintains a system for retrieving these passwords for the life of the module.
- If the part is returned to STMicroelectronics for FA, the customer must provide the Fuse Bypass password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA can only be performed if the die is removed from the package and the fuse blown.

86.5.6.1.3 Use Case: No Fuse. No Password

Customers who are less concerned with security and will accept neither fuse nor password to enter Flash Test Mode in FA lifecycle:

- Customer need do nothing special for this mode in customer assembly.
- When the part is returned to STMicroelectronics for FA, The DCF Client is still in the default state of 1. This is Fuse Bypass.
- The Fuse Bypass password should still be in the erased state (all 1). The tester can enter all 1 as the password to gain access to Flash Test Mode.

86.5.6.2 Fuse Bypass Password

The Fuse Bypass Password is a password entered by the STMicroelectronics via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA lifecycle. Flash blocks that are assigned as sealed during production

are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

86.5.6.2.1 Fuse Bypass Password Generation

The Fuse Bypass password is created by the customer during their module assembly process. It must be programmed into UTest Flash while in CUSTOMER_DELIVERY lifecycle.

When an MCU is returned to STMicroelectronics for FA, the MCU must be in FA lifecycle and this password must also be provided to STMicroelectronics to allow access to Flash Test Mode without blowing the fuse. Therefore the customer should develop a process for managing Fuse Bypass passwords for the life of the module.

If the password is not available when a device is returned for FA, STMicroelectronics must remove the die from the package and blow the fuse before entry is possible to Flash Test Mode and Flash FA can be undertaken.

86.5.6.2.2 Fuse Bypass Password storage

The Fuse Bypass Password is 224 bits (28 bytes) wide and is to be stored in UTest Flash at a fixed location. Refer to the device reference manual for the address of the Fuse Bypass password.

The password region of UTest Flash is readable only when in CUSTOMER_DELIVERY lifecycle. In any lifecycle after this (including FA lifecycle), this region is read protected.

86.5.6.2.3 Fuse Bypass Password Challenge entry

The Fuse Bypass password challenge is entered by an external tool to the password register in JTAGC.

As the Fuse Bypass Password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

86.5.6.2.4 Fuse Bypass Password compare

The Fuse Bypass Password challenged, is compared against the password stored in UTest Flash. Only the least significant 224 bits are compared.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

86.6 Initialization/application information

86.6.1 Reset

The reset state of each individual bit is shown within *Section 86.3.1: Register descriptions*. However, many bits receive their values based on DCF records stored in the UTest Flash memory block.

86.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 2227. CS/ADDR values for Lock registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xXXXX0100(1)
Lock1	0xXXXX0104(1)
Lock2	0xXXXX0108(1)
Lock3	0xXXXX010C(1)

PW Group3	
Lock0	0xXXXX0130(1)
Lock1	0xXXXX0134(1)
Lock2	0xXXXX0138(1)
Lock3	0xXXXX013C(1)

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 2228*.

Table 2228. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA55AF	Start Record
0x04	0x00000000	
0x08	0x000000FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xXXXX0110(1)	

Table 2228. Setting some bits in the MIDLOCK field (continued)

ADDR offset	DATA	Description
0x10	0xFFFFFFFF	Stop Record
0x14	0xFFFFFFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

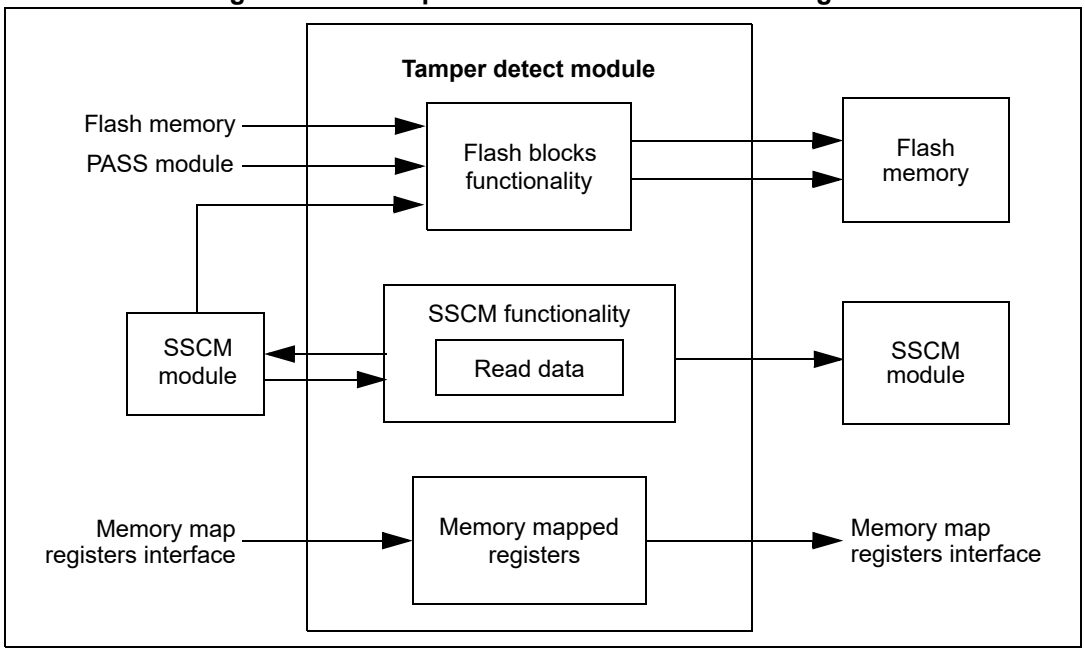
86.6.3 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTest Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS) and the address 0x00B0. Therefore 0xXXXX00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is censored.

87 Tamper Detection Module (TDM)



87.1 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not prevent an erase operation on any block within a TDR: it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

Figure 2333 shows the block diagram of the TDM and its interface to other system components.

Figure 2333. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One-Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information (via the DCF bus)
- Software tamper region override

The TDM module controls the flash blocks for erase operations and sets them as OTP

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

Note: The PASS module provides the control for erase operation for each flash block as well as for each region of the flash memory, and the PASS settings have priority over the settings of the TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

87.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 128-bit records
  - The diary block should be assigned as OTP region in flash
  - The diary area can store any type of relevant information
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled
- 32-bit Erase Lock DCF clients for each flash memory TDR defined
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[ab]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation
- Memory Map Registers Interface for reading via software of specific registers

87.3 External signal description

There are no external signals driving or being driven by the TDM.

87.4 DCF client

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

ab. The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 2229. DCF client address map

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write-once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR – "*n*" specifies a TDR – "*m*" specifies the flash blocks as per the LOCK registers of the flash memory	write 0 to 1 only

87.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. *Figure 2334* shows the diagram for this register.

Caution: This DCF client is implemented as Write Once and is writable from 1 to 0 only. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0000 Access: DCF write

Field	Description
0:31 DBA	Diary Base Address This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. **Note:** Diary Base Address must be on a 16KB boundary.

87.4.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. *Figure 2335* shows the diagram for this register.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

Blocks assigned to this TDR can NOT be erased until the diary is written 1 Diary override. The diary for this TDR can be erased WITHOUT writing to the diary

87.4.3 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. *Figure 2336* depicts this client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash block to OTP irreversible.

Refer to the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

87.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0)

This DCF client holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF client however holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. Therefore, the diagram of this register mirrors the LOCK0 register in the flash memory. *Figure 2340* depicts the TDR*n*_LOCK0 DCF client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

DCF client Address: 0x14 + ((n * 4) + 0) Access: DCF write

87.5 Memory Map and Registers

Note: The Tamper Detection Module's memory-mapped registers are read-only. Any attempted write generates a transfer error.

Table 2240. TDM memory map

Address offset (hex)	Register name	Location
0x00	TDR Status Register (TDM_TDRSR)	*Section 87.5.1*
0x04	Last Flash Programmed Address Register (TDM_LFPAR)	*Section 87.5.2*
0x08	Diary Base Address (TDM_DBA)	*Section 87.5.3*
0x10–0x24	Software Tamper Override Key Region (TDM_STO_KEY0–TDM_STO_KEY5)	*Section 87.5.4*

87.5.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, such as locked or unlocked, of each tamper region, such as TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

Note: TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.

If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Figure 2344. TDR Status and Diary Override Register (TDM_TDRSR)

Table 2241. TDM_TDRSR field descriptions

Field	Description
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

Table 2241. TDM_TDRSR field descriptions (continued)

Field	Description
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

87.5.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Offset: 0x04 Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Reset value depends on the Diary Base Address (DBA) DCF client.

Table 2243. TDM_DBA field descriptions

Field	Description
0:31 DBA	Diary Base Address These bits represent the address of the diary location in the flash. **Note:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

87.5.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)

The STO_KEYn register holds the service key for overriding the Tamper Detect Region *n*, where *n* denotes the Tamper Detect Region number.

Caution: The STO_KEY*n* registers can only be written once.
The associated DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Offset: 0x10 + *n* * 0x4 (*n* = 0 to 5) Access: User read/write

Table 2244. TDM_STO_KEY*n* field descriptions

Field	Description
0:31 STO_KEY	Software Tamper Override Key Diary *n* This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Note:** The STO_KEYn registers can only be written once. **Note:** Refer to the section *Section 61.3.7: TDM Diary Operation* for programming details.

87.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

87.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Dairy is defined by a DCF Record .

The diary is divided into 6 parts where each part consists of 256 × 128-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region . These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM , which defines if the associated flash block is Locked for Erase in a particular TDR:

- ‘1’ means the flash block is locked for erase
- ‘0’ means the flash block is not locked for erase

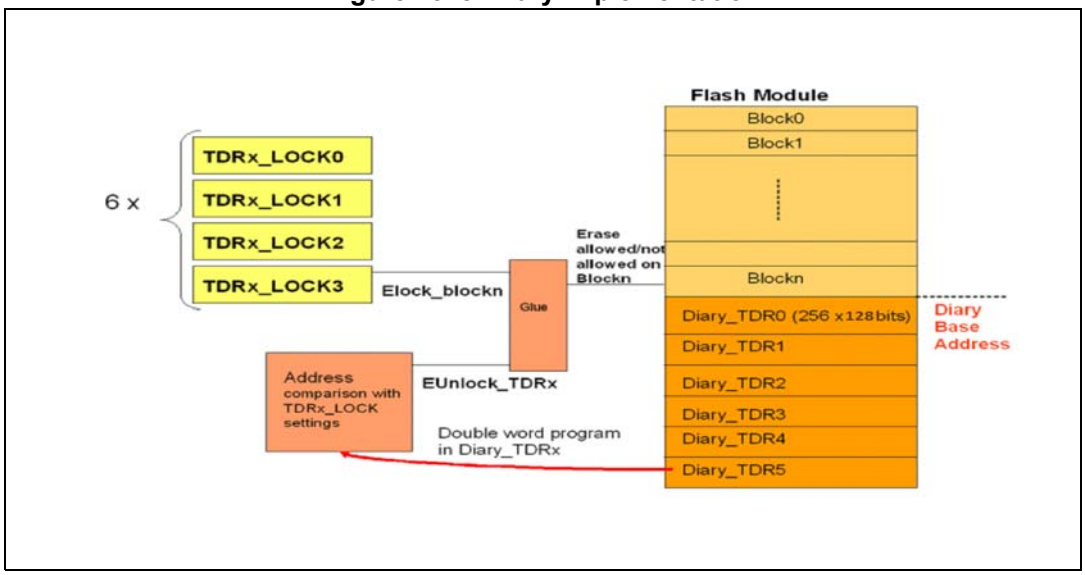
Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR Diary Location and then unlocks the blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the next program operation on any block, other than Diary, is performed with program completion interrupt enabled or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programmed in the diary. If diary is detected to be full, TDM provides a means to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programmed in the diary location is flexible, and may include count information or other important customer information.



Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from “override tamper region lock” DCF record (refer to *Section 87.6.3: Diary*) has priority over the settings in the TDRn_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDRn_LOCK*m* settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in *Figure 2348*.

Figure 2348. Diary implementation

Note: The settings in the Tamper Region Override Register have priority over the TDRn_LOCKm Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programmed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

87.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 × 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK

registers bits from the flash module. Hence, the block assignment registers are named as TDRn_LOCKm where n is the number of a tamper region, that is, 0-5 and m varies from 0-3 as flash contains four Lock registers .

In these DCF records:

- ‘1’ means that the corresponding flash block is assigned to this TDR
- ‘0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They cannot be read nor written. They can only be initialized by DCF record within the UTEST flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

Note: No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

87.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 4 KB, and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector to honor OTP restrictions. Therefore, each diary can hold a maximum of two-hundred and fifty-six 128-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients cannot be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

87.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records are defined by the customer. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is ‘0’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 4 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

87.6.5 Diary Base Address Verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as “TDR Erase Blocked”. Refer to *Section 87.5.1: TDR Status Register (TDM_TDRSR)* for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. Refer to *Section 87.5.1: TDR Status Register (TDM_TDRSR)*. The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. Refer to *Section 87.5.2: Last Flash Programmed Address Register (TDM_LFPAR)*.

87.6.5.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each record within the 4 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. Refer to the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

87.6.6 One Time Programmable (OTP)

87.6.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

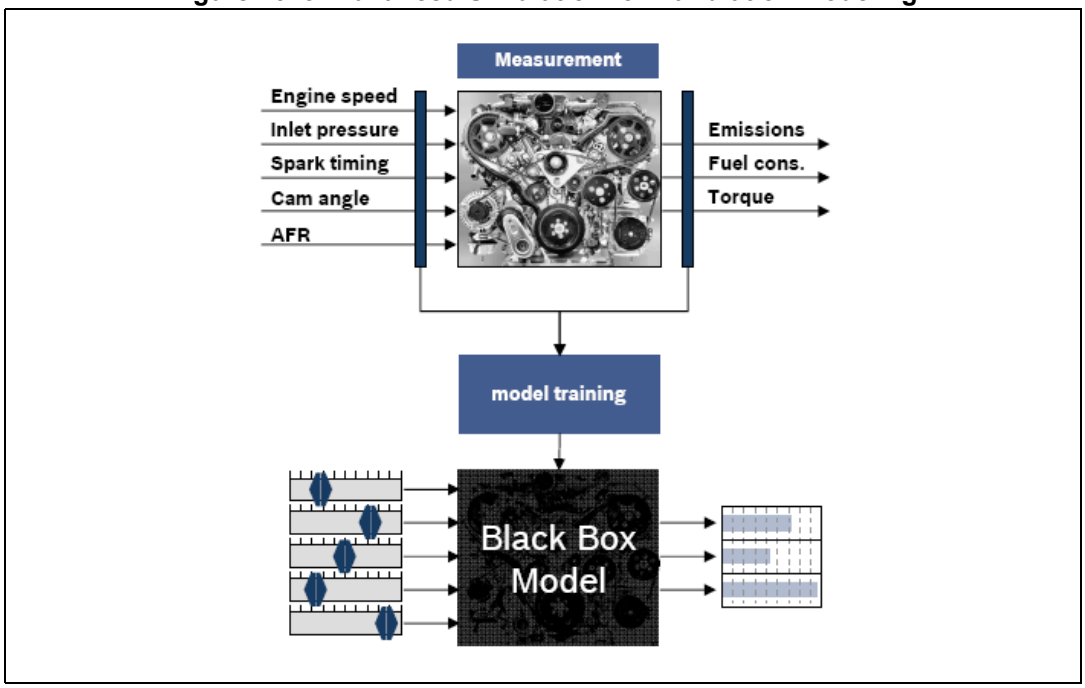
Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

88 ASC Modeling Unit version 2 (AMU2)

88.1 Introduction

The Advanced Simulation for Calibration (ASC) Modeling Unit (AMU) is a high performance floating-point arithmetic calculation engine implementing a specific pre-defined algorithm (see *Section 88.3.1: AMU2 algorithm* for details). This is a second generation implementation.

This computation unit is used to describe unknown systems using a model that is based on measured data. The model is based on mathematical approximations such that no physical description is necessary. Additionally, this approach minimizes the required number of measurements of the system through the use of a statistically optimal distribution.



There are various modeling algorithms typically used for this type of system analysis. Examples include classic polynomial descriptions and neural networks. The statistical machine learning method implemented by the AMU offers a number of significant improvements versus previous approaches, including:

- Ability to describe complex behaviors with very high accuracy
- No model parameterization is necessary
- Robust against measurement errors and data “outliers”
- Provides best trade-off between measurement number and model accuracy

In the past, a significant drawback to this approach was the high computational power necessary for this type of modeling. The AMU, which is a compact hardware implementation of a specific algorithm, provides the needed calculation capabilities within the context of a general purpose microcontroller.

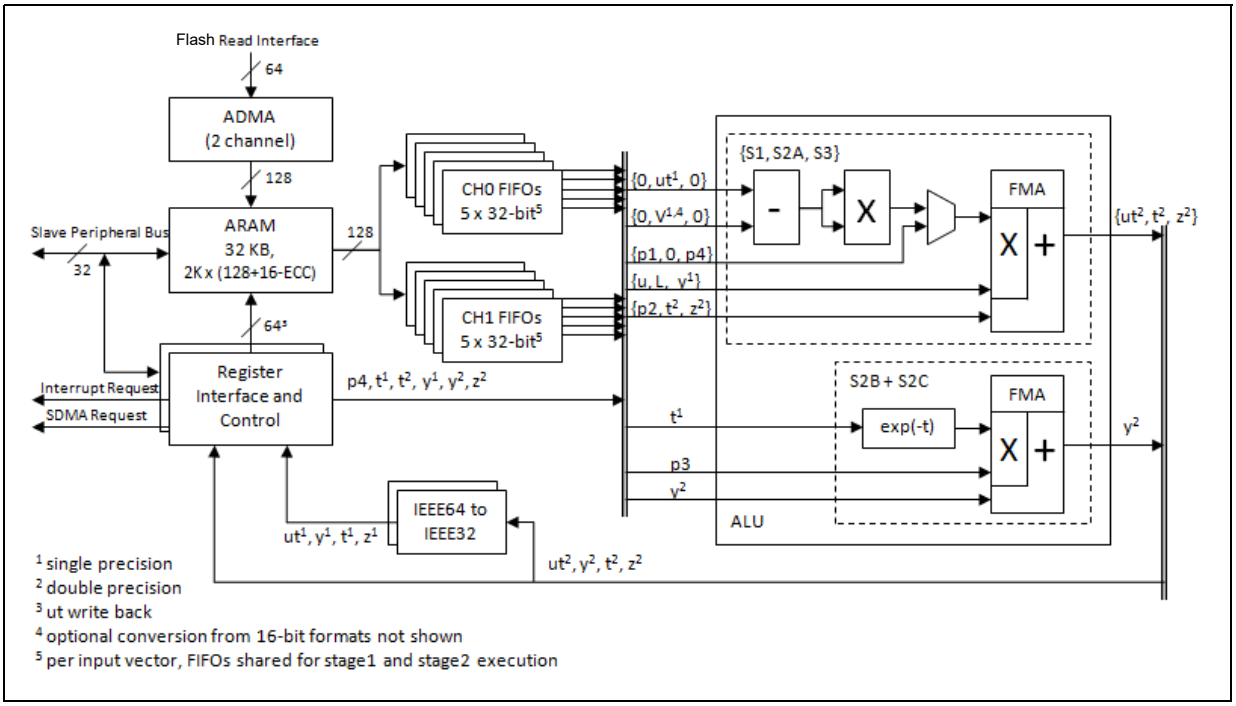
See *Figure 2349* for a simplified diagram of the intended use of the ASC Modeling Unit.

Figure 2349. Advanced Simulation for Calibration Modeling

Note the module names AMU and AMU2 are meant to be completely synonymous and are used here interchangeably.

88.1.1 Overview

The AMU2 implementation includes the pre-defined floating-point algorithm that includes:



- Multiple loop constructs with extensive vectored multiply-accumulate operations
- Single-precision exponential function, exp(x)
- 32 Kbytes of memory-mapped local RAM for parameter and coefficient storage
- Local DMA (ADMA) with private connection into system Flash for fetching data into the local memory
- Local RAM (ARAM) accessible via local DMA and system bus interface

The AMU contains two separate channels, which are timing-independent and register-independent. Each channel logically includes a calculation engine and a DMA channel. The calculation engines both share the same arithmetic logic using a time multiplexed scheme. Likewise, the DMA channels use a time multiplexed scheme to share common interfaces for fetching from the system Flash memory (or the calibration remapped destination memories, or both) and writing into the local RAM.

Within each calculation engine, there are two pipelined floating-point engines: one performs the stage 1, 2a and 3 calculations using a subtracter, a multiplier and an FMA (fused multiply-add), while the second performs the stage 2b and 2c operations using the exp(x) function and an FMA. This structure was selected to allow stage2a to be computed continuously in one pipeline, while stages 2b and 2c are computed in parallel in the other pipeline to maximize overall performance. Operations from the two channels are interleaved on the calculation engines and also include a number of blocks to feed these arithmetic blocks with data. The interleaving of the channels is such that operations on one channel do not influence the timing on the other channel. This includes a 128-bit read interface from the ARAM to dedicated input data FIFOs to source data to the ALU.

A block diagram of the AMU2 is shown in *Figure 2350*. The module consists of a local 32 KB RAM with a SEC-DED Error Correcting Code (ECC) organized on 64-bit doublewords, that is, 8 check bits per 64 bits of data, 2 DMA channels to support data transfers from Flash to the AMU local RAM, dedicated data FIFOs for input data and the hardwired data path to calculate the AMU2 function. The AMU local RAM is also visible over the peripheral bus to the system.

Figure 2350. AMU2 block diagram(ac)

The AMU2's system interfaces and local RAM, along with the register interface and control, are shown on the left side, and the two floating-point ALU pipelines on the right side of *Figure 2350*. The top pipeline calculates the results from stages 1, 2a and 3 using a generic function of the form:

result = ((in1 - in2) * (in1 - in2) + in3) * in4 + in5

where the inputs are simply labeled in1, in2, …, in5 from top to bottom. As shown in *Table 2245*, a different input operand set is sent into this pipeline structure for each stage, producing the required result calculations.

Table 2245. Stage 1, 2a, 3 Input Operands and Results

stage	in1	in2	in3	in4	in5	result, ((in1 - in2)*(in1 - in2) + in3) * in4 + in5
1	0	0	p1[*]	u[*]	p2[*]	p1[*] * u[*] + p2[*]
2a	ut[*]	V[*]	0	L[*]	t	((ut[*] - V[*]) * (ut[*] - V[*])) * L[*] + t
3	0	0	p4	y	z	p4 * y + z

For the stage 2b + 2c pipeline, the single input operand set produces the required calculation:

(exp(-t) * p3[*]) + y

ac. Refer to the device block diagram for the AMU2 connection to the Flash Controler

88.1.2 Features

- High performance floating-point calculation of pre-defined algorithm with extensive vectored multiply accumulate operations and an exp(x) evaluation
- Time multiplexed hardware structure for the calculation engine to minimize die size while still maintaining execution speed
- Two independent calculation channels
  - The two independent channels allow two concurrent processes to use the AMU to perform calculations; no interference between the two processes is guaranteed by the hardware.
- Two independent AMU DMA (ADMA) channels
  - The ADMA channels are high-bandwidth 64-bit direct memory access channels, supporting transfer of Flash (or remapped calibration) data to local AMU RAM
- 32 KB of local AMU RAM (ARAM) memory storage
  - Logically dual ported
  - Connected to system peripheral bus, ADMA channels and internal AMU calculation engines
- Programming model located in peripheral address space of system memory map
  - Includes ARAM memory space and registers
  - Optimized for system DMA result & save, data reload and calculation initiation
- Support for multiple use cases involving system DMA or local ADMA, or both

88.1.3 Modes of operation

The AMU2 module does *not* support any special modes of operation. As a memory-mapped device located on the peripheral bus as a slave module, the AMU2 responds strictly based on accesses to its programming model via the peripheral bridge bus controller. The module generates a number of control output signals that can be configured to generate processor core interrupts (to either the main core(s) or I/O Processor) or system DMA requests in response to changes in the AMU2's calculation state.

The module optionally supports the ability to run or stall the calculation engine if a processor core is halted due to a debug event; for the AMU2, this function is programmable. By default, the AMU2 stalls in response to a debug event as signaled by a module input signal. See the AMU2_CCR1CH*n*[DDSL] description in *Section 88.2.3.21: AMU Control & Configuration 1 Channel n Register (AMU2_CCR1CHn)* for more details.

The functionality associated with the AMU2 resides in two clock domains: the module operates at the frequency of the main cores while its peripheral bus interface to the programming model operates at the same speed as that domain (typically 0.5x the speed of the main cores).

88.2 Memory map and register definition

The AMU module supports its programming model mapped to standard 16 KB on-platform peripheral slots. The local AMU RAM is accessible for read and write via the slave peripheral bus interface and is mapped to four contiguous and properly aligned 16 KB peripheral slots for a maximum size of 64 KB. The programming model, including the ARAM, can only be referenced in supervisor mode using 32-bit (word) accesses, either as single or burst transfers. It implements a big-endian memory organization. Attempted

references while in user mode, using different access sizes, writing to a read-only address, or to *reserved* addresses generate an error termination. It should also be noted that byte and halfword-sized accesses can be emulated using the Decorated Storage Memory Controller to perform bit field inserts for writes, and simple processor loads with shift or masking operations for reads, or both. Unless noted otherwise, *unused* addresses are treated as RAZ/WI: read-as zero, writes ignored. There are specific unused addresses that are located in read-only space and are therefore marked as “RAZ”; attempted writes to these locations generate an error termination.All programming model register reads and writes complete in a single peripheral bus clock cycle.

88.2.1 AMU memory map

Table 2246 shows the memory map for the AMU module.This address space is partitioned into 3 regions: local ARAM, channel 0 registers and channel 1 registers.

Table 2246. AMU memory map

Address Offset	Register	Access	Reset Value	Section

88.2.2 ARAM memory map details

The 32 KB physical address space allocated to the AMU's local RAM (ARAM) is segmented into 2 regions. The first, a 31 KB space (offset addresses = 0x0_0000 - 0x0_7BFF), is intended for user-defined storage of the AMU input data. The second, a 1 KB space (offset addresses = 0x0_7C00 - 0x0_7FFF) is used by the AMU2 for temporary storage. This RAM space is used by the calculation engines to temporarily store the UT[*] vector generated as the stage1 output; additionally, it implements small FIFO memories to store "streamed data" associated with the V[*] and P3[*] vectors. The specific memory allocation within this 1 KB space is shown in *Table 2247*. Note if the streaming feature for the V[*] and P3[*] vectors is not enabled, the first 768 bytes of this 1 KB space can be used for general purpose ARAM data storage.

Table 2247. 1 KB ARAM Space Reserved for the Calculation Engines

Offset Start Address	Offset End Address	Size	Purpose
0x0_7C00	0x0_7CFF	256 bytes	Channel 0 Streaming v[*] FIFO
0x0_7D00	0x0_7DFF	256 bytes	Channel 1 Streaming v[*] FIFO
0x0_7E00	0x0_7E7F	128 bytes	Channel 0 Streaming p3[*] FIFO
0x0_7E80	0x0_7EFF	128 bytes	Channel 1 Streaming p3[*] FIFO
0x0_7F00	0x0_7F7F	128 bytes	Channel 0 ut[*] Storage
0x0_7F80	0x0_7FFF	128 bytes	Channel 1 ut[*] Storage

Given the 32 KB physical address space associated with the ARAM, all the pointers for this memory are implemented as 15-bit byte addresses that define the offset into the local memory. These local memory pointers are restricted to reference data items on their natural size boundaries, for example, with a 0-modulo-2 byte addresses (2-byte aligned) for 16-bit data, 0-modulo-4 byte addresses (4-byte aligned) for 32-bit data and 0-modulo-8 byte addresses (8-byte aligned) for 64-bit data. Additionally, software must manage the pointer values near the end of the address ranges as the hardware pointer calculations do *not* perform any special handling near the 31 KB or 32 KB boundaries.

Concerning the alignment of streamed V[*] or P3[*] data in their FIFOs, it should be noted that if the streamed data starts at offset 8 or 24 within the 32-byte Flash page, the first doubleword of data is stored at offset 8 in the associated FIFO, else it is stored at offset 0. During normal usage, this is completely transparent, but may be of interest during AMU debug if the contents of the FIFOs are examined.

If the ARAM is protected from single bit errors by enabling the ECC logic, it is the system's responsibility to initialize its contents with correct ECC before any AMU calculations are performed. This initialization can be performed by the system DMA performing 16-byte burst transfers to write the entire contents of the ARAM, using the memory initialization feature of the ADMA, or using the ADMA to load the entire memory from Flash. If the system DMA is used for ARAM initialization, both AMU2_CCR1CH{0,1}[EECC] configuration bits must be cleared until the initialization is complete.

Finally, it should be noted that the two 32-bit Control & Configuration Registers are treated in a special manner when configured as the last destination of an ADMA transfer. The AMU2_DCCRCH*n*[DARU] provides this specific configuration. For example, when configured with DARU = 0b01, the last 64-bit ADMA transfer associated with channel 0 writes to the CCR{1,2}CH0 registers to initiate an ALU calculation. Likewise, the last 64-bit ADMA transfer associated with channel 1 could write to the CCR{1,2}CH1 registers. This mechanism allows the basic data block transfer controlled by the ADMA to load new input data into the ARAM and then initiate a calculation by writing to the CCR{1,2}CH*n* registers.

88.2.3 Register descriptions

88.2.3.1 AMU ID and Version Channel *n* Register (AMU2_IDVCH*n*)

This read-only register provides information on the AMU channel number and revision.

28:31 VER	AMU version number This implementation is Version 2.

88.2.3.2 AMU N crossing Channel *n* Register (AMU2_NCH*n*)

This register provides a debug capability for the algorithm's stage2 calculation. If properly enabled (AMU2_CCR2CH*n*[ENCRS] = 1), when the outer loop in the stage2 calculation *completes* the iteration count defined by this register, the calculation engine stops (if AMU2_CCR2CH*n*[SNCRS] = 1) and optionally generates an interrupt request or system DMA request (based on AMU2_CCR1CH*n*[NCICFG]). If the calculation engine stops, the p8 outer loop count is NCRS+1.

The register also provides an optional bit masking capability so that multiple "N crossing" events can occur as the result of a single register write. As a limit, this mechanism could be used to stop the calculation after every iteration of the stage2 outer loop.

Offset: 0x1000C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2352. AMU N crossing Channel *n* Register (AMU2_NCH*n*)

Table 2249. AMU2_NCH*n* field descriptions

Field	Description
0:15 NMSK	N crossing Mask. This field provides the ability to mask individual bits in the N crossing comparison. If set, the bit is ignored in the equality comparison comparing the N crossing value and the outer loop iteration count from stage2 of the algorithm. if NMSK[i] == 0, then the corresponding bit in NCRS[i] is included in the comparison if NMSK[i] == 1, then the corresponding bit in NCRS[i] is excluded (masked) in the comparison
16:31 NCRS	N crossing value (unsigned integer). When enabled by AMU2_CCR2CH*n*[ENCRS], the stage2 calculation is stopped *after* the masked NCRS iterations of the outer loop. After the calculation is stopped, the p8 outer loop count contains an NCRS+1 value in this register. The intermediate value contained in the y64 register is consistent with this p8/NCRS value. Additionally, if the AMU2_CCR1CH*n*[NCICFG] is set to an appropriate value, an interrupt or a DMA request is triggered when the outer loop count reaches the masked NCRS value. The interrupt enable/disable control is independent of the AMU2_CCR2CH*n*[ENCRS] setting. The equality comparison is defined as: N crossing_event = ((p8[15:0] | NMSK[15:0]) == (NCRS[15:0] | NMSK[15:0])) where "|" is the boolean OR operator.

88.2.3.3 AMU P1 Pointer Channel *n* Register (AMU2_P1PTRCH*n*)

This register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit P1[*] input vector. This input vector is used in the stage1 calculation.

Offset: 0x10010 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Table 2251. AMU2_P2PTRCH*n* field descriptions

Field	Description
17:29 PTR	Pointer into ARAM for the p2[*] vector. PTR[14:0] is a byte address. Since this array contains aligned 32-bit data elements, the two least significant address bits are fixed at zero.

88.2.3.5 AMU P3 Pointer Channel *n* Register (AMU2_P3PTRCH*n*)

In the normal operating mode, this register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit P3[*] input vector. This input vector is used in the

stage2 outer loop calculation as a scale factor in the accumulation of results from the exp(x) evaluation.

Due to its size, there are two methods for accessing this vector. In normal mode (AMU2_DCCRCH*n*[STMP3] = 0), the entire contents of the vector are written into the ARAM before the stage2 calculation begins; for this mode, the standard PTR[14:2] field defines the offset pointer into the ARAM. In the data streaming mode (AMU2_DCCRCH*n*[STMP3] = 1), PTR[31:2] defines a starting system Flash address for the P3[*] input. Note this mode requires the system Flash address be 8-byte aligned like all the other ADMA source data addresses. As data values are fetched, they are temporarily stored in the last 1 KB region of the ARAM, an area managed by the AMU2 for special data handling. For both modes of operation, the pointer value remains unchanged, even when data streaming. Finally, the pointer must reference the 0th element in the data array, even when starting or resuming a calculation with a non-zero P8 value. To summarize:

- if AMU2_DCCRCH*n*[STMP3] = 0, then PTR[14:2] defines P3 offset pointer into the ARAM.
- if AMU2_DCCRCH*n*[STMP3] = 1, then PTR[31:3] defines P3 pointer as a system Flash address.

Offset: 0x10018 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2355. AMU P3 Pointer Channel *n* Register (AMU2_P3PTRCH*n*)

Table 2252. AMU2_P3PTRCH*n* field descriptions

Field	Description
0:29 PTR	Pointer for the p3[*] vector. Depending on the data mode for the p3[*] vector, this field is used in two different ways: if AMU2_DCCRCH*n*[STMP3] = 0, then PTR[14:2] defines offset pointer into ARAM if AMU2_DCCRCH*n*[STMP3] = 1, then PTR[31:3] defines system Flash address PTR[31:0] is a byte address. The two least significant address bits are fixed at zero to enforce 4-byte (32 bit) alignment for the non-streaming configuration and the low-order three bits are forced to zero for the streaming configuration.

88.2.3.6 AMU P4 Channel *n* Register (AMU2_P4CH*n*)

This is the P4 data register. It is a 32-bit single-precision value used as a scale factor at the stage3 output normalization calculation.

Offset: 0x1001C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Field	Description
27:31 UINT	Parameter P7 value in a 5-bit unsigned integer format. A 0b00000 in this field means P7 = 32.

88.2.3.10 AMU P8 Channel *n* Register (AMU2_P8CH*n*)

The P8 register contains two 16-bit unsigned integers related to the outer loop at the stage2 calculation. The upper halfword contains the threshold count for the ALU's speed control (see *Section 88.3.5.2: ALU speed control*), while the lower halfword is the starting value for the stage2 outer loop calculation.

As the stage2 outer loop iterates, the lower halfword of the AMU2_P8CH*n* register is incremented. If the calculation is stopped or halted, the register reflects the incremented loop count value. When the outer loop completes execution, it is restored to its initial value. This provides hardware support for the loop control such that this register does *not* have to be explicitly re-initialized for every calculation.

There is also an aliased read-only copy of this register available so that intermediate results associated with Y64 and P8 can be retrieved by the system DMA (SDMA) in a simple, sequential block transfer.

88.2.3.13 AMU V Pointer Channel *n* Register (AMU2_VPTRCH*n*)

In the normal operating mode, this register is a 4-byte aligned pointer into the ARAM defining the starting location for the 16-bit or 32-bit V[*] input array. It is used in the inner loop of the stage2 calculation in a difference evaluation.

The V[*] array supports three data formats as defined by the AMU2_CCR1CH*n*[V16, VFH, CMEXP] fields. The formats include a 32-bit single-precision floating-point, a 16-bit half-precision floating-point, and a 16-bit fixed-point format with a common 7-bit biased exponent. See *Section 88.2.3.21: AMU Control & Configuration 1 Channel n Register (AMU2_CCR1CHn)* for details on the selection of the formats and *Section 88.3.3.1: Floating-point data formats* and *Section 88.3.3.2: 16-bit fixed-point with common exponent* for information on these number formats.

The V[*] array is the only 2-dimensional data array used in the algorithm and is defined as V[p6, p7]. Its memory organization follows the standard C definition with a row-major ordering, that is, the sequential data elements as [0,0], [0,1], [0,2], …, [p6-1, p7-2], [p6-1, p7-1].

Due to its size, there are two methods for accessing this array. In normal mode (AMU2_DCCRCH*n*[STMV{32,16}] == 00), the entire contents of the array are written into the ARAM before the stage2 calculation begins; for this mode, the standard PTR[14:2] field defines the offset pointer into the ARAM. In the data streaming mode (AMU2_DCCRCH*n*[STMV{32,16}] != 00), PTR[31:3] defines a starting system Flash address for the V[*] input. Note this mode requires the system Flash address be 8-byte aligned like all the other ADMA source data addresses. As data values are fetched, they are temporarily stored in the last 1 KB region of the ARAM, an area managed by the AMU2 for special data handling. For both modes of operation, the pointer value remains unchanged, even when data streaming. Finally, the pointer must reference the [0,0] element in the data array, even when starting or resuming a calculation with a non-zero P8 value. To summarize:

- if AMU2_DCCRCH*n*[STMV{32,16}] = 00, then PTR[14:2] is V offset pointer into the ARAM.
- if AMU2_DCCRCH*n*[STMV{32,16}]!= 00, then PTR[31:3] is V pointer as Flash address.

Offset: 0x10038 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Figure 2363. AMU V Pointer Channel *n* Register (AMU2_VPTRCH*n*)

Table 2260. AMU2_VPTRCH*n* field descriptions

Field	Description
0:29 PTR	Pointer for the v[*] array. Depending on the data mode for the v[*] array, this field is used in two different ways: – if AMU2_DCCRCH*n*[STMV{32,16}] == 00, then PTR[14:2] is offset pointer into ARAM. – if AMU2_DCCRCH*n*[STMV{32,16}] != 00, then PTR[31:3] is system Flash address. PTR[31:0] is a byte address. The two least significant address bits are fixed at zero to enforce 4-byte (32 bit) alignment for the non-streaming configuration and the low-order three bits are forced to zero for the streaming configuration.

88.2.3.14 AMU L Pointer Channel *n* Register (AMU2_LPTRCH*n*)

This register is a 4-byte aligned pointer into the ARAM defining the starting location for the 32-bit L[*] input vector. It is used in the inner loop of the stage2 calculation as a scale factor in the accumulation of squared differences.

Offset: 0x1003C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

88.2.3.16 AMU DMA Source Address Channel *n* Register (AMU2_DSACH*n*)

This is the ADMA's source 8-byte aligned pointer into the system Flash region (including remapped accesses into on- and off-chip calibration memories or system RAM, or both). Depending on configuration information in the AMU2_DCCRCH*n* register, this register may be automatically updated during a data transfer, or left unchanged.

Field	Description
0:28 PTR	ADMA source address in Flash region of the system memory map. For best performance and efficiency, this byte address is forced to doubleword (8-byte aligned) alignment, matching the AMU's private interface to the Flash controller.

88.2.3.17 AMU DMA Destination Address Channel *n* Register (AMU2_DDACH*n*)

This is the ADMA's destination 8-byte aligned offset pointer into the ARAM. Depending on configuration information in the AMU2_DCCRCH*n* register, this register may be automatically updated during a data transfer, or left unchanged.

The ADMA also supports a mode where the last 8 bytes are written directly into the AMU2_CCR{1,2}CH*n* registers so that a data transfer can be coupled with the initiation of a calculation in the context of a single transfer. This mode is enabled by the AMU2_DCCRCH*n*[DARU] register field and affects the final value of the AMU2_DDACH*n* register.

Table 2264. AMU2_DDACH*n* field descriptions

Field	Description
17:28 PTR	ADMA destination address in the ARAM. For best performance and efficiency, this byte address is enforced to a doubleword (8-byte aligned) alignment, matching the AMU's private interface to the Flash controller.

88.2.3.18 AMU DMA Transfer Count Channel *n* Register (AMU2_DCNTCH*n*)

This register contains two unsigned 16-bit byte counts associated with the current ADMA transfer operation. The upper halfword contains the threshold byte count associated with the ADMA's speed control function (see *Section 88.3.6.5: ADMA speed control*). The lower halfword defines the number of bytes to be transferred in the current ADMA operation. Based on ADMA address alignments, both counts are forced to be a multiple of 8 bytes.

Offset: 0x1004C + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

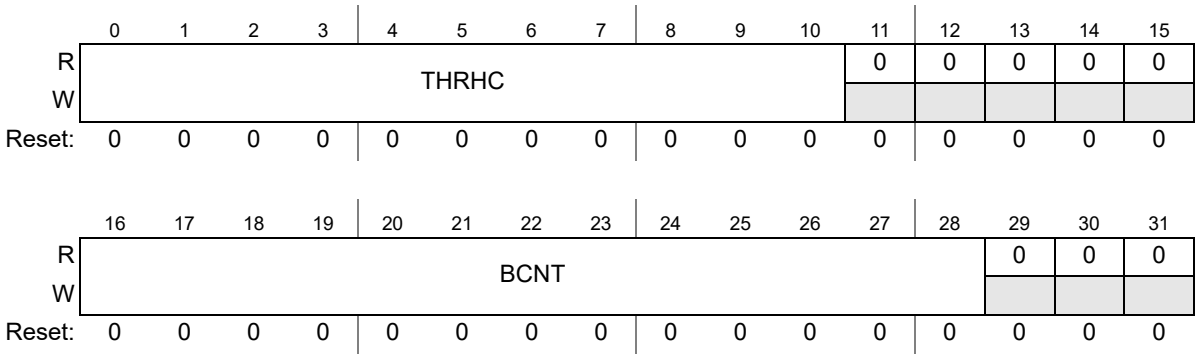

Figure 2368. AMU DMA Transfer Count Channel *n* Register (AMU2_DCNTCH*n*)

Table 2265. AMU2_DCNTCH*n* field descriptions

Field	Description
0:10 THRHC	Threshold Count. This 16-bit unsigned integer defines the threshold count used in the ADMA speed control function. There are additional control fields associated with this function in the AMU2_DCCRCH*n* register. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. The count is forced to be 32-byte aligned to match the ADMA's fetch size from the system Flash private connection.
16:28 BCNT	ADMA transfer byte count in a 16-bit unsigned integer format and forced to be an 8-byte aligned count.

88.2.3.19 AMU DMA Checksum Channel *n* Register (AMU2_DCKSCH*n*)

This is the expected ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the expected checksum result. If enabled, the checksum accumulated by the ADMA is compared to this value at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

Offset: 0x10050 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

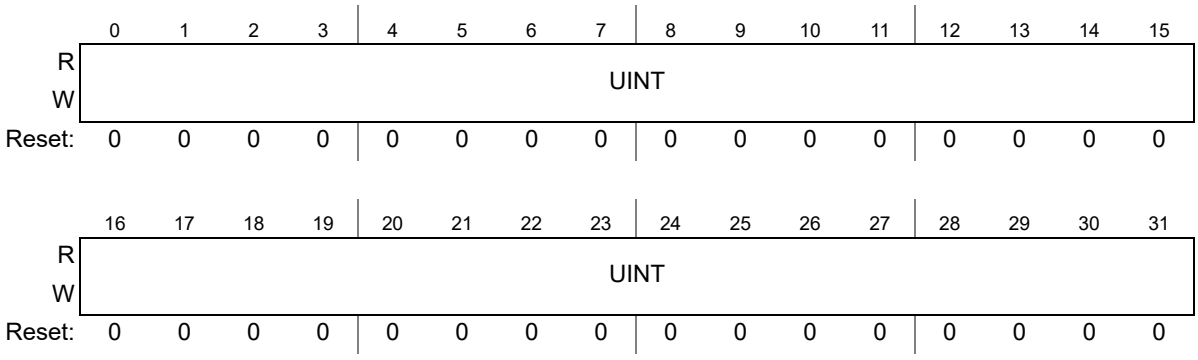

Figure 2369. AMU DMA Checksum Channel *n* Register (AMU2_DCKSCH*n*)

Table 2266. AMU2_DCKSCH*n* field descriptions

Field	Description
0:31 UINT	Expected ADMA checksum in a 32-bit unsigned integer format.

88.2.3.20 AMU DMA Control & Configuration Channel *n* Register (AMU2_DCCRCH*n*)

The AMU2_DCCRCH*n* register defines the operating configuration for the ADMA. It includes a speed control function, fields that configure the operation of the source and destination ADMA addresses, CRC configuration controls, fields to configure data streaming for the P3 and V vectors, an enable for an ARAM initialization function, conditional and unconditional start flags, plus stop and resume controls.

The conditional start flags (AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI]) can be used to trigger ADMA transfers after the ALU completes execution of specific parts of the algorithm.

Offset: 0x10054 + n * 0x100 (n = 0 to 1) Access: Supervisor Read/Write

Table 2267. AMU2_DCCRCH*n* field descriptions

Field	Description
1:3 SRTSP	Start Speed This 3-bit encoded value defines the start speed for the ADMA channel. It is used with the MAXSP field and AMU2_DCNTCH*n*[THRHC] with the current speed of the ADMA is reported in AMU2_SEIRCH*n*[DCURSP]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
5:7 MAXSP	Maximum Speed This 3-bit encoded value defines the maximum speed for the ADMA channel. It is used with the SRTSP field and AMU2_DCNTCH*n*[THRHC] with the current speed of the ADMA is reported in AMU2_SEIRCH*n*[DCURSP]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels and accessible from either the CH0 or CH1 programming models. This field uses the same definition as SRTSP above.
8:9 ADICFG	ADma Interrupt ConFiGuration This 2-bit field provides the reporting mechanism associated with the ADMA complete indicator flag (AMU2_SEIRCH*n*[ADIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ADMA completion 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement 11 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement
10:11 SARU	Source Address Register Update This 2-bit field controls the updating of the AMU2_DSACH*n* register. 00 ADMA does not modify the original starting value of AMU2_DSACH*n* 01 ADMA does not modify the original starting value of AMU2_DSACH*n* 10 ADMA increments the AMU2_DSACH*n* as the data transfer occurs. The final value points to the next 8-byte aligned system Flash address 11 ADMA increments the AMU2_DSACH*n* as the data transfer occurs and, after the final transfer, “rounds up” to the next 32-byte aligned system Flash page address

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
12:13 DARU	Destination Address Register Update This 2-bit field controls the updating of the AMU2_DDACH*n* register. 00 ADMA does not modify the original starting value of AMU2_DDACH*n* 01 ADMA uses AMU2_DDACH*n* + the current byte counter as the ARAM write address as each data transfer occurs *except for the final 8-byte transfer*. Both the AMU2_DDACH*n* and AMU2_DCNTCH*n* register values are unchanged. This value enables the special ADMA transfer where the last 8 bytes are *not* written into the ARAM, but instead are written into the AMU2_CCR{1,2}CH*n* registers. For this mode, the contents of AMU2_DCNTCH*n* defines the total number of data bytes to be transferred + 8 (for the final 8-byte transfer to the AMU2_CCR{1,2}CH*n*). Additionally, if DCCRCH*n*[DECC] = 0, any required single-bit corrections on the fetched data, including that destined for AMU2_CCR{1,2}CH*n*, are performed before being forwarded to the destination (either the ARAM or the control & configuration registers). If a non-correctable ECC event is detected on the last 64-bit data fetch, the update of the AMU2_CCR{1,2}CH*n* registers is not performed to avoid any inadvertent ALU activity 10 ADMA increments the AMU2_DDACH*n* as each data transfer occurs *including* the last transfer. The final value points to the next 8-byte aligned ARAM address 11 ADMA increments the AMU2_DDACH*n* as each data transfer occurs *including* the last transfer. The final value points to the next 8-byte aligned ARAM address
14 HCRCE	Halt on Cyclic Redundancy Check Error This bit determines the AMU2's response to a properly-enabled (ECRC == 1) CRC checksum error. 0 AMU2 continues calculation regardless of the error status associated with a CRC checksum 1 AMU2 halts execution if a CRC checksum error is detected when DCCRCH*n*[ECRC] = 1
15 ECRC	Enable Cyclic Redundancy Check This bit enables the ADMA's calculation of a CRC checksum as data is written into the ARAM. The expected 32-bit checksum result is defined in the AMU2_DCKSCH*n* register. 0 ADMA checksum is disabled 1 ADMA checksum is enabled
16 CADS	Clear ADMA State Setting this bit resets the DMA status state machine (AMU2_SEIRCH*n*[ADMAS]) to idle. The use of this bit is intended for situations where halted or stopped data transfers are *not* continued. This bit always reads as a zero. See *Section 88.3.6.2: ADMA execution states* for more information. 0 Do not reset the ADMA status state machine to idle 1 Reset the ADMA status state machines to idle
17 DECC	Disable ADMA ECC single bit corrections Setting this bit disables the ADMA's ECC logic from performing single-bit corrections and double-bit detections on data to be written into the ARAM and optionally sent to the CRC logic for checksum generation. This bit is intended for test and debug purposes. 0 Enable single-bit corrections and double-bit detections on corrupted data fetched from the system Flash address space 1 Disable single-bit corrections and double-bit detections on corrupted data fetched from the system Flash address space

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
18 STMP3	Stream the P3 vector into a 128-byte ARAM circular FIFO When enabled, the P3 vector is fetched from the system Flash using the AMU2_P3PTRCH*n* register (which is incremented) and written into a dedicated 128-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual P3 vector in Flash are likely - the AMU2_P3PTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is *not* supported. The streaming of P3 data is initiated when STMP3 = 1 and SRT = 1. Concurrent streaming of the V array can be supported by also setting STMV{32,16} != 00. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports either normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC18] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMP3] = AMU2_CCR2CH*n*[ADCCR18]. 0 P3 streaming mode is disabled 1 P3 streaming mode is enabled
19 STMV32	Stream the 32-bit V array into a 256-byte ARAM circular FIFO When enabled, the 32-bit V array is fetched from the system Flash using the AMU2_VPTRCH*n* register (which is incremented) and written into a dedicated 256-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual V array in Flash are likely - the AMU2_VPTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is *not* supported. The separate STMV{32,16} are required so the ADMA can begin the appropriate data transfer *before* the AMU2_CCR1CH*n*[V16] is configured. It is software's responsibility to insure the STMV{32,16} and AMU2_CCR1CH*n*[V16] settings are consistent. The definition of the 2-bit {STMV32, STMV16} configuration bits is: (00) All V streaming is disabled (01) 16-bit V streaming is enabled (10) 32-bit V streaming is enabled (11) 32-bit V streaming is enabled The streaming of V data is initiated when STMV{32, 16} != 00 and SRT = 1. Concurrent streaming of the P3 vector can be supported by also setting STMP3 = 1. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports *either* normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC19] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMV32] = AMU2_CCR2CH*n*[ADCCR19]. 0 V32 streaming mode is disabled 1 V32 streaming mode is enabled

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
20 STMV16	Stream the 16-bit V array into a 256-byte ARAM circular FIFO When enabled, the 16-bit V array is fetched from the system Flash using the AMU2_VPTRCH*n* register (which is incremented) and written into a dedicated 256-byte ARAM FIFO. The transfers are paced by the ALU's execution speed. Due to the inherent pipelining of the AMU2, speculative prefetches beyond the actual V array in Flash are likely - the AMU2_VPTRCH*n* register must be reloaded before the next calculation. When operating in this mode, the checksum function is not supported. The separate STMV{32,16} are required so the ADMA can begin the appropriate data transfer *before* the AMU2_CCR1CH*n*[V16] is configured. It is software's responsibility to insure the STMV{32,16} and AMU2_CCR1CH*n*[V16] settings are consistent. 0 V16 streaming mode is disabled 1 V16 streaming mode is enabled The definition of the 2-bit {STMV32, STMV16} configuration bits is: (00) All V streaming is disabled (01) 16-bit V streaming is enabled (10) 32-bit V streaming is enabled (11) 32-bit V streaming is enabled The streaming of V data is initiated when STMV{32,16} != 00 and SRT = 1. Concurrent streaming of the P3 vector can be supported by also setting STMP3 = 1. When a non-streamed ADMA data transfer is required, this flag must be cleared. The ADMA supports *either* normal data transfers or a streaming operation. Writes to AMU2_CCR2CH*n*[ADCC20] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[STMV16] = AMU2_CCR2CH*n*[ADCCR20].
21 EHP	Enable High Priority The ADMA's private connection with the platform Flash controller includes a signal that elevates the priority of a data request versus requests from the other system bus masters. By default, the ADMA's priority is lower than the other system bus masters. However, when this control signal is asserted, the ADMA's request is given highest priority within the platform Flash controller. The assertion of this high priority signal is controlled by three mechanisms: (1) For non-streamed ADMA transfers, the high priority control signal is asserted based on the setting of the ADMA speed control and the platform Flash controller's response time. If the responses are too slow, the ADMA asserts the high priority signal. (2) For streamed ADMA transfers, the high priority control signal is asserted based on the setting of the ALU speed control and the platform Flash controller's response time. Again, if the responses are too slow based on the ALU's need for new data, the ADMA asserts the high priority signal. (3) If this EHP bit is set, the high priority control signal is unconditionally asserted. 0 ADMA does not unconditionally assert the high priority signal to the platform Flash controller 1 ADMA does unconditionally assert the high priority signal to the platform Flash controller

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
22 DSAS	ADMA Stop if Alu Stops. This bit provides a mechanism to automatically stop the ADMA channel transfer requests if the ALU stops for any reason. This bit applies to non-streamed ADMA transfers. When streaming P3 or V, or both, the ADMA automatically stops streaming if/when the ALU is stopped or halted, and automatically resumes streaming when the calculation is resumed. 0 ALU stops do not affect the ADMA 1 ALU stops force the ADMA to also stop
23 STP	ADMA Stop request The setting of this indicator bit signals the ADMA to stop at the next appropriate point. The ADMA run status is available in AMU2_SEIRCH*n*[ADMAS]. If the P3 vector or V array, or both, are being streamed, the ADMA data transfers are paced by the ALU calculation speed, so any stop or halt condition to the ALU automatically stalls the ADMA. Note the simultaneous assertion of the STP and any conditional (WFS1D, WFS23D, WFDNI) or unconditional (SRT) start indicators causes the attempted ADMA initiation to *effectively be ignored* with no change in the AMU2_SEIRCH*n*[ADMAS] status. 0 No ADMA stop request; it operates normally 1 ADMA stop request; stop data transfer at the next appropriate point. Once the ADMA stops, this indicator is cleared.
24 DEICFG	ADMA Error Interrupt Conflguration This field controls the reporting mechanism associated with the ADMA error indicator flag (AMU2_SEIRCH*n*[DEIRQ]). 0 If an ADMA error is detected, set the indicator flag; the flag is explicitly cleared by software. 1 If an ADMA error is detected, set the indicator flag and assert core interrupt request; the flag is explicitly cleared by software.
25 WFDNI	Wait For ALU Done Interrupt request This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage2 + 3 calculations complete and set the AMU2_SEIRCH*n*[DNIRQ] indicator. This condition is signaled by (AMU2_SEIRCH*n*[DNIRQ] = 1'b1). If the ALU is idle when the AMU2_DCCRCH*n* register is loaded and a conditional ADMA start after the next ALU calculation completes is desired, the WFDNI indicator should be used. Once the ADMA transfer begins, this indicator bit is automatically cleared. Writes to AMU2_CCR2CH*n*[ADCC25] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFDNI] = AMU2_CCR2CH*n*[ADCCR25]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage2 + 3 calculations complete, and set AMU2_SEIRCH*n*[DNIRQ]

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
26 WFS23D	Wait For Stage23 Done This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage2 + 3 calculations are complete. This condition is signaled by (AMU2_SEIRCH*n*[S23XS] == 2'b00). Once the ADMA transfer begins, this indicator bit is automatically cleared. If the ADMA's data transfer must be delayed until the entire ALU calculation is complete, then both WFS1D and WFS23D must be asserted. Alternatively, the WFDNI flag can be used as the conditional ADMA start condition. Writes to AMU2_CCR2CH*n*[ADCC26] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFS23D] = AMU2_CCR2CH*n*[ADCCR26]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage2 + 3 calculations are complete
27 WFS1D	Wait For Stage1 Done This flag is a conditional ADMA start indicator. If asserted, the ADMA does not begin any data transfers until the ALU's stage1 calculation is complete. This condition is signaled by (AMU2_SEIRCH*n*[S1XS] == 2'b00). Once the ADMA transfer begins, this indicator bit is automatically cleared. If the ADMA's data transfer must be delayed until the entire ALU calculation is complete, then both WFS1D and WFS23D must be asserted. Alternatively, the WFDNI flag can be used as the conditional ADMA start condition. Writes to AMU2_CCR2CH*n*[ADCC27] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[WFS1D] = AMU2_CCR2CH*n*[ADCCR27]. 0 No ADMA start condition dependency 1 ADMA does not start until the ALU's stage1 calculation is complete
28 RSM	ADMA ReSuMe The assertion of a properly-qualified resume condition ((RSM == 1) && (STP == 0)) resumes the data transfer defined by the contents of the ADMA's registers, exiting from the stopped state. This bit applies to non-streamed ADMA transfers. When streaming P3 or V, or both, the ADMA automatically stops streaming if/when the ALU is stopped or halted, and automatically resumes streaming when the calculation is resumed. Once the ADMA resumes execution, this indicator bit is automatically cleared. 0 Do not resume the ADMA 1 Resume the ADMA's data transfer

Table 2267. AMU2_DCCRCH*n* field descriptions (continued)

Field	Description
30 FARZ	Force ARAM to Zero The assertion of this indicator flag enables a special ADMA mode of operation where up to 16 bytes of zero data (with the appropriate ECC check bits) are written into the ARAM destination defined by AMU2_DDACH*n* on alternating cycles. This ARAM initialization mode functions in a manner similar to a normal ADMA data transfer. Instead of fetching data from the Flash (or one of its remapped destination memories), the ADMA forces all zero data with correct ECC to be written into the ARAM. The AMU2_DSACH*n* register is *not* used, but the starting destination address is defined by AMU2_DDACH*n* and the size of the memory to be cleared by AMU2_DCNTCH*n*[BCNT]. The CRC is not supported in this mode, and AMU2_DCCRCH*n*[DARU] must be 0b00. The ARAM initialization is initiated by setting AMU2_DCCRCH*n*[SRT] = 1. All the ADMA status reporting operates like a normal data transfer. It is recommended that the other ADMA channel be idle during this initialization function. 0 The zeroing of the ARAM by the ADMA is disabled 1 The zeroing of the ARAM by the ADMA is enabled
31 SRT	ADMA Start request. This assertion of a properly-qualified start condition ((SRT == 1) && (STP == 0)) initiates the data transfer defined by the contents of the ADMA's registers. Once ADMA starts execution, this indicator bit is automatically cleared. Writes to AMU2_CCR2CH*n*[ADCC31] may affect this indicator, that is, if AMU2_CCR2CH*n*[ADCCRE] == 1, AMU2_DCCRCH*n*[SRT] = AMU2_CCR2CH*n*[ADCCR31]. 0 Do not unconditionally start the ADMA 1 Unconditionally start the ADMA

88.2.3.21 AMU Control & Configuration 1 Channel *n* Register (AMU2_CCR1CH*n*)

AMU2_CCR1CH*n* is the first of two control and configuration registers defining the operation of the ALU.

Table 2268. AMU2_CCR1CH*n* field descriptions

Field	Description
1:3 SRTSP	Start Speed This 3-bit encoded value defines the start speed for the ALU engine. It is used with the MAXSP field and AMU2_P8CH*n*[THRHC] with the current speed of the ALU is reported in AMU2_SEIRCH*n*[ACURSP]. The ALU speed control provides a mechanism to control the operation efficiency of the engine for coarse power control of the AMU. See *Section 88.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
5:7 MAXSP	Maximum Speed This 3-bit encoded value defines the maximum speed for the ALU engine. It is used with the SRTSP field and AMU2_P8CH*n*[THRHC] with the current speed of the ALU is reported in AMU2_SEIRCH*n*[ACURSP]. The ALU speed control provides a mechanism to control the operation efficiency of the engine for coarse power control of the AMU. See *Section 88.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models. 000 Maximum speed 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
8:9 AEICFG	ALU Error Interrupt ConFiGuration This 2-bit field provides the reporting mechanism associated with the ALU error indicator flag (AMU2_SEIRCH*n*[ERIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU error condition 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU error condition 11 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software

Table 2268. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
10:11 OVICFG	Overflow Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU overflow indicator flag (AMU2_SEIRCH*n*[OVIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU overflow condition. 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software. 10 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU overflow condition. 11 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software.
12:13 NCICFG	N Crossing Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU N crossing indicator flag (AMU2_SEIRCH*n*[NCIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU N crossing condition 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement.The AMU2_CCR2CH*n*[SNCRS] indicator should be set so the ALU stops its calculation so the correct intermediate result is available for the SDMA 11 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement.The AMU2_CCR2CH*n*[SNCRS] indicator should be set so the ALU stops its calculation so the correct intermediate result is available for the SDMA
14:15 DNICFG	ALU Done Interrupt Configuration This 2-bit field provides the reporting mechanism associated with the ALU done, that is, a calculation has successfully completed, indicator flag (AMU2_SEIRCH*n*[DNIRQ]). 00 Set indicator flag; the flag is explicitly cleared by software. This mode can be used by software to poll for ALU done condition. 01 Set indicator flag, assert core interrupt request. The flag is explicitly cleared by software. 10 Set indicator flag, assert SDMA request. The flag is cleared by an SDMA acknowledgement 11 Set indicator flag, initiate an ADMA transfer if one of the conditional start flags (AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI]) is also asserted. The AMU2_SEIRCH*n*[DNIRQ] flag is cleared by the AMU
16 BPRI	Bus Priority This indicator bit controls the bus arbitration priority associated with the ARAM and the programming model registers. Recall from *Figure 2350: AMU2 block diagram*, there are multiple master devices that can access the ARAM and programming model registers, specifically, the ADMA and ALU as well as system bus transfers routed via slave peripheral bus. This indicator bit controls the arbitration policy for selecting one master's request when concurrent accesses occur; idle cycles from the selected master provide opportunities for stalled accesses from other masters to be granted and complete. 0 ADMA has higher arbitration priority than the ALU which has higher priority than slave peripheral bus accesses (ADMA > ALU > slave peripheral bus) 1 ADMA has higher arbitration priority than slave peripheral bus accesses which have higher priority than the ALU (ADMA > slave peripheral bus > ALU)

Table 2268. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
17 EECC	Enable Error Correcting Code (ECC) in the ARAM This bit controls the checking of data read from the ARAM by the ALU and the slave peripheral bus. Note, ECC is generated on all writes to the ARAM from either the ADMA or the slave peripheral bus. If a single-bit error is detected by the ECC logic on an ARAM read, the corrected data is written back into the ARAM *only* in response to the read-modify-write sequence needed on all slave peripheral write accesses. 0 ECC checking of ARAM reads is disabled 1 ECC checking of ARAM reads is enabled If the system DMA is used for ARAM initialization, the EECC bits for *both* channels must be cleared until the initialization is complete.
18 DDSL	Disable Debug Stall This bit disables the AMU from stalling when an MCU debug event is underway. 0 All debug events, as signaled by an input signal, stall the AMU. The stall globally affects both channels of the ADMA and ALU 1 Debug events do not affect the AMU

19
SETZ
	Set Z result
	This bit controls the first operation performed in the ALU's stage3 output normalization. As the name implies, if this bit is asserted, the final result (z64) is set to the P5 data value, else it is unaffected. The second operation in stage3 involves a final accumulation with the result plus the product of y64 and p4.
	The stage3 output normalization pseudo-code is:
	`/* stage 3: output normalization */`
	`if (setz) {`
	`z64 = (ieee64) p5;`
	`}`
	`z64 = z64 + (ieee32) y64 * p4; // 32 x 32 -> 64 FMA`
	0 z64 is unaffected
	1 z64 is set to the 64-bit double-precision value of p5

20 ESTZC	Enable SETZ Clear If set, this bit forces the SETZ flag to be automatically cleared after a stage3 calculation as indicated by the assertion of AMU2_SEIRCH*n*[DNIRQ]. 0 SETZ flag is not cleared by the hardware. 1 SETZ flag is automatically cleared by the hardware after the stage3 calculation completes.
23 V16	V is a 16-bit data format This bit, along with VFH, defines the format for the V array: if V16 = 0, then V[*] is 32-bit single-precision format (ieee32) if V16 = 1 && VFH = 0, then V[*] is 16-bit half-precision format (ieee16) if V16 = 1 && VFH = 1, then V[*] is 16-bit fixed-point format with a common 7-bit biased exponent This bit cannot be changed while the ADMA is streaming V[*] data. See *Section 88.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.

Table 2268. AMU2_CCR1CH*n* field descriptions (continued)

Field	Description
24 VFH	V is Fixed Halfword format This bit, along with V16, defines the format for the V array: if V16 = 0, then V[*] is 32-bit single-precision format (ieee32) if V16 = 1 && VFH = 0, then V[*] is 16-bit half-precision format (ieee16) if V16 = 1 && VFH = 1, then V[*] is 16-bit fixed-point format with a common 7-bit biased exponent See *Section 88.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.
25:31 CMEXP	Common Exponent This 7-bit field defines the common exponent using an excess-63 format for the V array's 16-bit fixed-point format. See *Section 88.3.3.2: 16-bit fixed-point with common exponent* for details on the 16-bit fixed point format.

88.2.3.22 AMU Control & Configuration 2 Channel *n* Register (AMU2_CCR2CH*n*)

AMU2_CCR2CH*n* is the second of two control and configuration registers defining the operation of the ALU.

Table 2269. AMU2_CCR2CH*n* field descriptions

Field	Description
1 ADCCRE	Alternate DCCR write Enable This bit enables all the aliased AMU2_DCCRCH*n* indicators (AMU2_CCR2CH*n*[ADCR18, ADCCR19, ADCCR20, ADCCR25, ADCCR26, ADCCR27]) to be written when this register is updated. Clearing this bit allows software to write the AMU2_CCR2CH*n* without affecting the aliased control bits in the AMU2_DCCRCH*n*. The ADCCRE indicator always reads as a zero. 0 Contents of the write data for AMU2_CCR2CH*n*[ADCCR{18,19,20,25,26,27}] do not affect the AMU2_DcCRCH*n* 1 Contents of the write data for AMU2_CCR2CHn[ADCCR{18,19,20,25,26,27}] are loaded into AMU2_DCCRCH*n*
2 ADCCR18	Alternate AMU2_DCCRCH*n*[STMP3] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMP3], that is, AMU2_DCCRCH*n*[STMP3] = AMU2_CCR2CH*n*[ADCCR18], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMP3 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
3 ADCCR19	Alternate AMU2_DCCRCH*n*[STMV32] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMV32], that is, AMU2_DCCRCH*n*[STMV32] = AMU2_CCR2CH*n*[ADCCR19], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMV32 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
4 ADCCR20	Alternate AMU2_DCCRCH*n*[STMV16] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[STMV16], that is, AMU2_DCCRCH*n*[STMV16] = AMU2_CCR2CH*n*[ADCCR20], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the STMV16 indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
9 ADCCR25	Alternate AMU2_DCCRCH*n*[WFDNI] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFDNI], that is, AMU2_DCCRCH*n*[WFDNI] = AMU2_CCR2CH*n*[ADCCR25], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFDNI indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
10 ADCCR26	Alternate AMU2_DCCRCH*n*[WFS23D] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFS23D], that is, AMU2_DCCRCH*n*[WFS23D] = AMU2_CCR2CH*n*[ADCCR26], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFS23D indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
11 ADCCR27	Alternate AMU2_DCCRCH*n*[WFS1D] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[WFS1D], that is, AMU2_DCCRCH*n*[WFS1D] = AMU2_CCR2CH*n*[ADCCR27], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the WFS1D indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.

Table 2269. AMU2_CCR2CH*n* field descriptions (continued)

Field	Description
12 ADCCR31	Alternate AMU2_DCCRCH*n*[SRT] If a register write with AMU2_CCR2CHn[ADCCRE] == 1, then writes to this indicator flag directly affect AMU2_DCCRCH*n*[SRT], that is, AMU2_DCCRCH*n*[SRT] = AMU2_CCR2CH*n*[ADCCR31], else the AMU2_DCCRCH*n* indicator is unaffected. This alternate copy of the SRT indicator allows it to be written by the special ADMA mode that loads the AMU2_CCR{1,2}CH*n* registers as the last 8 bytes transferred.
14 ENCRS	Enable N CRoSsing event This bit enables the occurrence of an N crossing event. 0 The ALU's N crossing logic is disabled 1 The ALU's N crossing logic is enabled
15 SNCRS	Stop on N CRoSsing event This bit forces the ALU to stop execution on the occurrence of an N crossing event. 0 The ALU does not stop execution when an N crossing event occurs 1 The ALU stops execution when an N crossing event occurs
16 CSXXS	Clear Stage "X" eXecution State Setting this bit resets both the ALU execution state machines (AMU2_SEIRCH*n*[S1XS, S23XS]) to idle. The use of this bit is intended for situations where halted or stopped calculations are *not* continued. This bit always reads as a zero. 0 Do not reset the ALU execution state machines to idle 1 Reset both of the ALU execution state machines to idle See *Section 88.3.5.1: ALU execution states* for more information.
23 S23STP	Stage23 STop request The setting of this indicator bit signals the ALU to stop at the completion of the current outer loop execution. If asserted *after* the final stage2 outer loop completes, stage3 also finishes and S23STP remains asserted indicating the stop request was not granted.The ALU's stage23 status is available in AMU2_SEIRCH*n*[S23XS]. Once the ALU is stopped, this indicator bit is automatically cleared. 0 No stage23 stop request; the ALU operates normally 1 Stage23 stop request; stop execution at the completion of the current outer loop iteration
25 WFSS23	Wait For Sdma complete before starting Stage23 This is a conditional start bit for stage23. It signals the stage23 execution start is enabled by the completion of an SDMA data transfer. This indicator is used when the SDMA is used to copy an AMU result into system memory. The setting of this flag means the SDMA result retrieval must be finished before a stage23 calculation is initiated. Once stage23 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage23 start condition 1 Initiate stage23's execution when the SDMA completes its current data transfer

Table 2269. AMU2_CCR2CH*n* field descriptions (continued)

Field	Description
26 WFDS23	Wait For aDma complete before starting Stage23 This is a conditional start bit for stage23. It signals the stage23 execution start is enabled by the completion of the ADMA data transfer. The WFDS23 indicator is automatically cleared if the ADMA halts due to a bus or non-correctable ECC error, or if a checksum error is detected. This prevents the ALU stage23 execution from starting after the ADMA halt condition is processed by a service routine. The WFDS23 conditional start indicator can be combined with WFDS1. If both bits are asserted, as the ADMA completes its data transfer, the ALU begins execution of stage1, followed by stage23. Once stage23 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage23 start condition 1 Initiate stage23's execution when the ADMA completes its current data transfer
27 WFDS1	Wait For aDma complete before starting Stage1 This is a conditional start bit for stage1. It signals the stage1 execution start is enabled by the completion of the ADMA data transfer. The WFDS1 indicator is automatically cleared if the ADMA halts due to a bus or non-correctable ECC error, or if a checksum error is detected. This prevents the ALU stage1 execution from starting after the ADMA halt condition is processed by a service routine. The WFDS1 conditional start indicator can be combined with WFDS23. If both bits are asserted, as the ADMA completes its data transfer, the ALU begins execution of stage1, followed by stage23. Once stage1 begins execution, this indicator bit is automatically cleared. When streaming P3[*] or V[*] data, or both, this indicator bit is ignored. 0 No conditional stage1 start condition 1 Initiate stage1's execution when the ADMA completes its current data transfer.
28 S23RSM	Stage23 ReSuMe This bit resumes a stopped stage23 calculation. If stage23 is not stopped at the time of an attempted write to assert this bit, it is ignored. Once stage23 resumes execution, this indicator bit is automatically cleared. 0 Do not resume a stopped stage23 calculation 1 Resume a stopped stage23 calculation
30 S23SRT	Stage23 StaRT request. This assertion of a properly-qualified start condition ((S23SRT == 1) && (S23STP == 0)) initiates the ALU's stage23 execution. If S1SRT is also asserted, the ALU hardware sequences through the execution, first of stage1 and then stage23. Once stage23 starts execution, this indicator bit is automatically cleared. 0 Do not unconditionally start ALU's stage23 execution 1 Unconditionally start ALU's stage23 execution, either immediately or after stage1 completes
31 S1SRT	Stage1 StaRT request. This assertion of this start condition initiates the ALU's stage1 execution. Once stage1 starts execution, this indicator bit is automatically cleared. 0 Do not unconditionally start ALU's stage1 execution 1 Unconditionally start ALU's stage1 execution

88.2.3.23 AMU RES64M Channel *n* Register (AMU2_RES64MCH*n*)

This is the read-only final 64-bit double-precision result register. It is the z64 final accumulation from the stage3 output normalization calculation and is loaded into this register as the calculation completes. It is described here as the concatenation of two 32-bit words with RES64{M,L} defining the most significant and least significant words.

Offset: 0x10080 + n * 0x100 (n = 0 to 1) Access: Supervisor Read

Field	Description
0:31 IEEE64	Least significant word of the final result value in IEEE 64-bit floating-point format. This is the RES64LCH*n* register.

88.2.3.25 AMU Status, Error & Interrupt Channel *n* Register (AMU2_SEIRCH*n*)

This is the AMU's status register. The most significant three bytes contain read-only status and error flags, while the low-order byte contains the interrupt flag bits. Specifically, there are 15 status bits signaling the state of the ADMA, stage1 and stage23 ALU calculations, along with the current speed settings, 9 error flags signaling arithmetic faults in the ALU or other error conditions, and 6 interrupt request flags.

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address) and this status register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Certain error flag indicators in this register are cleared by a read of the register; there is an alternate location of this register (see *Section 88.2.3.33: AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)*) where a read does not affect these status flags. Accordingly, software polling of the CHBSY flag should use the alternate AMU2_SEINCCH*n* register so that no fault status bits are inadvertently cleared.

It should be noted the interrupt flags are intended to record the completion of an event or the occurrence of an error condition. These flags are set when the event occurs, while the subsequent reporting of the event is defined by the corresponding interrupt configuration field, specifically AMU2_DCCRCH*n*[ADICFG, DEICFG] and AMU2_CCR1CH*n*[AEICFG, OVICFG, NCICFG, DNICFG]. The event's reporting can be configured to *not* perform any type of asynchronous notification (intended for software polling applications), a processor interrupt, or depending on the event, a system DMA or ADMA request. For DMA requests (both system and AMU), the hardware clears the indicator event flag as the request is acknowledged; for the software polling configuration or processor interrupts, a service routine or another software task must explicitly clear the event flag by writing a logical 1 to the corresponding interrupt flag. This is a "write 1" clear protocol.

Table 2272. AMU2_SEIRCH*n* field descriptions

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. This flag is asserted when ((AMU2_SEIRCH*n*[ADMAS] == 0b11) || (AMU2_SEIRCH*n*[S1XS] == 0b11) || (AMU2_SEIRCH*n*[S23XS] == 0b11)). 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled

Table 2272. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
4:5 S1XS	Stage1 eXecution Status This read-only 2-bit field defines the execution status of the ALU's stage1 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execution cannot be stopped via a request 11 Running or stalled
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 88.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event.
9:11 ACURSP	Alu Current Speed This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.

Table 2272. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32. 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value.
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation. 1 Arithmetic fault associated with the ALU's stage3 calculation was detected.
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation. 1 Arithmetic fault associated with the ALU's stage1 calculation was detected.
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data 1 Arithmetic fault associated with the input data was detected

Table 2272. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such as bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does not include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other errors, was detected
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected

Table 2272. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error
27 ADIRQ	ADMA Interrupt ReQuest. This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2288: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition

Table 2272. AMU2_SEIRCH*n* field descriptions (continued)

Field	Description
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgement signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

88.2.3.26 AMU Actual Checksum Channel *n* Register (AMU2_ACKSCH*n*)

This is the actual read-only ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the actual checksum result. If enabled, this register is cleared at the beginning of the ADMA transfer, the actual checksum accumulated by the ADMA in this register and then compared to expected value contained in the AMU2_DCKSCH*n* register at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address), the status register and this register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Offset: 0x1008C + n * 0x100 (n = 0 to 1) Access: Supervisor Read

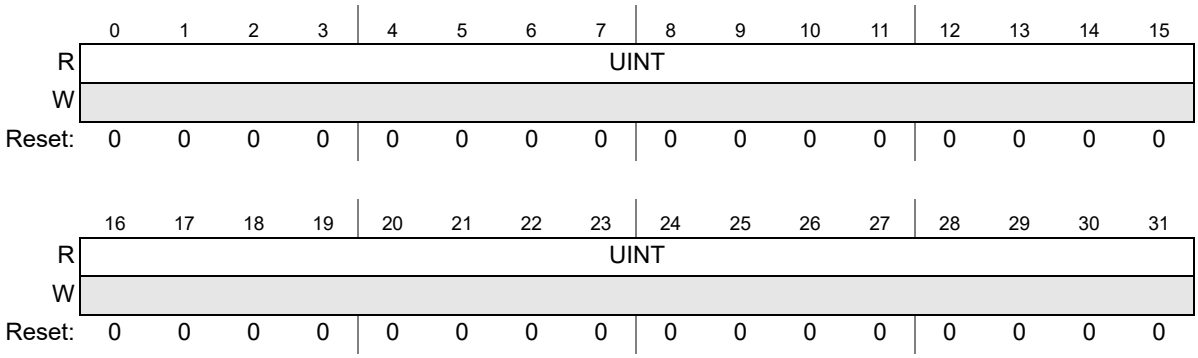

Figure 2376. AMU Actual Checksum Channel *n* Register (AMU2_ACKSCH*n*)

Table 2273. AMU2_ACKSCH*n* field descriptions

Field	Description
0:31 UINT	Actual ADMA checksum in a 32-bit unsigned integer format.

88.2.3.27 AMU RES32 Channel *n* Register (AMU2_RES32CH*n*)

This is the read-only 32-bit single-precision version of the final 64-bit double-precision result register, that is, this is “z32”, derived from the z64 final accumulation from the stage3 output normalization calculation.

Offset: 0x10090 + n * 0x100 (n = 0 to 1) Access: Supervisor Read

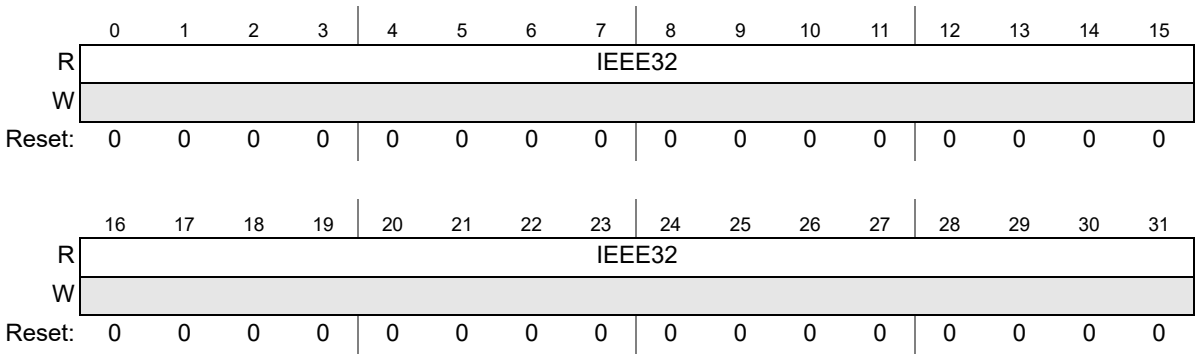

Figure 2377. AMU RES32 Channel *n* Register (AMU2_RES32CH*n*)

Table 2274. AMU2_RES32CH*n* field descriptions

Field	Description
0:31 IEEE32	Single-precision version (IEEE 32-bit floating-point format) of the final 64-bit result (z64) value.

88.2.3.28 Aliased copy of AMU Status, Error & Interrupt Channel *n* Register (AMU2_ASEIRCH*n*)

This is the AMU's status register. The most significant three bytes contain read-only status and error flags, while the low-order byte contains the interrupt flag bits. Specifically, there are 15 status bits signaling the state of the ADMA, stage1 and stage23 ALU calculations, along with the current speed settings, 9 error flags signaling arithmetic faults in the ALU or other error conditions, and 6 interrupt request flags.

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address) and this status register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Certain error flag indicators in this register are cleared by a read of the register; there is an alternate location of this register (see *Section 88.2.3.33: AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)*) where a read does not affect these status flags. Accordingly, software polling of the CHBSY flag should use the alternate AMU2_SEINCCH*n* register so that no fault status bits are inadvertently cleared.

It should be noted the interrupt flags are intended to record the completion of an event or the occurrence of an error condition. These flags are set when the event occurs, while the subsequent reporting of the event is defined by the corresponding interrupt configuration field, specifically AMU2_DCCRCH*n*[ADICFG, DEICFG] and AMU2_CCR1CH*n*[AEICFG, OVICFG, NCICFG, DNICFG]. The event's reporting can be configured to *not* perform any type of asynchronous notification (intended for software polling applications), a processor interrupt, or depending on the event, a system DMA or ADMA request. For DMA requests (both system and AMU), the hardware clears the indicator event flag as the request is acknowledged; for the software polling configuration or processor interrupts, a service routine or another software task must explicitly clear the event flag by writing a logical 1 to the corresponding interrupt flag. This is a "write 1" clear protocol.

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled

Table 2275. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
4:5 S1XS	Stage1 Execution Status This read-only 2-bit field defines the execution status of the ALU's stage1 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execution cannot be stopped via a request 11 Running or stalled
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 88.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event.
9:11 ACURSP	ALU Current Speed This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.

Table 2275. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation 1 Arithmetic fault associated with the ALU's stage3 calculation was detected
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation 1 Arithmetic fault associated with the ALU's stage1 calculation was detected
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data. 1 Arithmetic fault associated with the input data was detected.

Table 2275. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such as bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does *not* include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other rerrors, was detected
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected

Table 2275. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error
27 ADIRQ	ADMA Interrupt Request This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error

Table 2275. AMU2_ASEIRCH*n* field descriptions (continued)

Field	Description
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2288: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

88.2.3.29 Aliased copy of AMU Actual Checksum Channel *n* Register (AMU2_AACKSCH*n*)

This is the actual read-only ADMA checksum data register. The ADMA supports an optional calculation of a 32-bit checksum on the data transferred into the ARAM. This register defines the actual checksum result. If enabled, this register is cleared at the beginning of the ADMA transfer, the actual checksum accumulated by the ADMA in this register and then compared to expected value contained in the AMU2_DCKSCH*n* register at the completion of the data transfer. If the actual and expected checksums are equivalent, the AMU continues, else a data transmission error has been detected (AMU2_SEIRCH*n*[CKSERR] = 1) and the AMU responds according to the programmed configuration (AMU2_DCCRCH*n*[ADICFG]).

There are aliased copies of this register available at multiple addresses to allow the SDMA to retrieve the AMU2 result (either as a 64-bit double-precision or a 32-bit single-precision format based on the access address), the status register and this register in a simple, sequential block transfer. For example, a 16-byte block transfer beginning at offset address 0x1_0080 retrieves the AMU2_RES64{M,L}CH0 result, the AMU2_SEIRCH0 status and the AMU2_ACKSCH0 checksum result. Conversely, a 12-byte block transfer beginning at offset address 0x1_0090 retrieves the AMU2_RES32CH0 result, the aliased copy of the AMU2_SEIRCH0 register and the aliased copy of the AMU2_ACHKSCH0 register. Similar 16- and 12-byte block transfers in the CH1 section of the memory map return the comparable registers.

Field	Description
0:31 IEEE64	Least significant word of the y64 value in IEEE 64-bit floating-point format at the completion of the stage2 outer loop. This is the Y64LCH*n* register.

88.2.3.32 Aliased copy of AMU P8 Channel *n* Register (AMU2_AP8CH*n*)

The P8 register contains two 16-bit unsigned integers related to the outer loop at the stage2 calculation. The upper halfword contains the threshold count for the ALU's speed control (see *Section 88.3.5.2: ALU speed control*), while the lower halfword is the starting value for the stage2 outer loop calculation.

As the stage2 outer loop iterates, the lower halfword of the AMU2_P8CH*n* register is incremented. If the calculation is stopped or halted, the register reflects the incremented loop count value. When the outer loop completes execution, it is restored to its initial value. This provides hardware support for the loop control such that this register does *not* have to be explicitly re-initialized for every calculation.

There is also an aliased read-only copy of this register available so that intermediate results associated with Y64 and P8 can be retrieved by the system DMA (SDMA) in a simple, sequential block transfer.

Table 2279. AMU2_AP8CH*n* field descriptions

Field	Description
0:15 THRHC	Threshold Count This 16-bit unsigned integer defines the threshold count used in the ALU speed control function. There are additional control fields associated with this function in the AMU2_CCR1CH*n* register. There is a single ALU speed control function shared by the calculation engine and accessible from either the CH0 or CH1 programming models.
16:31 UINT	Parameter p8 value in a 16-bit unsigned integer format.

88.2.3.33 AMU Status, Error & Interrupt No Clear Channel *n* Register (AMU2_SEINCCH*n*)

This is an alternate view of the AMU's status register. It contains read-only status (SEIRCH*n*[31:16]) and error flags (SEIRCH*n*[15:7]), plus the module's interrupt bits (SEIRCH*n*[4:0]).

For this version of the register, specific error status indicators are not cleared by a read of the register. This specifically affects the operation of AMU2_SEINCCH*n*[YCAFLT, ZCAFLT, S23AFLT, S1AFLT, IDVERR, ADMERR, CKSERR, ECCERR, RGCERR].

This register is read-only. When clearing the state of the interrupt request flags, use the AMU2_SEIRCH*n* registers.

Figure 2383. AMU Status, Error & Interrupt No Clear Channel n Register (AMU2_SEINCCHn)

Table 2280. AMU2_SEINCCHn field descriptions

Field	Description
0 CHBSY	Channel Busy This read-only bit is intended to serve as a polling flag as it signals the AMU2 channel is busy. In this context, the “channel” status represents the logical summation of the ADMA data channel and the ALU calculation engine status fields indicating a non-idle “channel”. 0 Channel *n* is idle 1 Channel *n* is busy performing an ADMA data transfer or an ALU calculation
1 ADSTM	ADMA is Streaming This read-only flag signals whether the ADMA is performing a data streaming transfer of the P3[*] or V[*] input vectors as enabled by AMU2_DCCRCH*n*[STMP3, STMV{32, 16}] control bits. 0 The ADMA is not performing any P3[*] nor V[*] data streaming transfers 1 The ADMA is busy performing a P3[*] or V[*] data streaming transfers
2:3 S23XS	Stage23 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage23 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
4:5 S1XS	Stage1 Execution Status This read-only 2-bit field defines the execution status of the ALU’s stage1 logic. See *Section 88.3.5.1: ALU execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Unused, reserved as stage1 execu tion cannot be stopped via a request 11 Running or stalled

Table 2280. AMU2_SEINCCHn field descriptions (continued)

Field	Description
6:7 ADMAS	ADMA Status This read-only 2-bit field defines the status of the ADMA. See *Section 88.3.6.2: ADMA execution states* for more details on the execution states. The status encodings are: 00 Idle or pending start condition 01 Halted 10 Stopped 11 Running or stalled
8 QDSL	Qualified Debug Stali This read-only bit signals a qualified debug stall condition as defined by (debug_event == 1) && (AMU2_CCR1CH*n*[DDSL] == 0). 0 No qualified debug stall 1 The ALU calculation engine and ADMA are stalled due to a qualified debug event
9:11 ACURSP	Alu CURrent SPeed. This read-only 3-bit encoded value defines the current speed for the ALU engine. The ALU speed control is defined by AMU2_CCR1CH*n*[SRTSP, MAXSP] and AMU2_P8CH*n*[THRHC]. The ALU speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.5.2: ALU speed control* for more details on the ALU speed control mechanism. There is a single ALU speed control function shared by both channels. 000 Maximum speed; speed control disabled 001 1/8 speed 010 2/8 speed 011 3/8 speed 100 4/8 speed 101 5/8 speed 110 6/8 speed 111 7/8 speed
13:15 DCURSP	ADMA Current Speed This read-only 3-bit encoded value defines the current speed for the ADMA channel. The ADMA speed control is defined by AMU2_DCCRCH*n*[SRTSP, MAXSP] and AMU2_DCNTCH*n*[THRHC]. The ADMA speed control provides a mechanism to control the operation efficiency of the submodule for coarse power control of the AMU. See *Section 88.3.6.5: ADMA speed control* for more details on the ADMA speed control mechanism. There is a single ADMA speed control function shared by both channels. The DCURSP uses the same encodings as the ACURSP field above.
16 YCAFLT	Y Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the y64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of y64 to y32 1 Arithmetic fault associated with the conversion of y64 to y32 was detected. For the overflow case, the y32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value

Table 2280. AMU2_SEINCCHn field descriptions (continued)

Field	Description
17 ZCAFLT	Z Conversion Arithmetic Fault The assertion of this read-only flag indicates the conversion from double-precision ieee64 format of the z64 result to single-precision ieee32 format generated an arithmetic fault (overflow, underflow). This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the conversion of z64 to z32. 1 Arithmetic fault associated with the conversion of z64 to z32 was detected. For the overflow case, the z32 value is set to (+/-) INF, while an underflow produces a (+/-) 0 value.
18 S23AFLT	Stage2, 3 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage2 or stage3 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage3 calculation 1 Arithmetic fault associated with the ALU's stage3 calculation was detected
19 S1AFLT	Stage1 Arithmetic Fault The assertion of this read-only flag indicates an arithmetic fault (overflow, underflow) was detected in the ALU's stage1 calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No arithmetic fault associated with the ALU's stage1 calculation 1 Arithmetic fault associated with the ALU's stage1 calculation was detected
20 IDVERR	Input Data Validation Error The assertion of this read-only flag indicates an error (NaN, +/- INF) was detected in the input data before the ALU's calculation. The ALU's calculation is halted. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No error associated with the input data 1 Arithmetic fault associated with the input data was detected
21 ADMERR	ADMA Error The assertion of this read-only flag indicates an error (such bus error, illegal address, multi-bit ECC event) was detected by the ADMA. This flag does *not* include CRC checksum errors as these are directly signaled by SEIRCH*n*[CKSERR]. If the ADMA is streaming P3 or V data, or both, at the time of the error, this flag is set and the ALU calculation is stalled with AMU2_SEIRCH*n*[S{1,23}XS] indicating the running or stalled state. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No bus error, illegal address, multi-bit ECC, such as errors associated with the ADMA 1 An ADMA bus error, illegal address, multi-bit ECC event, other errors, was detected

Table 2280. AMU2_SEINCCHn field descriptions (continued)

Field	Description
22 CKSERR	ADMA Checksum Error The assertion of this read-only flag indicates an ADMA CRC checksum error was detected. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No CRC checksum error associated with the ADMA 1 An ADMA CRC checksum error was detected
23 ECCERR	Error Correcting Code Error The assertion of this read-only flag indicates a non-correctable ECC error was detected on an ARAM read by the ALU. Non-correctable ECC errors detected by the ADMA are reported with AMU2_SEIRCH*n*[ADMERR] = 1, while similar errors detected during a slave peripheral bus access from the CPU or SDMA are reported via an error-terminated bus cycle. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No ARAM ECC error 1 An ARAM non-correctable ECC error was detected
24 RGCERR	Register Conflict Error The assertion of this read-only flag indicates an unexpected write of the AMU2's programming model while the ALU is executing was attempted. The protected registers include: AMU2_{P1* - P9*, VPTR, LPTR, UPTR}CH*n*. Attempted writes to the AMU2_{P1PTR, P2PTR, P7, UPTR}CH*n* registers while the ALU is executing stage 1 set this indicator bit and halt the ALU. Attempted writes to the AMU2_{P3PTR, P4, P5, P6, P7, P8, P9{M,L}, VPTR, LPTR}CH*n* registers while the ALU is executing stage 23 set this indicator bit and halt the ALU. The AMU2_{N, DSA, DDA, DCNT, DCKS, DCCR, CCR1, CCR2}CH*n* registers can safely be written while the ALU is executing. This flag is cleared by a read of this register (r1c); reads of AMU2_SEINCCH*n* do not clear this flag. 0 No register conflict error 1 An AMU2 register conflict error was detected
26 DEIRQ	ADMA Error Interrupt Request This flag is set to signal the ADMA has detected an error. The error conditions which set this indicator flag include: – Multi-bit ECC event during a data transfer (ADMERR = 1) – Bus error termination during a data transfer (ADMERR = 1) – Detection of a checksum error (CKSERR = 1) The subsequent system behavior is defined by the AMU2_DCCRCH*n*[DEICFG] field. This flag must be cleared by an explicit write of a 1 ("write 1 clear") to the bit position. A read of this register does not affect the state of this indicator bit. 0 ADMA has not detected an error 1 ADMA has detected an error.

Table 2280. AMU2_SEINCCHn field descriptions (continued)

Field	Description
27 ADIRQ	ADMA Interrupt Request This flag is set to signal the ADMA has completed its data transfer. This flag is not set when streaming P3[*] or V[*] data, or both, completes. The subsequent system behavior is defined by the AMU2_DCCRCH*n*[ADICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_DCCRCH*n*[ADICFG] = 0b0-. For other configuration values, the SDMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ADMA has not completed its data transfer 1 ADMA has completed its data transfer
28 ERIRQ	ALU Error Interrupt Request This flag is set to signal the ALU has detected certain errors. The error conditions which set this indicator flag include: – Multi-bit ECC event on an ARAM read by the ALU (ECCERR = 1) – -Detection of a register conflict error (RGCERR = 1) – Detection of an input data validation error (IDVERR = 1) The subsequent system behavior is defined by the AMU2_CCR1CH*n*[AEICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an error 1 ALU has detected an error
29 OVIRQ	ALU Overflow Interrupt Request This flag is set to signal the ALU has detected an overflow condition. The error conditions which set this indicator flag include: – Arithmetic overflow during stage1 (S1AFLT = 1), stage2 (S23AFLT = 1), or stage3 (S23AFLT = 1) – Overflow when performing 64-bit to 32-bit conversions for ut[*] (S1AFLT = 1), t (S23AFLT = 1), y (YCAFLT = 1), z (ZCAFLT =1) The ALU halts execution at specific places within the algorithm if an overflow is detected: stage1 overflows halt at the end of its calculation, stage2 overflows halt at the completion of the outer loop iteration and stage3 overflows complete at the end of its calculation. See *Table 2288: ALU Completion State Details in AMU2_SEIRCHn* for additional details. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[OVICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position. A read of this register does not affect the state of this indicator bit. 0 ALU has not detected an overflow condition 1 ALU has detected an overflow condition

Table 2280. AMU2_SEINCCHn field descriptions (continued)

Field	Description
30 NCIRQ	ALU N Crossing Interrupt Request This flag is set to signal the ALU has completed “N” iterations of the stage2 calculation in response to a properly configured N crossing event. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[NCICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[NCICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed N iterations of a properly-configured N crossing event 1 ALU has completed N iterations of a properly-configured N crossing event
31 DNIRQ	ALU Done Interrupt Request This flag is set to signal the ALU has successfully completed an error-free calculation. The subsequent system behavior is defined by the AMU2_CCR1CH*n*[DNICFG] field. This flag must be cleared by an explicit write of a 1 (“write 1 clear”) to the bit position if AMU2_CCR1CH*n*[DNICFG] = 0b0-. For other configuration values, the SDMA or ADMA hardware provides an acknowledgment signal which clears this indicator bit. A read of this register does not affect the state of this indicator bit. 0 ALU has not completed its calculation 1 ALU has completed its calculation

88.2.3.34 AMU Y32 Channel *n* Register (AMU2_Y32CH*n*)

This is a read-only 32-bit single-precision (“y32”) version of the 64-bit double-precision y64 value at the completion of each iteration of the outer (stage 2) loop.

Offset: 0x100B0 + n * 0x100 (n = 0 to 1) Access: Supervisor Read

Table 2281. AMU2_Y32CH*n* field descriptions

Field	Description
0:31 IEEE32	Single-precision version (IEEE 32-bit floating-point format) of the 64-bit result (y64) value.

88.3 Functional description

The AMU2 includes two independent channels, named channel 0 (ch0) and channel 1 (ch1), and featuring independent registers. Each channel logically includes a calculation engine and a DMA channel. The calculation engines share the same arithmetic logic using a time multiplexed scheme. Likewise, the DMA channels use a time multiplexed scheme to share common interfaces for fetching from the system Flash memory and writing into the ARAM. Once a calculation is initiated, the ALU engine executes the defined algorithm using data from the local ARAM (which is visible in the system memory map via the peripheral bus) or data streamed into the module from the private Flash connection by the ADMA. The ADMA executes data transfers from the system Flash (or the calibration remapped destination memories, or both) to the ARAM using a private interconnect.

88.3.1 AMU2 algorithm

As mentioned previously, the defined floating-point algorithm includes several loops with vector multiply-accumulate operations plus an evaluation of an exponential function while calculating a single double-precision output value. The algorithm is partitioned into 3 stages:

- Stage1: Input normalization within a single for() loop
- Stage2: Within two nested for() loops, accumulation of t in the inner loop, followed by calculation of exp(-t) and accumulation of y in the outer loop
- Stage3: Output normalization using y

The AMU2's hardware structure segments the algorithm into two parts for implementation: stage1 and stage23, where the latter includes both stage2 + stage3. The terms stage1, stage2 and stage23 are used throughout the document.

The stage1 and stage23 algorithms are defined in the following C pseudo-code. This description uses explicit references to `ieeexy` tags where *xy* = {16, 32, 64} defines the cast (and associated rounding) to the indicated precision in the subsequent floating-point calculations and `uintxy` defines an unsigned *xy*-bit integer.

88.3.1.1 Stage1 of the algorithm

```
void amuStage1(
    ieee32*  u,             // pointer to  u[p7] 32-bit single data array
    ieee32*  p1,            // pointer to p1[p7] 32-bit single data array
    ieee32*  p2,            // pointer to p2[p7] 32-bit single data array
    ieee32*  ut,            // pointer to ut[p7] 32-bit single data array
    uint05   p7             // dimension of the ASC function
) {
    uint16   k;             // local loop counter

    /* stage 1 */
    for (k = 0; k < p7; k++) {
        ut[k] = (ieee32) (u[k] * p1[k] + (ieee64) p2[k]); // 32x32 -> 64 FMA
    }
}
```

88.3.1.2 Stage23 (2 & 3) of the algorithm

```
void amuStage23(
    ieee32*  ut,            // pointer to ut[p7] 32-bit single data array
    uint01   v16,           // v[p6*p7] is 16-bit data array
    uint01   vfh,           // v[p6*p7] is 16-bit half precision float
    ieee32*  v32f,          // pointer to v[p6*p7] as ieee32
    ieee16*  v16h,          // pointer to v[p6*p7] as ieee16
    uint16*  v16x,          // pointer to v[p6*p7] as 16-bit fixed-point
    uint07   cmExp,         // v[p6*p7] common exponent for 16-bit fixed
    ieee32*  L,             // pointer to  L[p7] 32-bit single data array
    ieee32*  p3,            // pointer to p3[p7] 32-bit single data array
    ieee32   p4,            // scalar factor in the output normalization
    ieee32   p5,            // optional start value in the output
normalization
    uint16   p6,            // size of the ASC function
    uint05   p7,            // dimension of the ASC function
    uint16   &p8,           // outer stage2 "for" loop count
    ieee64   p9,            // starting value of double-precision y
accumulator
    uint01   setz,          // configuration to define initial z64 value
    ieee64   y64,           // 64-bit double-precision outer loop output
value
    ieee32   y32,           // 32-bit single-precision version of y64
    ieee64   z64,           // 64-bit double-precision final output value
    ieee32   z32            // 32-bit single-precision version of final
output
) {
    ieee32   d, e, v_ieee32;// internal stage23 local single-precision
variables
    ieee64   t;             // internal stage23 local double-precision
accumulator
    uint16   p8_init;       // internal unsigned integer variable
    uint16   i,j,k;         // internal unsigned integer array index (i),
loop count variables (j,k)

    /* data initialization */
    y64 = p9;
    p8_init = p8;

    /* stage 2: t accumulation, exp(-t), y accumulation */
    for (j = p8; j < p6; j++) {
        i = j * p7;

        /* stage 2a: t accumulation */
        t = (ieee64) 0.0;
```

```
            for (k = 0; k < p7; k++) {
                switch ((v16 << 1) + vfh) {
                    case 0:
                    case 1:                 // V array = ieee32 format
                        v_ieee32 = v32f[i+k];
                        break;
                    case 2:                 // V array = ieee16 format
                        v_ieee32 = (ieee32) v16h[i+k];
                        break;
                    case 3:
                        v_ieee32 = convertFixedPoint (cmExp-63, v16x[i+k]);
                        break;
                }
                d = ut[k] - v_ieee32;
                d = (ieee32)(d * d);
                t += (L[k] * d);            // 32 x 32 -> 64 FMA
            }

            /* stage 2b: exp() */
            e = amuExp(-(ieee32)t);         // amu exp()

            /* stage 2c: y64 accumulation */
            y64 += p3[j] * e;               // 32 x 32 -> 64 FMA
            p8++;                           // update global loop counter

        // user stop requests pause the algorithm in-place at this point
        }

        y32 = (ieee32) y64;                 // ieee32 version of y

        /* stage 3: output normalization */
        if (setz) {
            z64 = (ieee64) p5;
        }

        z64 = z64 + y64 * p4;               // 32 x 32 -> 64 FMA
        z32 = (ieee32) z64;

        p8 = p8_init;                       // return p8 to original value

    }
```

88.3.2 The exp(x) function and implementation

As previously described, a single-precision evaluation of the exp(x) is a key function in the defined algorithm (part of the stage2 outer loop calculations). The AMU2's implementation consists of four steps:

1. Special case analysis, for example, value out of range produces +Inf
2. Argument reduction
3. Function evaluation
4. Range reconstruction

88.3.2.1 Special case analysis

The first step of the exp(x) function consists of a series of conditional tests to filter out these special cases and perform the proper operation, for example returning an infinity when the input argument is too large.

88.3.2.2 Argument reduction

Standard algorithms for exp(x) typically approximate e^x in a bounded domain, typically defined as [-ln(2)/2, ln(2)/2] or [0, ln(2)]. The AMU2 implementation uses the [0, ln(2)) range. Further, the following mathematical identity is applied to the function definition:

$e^x = e^{E*\ln(2)+z} = (e^{\ln(2)})^E * e^z = 2^E * e^z$

where E is a signed *integer* and z is such that |z| < ln(2). After a series of arithmetic manipulations, z and E can be computed as:

E = int(x / ln(2))

z = x - E * ln(2)

where E is the integer part of the (x/ln(2)) computation with the same sign.

Further, the e^z computation can be rewritten as:

$e^z = e^{(A+B)} = e^A * e^B$

The range of the input argument can be further reduced by rewriting z as the sum of two fixed-point numbers such that z = A + B. This can be accomplished trivially by assigning the first *n* bits of z to A and the remaining bits of z to B. For the AMU2, the first 6 bits of the input argument are assigned to A, and the remaining 17 bits to B, thus allowing the use of a simple 64-element lookup table to compute e^A and a polynomial approximation for e^B.

88.3.2.3 Function evaluation

The next step is the selection of a polynomial approximation of e^B that is sufficiently accurate in the range [0, ln(2)/64]. In the AMU2, a Minimax approximation is used to model the e^x function with a low-degree polynomial. Minimax approximations are polynomials of degree N that calculate a given function within a given interval such that the absolute maximum error is minimized. This allows an error bound on the approximation *without* incurring unnecessary terms in the polynomial.

The difficult part of finding a Minimax polynomial is the iterative nature of the algorithm to compute the coefficients. For this, the Remez Algorithm as implemented in an indefinite precision solver is applied. The form of the polynomial is:

$f(x) = a_0 + a_1 * x + a_2 * x^2 + a_3 * x^3 + ...$

Using the Remez Algorithm, the function implements a three-term expression of the form:

$exp(x) = 1 + x * (C_0 + x * (C_1 + x* C_2))$

where C_n represent the required coefficients and x is the range-limited input argument. This produces the following expression in a more typical polynomial form:

$exp(x) = 1 + C_0 * x + C_1 * x^2 + C_2 * x^3$

In solving for the C_n coefficients to provide the minimum error, it becomes obvious that C_0 is very close to 1.0 and C_1 is reasonably close to 0.5. Since the assignment of these two coefficients to these constants allows a simplified hardware implementation, the next step is calculation of a revised C_2 coefficient to account for the simplifications involving C_0 and C_1. This calculation produces the following coefficient values:

$C_0 = 1.0$

$C_1 = 0.5$

$C_2 = 0.167876224340382$

Using this form of the exp(x) function and comparing its precision and accuracy versus Excel's computation of e^x over the range [0, ln(2)/64] shows the following results:

- Error terms approximately bounded as [-7.0E-10, +7.0E-10]
- > 30 bits of precision across the entire input range

The AMU2 limits the datapath width to 25 bits to minimize the exp() implementation cost.

88.3.2.4 Range reconstruction

The final step in the exp(x) function is the use of multiplicative range reconstruction to return the answer back into the proper range. Recall the equations of interest are:

$e^x = 2^E * e^z$

$e^z = e^{(A + B)} = e^A * e^B$

$exp(x) = 2^E * e^A * e^B$

where E was calculated during argument reduction, e^A from a table lookup and e^B using the polynomial evaluation. Finally, the result must be converted into a single-precision floating point number. Due to the nature of floating point numbers, this is a simple step; because the range of z is [0, ln(2)), the range of e^z is [1, 2). Since floating point numbers must be normalized to the range [1, 2), the result is guaranteed to be normalized, and in the proper range. The calculated e^z is stored as the single-precision mantissa and E as the exponent.

Note: If the exp(x) evaluation generates an overflow, the single-precision function result is set to positive infinity (+Inf = 0x7F800000). Likewise, if an underflow is generated, the result is set to a positive zero (+0 = 0x00000000).

The AMU2 includes a single instance of the exp(x) hardware function which is shared via time-multiplexing across the two calculation channels.

88.3.3 AMU data types and formats

The algorithm calculations performed by the AMU2 use floating-point values for the parameters and data, and unsigned integers for all memory pointers and loop counts. This section provides details on the supported floating-point data types as well as one additional format available for the V[*] array.

As an example of the data set size, consider the following two variables as a typical use case:

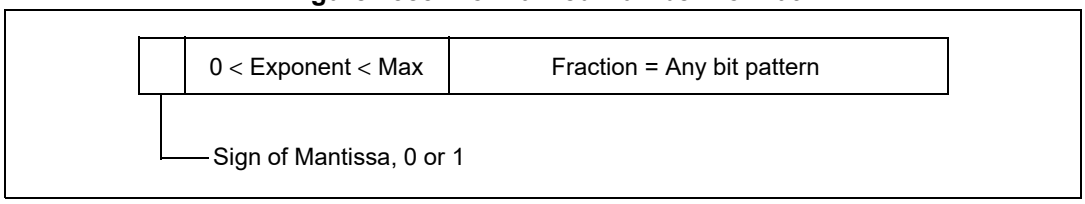
- Dimensionality of the ASC function, p7, with an example value of 10
- Size of the ASC function, p6, with an example value of 500

Based on these two variables, the input vector data can be categorized into three sizes:

- The V[*] array has a size of p6 * p7 = 500 * 10 = 5000 elements
- The P3[*] vector has a size of p6 = 500 elements
- All remaining vectors (L[*], P1[*], P2[*], u[*], ut[*]) have a size of p7 = 10 elements

88.3.3.1 Floating-point data formats

The AMU2 uses 16-bit half-, 32-bit single- and 64-bit double-precision floating-point data formats as defined in the IEEE 754-2008 “Standard for Floating-Point Arithmetic” specification. These formats are described in the following subsections. The multiple floating-point formats are used to minimize the data memory storage requirements for input operands and increase computational accuracy while allowing a reasonable module implementation size.



Each floating-point format supports five unique data types: normalized numbers, zeros, infinities, NaNs, and denormalized numbers. The normalized data type, as depicted in *Figure 2385*, never uses the maximum or minimum exponent value for a given format.

88.3.3.1.1 Normalized numbers

Normalized numbers include all positive or negative numbers with exponents between the maximum and minimum values. For half-, single- and double-precision normalized numbers, the implied integer bit (the so-called “hidden bit”, see more in the next paragraph) is one and the biased exponent cannot be zero.

In IEEE 754-2008, all normalized numbers are represented in sign-magnitude format as +/- 1.fff...fff * 2^e, where fff...fff is called the significant (or mantissa; it represents the fractional portion of the number), and e is called the exponent. Since all normalized numbers have a “1” as the first bit, it need not be stored in memory, and thus is often called the “hidden bit.” Implementations detect whether a number is normal or denormal by inspecting the exponent value. Denormalized numbers always have a zero exponent, and normalized numbers always have a non-zero exponent.

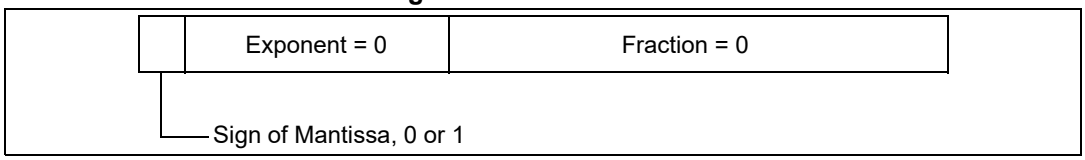


Figure 2385. Normalized Number Format

88.3.3.1.2 Zeros

Zeros can be positive or negative and represent real values, +0.0 and –0.0. See *Figure 2386*. The difference between +0.0 and -0.0 is significant: +0.0 is used to represent values that approach zero from the positive direction, and -0.0 is used to represent values that approach zero from the negative direction.

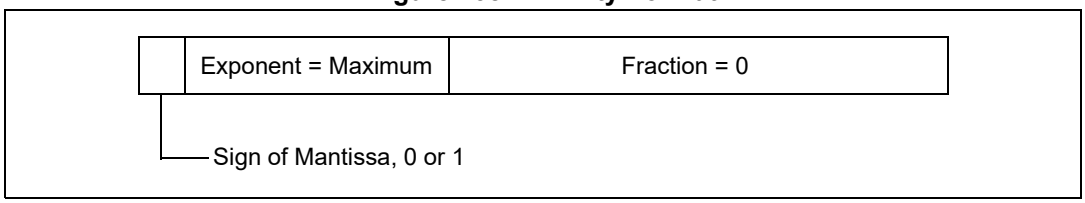

Figure 2386. Zero Format

88.3.3.1.3 Infinities

Infinities can be positive or negative and represent real values that exceed the overflow threshold. A result's exponent greater than or equal to the maximum exponent value indicates an overflow for a given data format and operation. This overflow description ignores the effects of rounding. For half-, single- and double-precision infinities, the fraction is a zero. See *Figure 2387*.

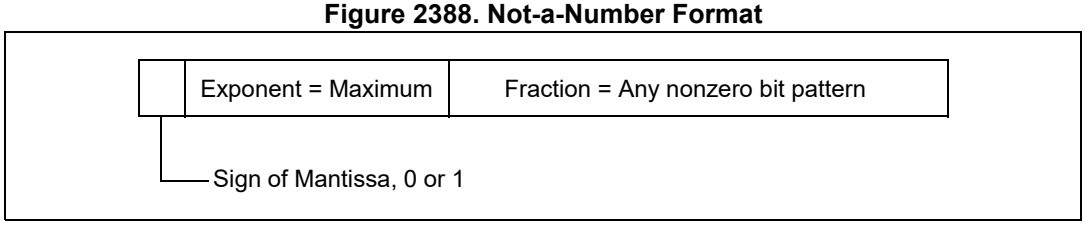

Figure 2387. Infinity Format

88.3.3.1.4 Not-A-Number

NaNs represent the results of operations having no mathematical interpretation, such as infinity divided by infinity. Operations using a NaN operand as an input return a NaN result. User-created NaNs can protect against uninitialized variables and arrays. See *Figure 2388*.

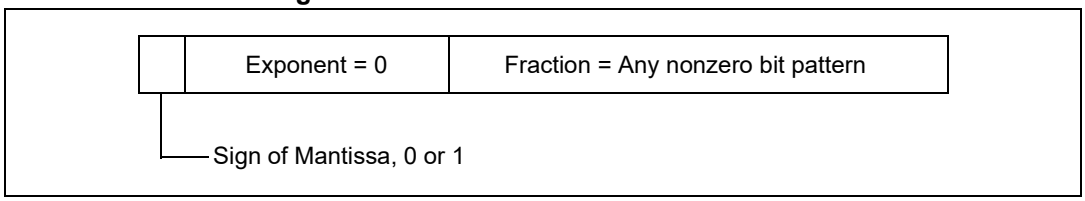
Figure 2388. Not-a-Number Format

The IEEE 754 specification defines quiet and signaling NaNs, based on the state of the most significant bit of the fraction. If set, the NaN is quiet, else it is a signaling NaN.

As the AMU2 performs each algorithm calculation, if one (or more) input operand is a NaN, the logic selects one NaN input and passes it as the result of that computation. Accordingly, if any input operand is a NaN, the result of the ALU calculation is also a NAN.

The IEEE 754 specification also defines a calculation producing an invalid operation should generate a quiet NaN that provides some diagnostic information. Accordingly, the AMU2 produces the following quiet NaN results from these invalid operations:

```
Inf - Inf// ieee32 = 0x7fc0_0001, ieee64 = 0x7ff8_0000_0000_0001
Inf * 0// ieee32 = 0x7fc0_0002, ieee64 = 0x7ff8_0000_0000_0002
0   * Inf// ieee32 = 0x7fc0_0003, ieee64 = 0x7ff8_0000_0000_0003
FMA(0,  Inf,  x)// ieee32 = 0x7fc0_0004, ieee64 = 0x7ff8_0000_0000_0004
FMA(Inf,  0,  x)// ieee32 = 0x7fc0_0005, ieee64 = 0x7ff8_0000_0000_0005
FMA(Inf,  0, -Inf)// ieee32 = 0x7fc0_0006, ieee64 = 0x7ff8_0000_0000_0006
FMA(x,  Inf, -Inf)// ieee32 = 0x7fc0_0006, ieee64 = 0x7ff8_0000_0000_0006
```



The following definition is used when converting an ieee64 NaN into an ieee32 NaN:

```
ieee32[31] = ieee64[63]// copy the sign bit
ieee32[30:23] = 0xff    // exponent = maximum
ieee32[22] = ieee64[51]// copy (signaling, quiet) bit from the ieee64 NaN
ieee32[21:0]  = if (ieee64[50:22] == 0) then ieee64[21:0], else 0x3f_ffff
```

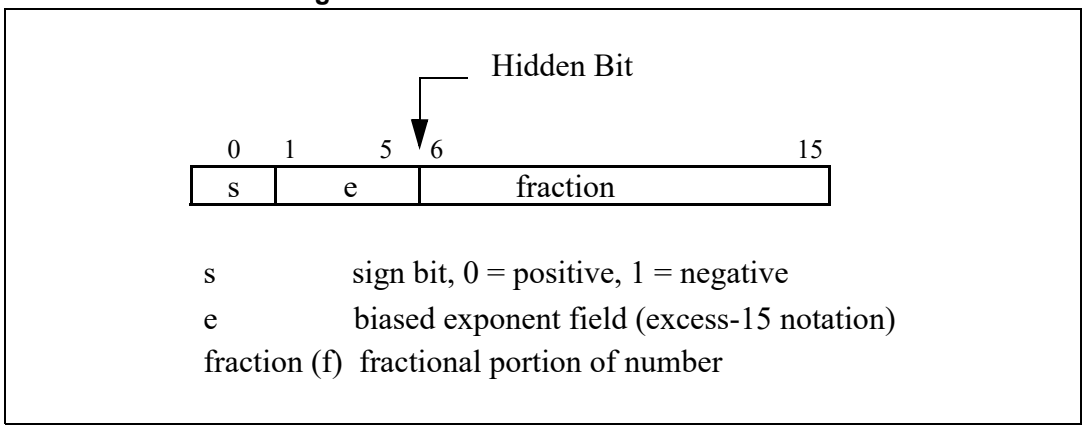
88.3.3.1.5 Denormalized numbers

Denormalized numbers represent real values near the underflow threshold. Denormalized numbers can be positive or negative. For denormalized numbers in half-, single- and double-precision, the implied (hidden) integer bit is a zero and the biased exponent is zero. See *Figure 2389*.

Figure 2389. Denormalized Number Format

Traditionally, the detection of underflow causes floating-point number systems to perform a flush-to-zero. The IEEE 754 standard implements gradual underflow: the result mantissa is shifted right (denormalized) while the result exponent is incremented until reaching the minimum value. If all the mantissa bits of the result are shifted off to the right during this denormalization, the result becomes zero.

In the AMU2, all denormalized numbers are treated as zeros.



88.3.3.1.6 Half-precision floating-point format

Half-precision (16-bit) floating-point storage format is supported by the AMU2 only for the V[*] array with automatic conversion to the 32-bit single-precision floating-point format. No computational operations are defined for half-precision numbers as this format is supported *to minimize the memory storage associated with the V[*] array*. Recall the V array is two dimensional of size [p6 * p7].

Each half-precision floating-point data element is 16 bits wide with one sign bit (s), 5 bits of biased exponent (*e*) and 10 bits of fraction (*f*).

In the IEEE 754-2008 specification, half-precision floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2390. Half-Precision Data Format

For normalized numbers, the biased exponent value ‘e’ lies in the [1 - 30] range corresponding to an actual exponent value E in the [-14 - +15] range, the hidden bit is a ‘1’, and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

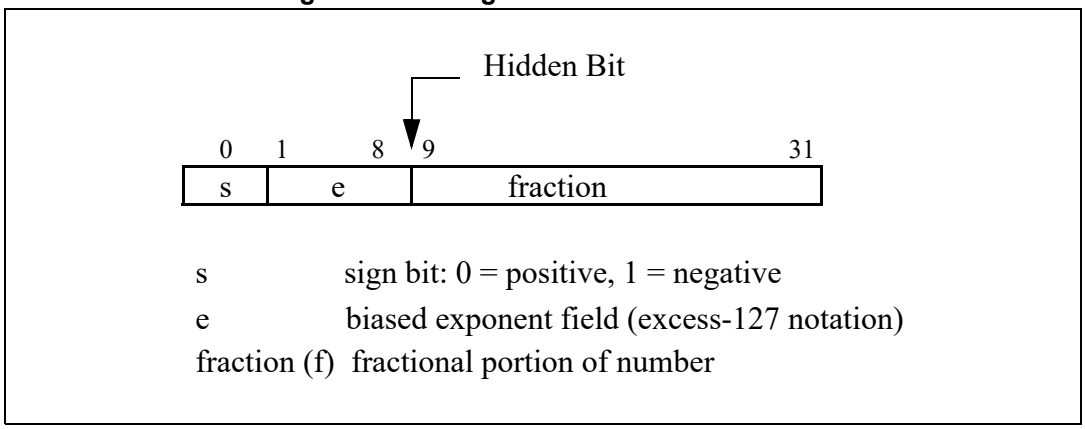
where E is the unbiased exponent and 1.fraction is the significand consisting of a leading ‘1’ (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number ($pmax_{hp}$) is represented by the encoding `0x7bff` which is 65504, and the minimum positive normalized number ($pmin_{hp}$) is represented by the encoding `0x0400` which is approximately 6.1E-5.

Two specific values of the biased exponent are reserved: 0 and 31, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 31 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined to be ‘0’. This number type is not directly supported in hardware and is converted to zero by the AMU2.



Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 31 and a fraction *f* which is non-zero.

88.3.3.1.7 Single-precision floating-point format

Each single-precision floating-point data element is 32 bits wide with one sign bit (s), 8 bits of biased exponent (*e*) and 23 bits of fraction (*f*).

In the IEEE-754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2391. Single-Precision Data Format

For normalized numbers, the biased exponent value ‘e’ lies in the [1 - 254] range corresponding to an actual exponent value E in the [-126 - +127] range, the hidden bit is a ‘1’, and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

where E is the unbiased exponent and 1.fraction is the significand consisting of a leading ‘1’ (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number (*pmax*) is represented by the encoding `0x7f7fffff` which is approximately 3.4E+38, and the minimum positive normalized number (*pmin*) is represented by the encoding `0x00800000` which is approximately 1.2E-38.

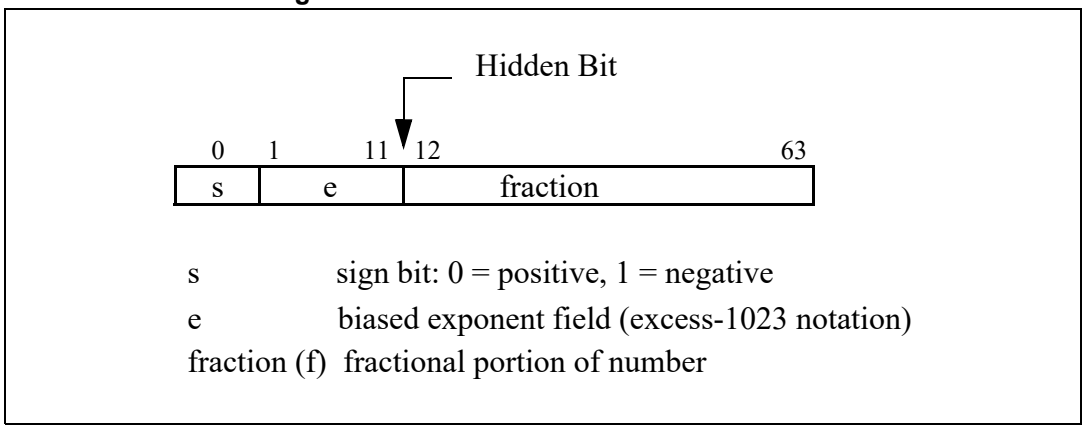
Two specific values of the biased exponent are reserved: 0 and 255, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction *f* which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 255 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined by the IEEE-754 standard to be ‘0’. This number type is not directly supported in hardware and is converted to zero by the AMU2.

Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 255 and a fraction *f* which is non-zero.



Defining *pmax* to be the most positive normalized number (farthest from zero), *pmin* the smallest positive normalized number (closest to zero), *nmax* the most negative normalized number (farthest from zero) and *nmin* the smallest normalized negative number (closest to zero), an overflow is said to have occurred if the numerically correct result (r) of an operation is such that r > *pmax* or r < *nmax*. An underflow is said to have occurred if the numerically correct result of an operation is such that 0 < r < *pmin* or *nmin* < r < 0. In this case, r may be denormalized, or may be smaller than the smallest denormalized number.

88.3.3.1.8 Double-precision floating-point format

Each double-precision floating-point data element is 64 bits wide with one sign bit (s), 11 bits of biased exponent (*e*) and 52 bits of fraction (*f*).

In the IEEE-754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 2392. Double-Precision Data Format

For normalized numbers, the biased exponent value ‘*e*’ lies in the [1 - 2046] range corresponding to an actual exponent value E in the [-1022 - +1023] range, the hidden bit is a ‘1’, and the value of the number is interpreted as:

$$(-1)^{s} \times 2^{E} \times (1.\text{fraction})$$

where E is the unbiased exponent and 1.fraction is the significand consisting of a leading ‘1’ (the hidden bit) and a fractional part (fraction field). With this format, the maximum positive normalized number (*pmax*) is represented by the encoding `0x7feeffff_ffffffff` which is approximately 1.8E+308, and the minimum positive normalized number (*pmin*) is represented by the encoding `0x00100000_00000000` which is approximately 2.2E-308.

Two specific values of the biased exponent are reserved: 0 and 2047, for encoding special values of ±0, ±∞, *NaN and Denorm*.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of zero and a fraction *f* which is zero.

Infinities of both positive and negative sign are represented by a biased exponent value of 2047 and a fraction which is zero.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is non-zero. For these numbers, the hidden bit is defined by the IEEE-754 standard to be ‘0’. This number type is not directly supported in hardware and is converted to zero by the AMU2.

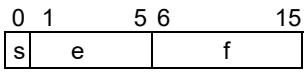
Not a Numbers (*NaNs*) are represented by a biased exponent value *e* of 2047 and a fraction *f* which is non-zero.

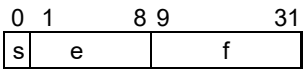
Defining *pmax* to be the most positive normalized value (farthest from zero), *pmin* the smallest positive normalized value (closest to zero), *nmax* the most negative normalized value (farthest from zero) and *nmin* the smallest normalized negative value (closest to zero), an overflow is said to have occurred if the numerically correct result (r) of an operation is such that r > *pmax* or r < *nmax*. An underflow is said to have occurred if the numerically correct result of an operation is such that 0 < r < *pmin* or *nmin* < r < 0. In this case, r may be denormalized, or may be smaller than the smallest denormalized number.

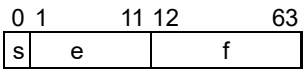
88.3.3.1.9 Floating-point data format summary

Table 2282 summarizes the data type specifications for the three supported floating-point formats.

Table 2282. Floating-point Format Summary







Parameter	Half-Precision	Single-Precision	Double-Precision
Data Format			
Field Size in Bits			
Sign (s)	1	1	1
Biased exponent (e)	5	8	11
Fraction (f)	10	23	52
Total	16	32	64
Interpretation of Sign			
Positive fraction	s = 0	s = 0	s = 0
Negative fraction	s = 1	s = 1	s = 1
Normalized Numbers			
Bias of biased exponent	+15 (0xf)	+127 (0x7F)	+1023 (0x3FF)
Range of biased exponent	0 < e < 31 (0x1F)	0 < e < 255 (0xFF)	0 < e < 2047 (0x7FF)
Range of fraction	Zero or Nonzero	Zero or Nonzero	Zero or Nonzero
Mantissa	1.f	1.f	1.f
Relation to representation of real numbers	$(-1)^s \times 2^{e-15} \times 1.f$	$(-1)^s \times 2^{e-127} \times 1.f$	$(-1)^s \times 2^{e-1023} \times 1.f$
Denormalized Numbers			
Biased exponent format minimum	0 (0x0)	0 (0x00)	0 (0x000)
Bias of biased exponent	+14 (0xE)	+126 (0x7E)	+1022 (0x3FE)

Table 2282. Floating-point Format Summary (continued)

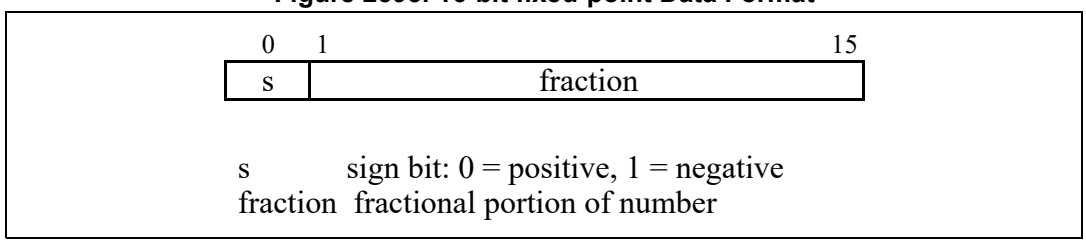
Parameter	Half-Precision	Single-Precision	Double-Precision
Range of fraction	Nonzero	Nonzero	Nonzero
Mantissa	0.f	0.f	0.f
Relation to representation of real numbers	$(-1)^s \times 2^{-14} \times 0.f$	$(-1)^s \times 2^{-126} \times 0.f$	$(-1)^s \times 2^{-1022} \times 0.f$
Signed Zeros			
Biased exponent format minimum	0 (0x0)	0 (0x00)	0 (0x00)
Mantissa	0.f = 0.0	0.f = 0.0	0.f = 0.0
Signed Infinities			
Biased exponent format maximum	31 (0x1F)	255 (0xFF)	2047 (0x7FF)
Mantissa	0.f = 0.0	0.f = 0.0	0.f = 0.0
NaNs			
Sign	0 or 1	0 or 1	0 or 1
Biased exponent format maximum	31 (0x1F)	255 (0xFF)	2047 (0x7FF)
Fraction	Nonzero	Nonzero	Nonzero
Representation of fraction Nonzero bit pattern created by user Fraction when created by AMU2	xxxxx…xxxx N/A	xxxxx…xxxx 10000…0[001-110]	xxxxx…xxxx 1000…0[001-110]

Table 2282. Floating-point Format Summary (continued)

Parameter	Half-Precision	Single-Precision	Double-Precision
Approximate Ranges			
Maximum positive normalized	6.5×10^{4}	3.4×10^{38}	1.8×10^{308}
Minimum positive normalized	6.1×10^{-5}	1.2×10^{-38}	2.2×10^{-308}

88.3.3.1.10 Calculation Precision

The AMU2 implementation uses the IEEE 754 floating-point precisions explicitly defined in *Section 88.3.1: AMU2 algorithm*. Other details include:



- The AMU2 supports the standard IEEE 754 “round-to-nearest, ties-to-even” mode for all rounding operations, including all conversions from double-precision to single-precision. Denormalized numbers are not supported. Denormalized numbers are interpreted as zero. Input NaNs are passed as the result of a computation and certain operations producing an invalid result generate a quiet NaN with a diagnostic value embedded in the fraction. More details on the handling of NaNs is presented in *Section 88.3.3.1.4: Not-A-Number*.
- If an overflow condition is detected, the result is forced to (+/-) Inf value before the ALU is halted.
- The exponential function inputs a 32-bit converted *t* operand and produces an IEEE 32-bit floating-point result. The externally-observable exp(x) precision is 24 bits, ± 1 ULP.

88.3.3.2 16-bit fixed-point with common exponent

The AMU2 also supports a fixed-point format for the V[*] array. This format specifies a signed 16-bit two’s complement fixed-point fraction in the [-1, 1.0) range with a common 7-bit exponent using an excess-63 format. This format provides more bits of fraction precision versus the IEEE 754 half-precision floating-point format at the cost of a reduced dynamic range within the same memory footprint.

In this format, values are represented with two explicit fields (sign field and fraction field) along with a 7-bit common biased exponent field (AMU2_CCR1CH*n*[CMEXP]) applied to all elements in the V[*] array.

Figure 2393. 16-bit fixed-point Data Format

Note that the 7-bit common biased exponent is not shown in *Figure 2393*.

Using the same variables as the floating-point data types, the biased exponent value '*e*' lies in the [0 - 127] range corresponding to an actual exponent value E in the [-63 to +64] range, the hidden bit is a '0', and the value of this 2's complement number is interpreted as:

((-1 x *s*) + 0.*fraction*) x 2^E

where E = CMEXP - 63.

When the V[*] array is specified in this format, the AMU2 automatically converts the number into a single-precision floating-point value before it is used in the stage2 calculation. This transformation is described by the following C language *convert fixed halfword-to-single precision floating-point* function:

```
ieee32 convertFixedPoint(uint07 cmExp, uint16 v16x)
{
    int i, s;

    if (v16x & 0x8000) {
        s = 1;
        v16x = (~v16x + 1) & 0xffff;              // same as v16x = -v16x
    } else
        s = 0;

    if (v16x & 0x8000)
        ieee32Result = 1<<31 | (64+cmExp)<<23;    // minimum value
    else if (v16x == 0)
        ieee32Result = 0x00000000;
    else {
        for (i = 0; i < 16; i++) {
            v16x <<= 1;
            if (v16x & 0x8000)
                break;
        }
        ieee32Result = s<<31 | (63+cmExp-i)<<23 | (v16x & 0x7fff)<<8;
    }

    return ieee32Result;
}
```

88.3.4 Register format and data types

As described in the pseudo-code of *Section 88.3.1: AMU2 algorithm*, the programming model provides address pointers and data values. The register types are defined in *Table 2283* and presented in their order of appearance in the pseudo-code.

Table 2283. Data types in registers

Operand	AMU2 Register	Data Type
u_pointer(1)	UPTRCH*n*	ARAM pointer to ieee32 floating-point data
p1_pointer(1)	P1PTRCH*n*	ARAM pointer to ieee32 floating-point data

Table 2283. Data types in registers (continued)

Operand	AMU2 Register	Data Type
p2_pointer(1)	P2PTRCH*n*	ARAM pointer to ieee32 floating-point data
ut_pointer(1)	Implicit	Special ARAM pointer to ieee32 floating-point data
p9	P9{M,L}CH*n*	ieee64 floating-point data
p8	P8CH*n*	Unsigned int16 data
p7	P7CH*n*	Unsigned non-zero int6 data (if value ==0, then p7 = 32)
p6	P6CH*n*	Unsigned int16 data
v_pointer(2)	VPTRCH*n*	ARAM or system pointer to ieee32 floating-point data, or ieee16 floating-point data, or 16-bit fixed-point data with 7-bit common exponent
L_pointer(1)	LPTRCH*n*	ARAM pointer to ieee32 floating-point data
p3_pointer(2)	P3PTRCH*n*	ARAM or system pointer to ieee32 floating-point data
y64	Y64{M,L}CH*n*	ieee64 floating-point data
y32	Y32CH*n*	ieee32 floating-point data
p5	P5CH*n*	ieee32 floating-point data
p4	P4CH*n*	ieee32 floating-point data
result, z64	RES64{M,L}CH*n*	ieee64 floating-point data
res32, z32	RES32CH*n*	ieee32 floating-point data

1. All pointers reference the AMU local RAM (ARAM), and are limited to 15 bits in size as the RAM is a maximum of 32 KB.
2. For “normal” operations, the v_pointer and p3_pointer are like the other pointers and reference the ARAM and are limited to 15 bits in size. When ADMA data streaming is enabled, these same registers are configured as a 8-byte aligned 32-bit system Flash address.

88.3.5 ALU calculation engine

The ALU calculation engine supports a time-multiplexed hardware computation pipeline supporting 2 execution channels. This structure implements the algorithm detailed in *Section 88.3.1: AMU2 algorithm* including the transcendental function described in *Section 88.3.2: The exp(x) function and implementation*.

88.3.5.1 ALU execution states

The ALU maintains two finite state machines that record the execution state of the stage1 and stage23 calculations and is visible in the AMU2_SEIRCH*n*[S23XS, S1XS] fields. The execution states and their descriptions are detailed in *Table 2284*.

Table 2284. ALU S1, S23 Execution States

State	AMU2_SEIRCH*n*[S{1,23}XS]	Description
Idle or Pending Start	0b00	Idle or pending start. A pending start is created when any of the conditional start bits, AMU2_CCR2CH*n*[WFS1D, WFS23D, WFSS23], are set.
Halted	0b01	Halted after detection of an error condition or arithmetic fault.
Stopped	0b10	Stopped due to an explicit request (AMU2_CCR2CH*n*[S23STP]) or a properly-enabled N crossing event. Note the stage1 execution cannot be stopped via either of these mechanisms and stage23 is stopped after the current iteration of the outer loop. N crossing events also stop at the same point in the algorithm execution.
Running or Stalled	0b11	Actively executing or stalled due to a properly-enabled debug event (AMU2_CCR1CH*n*[DDSL] = 0). The presence of a properly-qualified debug event is reflected in the AMU2_SEIRCH*n*[QDSL] indicator.

Once a state machine enters the halted state, the state needs to be cleared by starting a new calculation, or by explicitly resetting it by a register write with AMU2_CCR2CH*n*[CSXXS] = 1. Likewise, once the status signals a stopped state, it can be resumed by a register write with AMU2_CCR2CH*n*[S23RSM] = 1, cleared by starting a new calculation or explicitly reset by a register write with AMU2_CCR2CH*n*[CSXXS] = 1.

88.3.5.2 ALU speed control

The ALU includes a “speed control” function that can be used to throttle the execution rate of the channel. There are four registers associated with this function: three 3-bit registers defining the starting, maximum and current speed settings plus a threshold count. The 3-bit settings define a fractional operation “speed” as {1/8, 2/8, 3/8,..., 7/8, 8/8} where 8/8 represents the maximum, that is full speed. The registers for this function include:

AMU2_CCR1CH*n*[SRTSP] // start speed

AMU2_CCR1CH*n*[MAXSP] // maximum speed

AMU2_SEIRCH*n*[ACURSP] // ALU current speed

AMU2_P8CH*n*[THRHC] // threshold P8 count

The ALU controls its execution speed by stalling the calculation engine pipeline as defined by the current speed. As the ALU executes, the operation speed is increased by 1/8 from the starting value to the maximum value each time a multiple of the P8 threshold count is reached. As an example, if SRTSP = 1/8 and MAXSP = 8/8 (full speed), then the current speed reflected in the ACURSP field follows the following sequence:

For the 1st THRHC loops of stage 23 calculation, ACURSP = 1/8

For the 2nd THRHC loops of stage 23 calculation, ACURSP = 2/8

For the 3rd THRHC loops of stage 23 calculation, ACURSP = 3/8

For the 4th THRHC loops of stage 23 calculation, ACURSP = 4/8

For the 5th THRHC loops of stage 23 calculation, ACURSP = 5/8

For the 6th THRHC loops of stage 23 calculation, ACURSP = 6/8

For the 7th THRHC loops of stage 23 calculation, ACURSP = 7/8

For the 8th THRHC loops of stage 23 calculation until complete, ACURSP = 8/8

It is software's responsibility to initialize the three controlling registers (SRTSP, MAXSP, THRHC) with appropriate values (SRTSP < MAXSP) else the speed control behavior may be indeterminate.

Note: Recall the pipelined calculation engine hardware is shared by the two channels via a time multiplexing scheme. To make the speed control of the calculation engine manageable, there is a single ALU speed control mechanism implemented, affecting both channels. Note the four registers associated with this function are multiply-mapped into the programming models of both channels, but only a single function is implemented. Accordingly, the global values of the speed control registers are used if one (or both) channels are executing. If both channels are idle and one begins execution, the speed ramps up from SRTSP to MAXSP as described. If the other channel begins execution while the first channel is already executing, the second channel begins its execution at ACURSP. The speed is only returned to the SRTSP value when both channels are idle and one (or both) becomes active.

88.3.6 AMU Direct Memory Access (ADMA)

88.3.6.1 Basic ADMA data transfer capabilities

Each AMU2 channel is equipped with an ADMA channel. This allows optimized block copying of data from Flash and system calibration memories (if applicable) to the local RAM (ARAM).

The programming model associated with each ADMA channel contains five registers: source and destination addresses, transfer count, expected checksum and control & configuration. Since the AMU2 supports the ADMA transfers using a private 64-bit interface to the platform Flash memory controller, all addresses and transfer counts must be 8-byte aligned values.

The control & configuration register (AMU2_DCCRCH*n*) supports the ability to separately update the source or destination address registers, or both, so repeated ADMA transfers can sequence through a Flash data structure while keeping the local ARAM structure constant. See the AMU2_DCCRCH*n*[SARU, DARU] fields. The DARU register field supports the ability to transfer the last 64 bits fetched from the Flash source memory location to the two AMU Control & Configuration Registers (AMU2_CCR{1,2}CH*n*). This provides the ADMA with the ability to load a new vector data set from Flash, followed by writes to initiate a calculation. This special "last write to CCR{1,2}" mode is enabled when AMU2_DCCRCH*n*[DARU] = 0b01.

88.3.6.2 ADMA execution states

The ADMA maintains a finite state machine that records its current operating condition and is visible in the AMU2_SEIRCH*n*[ADMAS] field. These execution states and their descriptions are detailed in *Table 2285*.

Table 2285. ADMA Execution States

State	AMU2_SEIRCH*n* [ADMAS]	Description
Idle or Pending Start	0b00	Idle or pending start. A pending start is created when any of the conditional start bits, AMU2_DCCRCH*n*[WFS1D, WFS23D, WFDNI], are set.
Halted	0b01	Halted after detection of an error condition, such as a bus error, illegal address, multi-bit ECC event.

Table 2285. ADMA Execution States (continued)

State	AMU2_SEIRCH*n* [ADMAS]	Description
Stopped	0b10	Stopped due to an explicit request (AMU2_DCCRCH*n*[STP]) or an implicit request caused by an ALU stop condition enabled by AMU2_DCCRCH*n*[DSAS] = 1.
Running or Stalled	0b11	Actively executing the data transfer or stalled due to a properly-enabled debug event (AMU2_CCR1CH*n*[DDSL] = 0). The presence of a properly-qualified debug event is reflected in the AMU2_SEIRCH*n*[QDSL] indicator.

Once a state machine enters the halted state, the state needs to be cleared by starting a new data transfer or by explicitly resetting it by a register write with AMU2_DCCRCH*n*[CADS] = 1. Likewise, once the status signals a stopped state, it can be resumed by a register write with AMU2_DCCRCH*n*[RSM] = 1, cleared by starting a new data transfer or explicitly reset by a register write with AMU2_DCCRCH*n*[CADS] = 1.

88.3.6.3 Cyclic redundancy checking

The ADMA optionally supports a standard CRC checksum on transfers into the ARAM. If enabled (AMU2_DCCRCH*n*[ECRC] = 1), the checksum is calculated by the ADMA on each data transfer and accumulated. When the data transfers are complete, the final actual CRC value is compared against the expected checksum value contained in the AMU2_DCKSCH*n* register. If the checksums are identical, the AMU operation continues. However, if the checksums are not equal, a data transmission error has occurred and is signaled by AMU2_SEIRCH*n*[CKSERR] = 1. In the case of an enabled CRC checksum error, any ALU calculation which depends on the completion of the ADMA transfer (as defined by AMU2_CCR2CH*n*[WFDS1] == 1 or AMU2_CCR2CH*n*[WFDS23] == 1) is aborted and the corresponding AMU2_CCR2CH*n*[WFDS1, WFDS23] indicators cleared.

The ADMA supports the standard “Ethernet” CRC32 polynomial, which is defined as:

$$CRC32 = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + x^{0}$$

The checksum calculation initializes the CRC to 0xFFFF_FFFF, and processes the fetched data beginning with the most significant bit of the most significant byte. The C code in *Figure 2394* mirrors the ADMA’s hardware implementation. It uses a 256-entry table lookup function (containing unique 32-bit words based on the combined CRC state and a data byte) and is based on the algorithm detailed in “Byte-wise CRC Calculations”, Aram Perez, IEEE Micro June 1983. The `gen_crc_table()` function is executed once to populate the `crc_table[]` array; the `update_crc()` function is called for each CRC to be calculated.

Figure 2394. ADMA CRC32 C Language Function

```
#define POLYNOMIAL 0x04c11db7L
static unsigned long crc_table[256];
void gen_crc_table()
{
    /* generate the table of CRC remainders for all possible bytes */
    register int i, j;
    register unsigned long crc_accum;

    for (i = 0; i < 256; i++) {
        crc_accum = ((unsigned long) i << 24);
        for (j = 0; j < 8; j++) {
            if (crc_accum & 0x80000000L)
                crc_accum = (crc_accum << 1) ^ POLYNOMIAL;
            else
                crc_accum = (crc_accum << 1);
        }
        crc_table[i] = crc_accum;
    }
}

unsigned long update_crc(unsigned long crc_accum,
                         char *data_blk_ptr,
                         int data_blk_size)
{
    /* update the CRC on the data block one byte at a time */
    register int i, j;

    for (j = 0; j < data_blk_size; j++) {
        i = ((int)(crc_accum >> 24) ^ *data_blk_ptr++) & 0xff;
        crc_accum = (crc_accum << 8) ^ crc_table[i];
    }
    return crc_accum;
}
```

The actual checksum value calculated by the ADMA is available in the AMU2_ACKSCH*n* register or the aliased AMU2_AACKSCH*n*.

88.3.6.4 ADMA V and P3 Data Streaming Modes

Recall the V[*] and P3[*] input data vectors have larger array dimensions compared to all the other input data vectors. Accordingly, the ADMA supports a special type of data streaming for these 2 input vectors. At any point in time, the ADMA supports *either* normal data transfers *or* the special streaming modes.

Specifically, *it is not necessary to pre-load the contents* of V[*] or P3[*], or both, into the ARAM before initiating the ALU's stage23 calculation if one of the special data streaming modes is enabled. When enabled by AMU2_DCCRCH*n*[STMP3, STMV{32,16}], the ADMA

manages the streamed input vector(s) using the circular data FIFO(s) implemented in the ARAM. The ADMA prefetches the streamed data and writes it into the FIFOs and the FIFO contents are read based of the ALU's stage23 calculation speed.

The V[*] *and* P3[*] input data vectors can be streamed at the same time, if both AMU2_DCCRCH*n*[STMP3, STMV{32,16}] are [1, != 00]. Typically, the execution time of the ALU calculation engine increases when streaming P3 or V, or both, due to Flash arbitration delays as the AMU streaming traffic may be stalled due to requests from other bus masters.

When operating in the data streaming mode, certain register fields associated with a normal ADMA transfer are ignored, or are interpreted in a special manner. See *Table 2286*.

Table 2286. ADMA Register Definitions when V or P3 Data Streaming is Enabled

Register/Field	Used when Data Streaming	Description when Data Streaming
AMU2_P3PTRCH*n*	Yes	if AMU2_DCCRCH*n*[STMP3] = 1, this register defines the 32-bit system address for the P3[*] input data vector.
AMU2_VPTRCH*n*	Yes	if AMU2_DCCRCH*n*[STMV{32,16}] != 00, this register defines the 32-bit system address for the V[*] input data vector.
AMU2_DSACH*n*	No	The normal ADMA source address register is *not* used when data streaming is enabled; the AMU2_{P3,V}PTRCH*n* registers are used instead.
AMU2_DDACH*n*	No	The normal ADMA destination address register is *not* used when data streaming is enabled. The ADMA uses a reserved space within the ARAM to implement circular data FIFOs (256 bytes for V[*], 128 bytes for P3[*]). The offset ARAM addresses of interest are: 0x0_7C00 - 0x0_7CFF Channel 0 V[*] FIFO 0x0_7D00 - 0x0_7DFF Channel 1 V[*] FIFO 0x0_7E00 - 0x0_7E7F Channel 0 P3[*] FIFO 0x0_7E80 - 0x0_7EFF Channel 1 P3[*] FIFO
AMU2_DCNTCH*n*	No	The ADMA's fetching of V[*] or P3[*] data, or both, is paced by the ALU's stage23 calculation speed. Due to the execution pipeline structure, there may be speculative data fetches that are not actually used in the calculation.
AMU2_DCKSCH*n*	No	Due to the speculative, ALU-paced data transfers, CRC checking is not supported while data streaming. Note the data fetches from system Flash are still protected by the standard single-error correction, double-error detection ECC. A multi-bit non-correctable ECC event during a streaming operation causes the AMU2_SEIRCH*n*[ADMERR] bit to be set and the ADMA to be halted. The ALU calculation then stalls due to the lack of input data.
AMU2_DCCRCH*n*[SRTSP], AMU2_DCCRCH*n*[MAXSP]	No	Since the ADMA transfers are ALU-paced when data streaming, the normal "speed control" function is ignored.
AMU2_DCCRCH*n*[ADICFG]	No	Since the ADMA transfers are ALU-paced when data streaming, the normal interrupt configurations are ignored.
AMU2_DCCRCH*n*[SARU], AMU2_DCCRCH*n*[DARU]	No	Since the ADMA transfers use different source and destination addresses when data streaming, these fields are ignored.

Table 2286. ADMA Register Definitions when V or P3 Data Streaming is Enabled (continued)

Register/Field	Used when Data Streaming	Description when Data Streaming
AMU2_DCCRCH*n*[HCRCE], AMU2_DCCRCH*n*[ECRC]	No	Due to the speculative, ALU-paced data transfers, CRC checking is not supported while data streaming.
AMU2_DCCRCH*n*[STMP3]	Yes	When asserted in conjunction with AMU2_DCCRCH*n*[SRT] = 1, this bit enables the P3[*] data streaming mode.
AMU2_DCCRCH*n*[STMV{32,16}]	Yes	When asserted in conjunction with AMU2_DCCRCH*n*[SRT] = 1, this bit enables the V[*] data streaming mode.
AMU2_DCCRCH*n*[DSAS]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, stopping the ALU also stops the ADMA.
AMU2_DCCRCH*n*[STP]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, stopping the ALU also stops the ADMA, given AMU2_DDCRCH*n*[DSAS] = 1.
AMU2_DCCRCH*n*[WFS23], AMU2_DCCRCH*n*[WFS1]	No	Since the ADMA data transfers are paced by the ALU stage23 execution speed, these bits are ignored when data streaming is enabled.
AMU2_DCCRCH*n*[RSM]	No	This bit is ignored when data streaming is enabled. Since the ADMA data transfers are ALU-paced, resuming the ALU also resumes the ADMA.
AMU2_DCCRCH*n*[SRT]	Yes	The simultaneous assertion of SRT = 1 and (STMV{32,16} != 00 or STMP3 = 1) initiates an ADMA transfer with data streaming enabled.

88.3.6.5 ADMA speed control

The ADMA includes a “speed control” function that can be used to throttle its access rate. There are four register fields associated with this function: three 3-bit registers defining the starting, maximum and current speed settings plus a threshold count. The 3-bit settings define a fractional operation “speed” as {1/8, 2/8, 3/8,..., 7/8, 8/8} where 8/8 represents the maximum, that is full speed. The registers for this function include:

AMU2_DCCRCH*n*[SRTSP] // start speed

AMU2_DCCRCH*n*[MAXSP] // maximum speed

AMU2_SEIRCH*n*[DCURSP] // ADMA current speed

AMU2_DCNTCH*n*[THRHC] // threshold byte count (32-byte aligned)

The ADMA controls the transfer speed by inserting idle states between the receipt of data and the initiation of the next Flash read. As the ADMA fetches data, the operation speed is increased by 1/8 from the starting value to the maximum value each time a multiple of the byte threshold count is reached. As an example, if SRTSP = 1/8 and MAXSP = 8/8 (full

speed), then the current speed reflected in the DCURSP field follows the following sequence:

For the 1st THRHC bytes, DCURSP = 1/8

For the 2nd THRHC bytes, DCURSP = 2/8

For the 3rd THRHC bytes, DCURSP = 3/8

For the 4th THRHC bytes, DCURSP = 4/8

For the 5th THRHC bytes, DCURSP = 5/8

For the 6th THRHC bytes, DCURSP = 6/8

For the 7th THRHC bytes, DCURSP = 7/8

For the 8th THRHC bytes until the transfer is complete, DCURSP = 8/8

It is software's responsibility to initialize the three controlling registers (SRTSP, MAXSP, THRHC) with appropriate values (SRTSP < MAXSP) else the speed control behavior may be indeterminate.

Note: Recall the ADMA hardware is shared by the two channels via a time multiplexing scheme. To make the speed control of the ADMA manageable, there is a single ADMA speed control mechanism implemented, affecting both channels. Note the four registers associated with this function are multiply-mapped into the programming models of both channels, but only a single function is implemented. Accordingly, the global values of the speed control registers are used if one (or both) channels are executing. The speed is only returned to the starting value when both channels are idle and one (or both) becomes active.

88.4 Use case examples

This section presents overviews of multiple use cases describing different scenarios for data loading, ALU calculation and post-processing of the result. This is *not* intended to provide a complete list, but rather examples of the types of configurations supported by the AMU2.

In general, there are three distinct phases associated with an AMU2 calculation: data loading, the ALU calculation and result retrieval & post-processing. The data loading can be performed by any processing element, such as a processor core, the system DMA or the ADMA, or both. The actual algorithm execution is always performed by the AMU2's ALU calculation engine. The retrieval of results and status can be performed by a processor core or the system DMA, while the post-processing is typically handled by a processor core. Recall, the AMU2's programming model is specifically organized in a manner that promotes the use of a DMA, either the system DMA or the ADMA, to handle the data loading operations.

In general, the relative data load speeds among the possible masters are:

CPU < SDMA < ADMA

that is, the CPU is the slowest, the system DMA is faster and the ADMA is the fastest. Additionally, for certain scenarios, the ADMA's data transfers can be overlapped with the ALU calculation to further reduce the execution times for multiple algorithm evaluations.

Consider the following use case examples presented in order of increasing complexity.

88.4.1 Single calculation using a CPU as the master device

For this scenario, a processor core performs *all the required data loading*, moving the coefficients and parameters from system Flash into the ARAM and then initializing all the

corresponding pointer and parameter registers. Once the data load and register initialization are completed, the calculation is started by writing the AMU2_CCR{1,2}CH*n* registers. In this case, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the AMU2_CCR2CH*n*[S1SRT, S23SRT] bits are set.

The AMU2 performs the calculation and then typically generates an interrupt, signaling successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a “1” to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

The preceding description assumes the processor is interrupted when the AMU2 completes as this would be the typical scenario. The AMU2 also provides a channel busy flag (AMU2_SEIRCH*n*[CHBSY]) that the processor can poll to determine whether the calculation is finished.

88.4.2 Single calculation using SDMA for data load, CPU for post-processing

In this example, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA can perform the data load into the ARAM plus the initialization of the pointer and parameter registers.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move “links” to the second channel performing the register loads. In any case, the second data transfer loads the programming model using an 80-byte block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation.

It should be noted the programming model of the AMU2 is organized such that an optimized 80-byte burst transfer (5 x 8-byte 8-beat bursts) can be used to load the registers. The optimized block transfer does not include the AMU2_NCH*n* register for two reasons:

1. The use of the N crossing functionality is a debug feature and not intended for normal system operation;
2. The inclusion of the AMU2_NCH*n* functionality must be properly enabled by setting AMU2_CCR2CH*n*[ENCRS] = 1. Stated differently, the AMU2_NCH*n* functionality is completely disabled if AMU2_CCR2CH*n*[ENCRS] = 0. In the optimized block transfer, the AMU2_NCH*n* register does not need to be initialized, and AMU2_CCR2CH*n* register (with ENCRS = 0) is always the last register written.

Note, the AMU2_NCH*n* register can be included in the sequential data transfer for the register writes by increasing the total number of bytes to be transferred to 84 and using 32-bit writes.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the AMU2_CCR2CH*n*[S1SRT, S23SRT] bits are set by the SDMA's last transfer.

The channel performs the calculation and generates an interrupt, signaling a successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a "1" to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

88.4.3 Single calculation using SDMA + ADMA for data load, CPU for post-processing

For this case, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA and the ADMA collectively can perform the data load into the ARAM plus the initialization of the pointer and parameter registers.

In this example, let the ADMA move the U[*] vector into the ARAM and the SDMA move all the rest of the data.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move "links" to the second channel performing the register load. The second data transfer loads the programming model using an 80-byte (5 x 16 byte 4-beat bursts) block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation. In this example, the programming model initialization configures the ADMA to move the U[*] vector into the ARAM and the AMU2_CCR2CH*n*[WFDS1, WFDS23] conditional start bits are set (and [S1SRT, S23SRT] cleared) to signal the start of the calculation engine is dependent on the completion of the ADMA.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation actually begins when the ADMA completes the data transfer of the U[*] vector into the ARAM.

The channel performs the calculation and generates an interrupt, signaling a successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a "1" to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

88.4.4 Single calculation using SDMA for partial data load, streaming ADMA for V[*], CPU for post-processing

For this case, it is assumed the processor has created the appropriate data structure in system Flash memory so that the System DMA can perform the partial data load into the ARAM plus the initialization of the pointer and parameter registers.

In this example, let the ADMA use the special data streaming mode to fetch the V[*] array into the ARAM with the SDMA moving all the rest of the data including the programming model register initialization.

The SDMA would typically require two separate TCDs (Transfer Control Descriptors): one to perform the data move from system Flash into the ARAM, and a second to load the programming model registers. The SDMA can use the scatter/gather feature to process the two TCDs in a single channel, or 2 channels can be used where the first channel performing the data move “links” to the second channel performing the register load. In any case, the second data transfer loads the programming model using an 80-byte (5 x 16 byte 4-beat bursts) block transfer. Using CH0 as an example, this block data transfer writes from the AMU2_P1PTRCH*n* register (offset address 0x1_0010) to the AMU2_CCR2CH*n* registers (offset address 0x1_005c) before beginning the actual calculation. In this scenario, the programming model initialization configures the ADMA to stream the V[*] array into the ARAM by setting both AMU2_DCCRCH*n*[STMV{32,16}, SRT] and the AMU2_CCR2CH*n*[S1SRT, S23SRT] indicators set to signal the start of the calculation engine for this special data streaming mode.

As before, the AMU completion and error indicators are configured to generate interrupts to the processor; the calculation is paced by the availability of V[*] input data being managed by the ADMA.

The channel performs the calculation and generates an interrupt, signaling successful completion or some type of error termination or an N crossing debug event.

As the processor handles the interrupt, the 64-bit double precision result (AMU2_RES64{M,L}CH*n*) is retrieved along with the status flags in the AMU2_SEIRCH*n* register. After processing the interrupt, the service routine clears the interrupt source by writing a “1” to clear the appropriate flag in the low-order byte of the AMU2_SEIRCH*n* register. The processor then performs any required analysis of the status indicators before saving the result.

As detailed in *Section 88.3.6.4: ADMA V and P3 Data Streaming Modes*, the AMU2 supports streaming of V or P3, or both, concurrently. Additionally, neither the checksum nor the ADMA speed control is supported in this mode. Additionally for this case, the AMU2_VPTRCH*n* register must be reloaded before the next calculation.

88.4.5 Multiple calculations using ADMA for partial data load, SDMA for result retrieval

For this example, let a processor or system DMA perform the *initial* data and programming model register load, and configuring the AMU2 for the first calculation. Next, configure the ADMA to perform repeated loads of the second, third, fourth, … last U[*] vectors and the SDMA to retrieve results as each calculation is finished.

For this scenario, the ADMA would load a data structure from Flash (or a calibration remapped destination memories, or both) having the U[*] vectors and the values for the AMU2_CCR{1,2}CH*n* registers. The configuration sequences through the Flash data

structure and loads each U[*] vector into the same ARAM locations for all calculations. Consider the following sequence of events:

1. A processor or system DMA loads the initial data set and initializes the programming model registers. The initial register load sets AMU2_DCCRCH*n*[WFDNI] to delay the fetching of the next (2nd) U[*] until the first calculation is complete. Additionally, the ADMA is configured to load the next U[*] input vector and the AMU2_CCR{1,2}CH*n* registers by setting AMU2_DCCRCH*n*[SARU, DARU] = [0b10, 0b01]. Finally, as part of the initial register writes, AMU2_CCR1CH*n*[DNICFG] = 0b10 to generate a SDMA request after the ALU calculation completes, and AMU2_CCR2CH*n*[S1SRT, S23SRT] = 1,1 to start the first calculation.
2. As the first complete calculation finishes, the assertion of AMU2_SEIRCH*n*[DNIRQ] is configured to assert an SDMA request and initiate the ADMA to fetch the next U[*] vector from Flash and writing it into the same ARAM locations. Since AMU2_DCCRCH*n*[DARU] = 0b01, the last 64 bits of fetch data are written into the AMU2_CCR{1,2}CH*n* registers. The write sets AMU2_CCR2CH*n*[WFDS1, WFSS23] = 1,1 to conditionally start the second calculation when the ADMA completes the new U[*] fetch. The ADMA fetch also needs to set AMU2_CCR2CH*n*[ADCCR25] = AMU2_DCCRCH*n*[WFDNI] = 1 on all data sets *except* the final iteration. The SDMA responds by copying the AMU2_RES64{M,L}CH*n* and AMU2_SEIRCH*n* registers into system RAM; the AMU2_SEIRCH*n*[DNIRQ] indicator is cleared by the SDMA acknowledge.
3. The process continues with the ALU performing the calculation, the ADMA fetching a new U[*] vector, and the SDMA copying the 64-bit result and status into system RAM until the last U[*] vector is fetched from Flash. The final value loaded into AMU2_CCR1CH*n*[DNICFG] = 0b01 to generate a processor interrupt request when the final calculation completes.

88.5 Operation details

88.5.1 Details on operation completion status indicators

Recall the AMU2_SEIRCH*n* register provides a sizable number of status flags. See *Section 88.2.3.25: AMU Status, Error & Interrupt Channel n Register (AMU2_SEIRCHn)* for the details. This section provides information on the detailed bit status based on a number of expected operation completion states. For ADMA completion state information, see *Table 2287*, while *Table 2288* contains the ALU completion state details.

Table 2287. ADMA Completion State Details in AMU2_SEIRCH*n*

ADMA Completion State	ADMAS	ADMERR	CKSERR	DEIRQ	ADIRQ
Completed error-free	00	0	0	0	1
Error (Bus error, non-correctable ECC event)	01	1	0	1	0
Checksum error with AMU2_DCCRCHn[HCRCE] = 0	00	0	1	0	1
Checksum error with AMU2_DCCRCHn[HCRCE] = 1	01	0	1	1	0

Table 2288. ALU Completion State Details in AMU2_SEIRCH*n*

ALU Completion State	S23XS	S1XS	YCAFLT	ZCAFLT	S23AFLT	S1AFLT	IDVERR	ECCERR	RGCERR	ERIRQ	OVIRQ	NCIRQ	DNIRQ
S1 error-free completion	00	00	0	0	0	0	0	0	0	0	0	0	1(1)
S1 input data validation error	00	01	0	0	0	0	1	0	0	1	0	0	0
S1 ECC error	00	01	0	0	0	0	0	1	0	1	0	0	0
S1 register conflict error	00	01	0	0	0	0	0	0	1	1	0	0	0
S1 overflow	00	01	0	0	0	1	0	0	0	0	1	0	0
S1 underflow	00	00	0	0	0	1	0	0	0	0	0	0	1(1)
S23 error-free completion	00	00	0	0	0	0	0	0	0	0	0	0	1
S23 N crossing	10	00	0	0	0	0	0	0	0	0	0	1	0
S23 input data validation error	01	00	0	0	0	0	1	0	0	1	0	0	0
S23 ECC error	01	00	0	0	0	0	0	1	0	1	0	0	0
S23 register conflict error	01	00	0	0	0	0	0	0	1	1	0	0	0
S23 overflow	01	00	0	0	1	0	0	0	0	0	1	0	0
S23 underflow	00	00	0	0	1	0	0	0	0	0	0	0	1
Final Y32 overflow	01	00	1	0	0	0	0	0	0	0	1	0	0
Final Y32 underflow	00	00	1	0	0	0	0	0	0	0	0	0	1
Z32 overflow	01	00	0	1	0	0	0	0	0	0	1	0	0
Z32 underflow	00	00	0	1	0	0	0	0	0	0	0	0	1

1. For these completion states, if there is a pending Stage23 calculation, the AMU2_SEIRCH*n*[DNIRQ] indicator does *not* set until and unless that calculation completes error-free or with any underflow.

88.5.2 Details on operation stop/resume

The AMU2 supports the ability to temporarily stop an operation and later resume execution. Consider the following examples of the required operations to support this stop/resume control.

88.5.2.1 Stop ALU calculation, check progress, then resume

For this basic stop/resume sequence, the following steps are needed:

1. Set AMU2_CCR2CH*n*[S23STP] = 1.
2. Wait for AMU2_CCR2CH*n*[S23STP] to (auto)clear, indicating the stop request has been processed and the ALU has entered the stopped state. The ALU's stopped state is signaled by AMU2_SEIRCH*n*[S23XS] = 2 (stopped).
3. Check calculation progress as needed.
4. Resume the calculation by setting AMU2_CCR2CH*n*[S23RSM] = 1. As the ALU continues the calculation, AMU2_SEIRCH*n*[S23XS] = 11 (running).

This sequence can be used whether P3[*] or V[*], or both, streaming is enabled or not. If data streaming is enabled, the stopping of the ALU automatically causes the ADMA to stop fetching data since the data transfers are paced by the ALU execution.

If a stop request is made during the final iteration of the stage2 outer loop, the AMU honors the request and stops prior to executing stage3.

88.5.2.2 Stop ALU calculation, perform a new calculation, then restore and resume the original calculation

For this stop/resume sequence, the following steps are needed:

1. Set AMU2_CCR2CH*n*[S23STP] = 1.
2. Wait for AMU2_CCR2CH*n*[S23STP] to (auto)clear, indicating the stop request has been processed and the ALU has entered the stopped state. The ALU's stopped state is signaled by AMU2_SEIRCH*n*[S23XS] = 2 (stopped).
3. Temporarily save the contents of the required programming model. This includes the AMU2_{P3PTR, P4, P5, P6, P7, P8, VPTR, LPTR, CCR{1,2}, Y64, RES32} registers as well as the CH*n* UT[*] in the ARAM data FIFO.
4. Load the new data set, execute the calculation, store the results as required.
5. Restore the saved data contents from Step 3, including restoring the saved Y64 to P9 and RES32 to P5 (see Note below).
6. Continue the calculation by setting AMU2_CCR2CH*n*[S23SRT] = 1. As the ALU continues the calculation, AMU2_SEIRCH*n*[S23XS] = 11 (running).

Again, this sequence can be used whether P3[*] or V[*], or both, streaming is enabled or not. This sequence assumes the two calculations *do not corrupt each other's input data in ARAM*, otherwise software must save/restore the ARAM contents as required.

Note: In the case where the interrupted calculation is configured to initialize Z to P5 as indicated by AMU2_CCR1CHn[SETZ] = 1, then P5 is restored to the original P5 value. Otherwise, P5 is restored to the saved RES32 value. Note that in the latter case, the double precision RES64 value is lost when resuming the interrupted calculation as only the single-precision RES32 can be saved and restored using P5.

88.5.3 AMU2 Performance

The execution time for the M=p7=10, N=p6=500 test case is 10,084 cycles with all the operands pre-loaded into the ARAM. At 200 MHz, this corresponds to an execution time of 50.42 microseconds. This time applies for both a single or two simultaneous channel execution.

The AMU2 execution time, when all operands are pre-loaded into the ARAM, can be approximated by the equation:

Estimated AMU2 Execution Time [cycles] ~= 66 + 2*M + 2*M*(N + (N & 1))

where the constant represents the summation of the time associated with the stage1 and stage2 startup including the initial data FIFO loading and filling the execution pipeline plus the stage3 execution, the second term represents the stage1 time, and the third term represents the stage2 time. The stage1 and stage2 times include the “2*” multiplier since these operations are time-multiplexed across the two ALU channels.

See *Table 2289* for a few estimated and measured execution times with varying M and N values.

Table 2289. AMU2 Execution Times, all data pre-loaded into ARAM

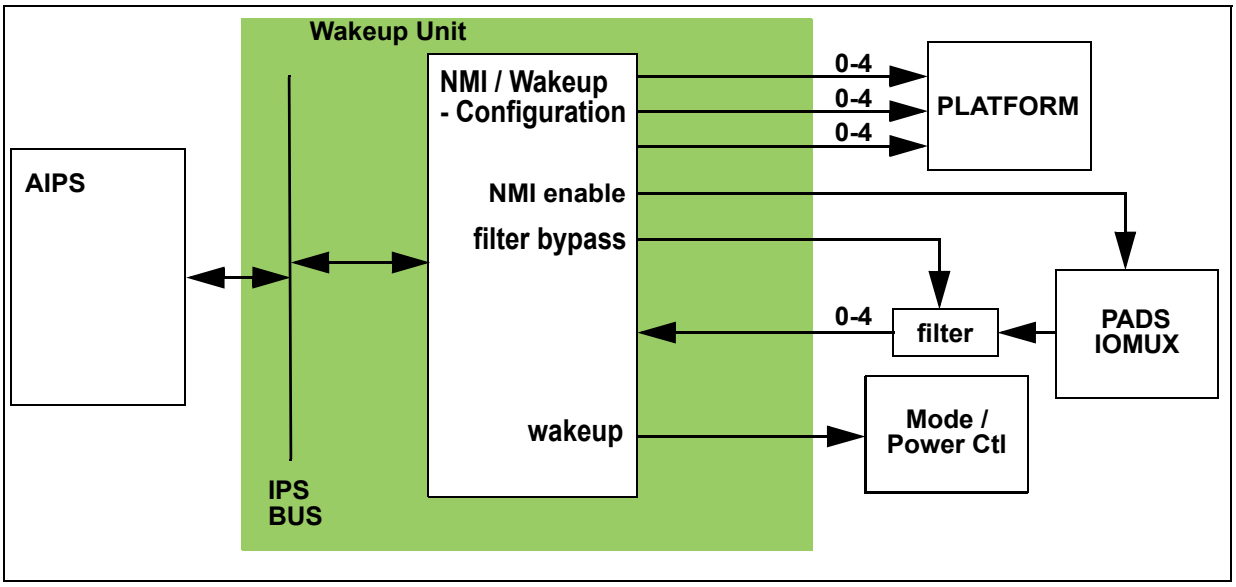
M (p7)	N (p6)	Estimated Execution Time [cycles]	Measured Execution Time [cycles]	Measured Execution Time [usec @ 200 MHz]
10	500	10086	10084	50.42
10	250	5086	5084	25.42
5	500	5076	5076	25.38
5	250	2576	2576	12.88
5	249	2576	2576	12.88
5	248	2556	2556	12.78
5	247	2556	2556	12.78
5	246	2536	2536	12.68

For a 200 MHz operating speed, the Flash access time set to the normal value (RWSC=6) and an otherwise idle Flash, if both P3[*] *and V[*] are streamed by the ADMA* with all the *other* input data already loaded in the ARAM, the incremental execution time is estimated at 1000 cycles producing a total execution time of 11,084 cycles.

Table 2290. Single Channel AMU2 Performance for M=p7=10, N=p6=500

Input Operand Mode	Execution Cycles	Execution Time @ 200 MHz
All pre-loaded into ARAM	10084	50.42 usec
ADMA load of new P3[*] + V32[*][*], all else pre-loaded into ARAM	16959	84.80 usec
ADMA load of new P3[*] + V16[*][*], all else pre-loaded into ARAM	13834	69.17 usec
Stream V32[*][*], all else pre-loaded into ARAM	10086	50.43 usec
Stream V16[*][*], all else pre-loaded into ARAM	10086	50.43 usec
Stream P3[*] + V32[*][*], all else pre-loaded into ARAM	11524	57.62 usec
Stream P3[*] + V16[*][*], all else pre-loaded into ARAM	10090	50.45 usec

89 Wakeup unit (WKPU)



89.1 Introduction

89.1.1 Overview

The Wakeup unit supports up to 3 external sources that can cause non-maskable interrupt requests or wakeup events. In addition, it combines its wakeup events to supply a single wakeup to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 2395* is a block diagram of the Wakeup unit and its interfaces to other system components.

Note: For the chip-specific implementation details of this module refer to the Device Configuration chapter.

Figure 2395. Wakeup unit block diagram

89.1.2 Features

The Wakeup unit supports these distinctive features:

- Non-maskable interrupt support with:
  - Up to 4 NMI sources
  - Up to 4 analog glitch filters
  - Independent CPU exceptions destination: non-maskable interrupt, critical interrupt, or machine check request
  - Edge detection
  - Configurable system wakeup triggering from all NMI sources

Note: For the chip-specific feature details of this module refer to the Device Configuration chapter.

89.2 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

89.2.1 Memory map

Table 2291 gives an overview on the WKPU registers implemented.

Table 2291. WKPU memory map

Address offset	Registers	Supported access sizes	Location
0x0000	NMI Status Flag Register (NSR)	32/16/8	*Section 89.2.2.1*
0x0004–0x0007	Reserved		
0x0008	NMI Configuration Register (NCR)	32/16/8	*Section 89.2.2.2*
0x000C–0x3FFF	Reserved		

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

89.2.2 Register descriptions

This section describes in address order all the Wakeup unit registers.

89.2.2.1 NMI Status Flag Register (NSR)

This register holds the non-maskable interrupt status flags.

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NIF0	NOVF0	0	0	0	0	0	0	NIF1	NOVF1	0	0	0	0	0	0	NIF2	NOVF2	0	0	0	0	0	0	RIF	ROVF	0	0	0	0	0	0
W	w1c	w1c							w1c	w1c							w1c	w1c							w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2396. NMI Status Flag Register (NSR)

Table 2292. NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE0 and NFEE0 has occurred. 0 No event has occurred on the pad.
1 NOVF0	NMI Overrun Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 1 An overrun has occurred on NMI input 0. 0 No overrun has occurred on NMI input 0.
8 NIF1	NMI Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE1 and NFEE1 has occurred. 0 No event has occurred on the pad.
9 NOVF1	NMI Overrun Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 1 An overrun has occurred on NMI input 1. 0 No overrun has occurred on NMI input 1.
16 NIF2	NMI Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE2 and NFEE2 has occurred. 0 No event has occurred on the pad.
17 NOVF2	NMI Overrun Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 1 An overrun has occurred on NMI input 2. 0 No overrun has occurred on NMI input 2.

Table 2292. NSR field descriptions (continued)

Field	Description
24 RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (that is if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An event as defined by RREE and RFEE has occurred. 0 No event has occurred on the pad.
25 ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An overrun has occurred on NMI input. 0 No overrun has occurred on NMI input.

Note: Refer to the Device Configuration chapter to see how the NMI Status Flag Register (NSR) is used in the device.

89.2.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 2397. NMI Configuration Register (NCR)

1. Writing this bit has no functional impact.

Table 2293. NCR field descriptions

Field	Description
0 NLOCK0	NMI Configuration Lock Register 0 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
1:2 NDSS0	NMI Destination Source Select 0 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request

Table 2293. NCR field descriptions (continued)

Field	Description
3 NWRE0	NMI Wakeup Request Enable 0 1 NMI0 wakeup is enabled. A set NIF0 bit or set NOVF0 bit causes a system wakeup request. 0 NMI0 wakeup is disabled. System wakeup requests from the corresponding NIF0 bit are disabled.
5 NREE0	NMI Rising-edge Events Enable 0 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
6 NFEE0	NMI Falling-edge Events Enable 0 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
7 NFE0	NMI Filter Enable 0 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
8 NLOCK1	NMI Configuration Lock Register 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
9:10 NDSS1	NMI Destination Source Select 1 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request
11 NWRE1	NMI Wakeup Request Enable 1 1 NMI1 wakeup is enabled. A set NIF1 bit or set NOVF1 bit causes a system wakeup request 0 NMI1 wakeup is disabled. System wakeup requests from the corresponding NIF1 bit are disabled
13 NREE1	NMI Rising-edge Events Enable 1 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
14 NFEE1	NMI Falling-edge Events Enable 1 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
15 NFE1	NMI Filter Enable 1 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
16 NLOCK2	NMI Configuration Lock Register 2 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.

Table 2293. NCR field descriptions (continued)

Field	Description
17:18 NDSS2	NMI Destination Source Select 2 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request
19 NWRE2	NMI Wakeup Request Enable 2 1 NMI2 wakeup is enabled. A set NIF2 bit or set NOVF2 bit causes a system wakeup request. 0 NMI2 wakeup is disabled. System wakeup requests from the corresponding NIF2 bit are disabled.
21 NREE2	NMI Rising-edge Events Enable 2 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
22 NFEE2	NMI Falling-edge Events Enable 2 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
23 NFE2	NMI Filter Enable 2 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
24 RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
25:26 RDSS	Reset Destination Source Select This value is reset on system reset. 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request. 0 System wakeup requests from the corresponding RIF bit are disabled.
29 RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
30 RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
31 RFE	Reset Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Note: Refer to the Device configuration chapter to see how the NMI Configuration Register (NCR) is used in the device.

Note: Writing a '0' to both NREEx and NFEEx disables the NMI functionality completely (no system wakeup or interrupt will be generated on any pad activity).

89.3 Functional description

89.3.1 General

This section provides a complete functional description of the Wakeup unit.

89.3.2 Non-maskable interrupts

The Wakeup unit supports up to 4 non-maskable interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports the generation of 3 types of interrupts per NMI input to the SoC. The Wakeup unit supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a by-passable analog glitch filter.

Note: Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

89.3.2.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 2397*). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note: After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 2293* for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see *Figure 2396*). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (it has not yet been cleared).

Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

90 Emulation and Debug Device Introduction

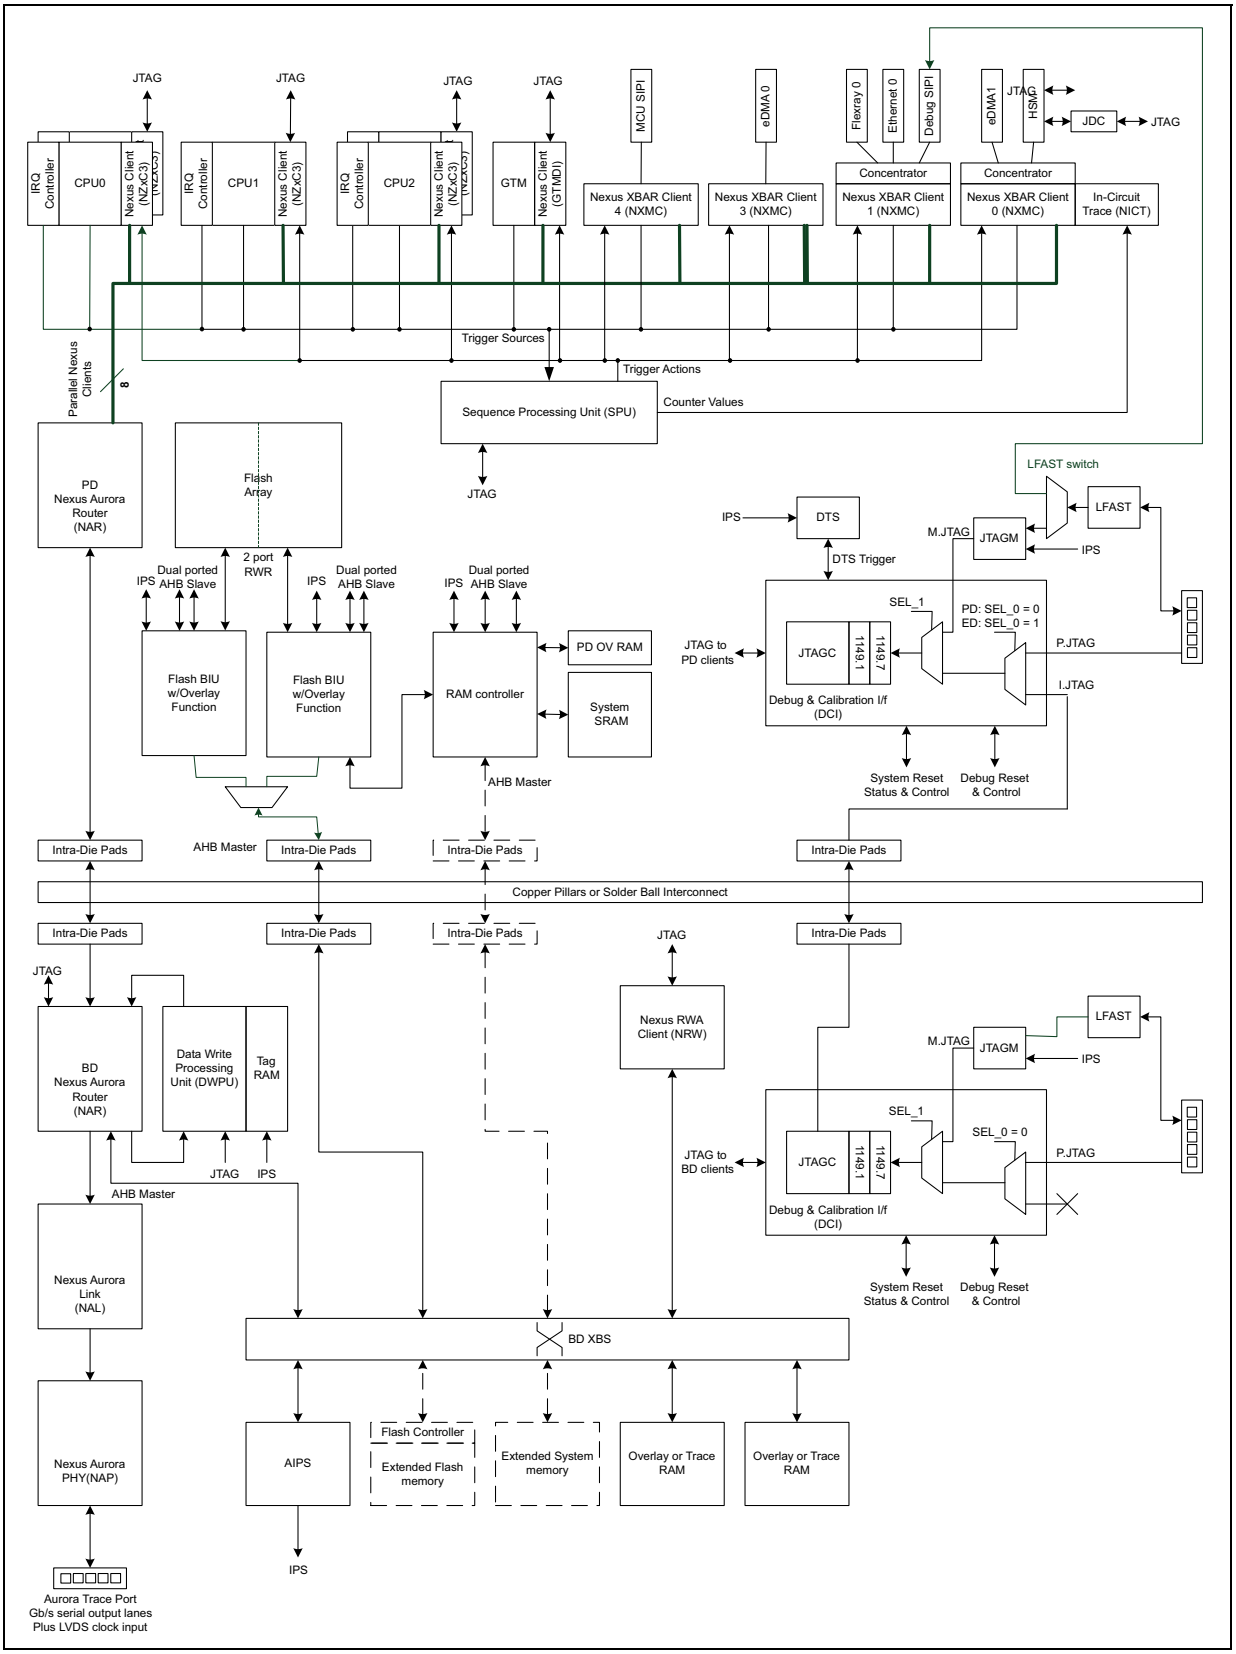
The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD).

90.1 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications for 4- to 8-cylinder engines. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface: it allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the DCI, JTAGM and LFAST functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2012 Nexus Aurora standard)
- 2 MB on-chip SRAM usable as calibration overlay or trace RAM. Entire SRAM contents are maintained as long as ED debug supply is maintained.

90.2 Feature summary



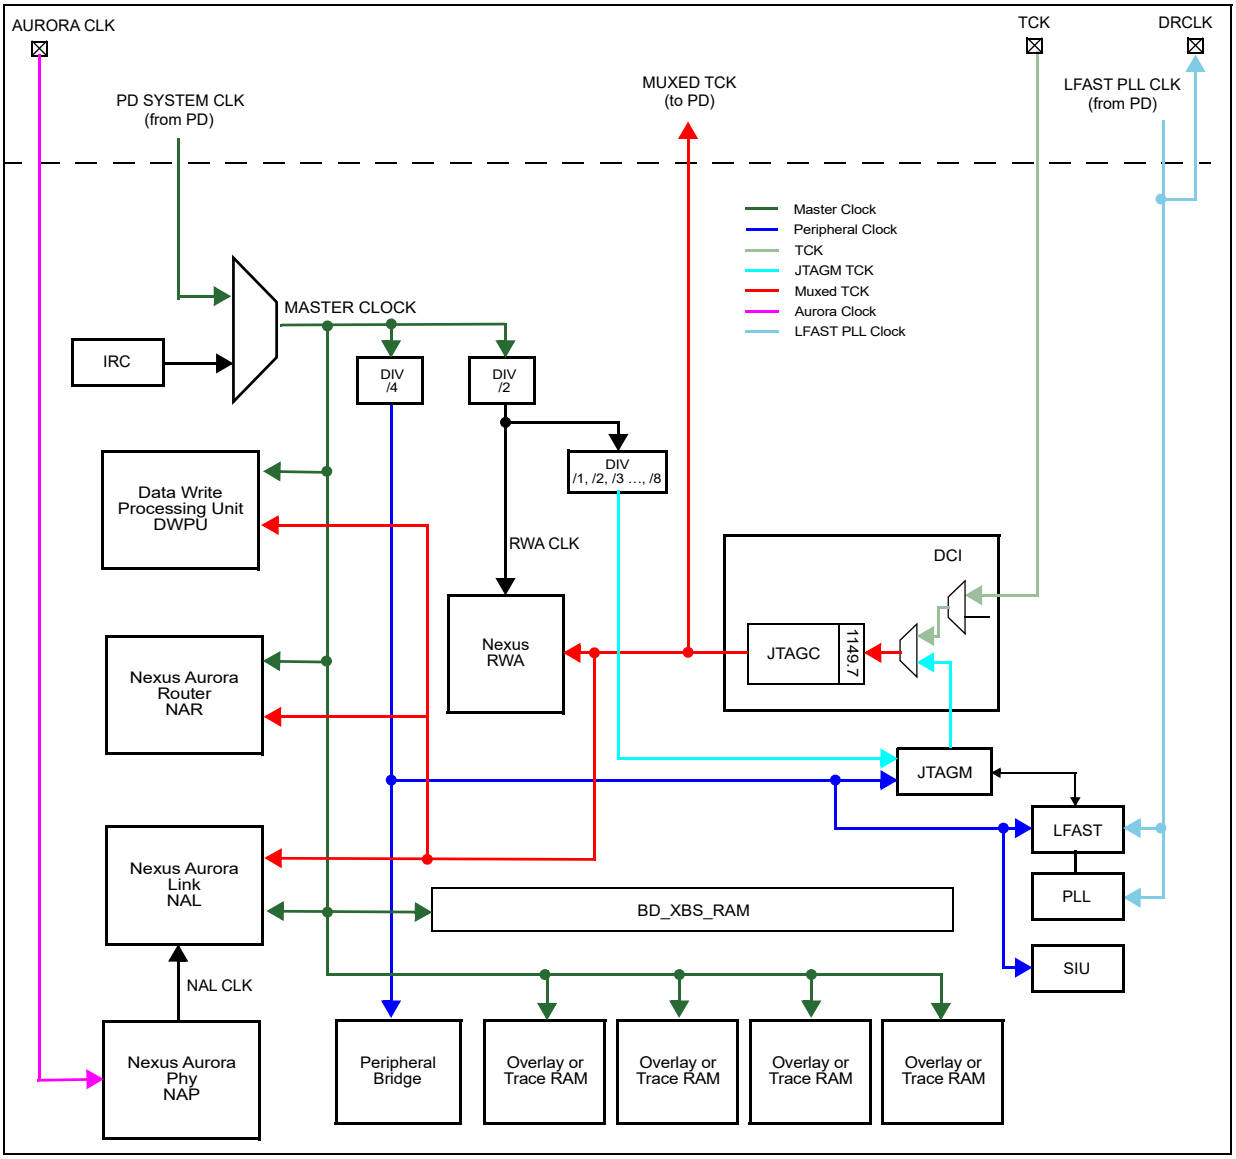
On-chip modules available on the BD include the following features:

- 2 MB on-chip SRAM
  - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
  - Includes ECC
  - Implemented as 4 × 512 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
  - 64-bit data width with ECC checkbits
  - Supports “Early Write” AHB protocol (AHB-EW) for one clock trace data writes
  - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources. Memory-mapped resources include buddy device SRAM and PBRIDGE resources
- Nexus Aurora auxiliary trace port
  - 1.25 Gbit/s maximum data rate per lane
  - Four lanes supported in ED package
  - Port configurable to operate in 2- or 4-lane width
  - One lane LVDS reference clock in
  - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2012 standard
- Data Write Processing Unit (DWPU)
  - Filters data trace stream to retain only writes to user selected locations
  - Detects user configured out of range condition on writes to selected locations
- Debug and Calibration Interface: supports both JTAG (IEEE 1149.1 and IEEE 1149.7) mode and LFAST mode
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)

90.3 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

Figure 2398. Emulation and debug device architecture



90.4 Clocking

Figure 2399 shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- LFAST PLL reference clock coming from the PD (BD LFAST PLL clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Nexus Aurora PHY clock coming from differential LVDS pins in the ED

Figure 2399. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible register and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of ±30%.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 200 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4): Provides the clock to memory mapped registers and other low-speed logic.
- Nexus RWA clock (divided by 2): Provides the clock to the Nexus Read Write Access module.
- JTAGM TCK (divided by 1, 2, …, 8): Provides a high speed TCK clock to the JTAGM module.

The LFAST PLL clock from the PD (also referred to as lfast_sysclk) feeds the LFAST PLL, but it can also directly clock the LFAST in the low data rate mode. This clock is also made available as an output clock to the DRCLK package pin.

The internal TCK clock (referred to as muxed clock in *Figure 2399*) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock can come from two sources (see the Buddy Device–Debug and Calibration Interface (DCI) chapter):

- TCK package pin, when using IEEE 1149.1 or IEEE 1149.7 access
- Divided down version of the master clock to be used in LFAST/JTAGM debug accesses

Note: The division factor for the LFAST/JTAGM clock is defined by the TCKSEL field of the JTAGM_MCR (refer to the JTAGM chapter for more details). However the division factor described there applies to an already divided-by-2 clock, as shown in Figure 2399.

When the PD is unpowered, access through LFAST/JTAGM is not possible. In this case, JTAG accesses can be done only by IEEE 1149.1 or IEEE 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

In the LFAST/JTAGM mode of operation, both RWA clock and internal TCK are synchronous to each other, therefore they can both be the same frequency. This means that TCK frequency can be half of the master clock frequency. *Table 2294* summarizes the frequency restrictions on the Nexus RWA accesses.

Table 2294. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	200	200	27.7	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns)
Powered, out of reset, PLL engaged	LFAST/JTAGM	200	200	100	—

90.5 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described by *Table 2295*:

1. BD power-on reset: asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset: asserts two clock rising edges after assertion of reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset: asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.
4. JTAG controller reset: asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset: asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In *Table 2295*, an ‘X’ indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins. When the debug interface is running through the LFAST interface or by software through JTAGM, those blocks are not reset by the mentioned reset sources.

Table 2295. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
JTAGM	X	—	JTAG mode only	JTAG mode only	—
LFAST	X	—	JTAG mode only	JTAG mode only	—
NAR/DWPU	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

Note: The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

90.6 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as LFAST, JTAGM, XBAR configuration. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 2296. BD memory map

Start address	End address	Allocated size (KB)	Description

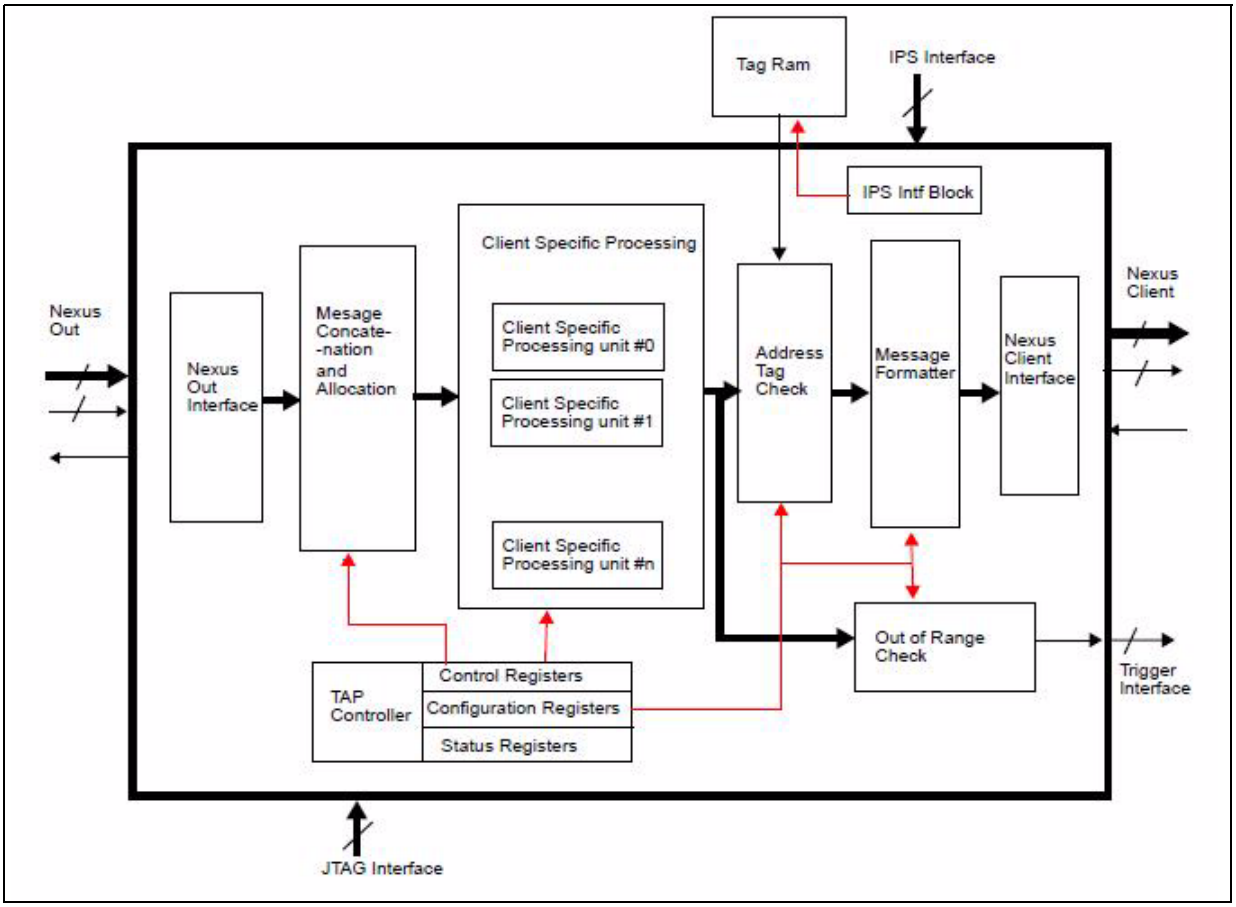
91 Buddy Device—Data Write Processing Unit (DWPU)

91.1 Introduction



The Data Write Processing Unit (DWPU) supports two specific debug and calibration functions:

- Data trace filtering
- Out of range parameter identification

DWPU takes the Nexus standard messages and processes the data write trace messages to filter out messages based on the tagged addressing schema contained in the Tag RAM. DWPU also generates triggers indicating out of range data values for a set of identified addresses and data ranges.

This figure shows the block diagram of the DWPU identifying various functional blocks and the data flows.

Figure 2400. DWPU block diagram

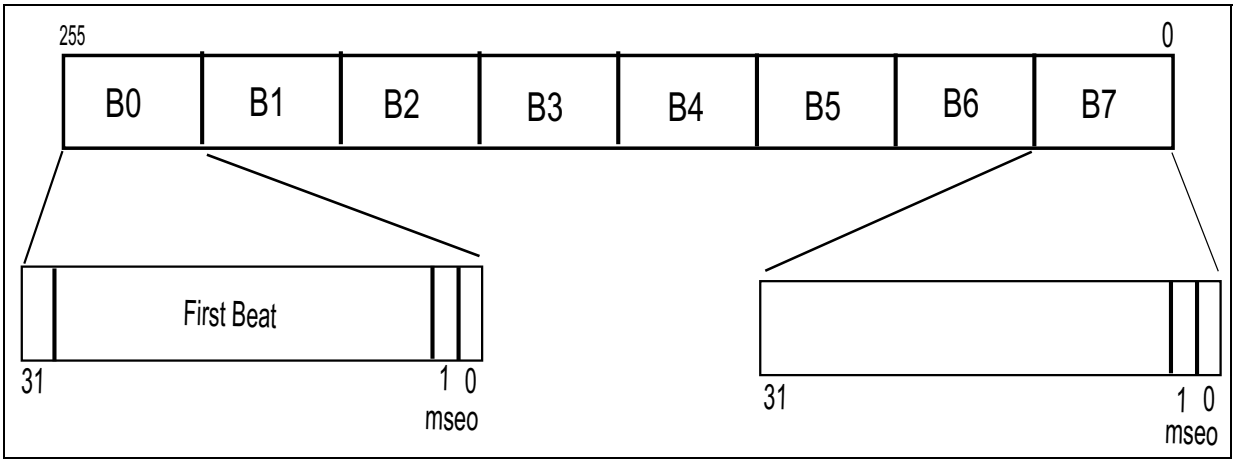
91.2 Features

DWPU supports the following features:

- Out of range data value detection and data write trace filtering simultaneously from up to five Nexus clients
- Filtering operation that can be individually enabled or disabled for each 64-bit word in system RAM or data memory
- High bandwidth throughput
- Filtered trace stream is returned to the BD NAR to allow routing to the trace port or overlay RAM.
- Detection of out of range data values writes within data write trace stream

91.3 Functional description

DWPU includes the following functional blocks:



- Nexus Out Interface (NOI)
- Message Concatenation and Allocation (MCA)
- Client Specific Processing (CSP)
- Address Tag Check (ATC)
- Out of Range Check (ORC)
- Message Formatter (MF)
- Nexus Client Interface (NCI)

91.3.1 Nexus Out Interface (NOI)

The Nexus Out Interface (NOI) enables DWPU to receive Nexus message for data write filtering from NAR. NOI maintains a minimum queue of two buffers to accommodate incoming messages. The NAR only initiates a transfer to the DWPU when it has all the beats of a message. The incoming messages are buffered and then forwarded to the Message Concatenation and Allocation (MCA) for message concatenation and allocation. NOI ensures the temporal order of the incoming messages while forwarding to MCA. NOI also acknowledges the processing of data write messages by MCA.

The format for incoming message with NEXUS_WORD = 32 and NUM_BEAT_IN = 8 is shown below.

Figure 2401. Incoming message format

91.3.2 Message Concatenation and Allocation (MCA)

Message Concatenation and Allocation (MCA) starts concatenating message beats once the NOI has a valid input message to form a complete message. Concatenated messages with selected source IDs contained in Nexus messages are passed over to appropriate Client Specific Processing Unit (CSPU) for further processing. The following messages are dropped by MCA:

- Messages that do not have a selected source ID
- IDLE messages
- Messages with number of beats larger than defined beats for data-write messages

MCA has the capability of providing one fully concatenated message to a CSPU each clock.

91.3.3 Client Specific Processing (CSP)

The Client Specific Processing (CSP) block receives the messages from MCA. The received message are processed after extracting all the relevant fields. Different types of message from various clients are received and processed differently based on their type by a specialized unit called the Client Specific Processing Unit (CSPU).

The CSPU receives concatenated data write messages (including synchronization messages) from MCA and provides the following for the Out of Range Check (ORC) and Address Tag Check (ATC) logic to perform filter checks:

- Reconstructed address
- Data value
- Source ID
- Master ID
- Timestamp

CSPU also confirms that each message is a data write message. All other message types are dropped.

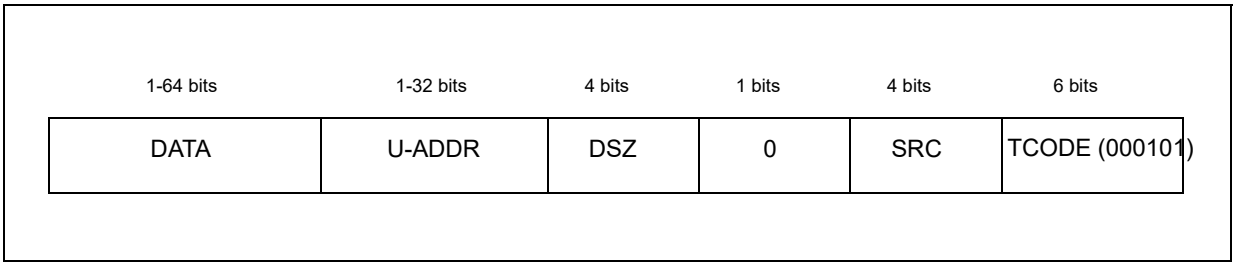
There are two CSPU types, one associated with Core Nexus clients and another associated with NXMC clients. Each CSPU simultaneously supports data write messages with up to four different source IDs.Data write with synchronization message is always required to start an address thread for a particular source ID, then each subsequent data write message

associated with that source ID contains an encoded address. *Table 2297* shows the CSPU type encoding to be used while mapping the source IDs to a CSPU type using SRC_MAP_CTLR.

Table 2297. CSPU encoding

CSTU type	Encoding
Standard	01
NXMC	10

91.3.3.1 Input message formats



DWPU supports various message formats from different source clients. These formats are further processed by the CSPU. The following message formats are supported by the CSPUs, as also described in details the sub-sections:

- Standard data write message format (SDWM)—Includes sync and non-sync type. This is used by most of the clients, such as e200 peripheral and e200 main cores.
- AHBMM (modified) data write message format (MDWM)—Includes both sync and non-sync type of messages. Used by NXMC clients only.

91.3.3.1.1 Standard data trace write message format

The standard data trace write messages are of two types, sync and non-sync. The non-sync type contains the data write value and the address of the write access, relative to the previous data trace message. The address and DATA field is considered variable. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

Figure 2402. Non-sync data trace write message format

The TSTAMP field not shown is an optional fixed field of 26 bits, is inserted optionally by the core clients based on controls received from the BD NAR.

The second type is the DWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

Figure 2403. Sync data trace write message format

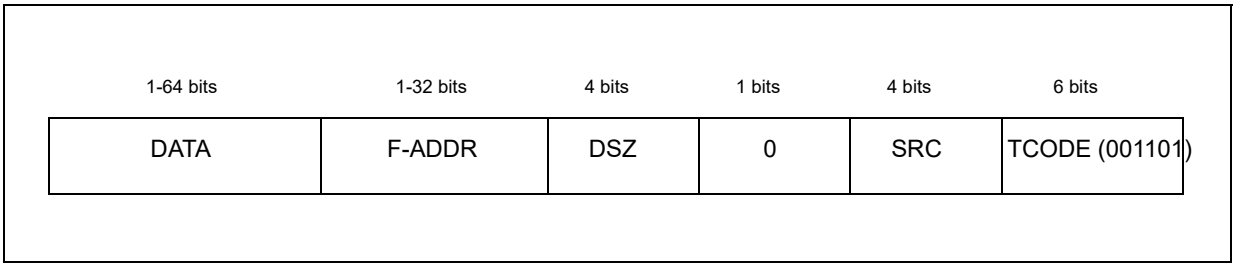


Table 2298 shows the data size (DSZ) encoding for standard data trace message.

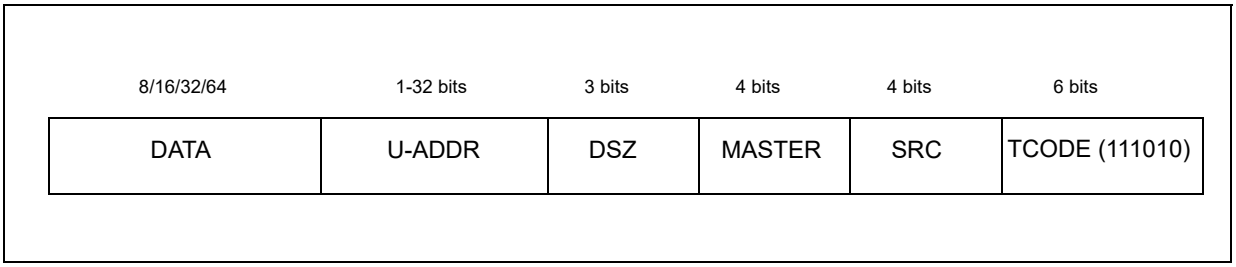

Table 2298. Standard DSZ encoding

DSZ	Data size
0000	0-byte
0001	1-byte
0010	2-byte
0011	3-byte
0100	4-byte
0101	5-byte
0110	6-byte
0111	7-byte
1000	8-byte
1001–1111	Reserved

91.3.3.1.2 NXMC (modified) data trace write message format

The NXMC (modified) data trace write sync messages contain the data write value and the address of the write access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encoding to either 8, 16, 32 or 64. The TSTAMP field is 26 bits. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

Figure 2404. Non-sync M-Data data trace write message format

The TSTAMP field not shown over here is an optional fixed field of 26 bits, is inserted optionally by the AHBMM clients based on controls received from NAR.

The second type is the MDWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent MDWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

Figure 2405. Sync M-Data data trace write message format

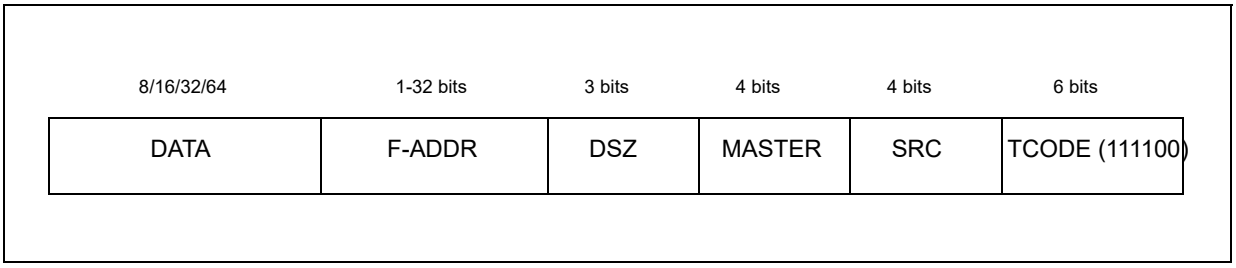

Table 2299 shows the data size (DSZ) encoding for NXMC data trace message.

Table 2299. NXMC DSZ encoding

DSZ	Data size
001	1-byte
010	2-byte
011	3-byte
100	4-byte
000,101–111	Reserved

91.3.4 Address Tag Check (ATC)

DWPU allows filtering operation on data writes to any address within system RAM and tightly coupled data memory. Each 64-bit word in the supported system RAM or data memory address space corresponds to a single bit in Tag RAM; therefore, the required Tag RAM size is $1/64^{th}$ of the address space to be filtered. Data write messages within the supported address range are dropped by ATC if the corresponding bit in Tag RAM is not set. The data write messages with the corresponding Tag bit set are passed over to Message Formatter for further processing.

Writes to addresses outside of the supported address range can be configured to be either removed from the trace stream or retained. This option is controlled by a single user accessible control bit. Data reads and other Nexus message formats submitted in the DWPU trace stream are always dropped by DWPU. Tag RAM is accessible through software (IPS) as well as JTAG interface via PD addressing. All the IPS access is possible in supervisor mode only. The access to Tag RAM is carried out indirectly through three registers: TRC_CTRL, TRC_ADR and TRC_DATA registers. Users should write the TRC_CTRL register followed by the TRC_ADR register before accessing the TRC_DATA register. Any write access to the TRC_ADR register results in a Tag RAM access request. Users should ensure that the Tag RAM request is completed by providing the required TRC_DATA access based on the length of the transfer. In case of block access, the TRC_DATA register is accessed subsequently and users should ensure that the block

access length does not cross the region boundary. Deviation in the sequence of register access for Tag RAM access results in erroneous and incomplete transfers.

In PD addressing, the configured PD address in the TRC_ADR register is translated to a Tag RAM address using mapping derived from the FAR_SA_CFGn and FAR_RS_CFGn register. The PD address configured in the FAR_SA_CFG0 register is always translated to the zeroth address of Tag RAM.

The equation to convert system/PD address to Tag RAM address where the System/PD address falls within region n is given below:

Tag RAM address = System/PD address[31:8] - Region n base address[31:8] + Total sum of previous region (n-1) size[31:8]

The Tag RAM address for System/PD address that falls on region 2 is given by:

System/PD address[31:8] - Region 2 base address[31:8] + (region 0 size[31:8] + region 1 size[31:8])

Figure 2406 shows an example of the Tag RAM organization for 8 Kbyte Tag RAM with PD base address configured.

Figure 2406. Tag RAM organization example

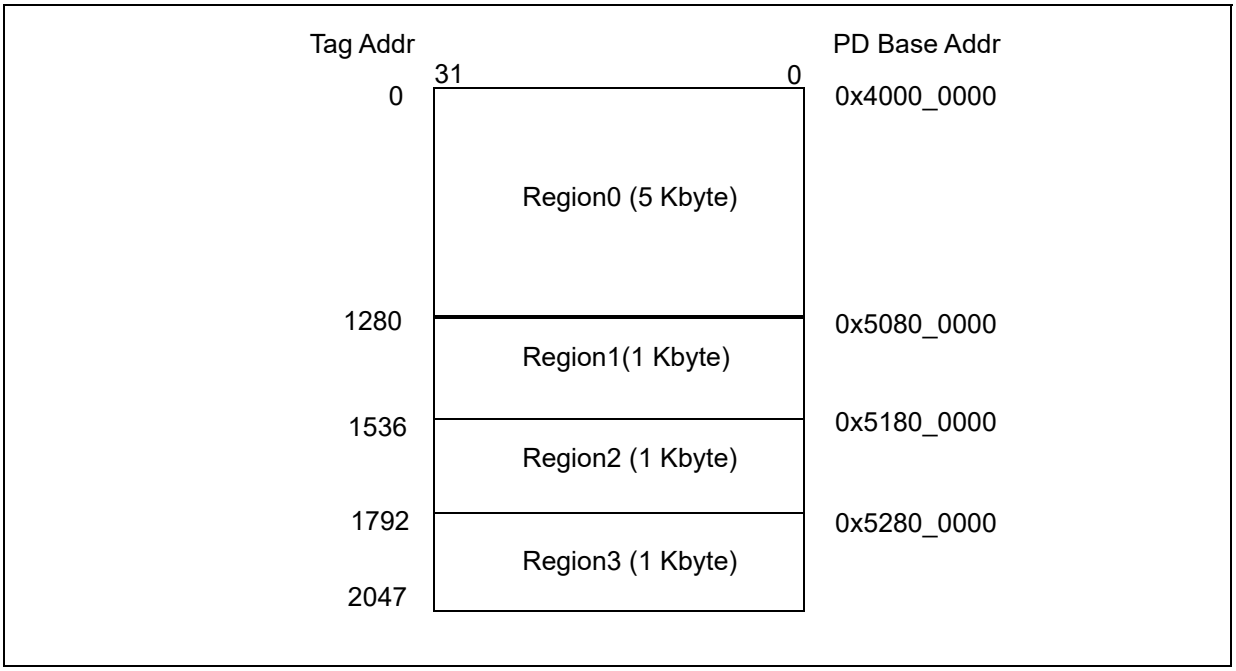

Table 2300 shows an example of address translation from PD addresses to Tag RAM address.

Table 2300. Address translation example

PD address		Tag RAM address
Start	End	
0x4000_0000	0x4000_00FF	0x0
0x4000_0100	0x4000_01FF	0x1
0x4004_FF00	0x4004_FFFF	0x4FF

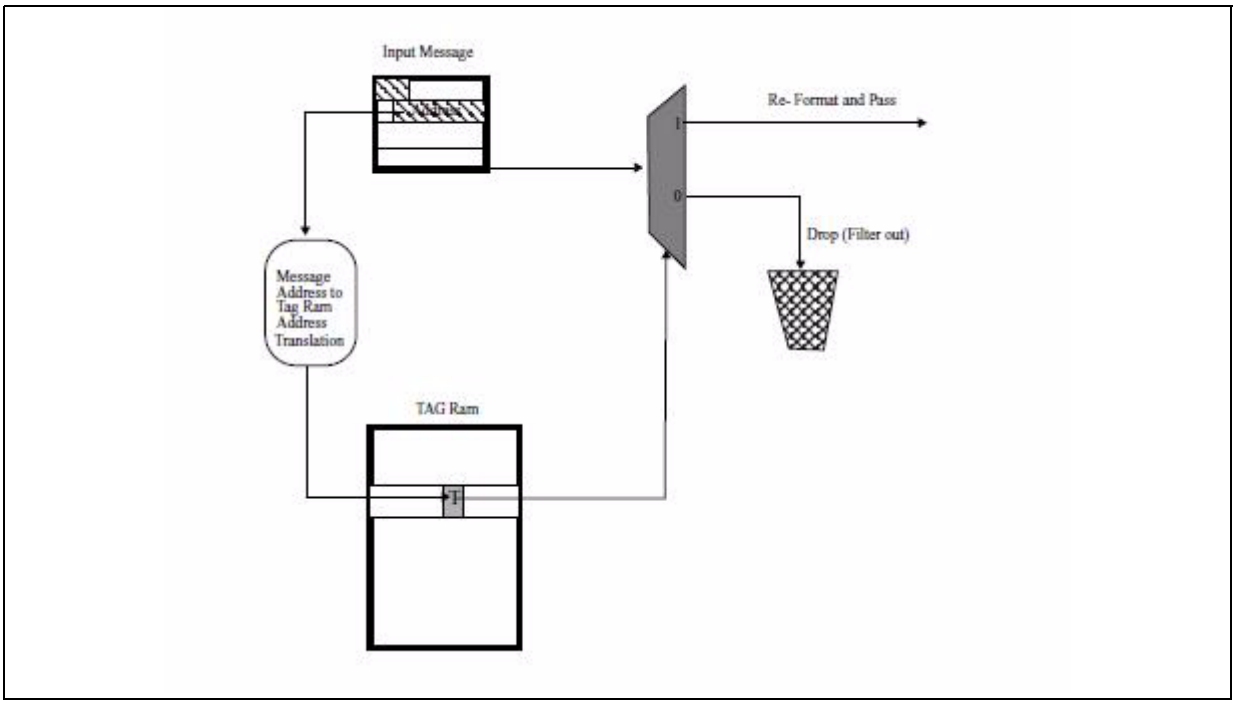

Table 2300. Address translation example (continued)

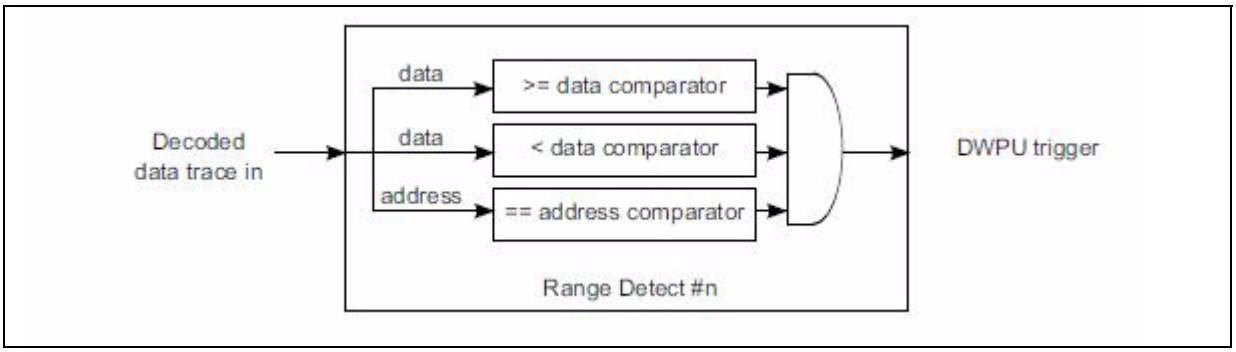
PD address		Tag RAM address
Start	End	
0x5080_0000	0x5080_00FF	0x500
0x5180_0000	0x5180_00FF	0x600
0x5280_0000	0x5280_00FF	0x700
0x5280_FF00	0x5280_FFFF	0x7FF

During the data write filtering operation, the system RAM or data memory address is extracted from the input message. It is then compared to ascertain the address space (whether it is within system RAM space or data memory or outside the supported address range). Finally it is translated to Tag RAM address and initiate a read to Tag RAM. From the Tag RAM 32-bit read accessed, the system/PD address bit [7:3] determine the Tag bit position that is associated with the decoded absolute system/PD address. If the corresponding bit is set, then the input message is passed for message formatting else it is dropped by ATC.

This figure shows the data flow for address Tag filtering.

Figure 2407. Address tag filtering



91.3.5 Out of Range Check (ORC)

In addition to the trace filtering function, the DWPU also supports detection of outside/inside range writes to RAM locations. Both the data range values and address of RAM locations to be checked are user specified. It also has configurable support to detect target inside or outside data range values specified.

A total of four sets of address and data range comparators are supported, where each set of comparators include an address match comparator, a greater than or equal data value comparator and a less than or equal data value comparator. This figure shows the block diagram for range detect comparators.

Figure 2408. Range detect comparators

ORC supports unsigned, signed and floating point data ranges. Signed numbers are represented in 2's complement. 32-bit IEEE-754 single-precision floating-point format is used for floating point representation.

ORC has a configurable option to support for 8/16/32 bit unsigned/signed range detection and 32-bit floating point range comparison. Address comparison is carried out with full the device address. An output signal from DWPU is triggered in response to a detected out of range condition along with a status bit being set in an ORC status register indicating which range comparator has caused the trigger.

91.3.5.1 Comparator capabilities

The primary usage for out of range detect function is to detect out of range conditions on unsigned integer and pointer variables, although it also supports signed and floating point data types comparison. It also has a configurable option to support for 8/16/32 bit unsigned range detection. The unsigned data is directly compared with the stored data ranges.

To support use with signed variables, each data comparator supports 8/16/32 bit signed operation. All the signed numbers are represented in two’s complement. Data comparison happens only when the sign bit matches.

To detect range of floating point variables, each data comparator supports only 32-bit comparison mode. All the floating point numbers are represented in 32-bit IEEE-754 single precision with biased exponent. The floating point data is directly compared with the stored floating point ranges which are also represented in 32-bit IEEE-754 single precision with biased exponent.

91.3.6 Message Formatter (MF)

Message Formatter (MF) module receives message information from ATC and reformats the data write messages to comply with output Nexus message format. A user defined message format is used for sending out the filtered messages as shown in *Figure 2409* below.

Figure 2409. DWPU message format

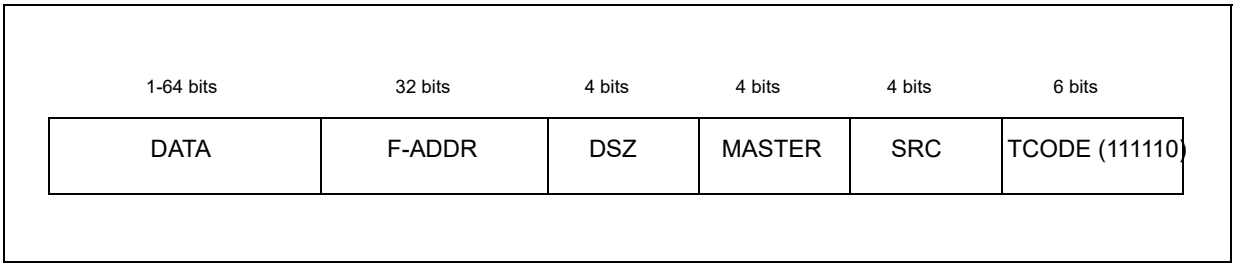


Table 2301. Message field description

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
DWPU message	6	6	TCODE	fixed	TCODE number = 62
	4	4	SRC	fixed	Source client identifier
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access. For core clients 1111 is inserted. For the NXMC clients, same value is inserted as received.
	4	4	DSZ	fixed	Data size
	32	32	F-ADDR	fixed	Full data write address
	1	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	26	26	TSTAMP	fixed	Timestamp (Optional and omitted if there is no valid timestamp)

91.3.7 Nexus Client Interface (NCI)

The Nexus Client Interface (NCI) sends out the formatted filtered data write messages to BD NAR. It also supports the buffer reallocation to increase the Q size.

91.4 Non-memory mapped registers

This section describes the DWPU Nexus register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. In addition, some register are accessible through the IPS interface.

The table below shows the JTAG mapped DWPU registers.

Table 2302. JTAG DWPU registers

Nexus register index	Register	Access	Read address	Write address	Reset value

22 PROG	JTAG access to Tag RAM in progress 0 No Tag RAM access by JTAG 1 Tag RAM access by JTAG is in progress
23 INV	Invalid JTAG access. Generated when the targeted system/PD address in the TRC_ADR register falls outside the configured Tag RAM region 0 No error 1 Invalid address
25:27 DSM	Data Size Mode. Valid only for writes, all reads are fixed 32 bits only. 000 Word (32 bit) Access to the Tag RAM. 001 Half-Word (16-bit) access to Tag RAM. 16-bit LSBs of the TRC_DATA is used. 010 Byte (8-bit) access to the Tag RAM. 8-bit LSBs of the TRC_DATA is used. 100 Bit Access to the Tag RAM. LS bit of the TRC_DATA is used.
29 BAE	Block Access Enable. Block access is carried out with 32-bit Data Size Mode only. 0 Block Access disable 1 Block Access enable
30:31 CMD	00 No read or write access to Tag RAM 01 Read access to Tag RAM. Any write to TRC_ADR register results in read access to the Tag RAM. Read data is stored in the TRC_DATA register. 10 Write access to Tag RAM. Any write to TRC_ADR register results in write access request to the Tag RAM and subsequent TRC_DATA writes result in actual data to be written into tag RAM addressed by the TRC_DATA register. 11 Reserved

91.4.1.6 Tag RAM Configuration Address (TRC_ADR)

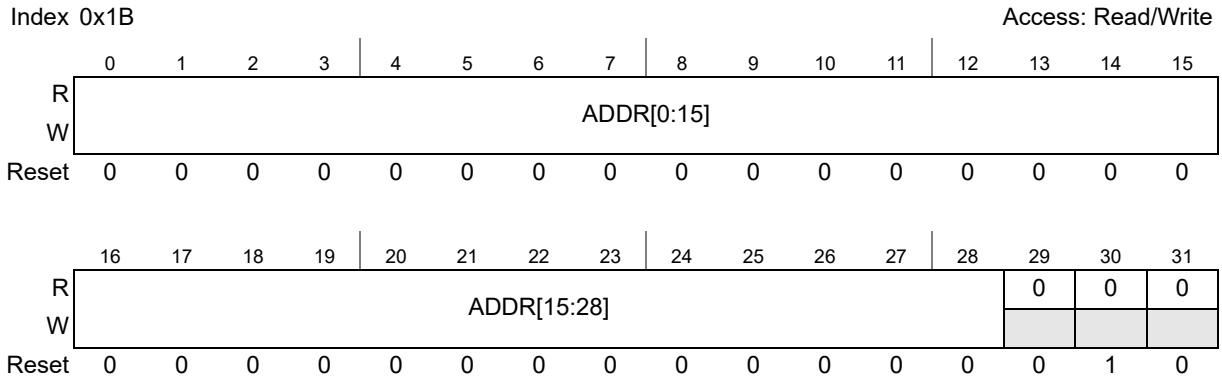

Figure 2415. Tag RAM Configuration Address (TRC_ADR)

Table 2308. TRC_ADR field descriptions

Field	Description
0:28 ADDR	PD Address. It should be aligned depending on Data Size mode field. DSM = 000, 256 byte aligned DSM = 001, 128 byte aligned DSM = 010, 64 byte aligned DSM = 100, 8 byte aligned (default) **Note:** If the PD address is not aligned to the DSM, this results in a erroneous data read/write.

Figure 2424. Tag RAM Control (DPWU_TRC_CTRL)

Table 2318. DPWU_TRC_CTRL field descriptions

Field	Description
4:15 BAL	Block Access Length.Should not cross the region boundary. Valid only when BAE = 1
21 EXC	Excess Tag RAM access by IPS. Generated when the IPS access to Tag RAM exceeds the configured access length 0 No excess access to Tag RAM 1 Exceeds the configure access length
22 PROG	IPS access to Tag RAM in progress 0 No Tag RAM access by IPS 1 Tag RAM access by IPS is in progress
23 INV	Invalid IPS access. Generated when the targeted PD/system address in the TRC_ADR register falls outside the configured Tag RAM region 0 No error 1 Invalid address
25:27 DSM	Data Size Mode. Valid only for writes, all reads are fixed 32 bits only. 000 Word (32 bit) Access to the Tag RAM. 001 Half-Word (16-bit) access to Tag RAM. 16-bit LSBs of the TRC_DATA is used. 010 Byte (8-bit) access to the Tag RAM. 8-bit LSBs of the TRC_DATA is used. 100 Bit Access to the Tag RAM. LS bit of the TRC_DATA is used.
29 BAE	Block Access Enable. Block access is carried out with 32-bit Data Size Mode only. 0 Block Access disable 1 Block Access enable
30:31 CMD	Read/Write access 00 No read or write access to Tag RAM 01 Read access to Tag RAM. Any write to TRC_ADR register results in read access to the Tag RAM. Read data is stored in the TRC_DATA register. 10 Write access to Tag RAM. Any write to TRC_ADR register results in write access request to the Tag RAM and subsequent TRC_DATA register writes result in actual data to be written into Tag RAM addressed by the TRC_DATA register. 11 Reserved

91.5.2 Tag RAM Configuration Address (DWPU_TRC_ADR)

Tag RAM Configuration Address provides the system address for Tag RAM access. Any write to this register initiates a Tag RAM access request at the address which is being translated from system address configured. It is always accessed in 32-bit only.

Offset: 0x0004 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2425. Tag RAM Configuration Address (DWPU_TRC_ADR)

Table 2319. DWPU_TRC_ADR field descriptions

Field	Description
0:28 ADDR	PD Address. It should be aligned depending on Data Size mode field. DSM = 000, 256 byte aligned DSM = 001, 128 byte aligned DSM = 010, 64 byte aligned DSM = 100, 8 byte aligned (default) **Note:** If the PD address is not aligned to the DSM, this results in a erroneous data read/write.

91.5.3 Tag RAM Configuration Data (DWPU_TRC_DATA)

Tag RAM Configuration read/write data register. Generate ips_xfer_err on accessing this register before configuring the TRC_ADR register. Also on read access to this register while Tag RAM write is in progress and vice versa. Access is always 32-bit. During write, TRC_ADR.DSM determines which part of TRC_DATA should be written irrespective of byte enable.

Offset: 0x0008 Access: Read/Write

Table 2320. DWPU_TRC_DATA field descriptions

Field	Description
0:31 DATA	Reflects the content of Tag RAM on Tag RAM read access. Also provides data for Tag RAM write access.

92 Buddy Device—Nexus Read Write Access (RWA)

92.1 Introduction

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in *Section 92.3: Nexus register access via JTAG*. The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

92.2 Register definition

Table 2321 details the register map for the RWA module.

Table 2321. RWA register map

Register	Nexus access opcode	Read/ write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

92.2.1 Register descriptions

92.2.1.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in *Table 2323*.

1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

92.2.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.

Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Read/Write Data[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Read/Write Data[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Figure 2428. Read/write access data (RWD) register

Read/write accesses to the memory require that the debug firmware properly retrieve/place the data in the RWD. *Table 2325* shows the proper placement of data into the RWD.

Table 2325. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

Table 2326 shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 2326. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]

Table 2326. RWD byte lane mapping (continued)

Transfer size and byte offset	RWA(2:0)	RWD[1]			
		31:24	23:16	15:8	7:0
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—-	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—-	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]

Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

92.2.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.

Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Read/Write Address[0:15]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Read/Write Address[16:31]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Figure 2429. Read/write access address (RWA) register

92.3 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 2321*.

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in *Table 2321*. This is achieved by loading an 8-bit value into the JTAG data register (DR).

   This register has the following format:

Figure 2430. JTAG DR for Nexus register access

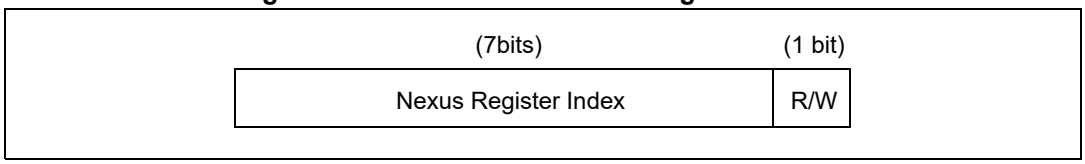

Table 2327. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 2321*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

92.4 Memory access examples

The following subsections describe the steps which are required to access memory.

92.4.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Write Address = 32h’xxxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b’1 (to indicate start access)
   – Map Select (MAP) = 3b’000 (primary memory map)
   – Access Priority (PR) = 2b’00 (lowest priority)
   – Read/Write (RW) = 1b’1 (write access)
   – Word Size (SZ) = 3b’0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h’0000 or 14h’0001(single access)

Note: Access Count (CNT) of 14’h0000 or 14’h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
   – Write Data = 32h’xxxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1’b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

92.4.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 92.4.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in *Section 92.4.1: Single write access* until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note: The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

92.4.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Read Address = 32h'xxxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b'1 (to indicate start access)
   – Map Select (MAP) = 3b'000 (primary memory map)
   – Access Priority (PR) = 2b'00 (lowest priority)
   – Read/Write (RW) = 1b'0 (read access)
   – Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

92.4.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 92.4.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.
4. Repeat Steps 3 and 4 in *Section 92.4.3: Single read access* until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note: The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

93 Buddy Device—Crossbar and RAM (BD_XBS_RAM)

Within the buddy device (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note: Throughout this description, the term "overlay RAM" is applied to the BD memory, even though this memory can be used for both overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
  - Bus masters include the BD's Nexus Aurora Router (BD-NAR), the production device's flash controller (PFLASH) and the BD's Nexus Read/Write Access Client (RWA)
  - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge bus controller
    - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
    - End-to-End ECC32 address and data protection
    - ECC scheme based on 29-bit address and 32-bit data
    - Overlay RAM supports a 64-bit "early write" datapath and a 128-bit read datapath
- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note: Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

93.1 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit "early write" datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, m0 > m1 > m2 (PFLASH > BD-NAR > Nexus RWA). Each slave port is "parked" on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

93.2 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

e2eECC64[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0] ^ ecc_data_lower[7:0]

where `ecc_addr` is H-matrix evaluation of the 29-bit access address (addr[31:3]), `ecc_data_upper` is the H-matrix evaluation of the upper data word (data[63:32]) and `ecc_data_lower` is the comparable evaluation of the lower data word (data[31:0]).

For the BD RAM definition, the following (re)definitions apply:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]; data_lower[31:00] = 0

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]; data_upper[63:32] = 0

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in *Table 2328*. A '*' in *Table 2328* indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 2328. e2eECC Basic H-Matrix Definition

      return(ecc);
}
```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

94 Buddy Device—System Integration Unit Lite (BD_SIUL2)

94.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

These registers are also indirectly accessible by software via BD_JTAGM in software debug mode.

94.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type.
- A version field that is changed for every major mask revision of the BD.
- A parameterized field that indicates the amount of extended overlay RAM included
  - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps.

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC.
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants).

94.3 Device status information

94.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically.
  - BD_INIT is not cleared by external BD reset input.
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration).
- The calibration tool or calibration software sets BD_INIT.
- After PD POR, the BAF executes and reads BD_INIT.
  - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap.
  - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used).

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

94.3.2 PD reset status

The IPS accessible BD_SIU_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

94.4 Memory map

Table 2329 gives an overview of the BD_SIUL2 registers.

24:31	Reserved.

94.4.1.3 BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset).
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration).
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT.
  - If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap.
  - If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used).

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

31 PD_POR	PD POR Flag Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed. 1 PD is powered and power on reset has completed.

94.4.1.5 BD_SIUL2 Multiplexed Signal Configuration Registers (BD_SIUL2_MSCR1, BD_SIUL2_MSCR2)

The BD_SIUL2_MSCR1–2 registers contain pad multiplexing and control bits. It is reset by system reset.

The debug interface on the BD requires five pins when operating in JTAG 1149.1 and LFAST modes, but can be reduced to three pins when operating in JTAG 1149.7 reduced pin mode, allowing the use of two pins for GPIO. The BD_SIUL2_MSCR registers provides bits to control pad electrical characteristics when the pins are working as GPIO. Note that the registers do not control the multiplexing, but the electrical characteristics for GPIO only. Multiplexing is controlled by the function of the pads. If the debug tool is disconnected and JCOMP negated, the pads are GPIO. When the tool is connected and JCOMP asserted, the pads are automatically assigned to JTAG. If the tool then configures JTAG to work in 1149.7 mode, the pads are assigned back to GPIO. And if the tool selects LFAST mode, the pads are assigned to LFAST.

Note: Multiplexing of GPIO into JTAG pins is not supported.

95 Buddy Device: Debug and Calibration Interface (DCI)

95.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

95.1.1 Features

The ED DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

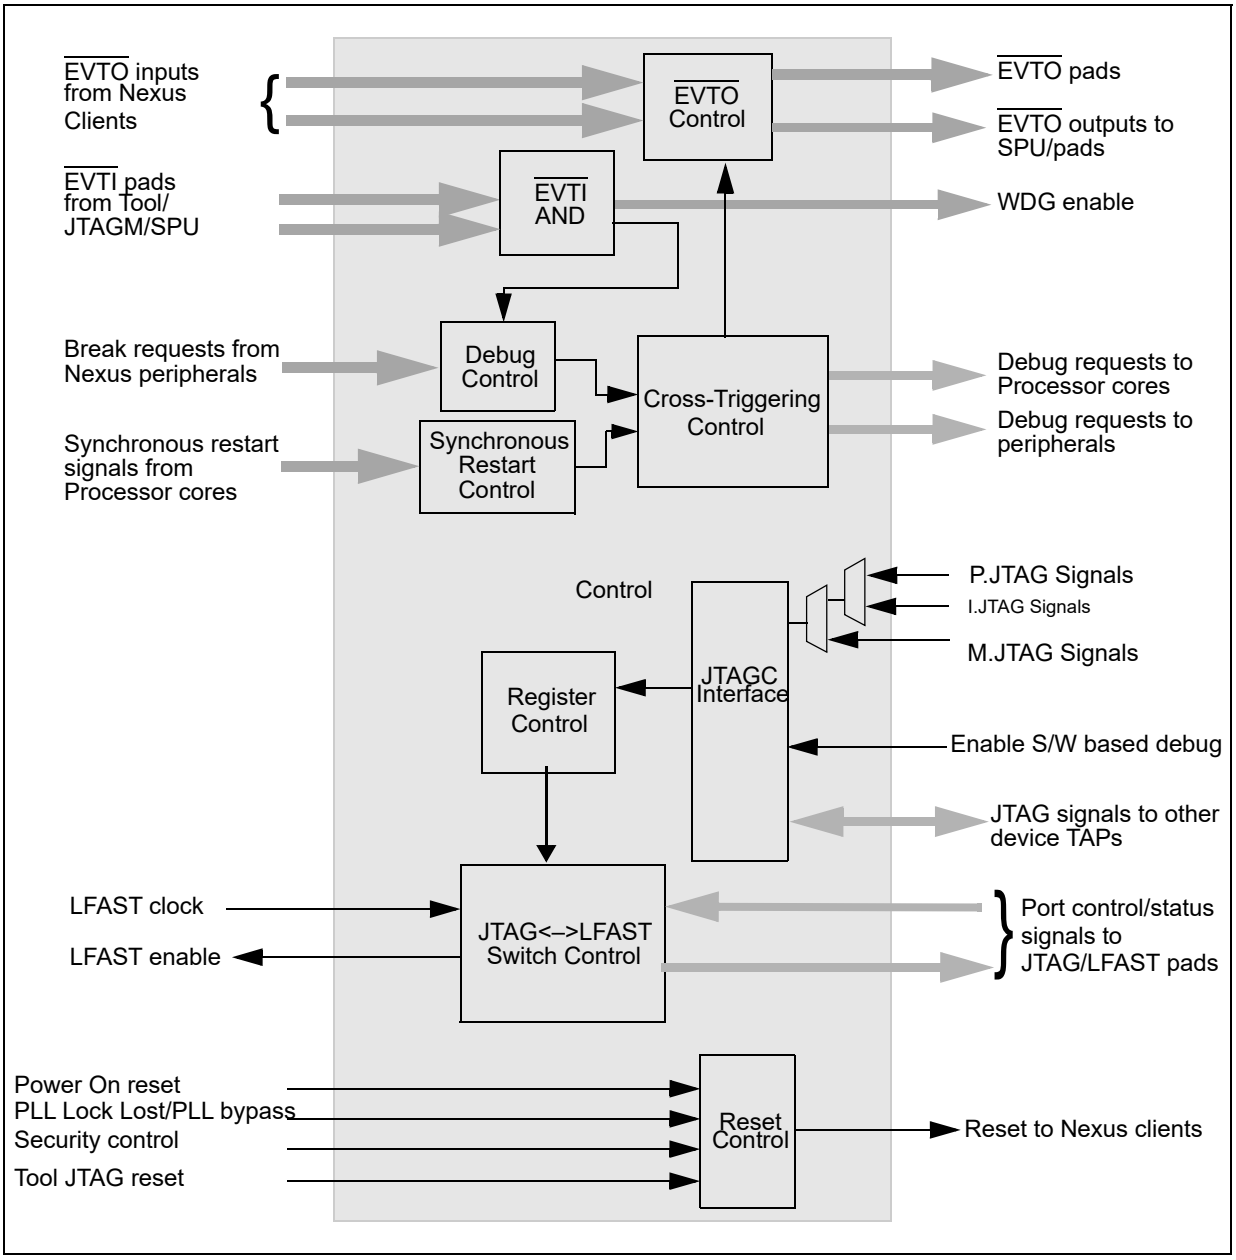
95.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.

  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.
- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.



When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The ED DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as SPU. The ED DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

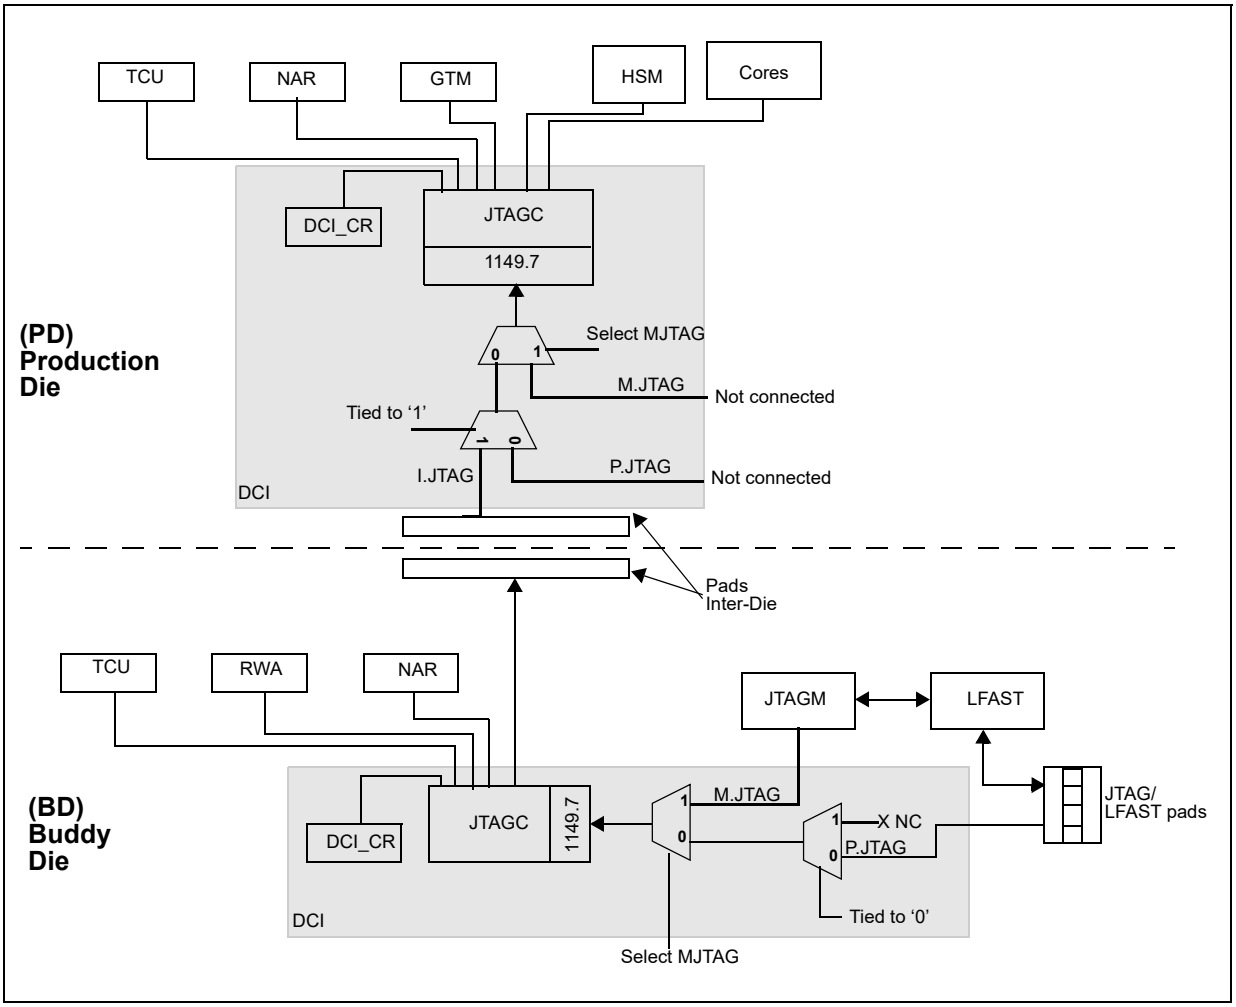


Figure 2440 shows the DCI block diagram.

Figure 2440. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in *Figure 2441*. In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

Figure 2441. DCI in an emulation configuration

95.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 2335 shows a summary of the configuration options.

Table 2335. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

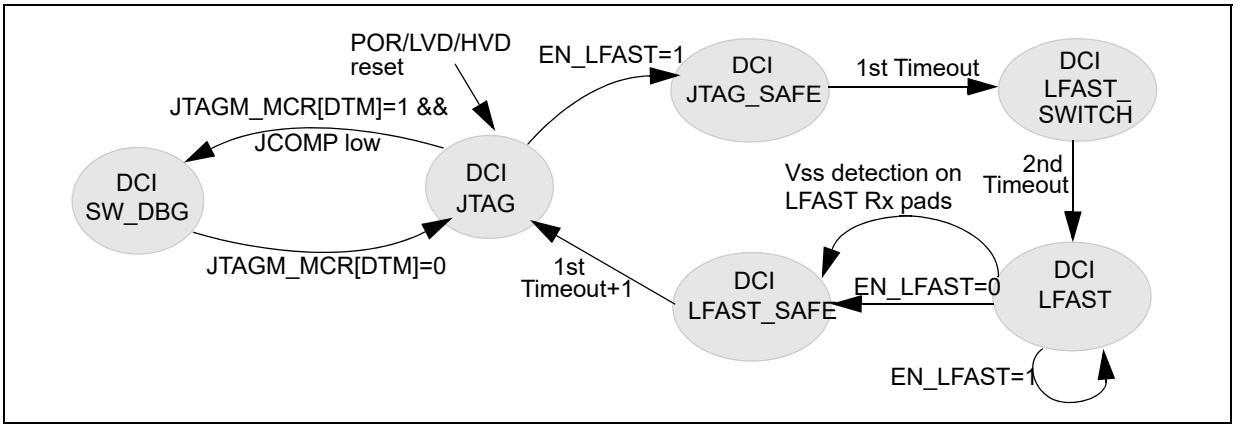
The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the BD LFAST and BD JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 95.1.3.1: Port sharing between JTAG and LFAST modes on page 3976*. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 2336* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1’b0). There is no change in port values if no debug tool is connected.

Table 2336. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

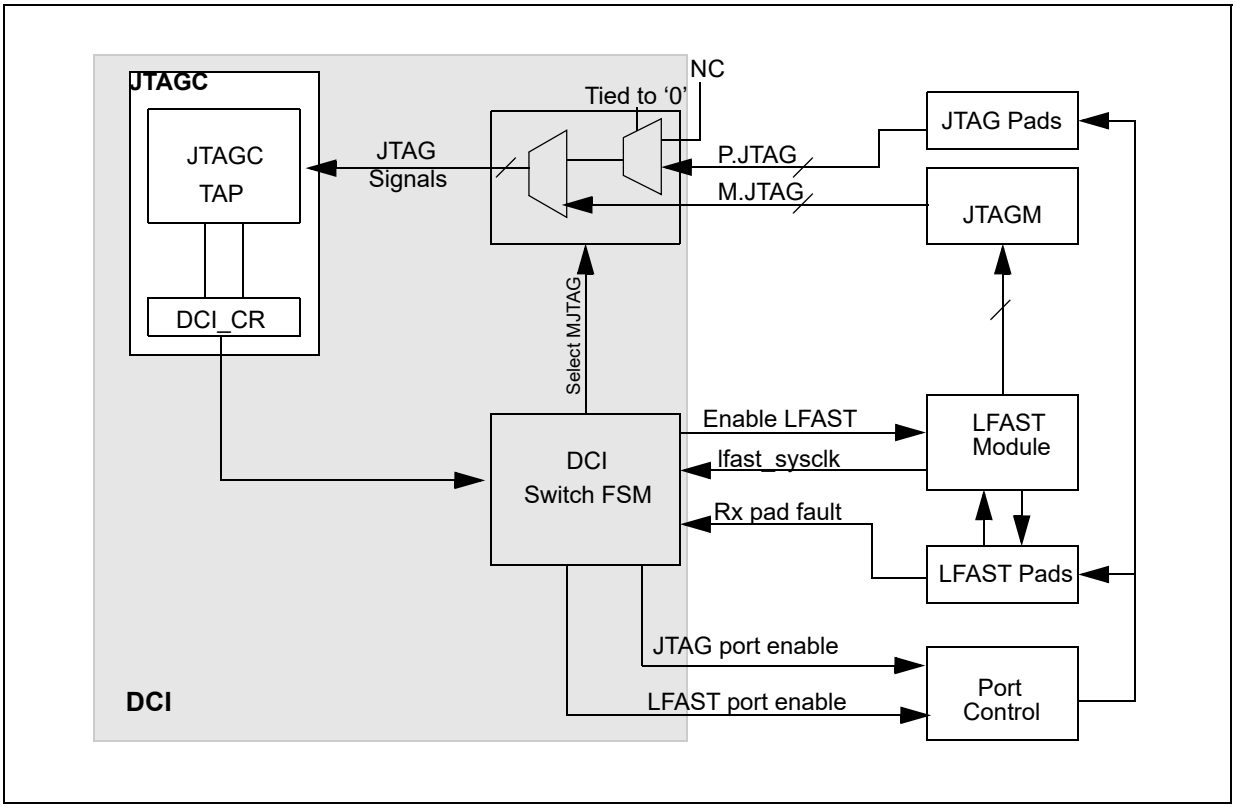
Figure 2442 shows the DCI mode switching operation.

Figure 2442. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

Table 2337 contains the operating mode descriptions.

Table 2337. DCI operating modes



Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.

Table 2337. DCI operating modes (continued)

Mode	Description
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

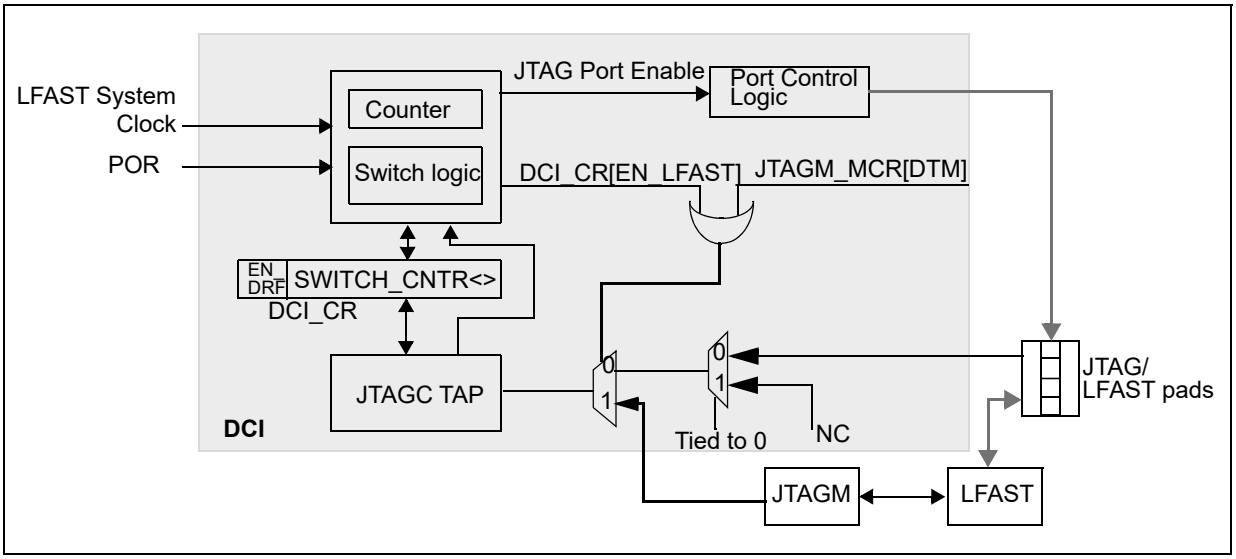
Figure 2443 shows a block diagram of the JTAG/LFAST connections.

Figure 2443. DCI JTAG/LFAST switch integration

95.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch

from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):



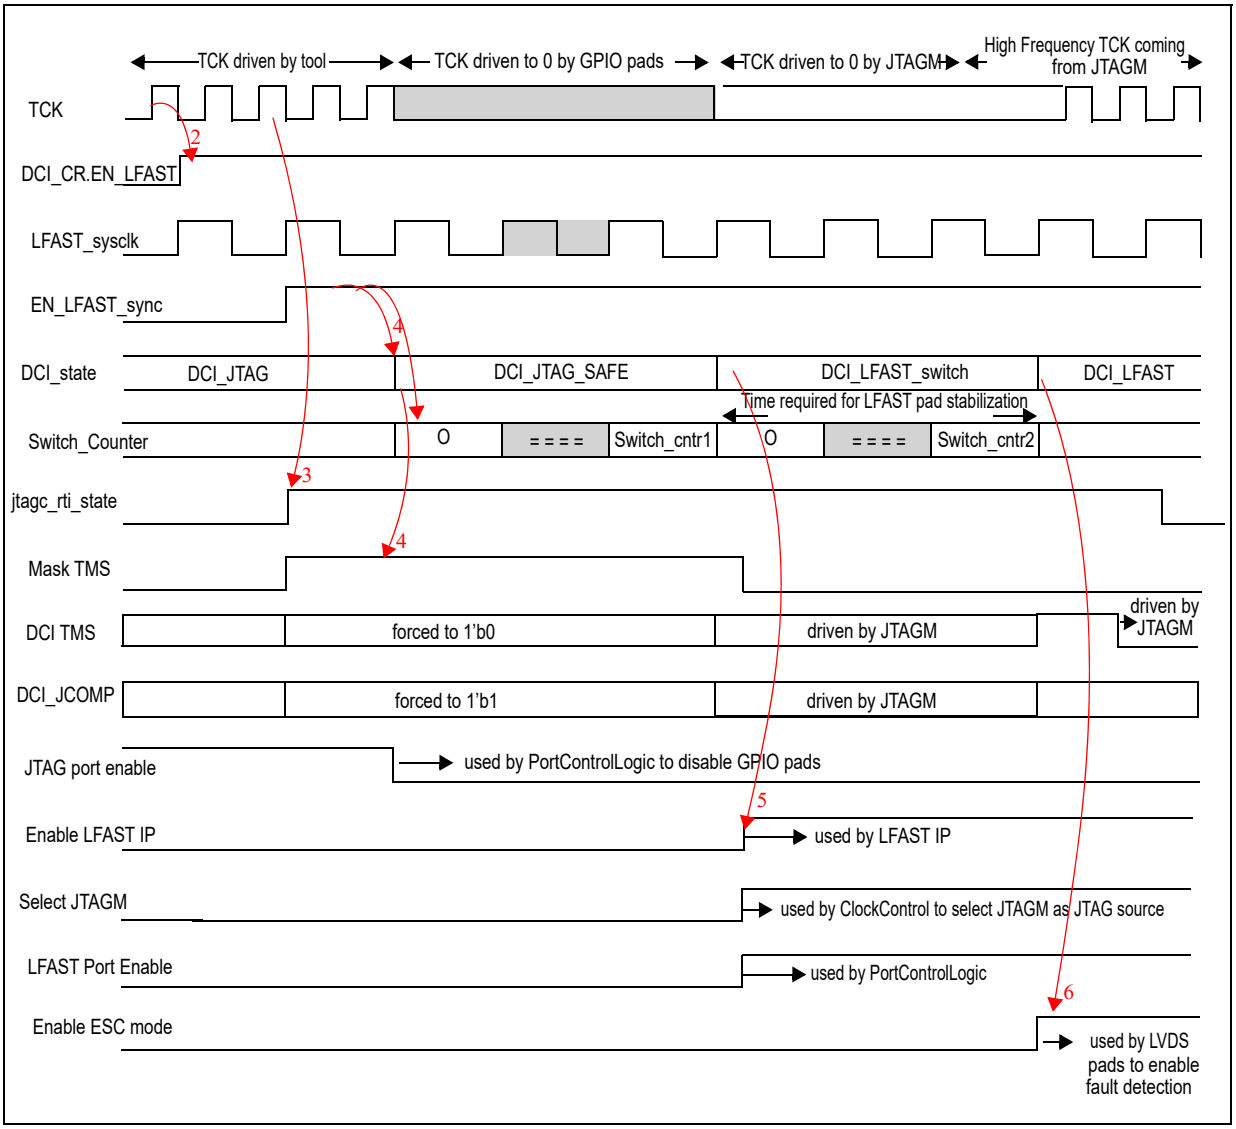
- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 2444*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 2444. DCI switching between JTAG and LFAST modes



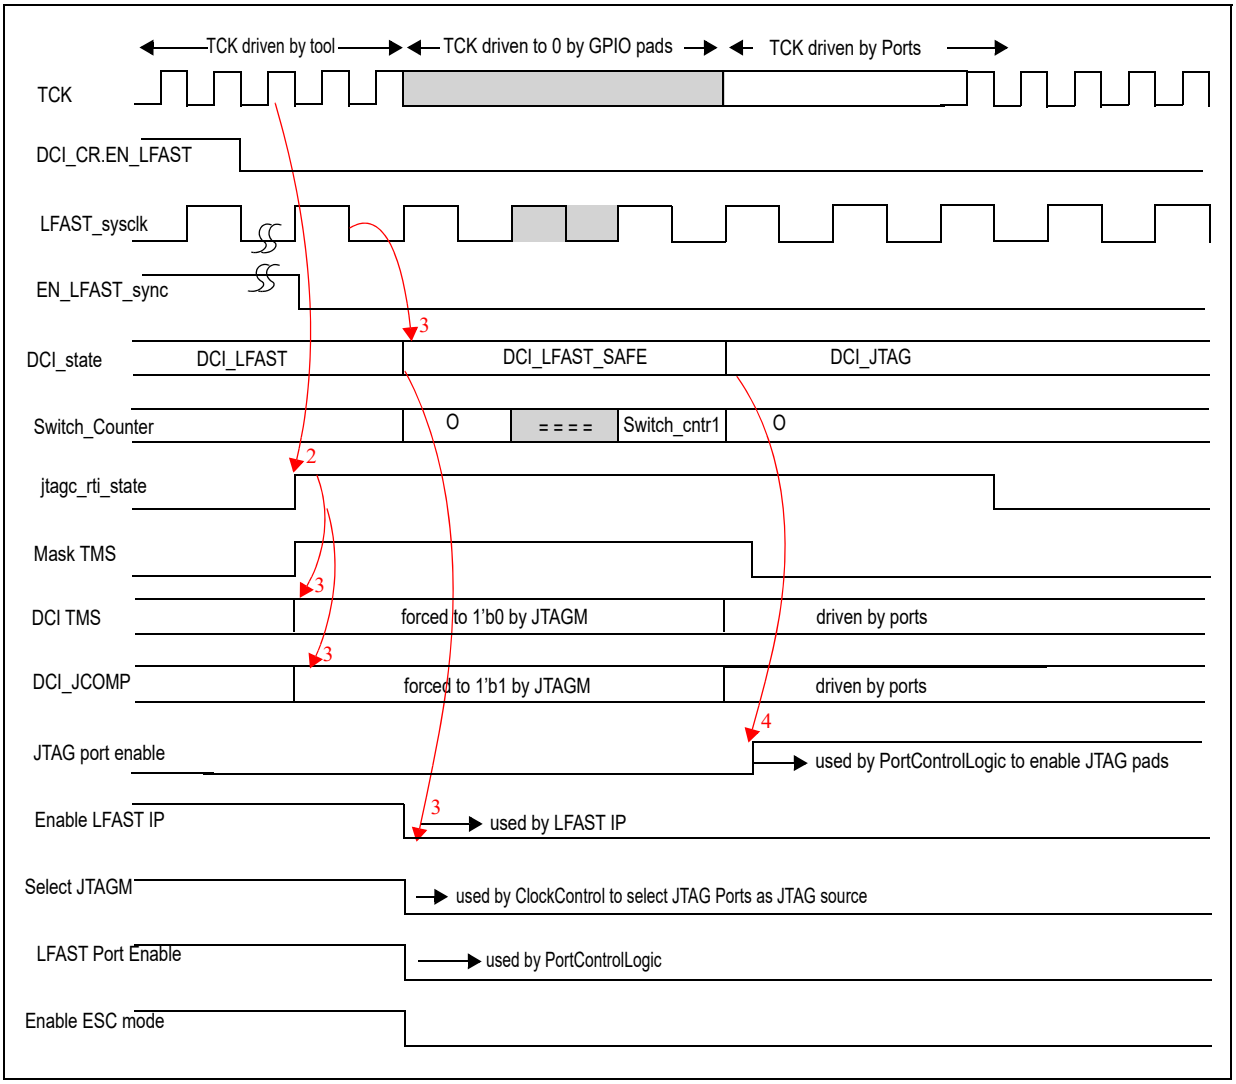
95.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   – EN_LFAST
   – SWITCH_CNTR1
   – SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 2445 shows the timing sequence.

Figure 2445. DCI JTAG to LFAST switching diagram



95.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 2341 and *Table 2343* summarize the MCU and tool behaviors. *Figure 2446* shows the timing sequence.

Figure 2446. DCI LFAST to JTAG switching diagram

95.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

95.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

95.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 2338. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

95.1.3.5 System watchdog control

The BD DCI does not include the Software Watchdog Timer (SWT) disable feature

95.1.3.6 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

95.1.3.7 Security

The SoC security logic provides a Debug_Enable signal to the PD DCI. The PD DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the PD DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

95.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

95.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the

DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

95.3.1 DCI control register (BD_DCI_CR)

The BD_DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 2447* shows the format of the BD_DCI_CR.

Note: The BD version of this register is referred to as DCI_CR in the other sections of this chapter.

In an ED which has both PD and BD instances of the DCI, all bits controlling the switch between LFAST and JTAGM must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

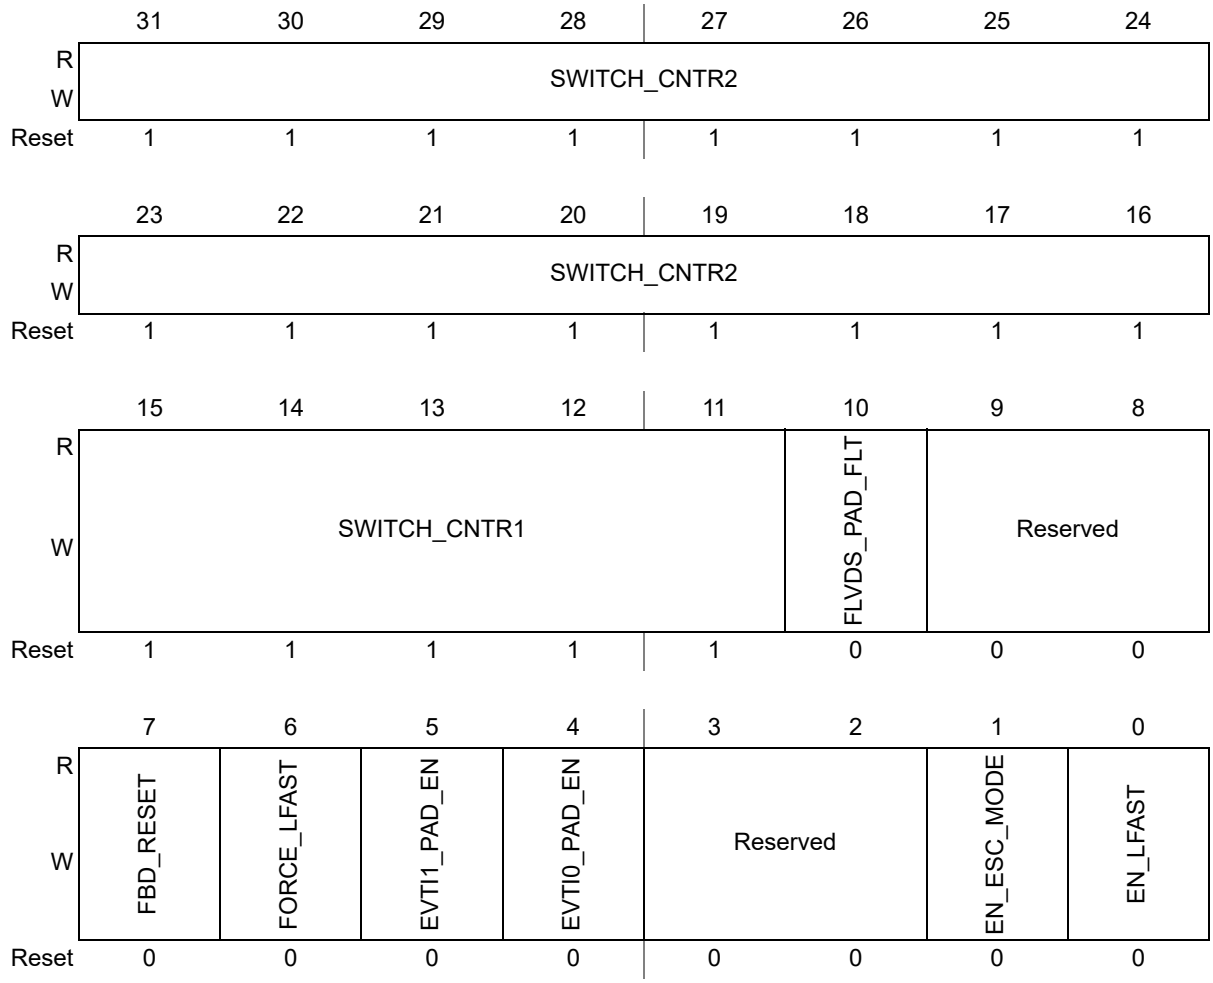


Figure 2447. DCI control register (DCI_CR)

The DCI_CR is described in *Table 2339*.

Table 2339. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2 Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1 Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
7 FBD_RESET	Force Reset 0 Do not force Reset 1 Force Reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN(1)	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN(2)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
1 EN_ESC_MODE	Enable Escape Mode Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(2)	Enable for LFAST-based tool selection This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

95.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter (or the Debug and Trace chapter) which describes how the modules are configured.

95.4 Functional description

95.4.1 DCI mode transition

After power-on reset, the BD DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 2340* and *Table 2341* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 2342* and *Table 2343* contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 2340. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN
TMS	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxP
TDO	Hi-Z	Logic Output	Logic Output	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxP
JCOMP	Logic Input	Logic Input	Logic Input Latch	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxN

TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP

Table 2341. Tool operation (JTAG to LFAST switching) (continued)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don't Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 2342. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 2343. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

95.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the BD LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the BD DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 2344* and *Table 2345* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

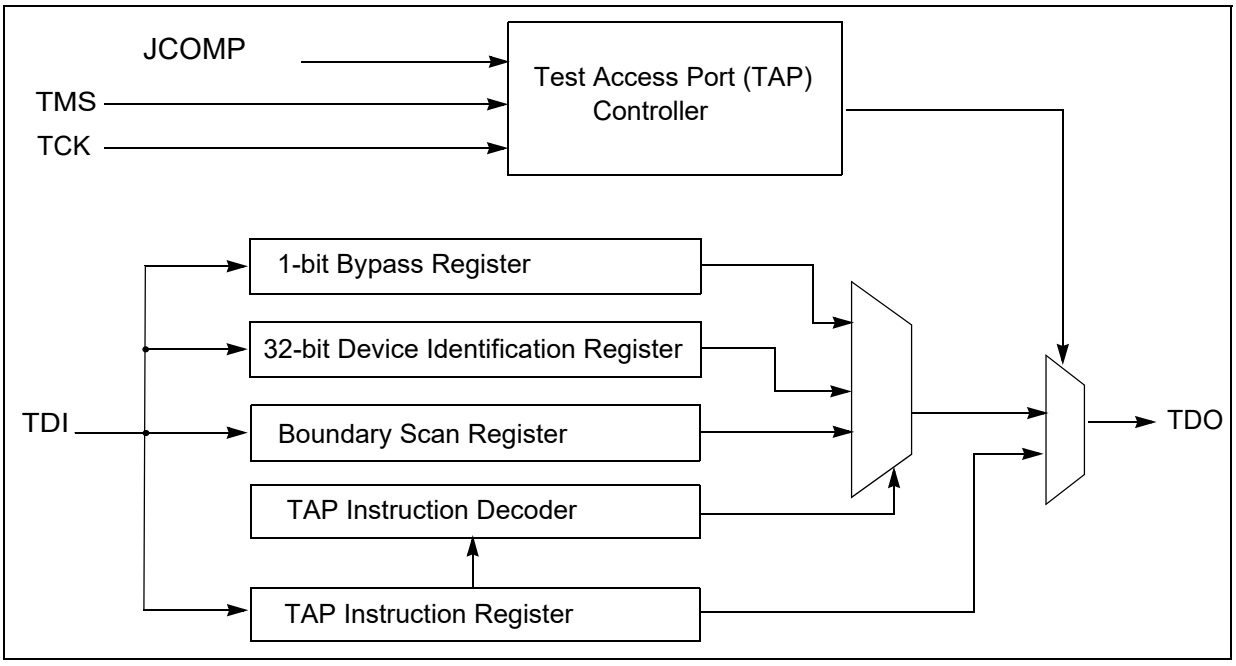
Table 2344. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 2345. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low
TDI	LVDS TxN	Don’t Care
TMS	LVDS TxP	Don’t Care
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don’t Care

96 Buddy Device—JTAG Controller (JTAGC)



96.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

96.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 2448. JTAG (IEEE 1149.1) block diagram

96.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 2349* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

96.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

96.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

96.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 96.4.4*.

96.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

96.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 2346. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

96.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

96.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

96.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 96.4.3*.

96.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

96.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

96.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

96.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

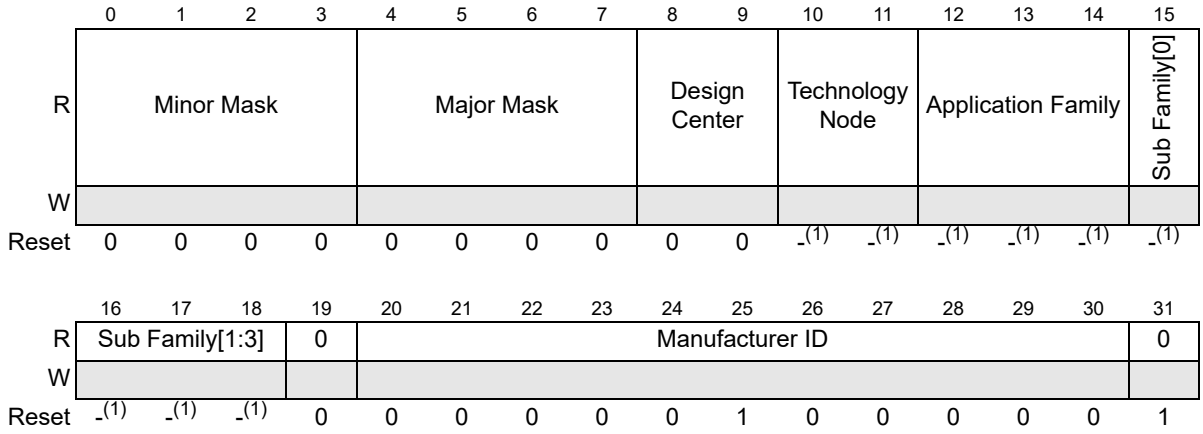


Figure 2449. 6-bit instruction register

96.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

96.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 2347*

Figure 2450. Device identification register

The following table describes the device identification register functions.

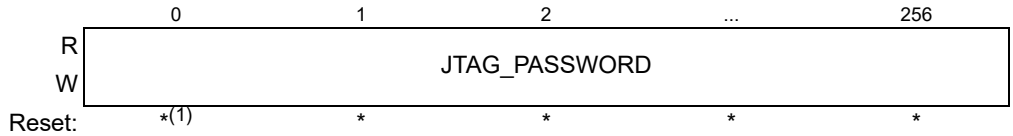

Table 2347. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 00 40nm
12:14 Application Family	Application Family These bits indicate the device application family 101 SPC58N - Chassis & Safety 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 0100 SPC58NE84C3 , SPC58NE84E7
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

96.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value

to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 2451. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 2348. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

96.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 96.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

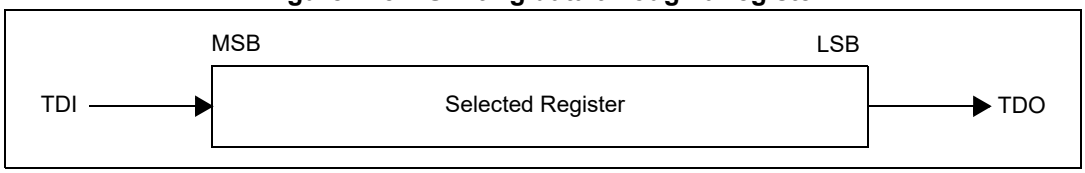
The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

96.4 Functional description

This section explains the JTAGC functional description.

96.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.



96.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the

value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 96.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

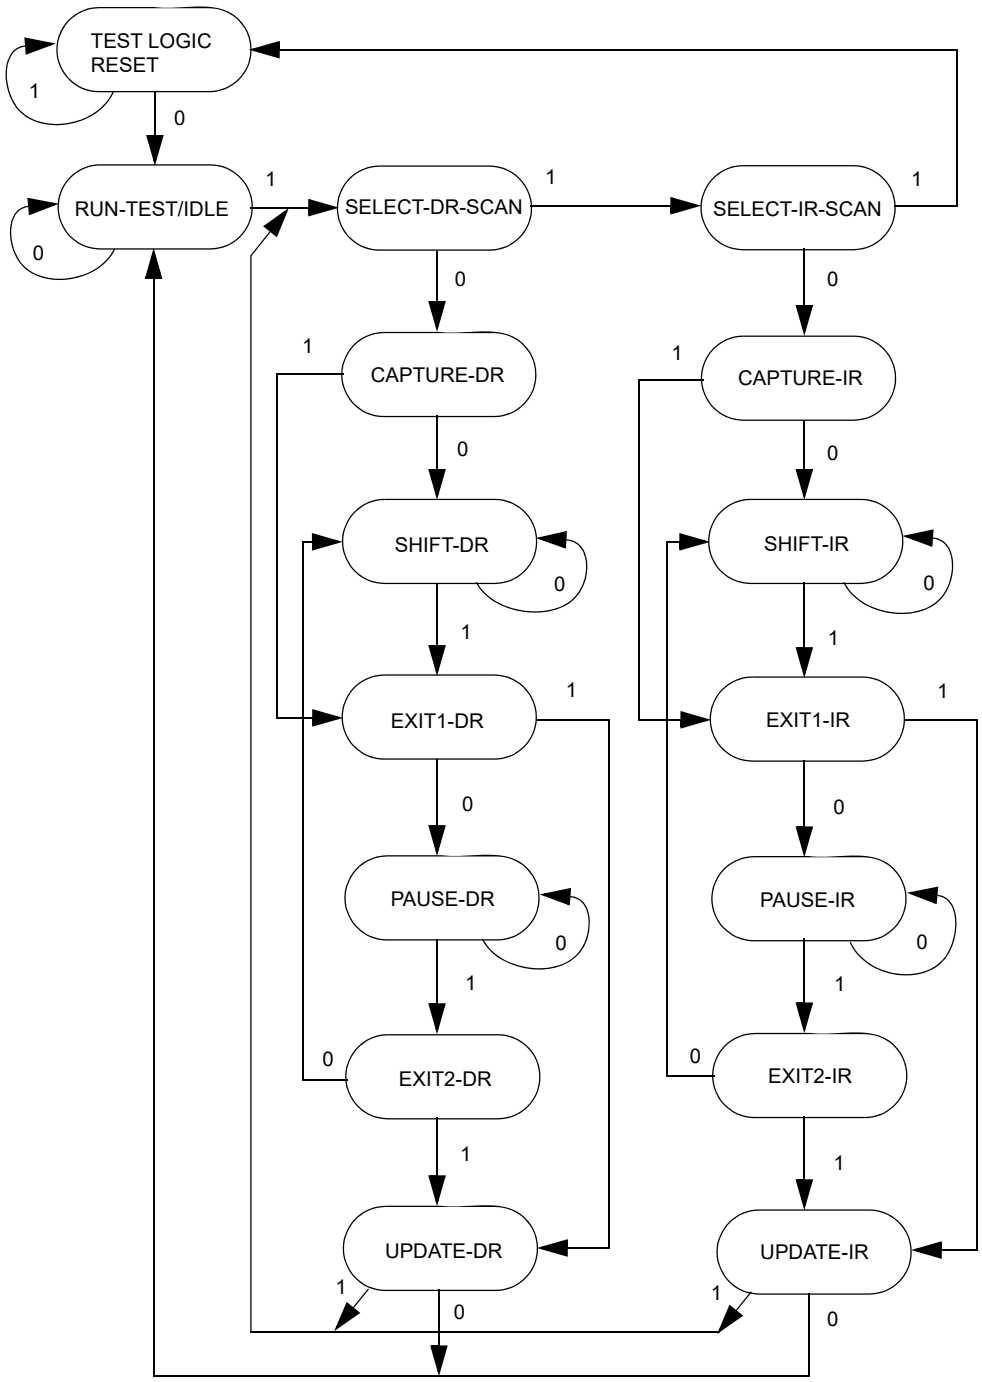


Figure 2452. Shifting data through a register

96.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 2453. IEEE 1149.1-2001 TAP controller finite state machine

Note:

1. The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

96.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

96.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

96.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 2349. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NR_BD	100000	Enables access to the NAR TAP controller on BD
Reserved	100001	Reserved
ACCESS_AUX_NAL	100010	Enables access to the NAL TAP controller

Table 2349. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ACCESS_AUX_RWA_BD	100011	Enables access to the RWA TAP controller
Reserved	100100	Reserved
Reserved	100101	Reserved
Reserved	100110	Reserved
Reserved	100111	Reserved
Reserved	101000	Reserved
Reserved	101001	Reserved
Reserved	101010	Reserved
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved

Reserved	111001	Reserved
ACCESS_AUX_DWPU	111001	Reserved
Reserved	111010	Reserved
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
ACCESS_AUX_DCI_PD	111110	Enables access to pass control from BD to PD
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

96.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

96.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

96.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

96.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

96.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

96.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

96.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

96.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

96.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

96.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

96.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

97 Buddy Device—JTAG Master (JTAGM)

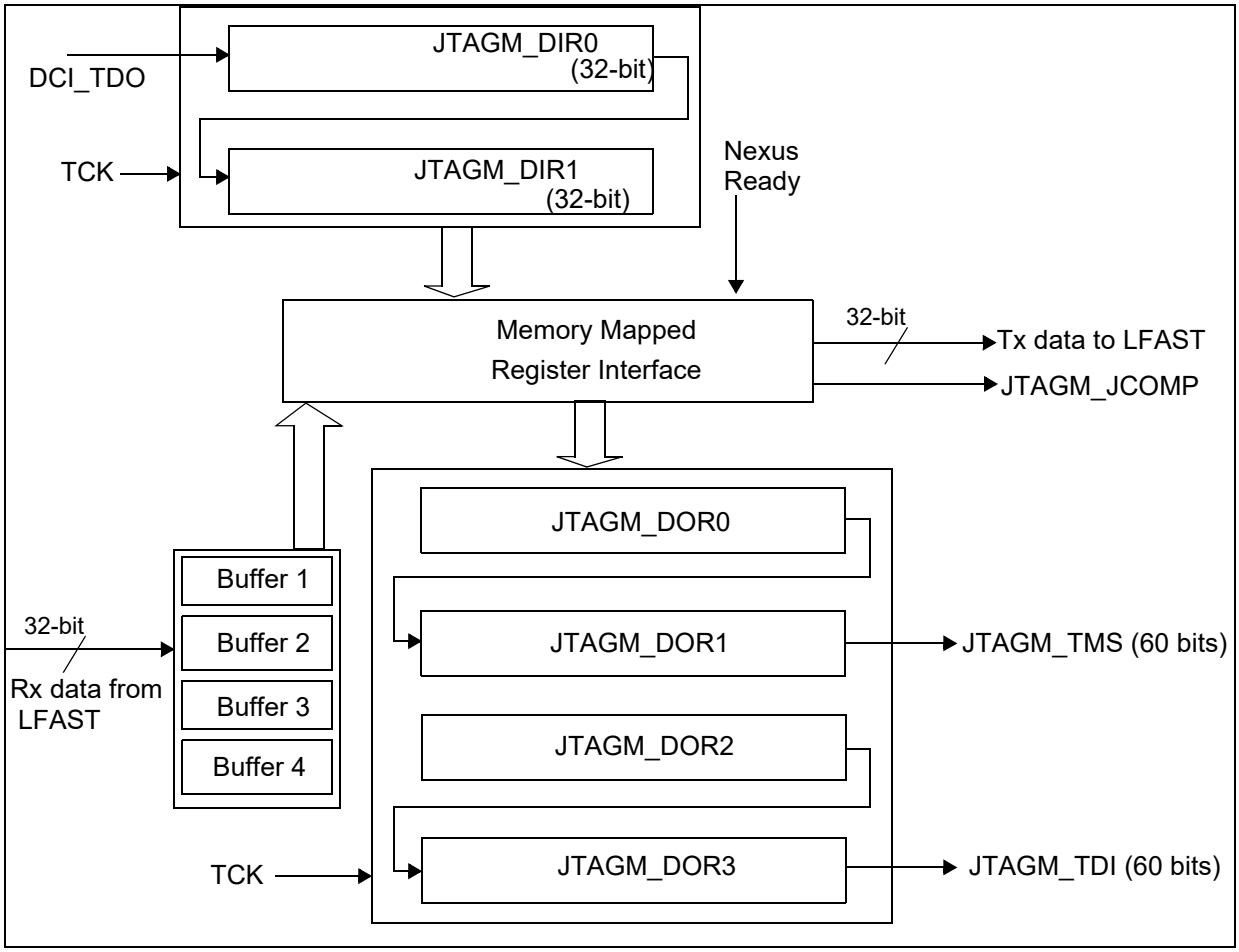
97.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

97.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers, described in detail in *Section 97.4*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 2454 shows the block diagram of the JTAGM.

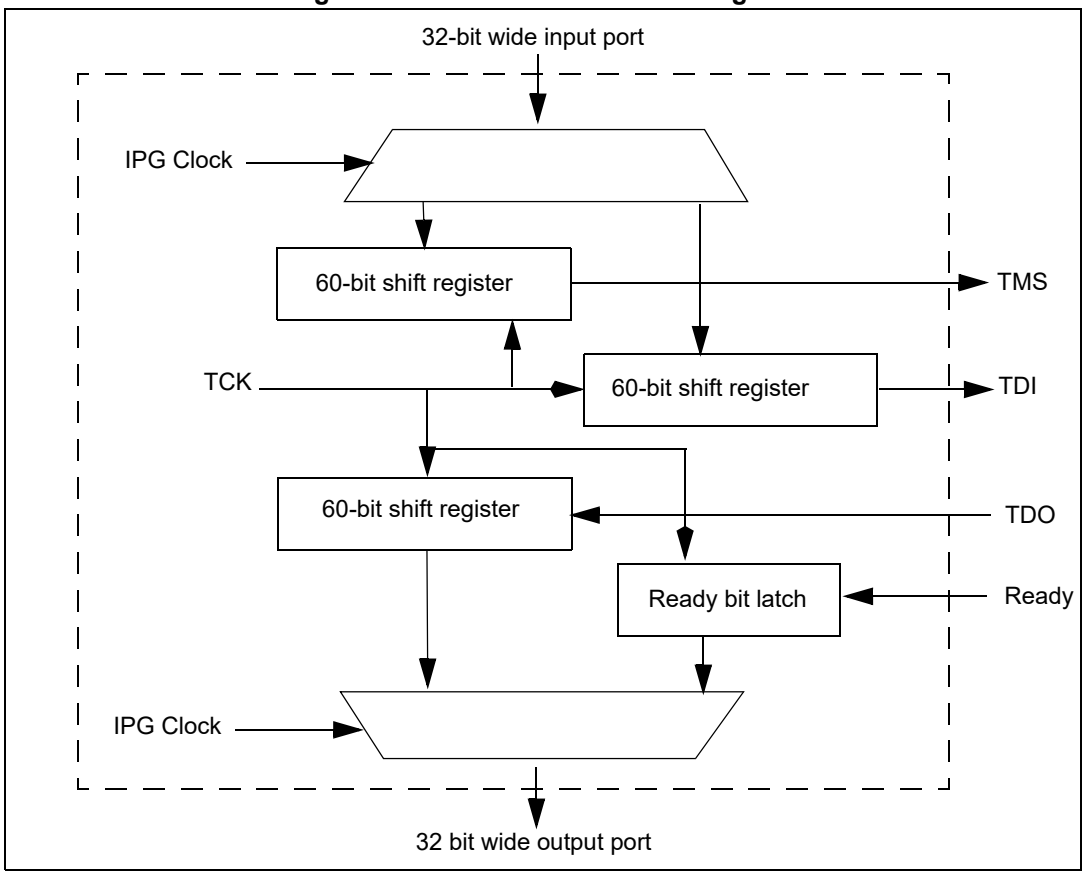
Figure 2454. JTAGM block diagram

97.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

97.2 Functional description



97.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 2455 shows the flow diagram of the LFAST to DCI connection.

Figure 2455. LFAST-to-DCI flow diagram

97.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

97.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

97.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

97.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

97.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK

shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

97.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

97.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

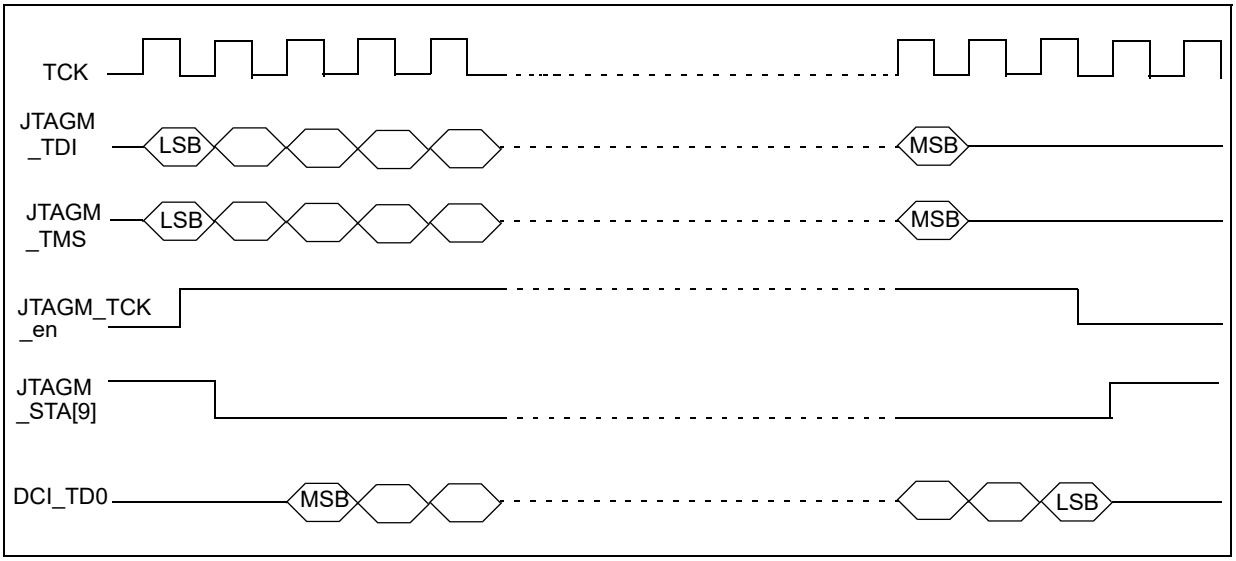
Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.

97.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 97.2.5.1: Status register*

ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written
- 32-bit value to be written to the configuration register
- 24-bit mask of which bits within the status register should be written
- 8 bits of zero-padding
- 24 bits of data to be written to the status register
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data)



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

[BLG_JTAGM_0008][Covers: ADD23.035]While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

97.2.8 JTAGM to DCI serial interface

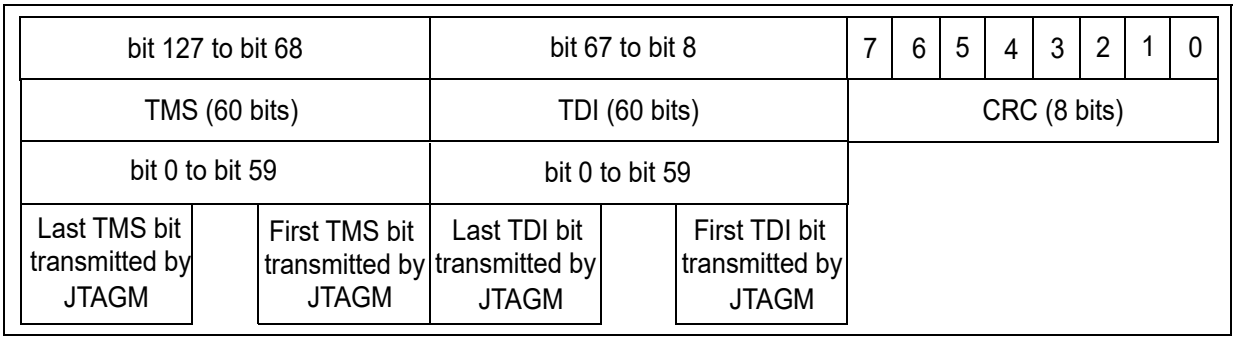
Figure 2456 shows the data transfer timings between JTAGM and DCI.

Figure 2456. JTAGM to DCI serial interface diagram

97.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 2457 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 2457. Bit ordering for LFAST to JTAGM transfer



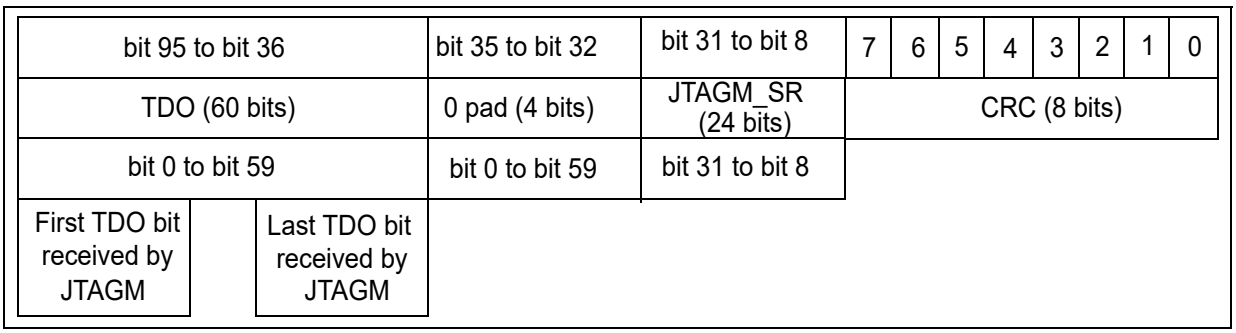


Figure 2458 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 2458. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 2458*).

97.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

97.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

97.4 Memory map and register definition

Table 2350 contains the memory map of the JTAGM registers.

Table 2350. Memory map

97.4.1 Register descriptions

97.4.1.1 Module configuration register (JTAGM_MCR)

This register contains the status bits for the current transfer. *Figure 2459* shows the format of the JTAGM_MCR. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. The only exception is the SIE bit, which always needs to be programmed in the Production Device instance of the JTAGM, regardless of being ED or not.

27:29 TCKSEL	TCK Divider division factor control value. (TCK Divider divides the clock input to JTAGM IP to generate TCK out(input to DCI)). 000 TCK Divider division factor is 1 001 TCK Divider division factor is 2 010 TCK Divider division factor is 3 011 TCK Divider division factor is 4 100 TCK Divider division factor is 5 101 TCK Divider division factor is 6 110 TCK Divider division factor is 7 111 TCK Divider division factor is 8 **Note:** It should be taken care that the maximum frequency of TCK input to DCI, should be equal or less than half of system clock.
30 jtagm_JCOMP	JTAG reset 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data for JTAG transferred by LFAST 1 Data for JTAG transferred by software

1. The BD JTAGM instance does not receive signals from the SPU. If required, this feature needs to be enabled in the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

97.4.1.2 Status register (JTAGM_SR)

97.4.1.2.1 LFAST mode

Figure 2460 shows the format of the JTAGM_SR in LFAST mode. In the ED, all bits of this register need to be accessed in the BD instance of the JTAGM. The exceptions are the bits related to the SPU interrupts (SPU_INT, SPU_INT_CLR), which always need to be accessed from the PD JTAGM, regardless of being ED or not.

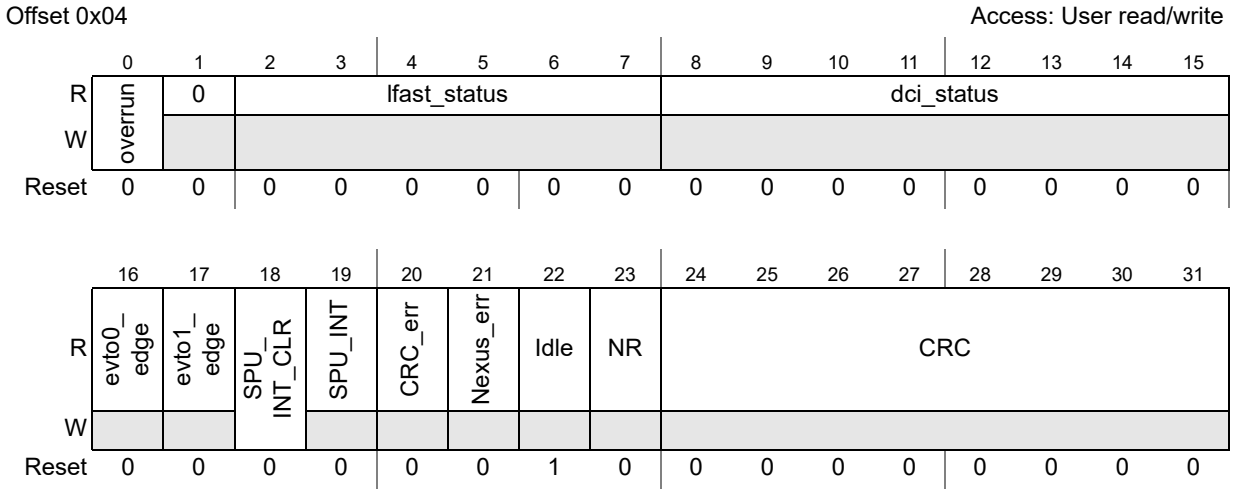

Figure 2460. JTAGM_SR register in LFAST mode

97.4.1.2.2 SW mode

Figure 2461 shows the format of the JTAGM_SR in SW mode.

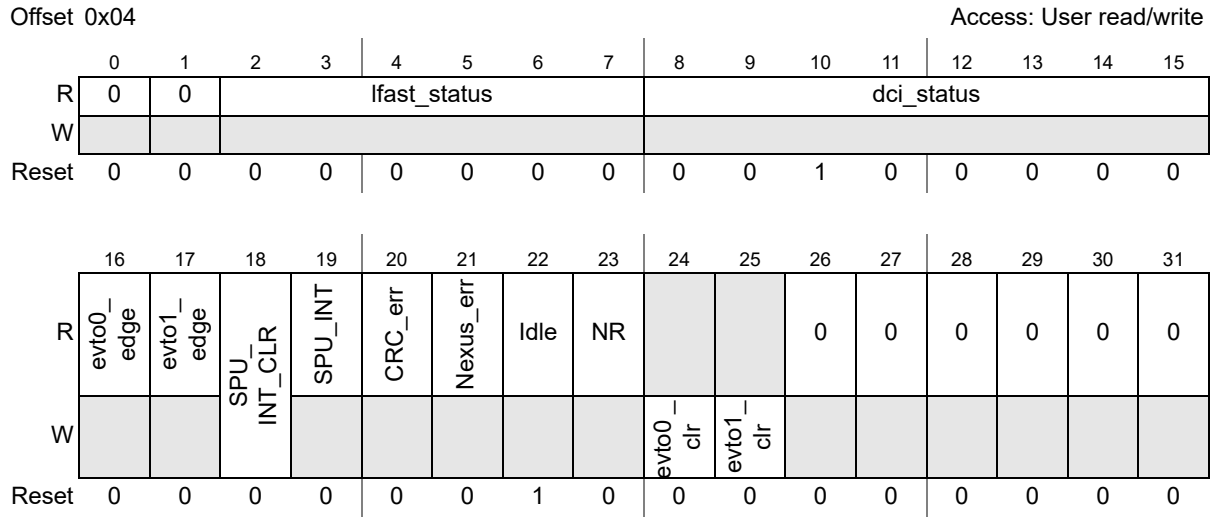

Figure 2461. JTAGM_SR register in SW mode

The JTAGM_SR register is described in *Table 2352*.

Table 2352. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$0
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1
18 SPU_INT_CLR	Write 1 clears the SPU_INT(1) This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit. (1)
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to ‘1’ when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.

Table 2352. JTAGM_SR register field descriptions (continued)

Field	Description
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode(when DTM =0) , this bit has no effect and acts as a “dont care” . This bit should not be used by the application in the LFAST mode
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

1. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

98 Buddy Device—Nexus Aurora Router (NAR)

98.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 2469*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

Figure 2469. NAR top level diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora

formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

Aurora type interface with clock domain transfer at the same frequency

98.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port or the Trace port, or both The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

98.3 Features

The NAR supports the following features:

- Connects 10 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

98.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 2360. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	on page 4019
NAR_ST—NAR Status Register	R	1	on page 4021
NAR_SFR—Source Filter Register	R/W	2	on page 4023

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2470. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 2361. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 98.5.2.2: Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). *Note: Some clients may only support timestamps on every message.* 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 1/2 of queue is dedicated to alternate partition 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.

Table 2361. NAR_CR field descriptions (continued)

Field	Description
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications. 00 No message select port. 0–1 port is active. 01 HBDP is the MSP 10 Trace memory bus is the MSP 11 Reserved
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 HBDP is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2 FSD	Frame Serial Data. 0 Framing disabled. Data is streamed through the Aurora out port. 1 Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

98.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 2471. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 2362. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 2377* for coding
23 MPF	MSP Partition Full. 0 MSP partition not full 1 MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled that is the main queue is partitioned. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%
20 APF	ALT Partition Full. 0 ALT partition not full 1 ALT partition full
19–18 ALV	ALT Partition Queue Level. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%

Table 2362. NAR_ST field descriptions (continued)

Field	Description
17–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)

98.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 98.5.6: Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

98.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

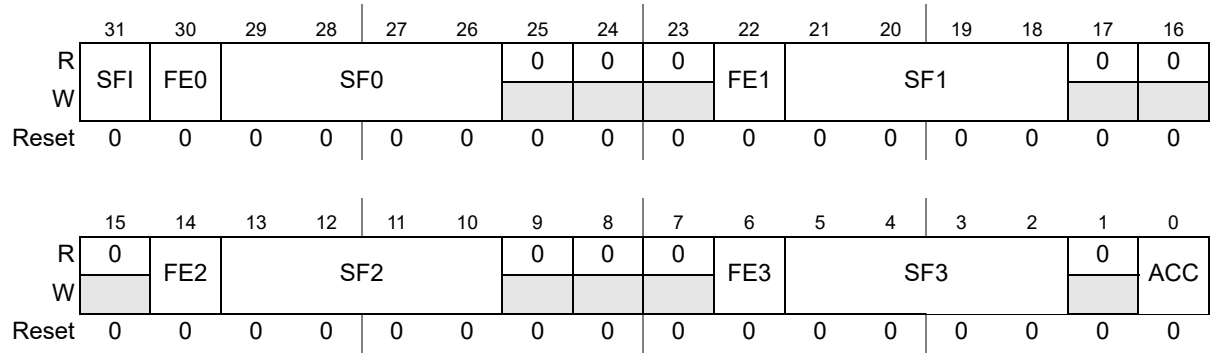

Figure 2472. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2363. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3

Table 2363. NAR_SFR field descriptions (continued)

5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

98.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

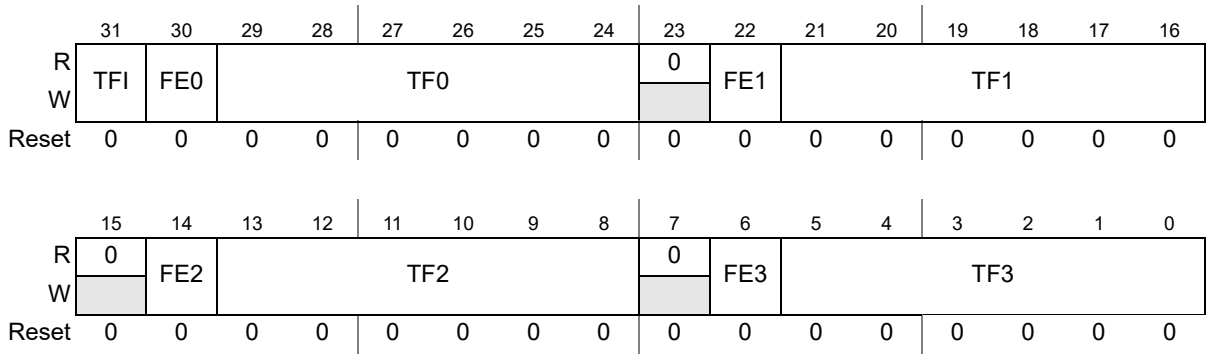

Figure 2473. Message type filter register (NAR_TFR)

The NAR_TFR is described in the following table.

Table 2364. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See *Section 98.5.6: Output arbitration* for an example.

Table 2364. NAR_TFR field descriptions (continued)

15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 98.5.6: Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 98.5.6: Output arbitration* for an example.

98.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

98.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TBAHI																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2474. Trace memory base address register NAR_TBAHI

Register index: 4

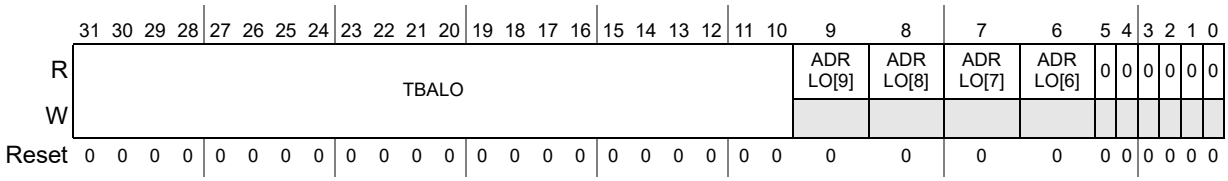

Figure 2475. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 2365. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 2366. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

98.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

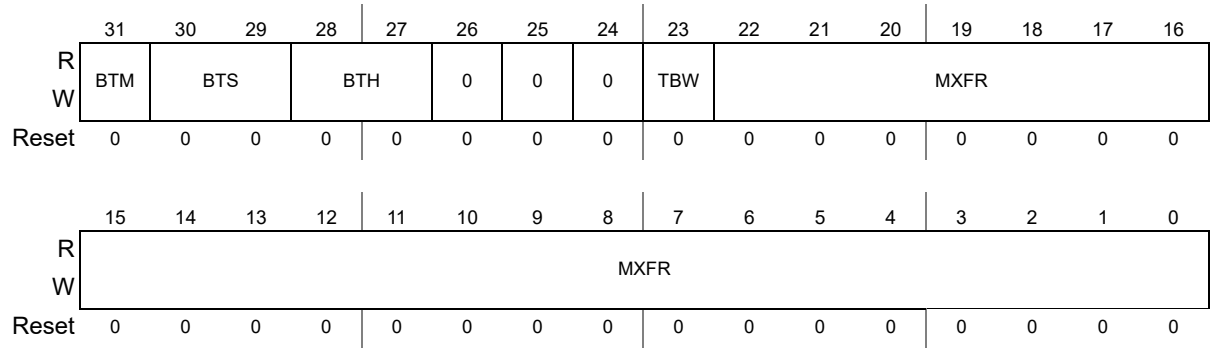

Figure 2476. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 2367. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

98.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 98.5.4: Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each

Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2477. Suppress trigger control registers (NAR_STCR1–4)

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2368. NAR_STCR field descriptions

Field	Description
31 GST	Global Suppress Trigger. 0 The associated trigger cannot cause NAR to enter global suppress mode 1 The associated trigger is enabled for global suppress mode
29–16	Reserved
15–0 LST	Local Suppress Trigger. 0000000000000000The associated trigger is disabled for local suppress mode for all clients xxxxxxxxxxxxxxx1Trigger is enabled for Client 1 local suppress xxxxxxxxxxxxxx1xTrigger is enabled for Client 2 local suppress xxxxxxxxxxxxx1xxTrigger is enabled for Client 3 local suppress xxxxxxxxxxxx1xxxTrigger is enabled for Client 4 local suppress xxxxxxxxxxx1xxxxTrigger is enabled for Client 5 local suppress xxxxxxxxxx1xxxxxTrigger is enabled for Client 6 local suppress xxxxxxxxx1xxxxxxTrigger is enabled for Client 7 local suppress xxxxxxxx1xxxxxxxTrigger is enabled for Client 8 local suppress xxxxxxx1xxxxxxxxTrigger is enabled for Client 9 local suppress xxxxxx1xxxxxxxxxTrigger is enabled for Client 10 local suppress xxxxx1xxxxxxxxxxTrigger is enabled for Client 11 local suppress xxxx1xxxxxxxxxxxTrigger is enabled for Client 12 local suppress xxx1xxxxxxxxxxxxTrigger is enabled for Client 13 local suppress xx1xxxxxxxxxxxxxTrigger is enabled for Client 14 local suppress x1xxxxxxxxxxxxxxTrigger is enabled for Client 15 local suppress 1xxxxxxxxxxxxxxxTrigger is enabled for Client 16 local suppress All other options Reserved

98.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status

(NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

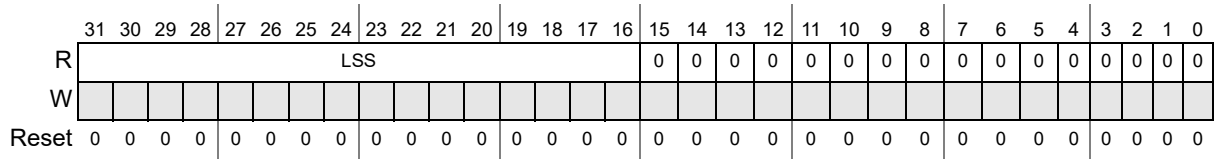

Figure 2478. Client suppress status register (NAR_CSSR)

The NAR_CSSR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress status, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2369. NAR_CCSR field descriptions

Field	Description
31–16 LSS	Local Suppress Status. 0000000000000000No client is in local suppress mode xxxxxxxxxxxxxxx1Client 1 is suppressed xxxxxxxxxxxxxx1xClient 2 is suppressed xxxxxxxxxxxxx1xxClient 3 is suppressed xxxxxxxxxxxx1xxxClient 4 is suppressed xxxxxxxxxxx1xxxxClient 5 is suppressed xxxxxxxxxx1xxxxxClient 6 is suppressed xxxxxxxxx1xxxxxxClient 7 is suppressed xxxxxxxx1xxxxxxxClient 8 is suppressed xxxxxxx1xxxxxxxxClient 9 is suppressed xxxxxx1xxxxxxxxxClient 10 is suppressed xxxxx1xxxxxxxxxxClient 11 is suppressed xxxx1xxxxxxxxxxxClient 12 is suppressed xxx1xxxxxxxxxxxxClient 13 is suppressed xx1xxxxxxxxxxxxxClient 14 is suppressed x1xxxxxxxxxxxxxxClient 15 is suppressed 1xxxxxxxxxxxxxxxClient 16 is suppressed All other optionsReserved
15–0	Reserved

98.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note: Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Register index: C

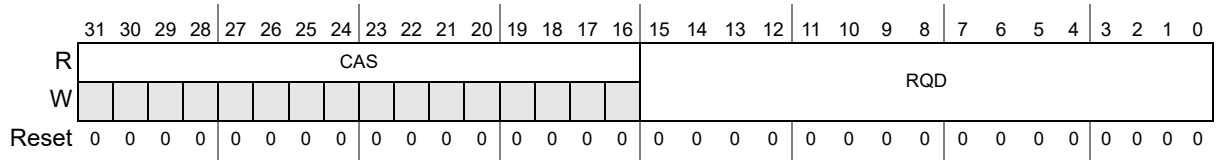

Figure 2479. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2370. NAR_CDR field descriptions

Field	Description

Figure 2480. Nexus Aurora Phy control register (NAR_NAPCR)

The NAR_NAPCR is described in the following table.

Table 2371. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. This field is device specific. For a description of this field see the Calibration and Debug configuration chapter which describes how the modules are configured.
11–8 LVDS_TXOPT	This is an internal characterization field.
7 LVDS_RX_TERM_EN	This is an internal characterization field.
6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

98.4.7 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	GSE	0	0	0	GLOBAL_STALL_COUNT				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0				

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2481. Trace memory fill level and partition configuration register (NAR_AHFPAR)

The NAR_AHFPAR is described in the following table.

Table 2372. NAR_AHFPAR field description

Field	Description
31-25	Reserved and must be written with 0s
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on dci_evti[0] event to generate a global stall
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See *Section 98.5.13: Global (Development tool client) stall control*
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 98.5.14: Overlay and internal trace memory full status generation* **Note:** This is used in BD as it has memory ranges from 65K to 983K
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 98.5.14: Overlay and internal trace memory full status generation* **Note:** This is used in PD as it has memory ranges from 1K to 15K

98.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

98.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 98.5.4: Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

98.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 2373. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled

Table 2373. NAR operational modes truth table (continued)

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

98.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

98.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

98.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

98.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

98.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 2374. NAR transmit operations

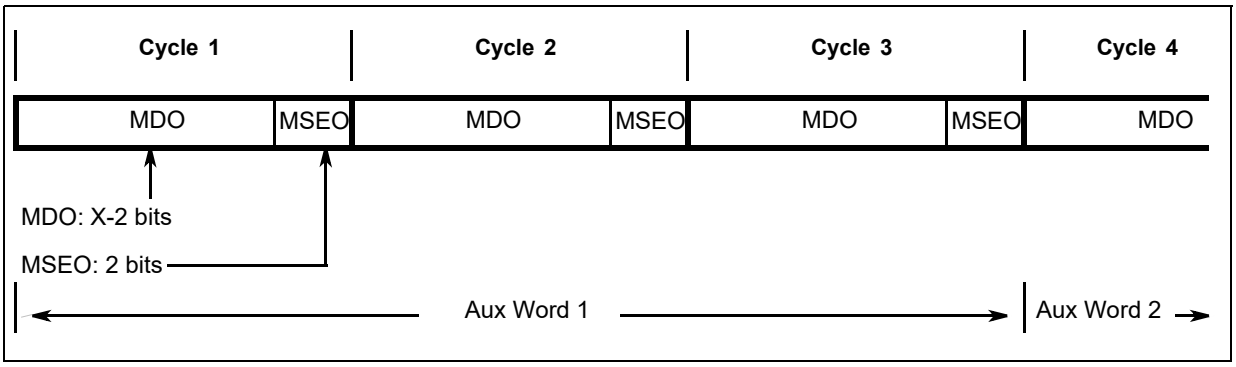
Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

98.5.3 Data reception and arbitration

The BD NAR supports 10 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never

sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn $\times$ 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2482. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request

level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

98.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client’s Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then

all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

98.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

98.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type or messages from a particular client, or both, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

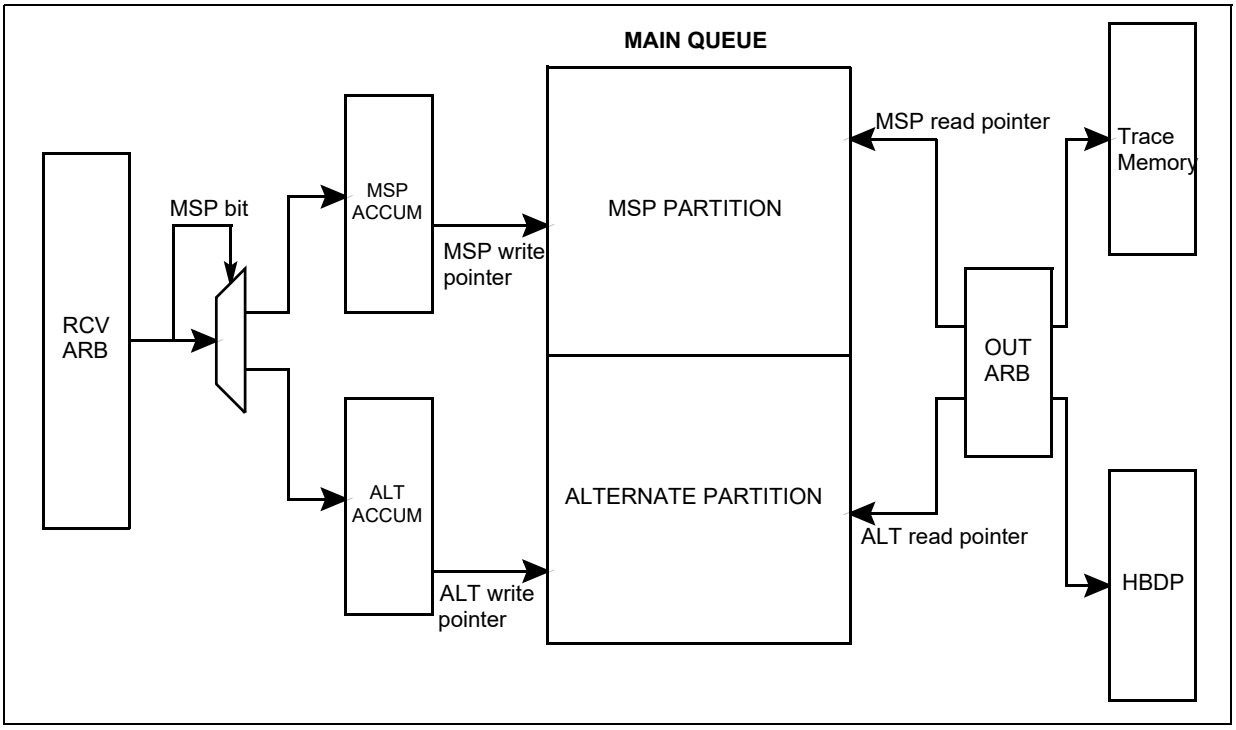
If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types or four sources, or both.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP



Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

98.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in *Figure 2483*. Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

Figure 2483. Queue partitioning

98.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

98.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

98.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and

resizing in the likely case where the trace memory bus width does not equal the queue entry size.

98.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

98.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (that is unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 $\times$ 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

98.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 2378*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 2375. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 2376*
	12	12	fixed	ECODE	See *Table 2377*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC2	NAR source ID
	6	6	fixed	WPHIT	See *Table 2378*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

98.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 2376. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 2377*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 2377*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 2377*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 2377. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering or queue partitioning disabled, or both	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

98.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

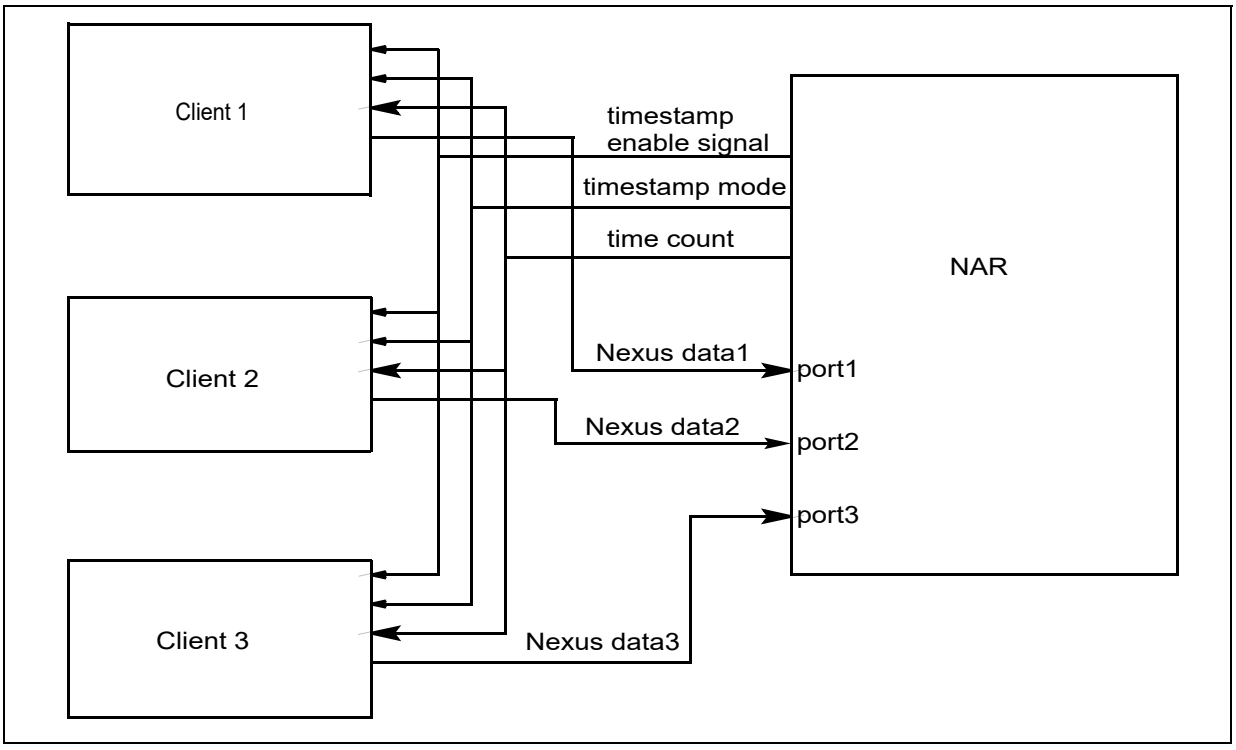


Table 2378. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

98.5.12 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 2484*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2484. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

98.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to NAR block. The dci_evti[0] carries this information. NAR detects the falling edge of dci_evti[1] and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

98.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (that is TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

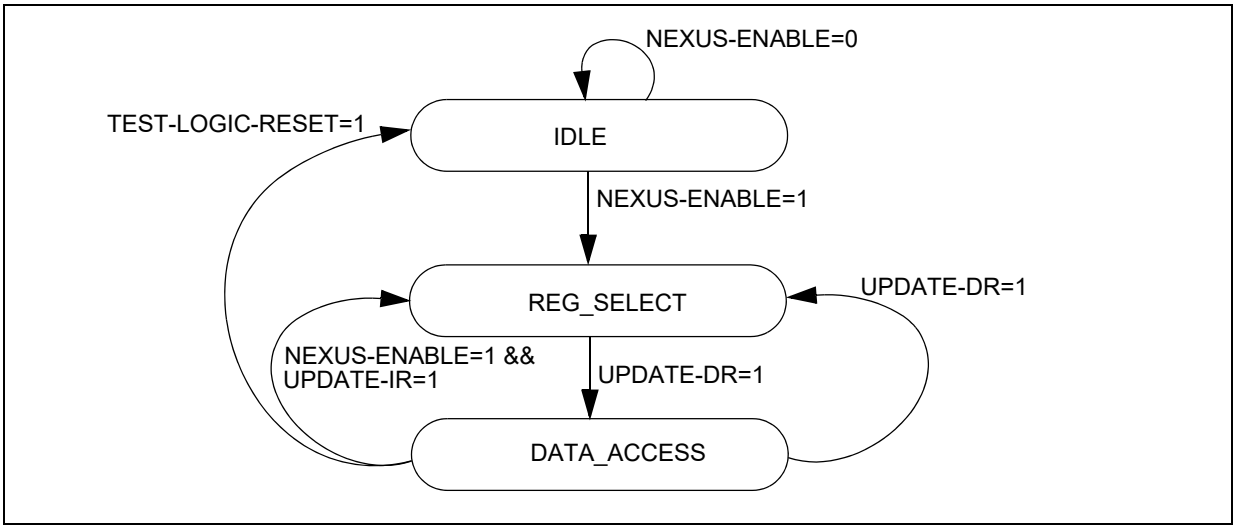
98.5.15 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 2379*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2485. Nexus controller state machine



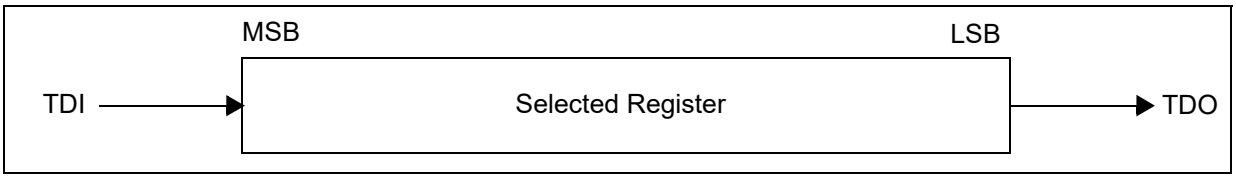


Table 2379. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2486. Shifting data into register

98.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

98.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2485*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 2380. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

98.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2487*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 2360*.

Figure 2487. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 2381. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

98.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

98.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

98.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

98.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

98.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width $\times$ 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as Bn $\times$ 32, where 32 = MDO bits + 2 MSEO bits and Bn is the number of beats.

Thus:Aurora data width = the Nexus client data

Aurora width $\times$ 16 = Bn $\times$ 32

Aurora width = 2 $\times$ Bn.

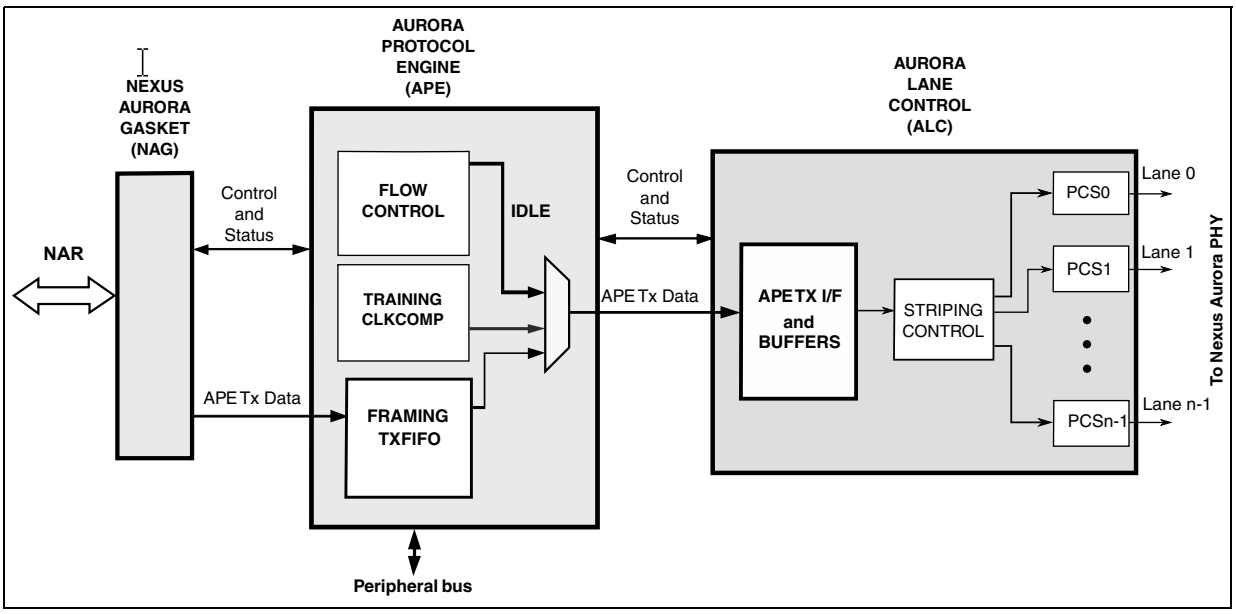
This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block. The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

98.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 98.5.2.1: Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

98.7 Application information



The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 98.5.6: Output arbitration*.

99 Buddy Device—Nexus Aurora Link (NAL)

99.1 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. *Figure 2488* details the NAL block diagram. The number of lanes, n, is 4.

Figure 2488. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Router (NAR); messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. *Table 2382* lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 2382. NAL and NAP feature summary

Sub-component	Feature
NAR Aurora Gasket (NAG)	– Transmit FIFO to buffer data as it crosses the NAR / NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. – Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	– Link training – Per the Aurora Protocol specification, clock-compensation, and data framing – Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	– Striping of data stream from the Aurora core across all available lanes in two-byte chunks – PCS functionality for NAL
Nexus Aurora PHY (NAP)	– Physical transmission of serial data to device pins – External clock source for SerDes clock domain

99.2 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each packet is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each payload transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

Note: Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

99.3 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

99.4 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note: Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

99.5 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 2383. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0x0	NAL General Status Register (NAL_GSR)	32	R	0x0000_8000

Figure 2489. Nexus Aurora Link General Status Register (NAL_GSR)

Table 2384. NAL_GSR field descriptions

Field	Description
0:11	Reserved
12 TXONLY	Transmit Only mode. Indicates that Aurora is configured in a transmit-only mode. 0 Reserved 1 Aurora is configured for transmit-only simplex communication. Training method is configured to use Static Training.
13:18	Reserved
19:21 TXCFG	TX Lane Configuration Number of enabled TX lanes. These bits are read-only and are controlled external to the NAL. 000 Reserved 001 2 TX lanes 010 Reserved 011 4 TX lanes 100 Reserved 101 Reserved 110 Reserved 111 Reserved
22:30	Reserved
31 AS	Aurora Status 0 Aurora is not enabled. 1 Aurora is enabled.

99.5.2 NAL General Control Register (NAL_GCR)

The NAL_GCR configures the behavior of the APE. It can be programmed to reset the Aurora channel, or to configure simplex/duplex initialization and to enable debug features.

Access: Read/Write

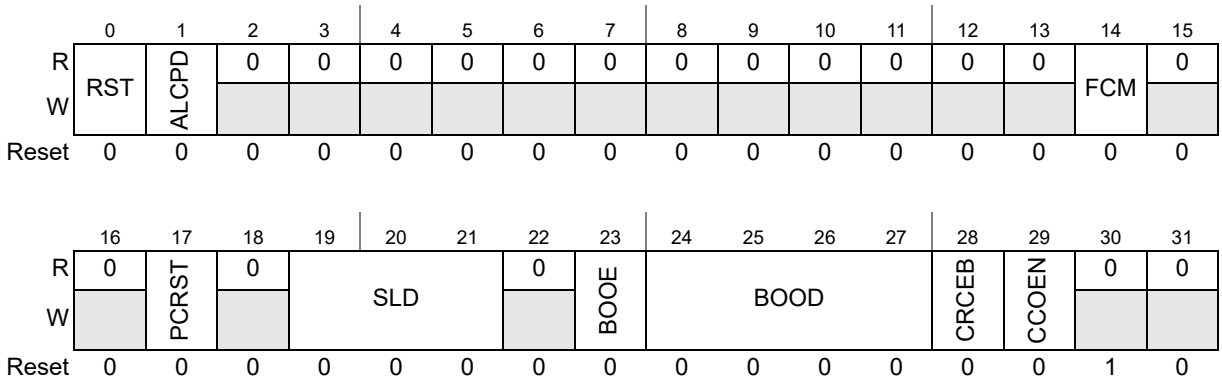

Figure 2490. NAL General Control Register (NAL_GCR)

Table 2385. NAL_GCR field descriptions

Field	Description
0 RST	Reset the Aurora Channel 0 to 1 transition resets the channel and begins the training sequence. 0 normal operation 1 transition from 0 to 1 resets channel and starts training sequence
1 ALCPD	ALC/NAL Power Down Gate off clocks to the NAL blocks (ALC and APE). 0 NAL is enabled with all clocks running provided other mechanisms of powerdown (such as alc_num_lanes) are not in effect. 1 NAL is powered down and inactive.
2:13	Reserved This read-only bitfield is reserved and always has the value zero.
14 FCM	Flow Control Mode 0 Completion Mode 1 Immediate Mode
15:16	Reserved and must be written with zero.
17 PCRST	Protocol Converter Reset Resets the ALC when asserted.
18	Reserved This read-only bit is reserved and always has the value zero.
19:21 SLD	Symbol Lock Delay 000 Allow 3 characters to accumulate in elastic buffer before starting to read 001 Allow 4 characters to accumulate in elastic buffer before starting to read 010 Allow 5 characters to accumulate in elastic buffer before starting to read 011 Allow 6 characters to accumulate in elastic buffer before starting to read 100 Allow 7 characters to accumulate in elastic buffer before starting to read 101 Allow 8 characters to accumulate in elastic buffer before starting to read 110 Allow 9 characters to accumulate in elastic buffer before starting to read 111 Allow 10 characters to accumulate in elastic buffer before starting to read
22	Reserved This read-only bit is reserved and always has the value zero.

Table 2385. NAL_GCR field descriptions (continued)

Field	Description
23 BOOE	Bond Offset Override Enable 0 ALC channel bond attempts to determine channel bond offset. 1 ALC uses user override setting for channel bond offset.
24:27 BOOD	Bond offset override data Only valid when BOOE is set. 0000/1000 use 0-cycle offset 0001 use -7 cycle offset 0010 use -6 cycle offset 0011 use -5 cycle offset 0100 use -4 cycle offset 0101 use -3 cycle offset 0110 use -2 cycle offset 0111 use -1 cycle offset 1001 use +1 cycle offset 1010 use +2 cycle offset 1011 use +3 cycle offset 1100 use +4 cycle offset 1101 use +5 cycle offset 1110 use +6 cycle offset 1111 use +7 cycle offset
28 CRCEB	CRC Enable 0 CRC generation and checking is disabled for TX and RX data. 1 CRC is inserted for TX frames and CRC is checked for RX paths.
29 CCOEN	Clock Compensation Override Enable This is a debug feature which allows the duration between clock compensation sequences to be reduced to 1280 cycles. 0 Clock compensation counter times out at 7424 cycles 1 Clock compensation counter times out at 1280 cycles
29	Reserved and must be written with zero.
30:31	Reserved This read-only bitfield is reserved and always has the value zero.

99.5.3 NAL Training Control Register (NAL_TCR)

The NAL_TCR supports static training as described in *Section 99.4: Static training*.

Access: Read/Write

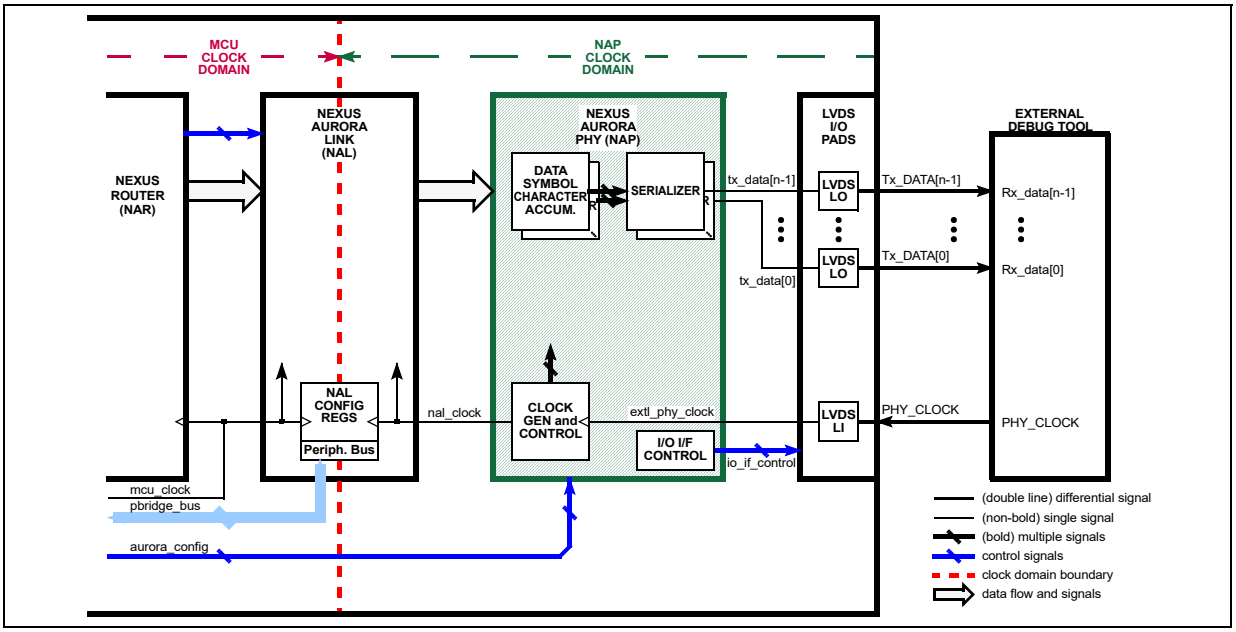
100 Buddy Device—Nexus Aurora PHY (NAP)

100.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.



Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

Figure 2492 shows a high level block diagram of the High Speed Nexus Interface and the NAP.

Figure 2492. High speed Nexus interface block diagram

100.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

100.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

100.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

100.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

100.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 4 Transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

100.2 External signal description

The external signals of the NAP are listed in *Table 2387*. Each of the NAP signals consists of a positive and negative differential pair.

Table 2387. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2(TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3(TX3P/TX3N)	Output	NAP Tx data for lane 3

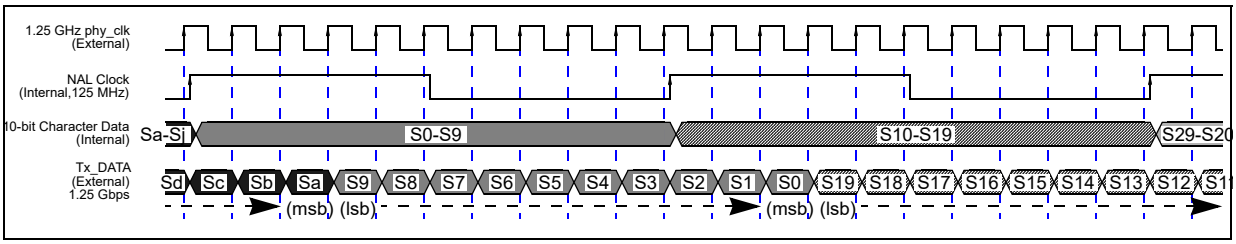
100.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

100.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

100.4.1 Data symbol character accumulator



The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

100.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

Figure 2493 shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

Figure 2493. Serializer timing diagram

100.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

100.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

Appendix A Acronyms and abbreviations

Table 2388 lists acronyms and abbreviations used in this document.

Table 2388. Acronyms and abbreviations

Term	Meaning
ADMA	AMU's Direct Memory Access
AHB	Advanced high-performance bus
AIC	PBRIDGE (AIPS) integrity checker
ALU	Algorithmic Logic Unit
AMBA	Advanced microcontroller bus architecture
APU	– Advanced protocol unit – Auxiliary processing unit
ARAM	AMU's Random Access (local) Memory
ASC	Advanced Simulation for Calibration
ASILD	Automotive SIL D
AUTOSAR	Automotive Open System Architecture
BAF	Boot assist flash
BIST	Built-in self test
BIU	Bus interface unit
CAN	Controller area network
CF	Critical fault
CGM	Clock generation module
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check
CSI	Combined serial interface. DSPI configuration that alternates DSI and SPI frames.
CTU	Cross triggering unit
DCF	Device configuration format
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DSI	Deserial serial interface. DSPI configuration that serializes and deserializes registers or signals to allow for pin reduction.
ECC	Error correction code
ECSM	Error correction status module
EIM	Error injection module

Table 2388. Acronyms and abbreviations (continued)

Term	Meaning
EMI	Electromagnetic interference
EOUT	Error out
ESD	Electromagnetic static discharge
FCCU	Fault collection and control unit
FMPLL	Frequency-modulated phase-locked loop
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
FTTI	Fault tolerant time interval
GPIO	General-purpose I/O
HVD	High voltage detector
HW	Hardware
ID	LIN identifier field
IEEE	Institute of Electrical and Electronics Engineers
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety
IPS	– Internal peripheral system – IPI slave bus
IRQ	Interrupt request
ISR	Interrupt service routine
JDC	JTAG data communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
KGD	Known Good Die
LBIST	Logic built-in self test
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LVD	Low voltage detector
LWB	Late-write buffer
MB	Message buffer
MBIST	Memory built-in self test
MBM	Message buffer management
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit

Table 2388. Acronyms and abbreviations (continued)

Term	Meaning
MFD	Multiplication factor divider
Mux	Multiplex
NCF	Non-critical fault
NMI	Non-maskable interrupts
NVM	Non-volatile memory
OPP	Over-program protection
OSC	Oscillator
OTP	One time programmable
PASS	Password and device security module
PBRIDGE	Peripheral bridge
PCM	Platform configuration module
PCU	Power control unit
PFLASH	Platform flash controller
PIT	Periodic interrupt timer
PLL	Phase-locked loop
PMC	Power management controller
PRAM	Platform RAM controller
PWD	Password
RC	– Resistance-capacitance – Resistor-capacitor
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RTL	Register transfer language
RWW	Read-while-write
RX	Receive
SAG	Safety application guide
SAR ADC	Successive approximation register analog-to-digital converter
SDMA	System Direct Memory Access
SIL	Safety integrity level
SIUL	System integration unit lite

Table 2388. Acronyms and abbreviations (continued)

Term	Meaning
SMPU	System memory protection unit
SoC	System-on-chip
SOR	Sphere of redundancy
SPI	Serial peripheral interface
SSCM	System status and configuration module
STCU	Self-test control unit
STM	System timer module
SW	Software
SWT	Software watchdog timer
TBD	To be defined
TCD	Transfer control descriptor
TSENS	Temperature sensor
TX	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault
VCO	Voltage controlled oscillator
VREG	Voltage regulator
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar
XBIC	XBAR integrity checker

Revision history

Table 2389. Document revision history

Date	Revision	Changes
28-Mar-2017	1	Initial version.
04-Apr-2017	2	Attached SPC58xNx_IO_Definition_v2.1.xlsx to this Reference Manual.

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3	Following are the updates in this revision of the document: *Chapter 4: Signal Description* *Section 4.1: Production packages*: Replaced BGA292 with FPBGA292. *Chapter 5: Memory Map* *Table 6: Flash memory map*: – Updated the description naming of some Flash blocks – Added footnote to PFLASH Controller Assignment (RWR Partition ID) in header column. – Added footnote to reserved space at start address 0x015C0000. *Table 14: UTest memory map*: – Changed stop offset from 0x0347 to 0x035F (reserved space). – Changed start offset from 0x0348 to 0x0360 at UTEST DCF Records. Updated *Table 10: HSM memory map* *Chapter 6: Functional safety* *Table 16: PMHF module categories*: Updated definition of Non-safety modules *Section 6.4.4.2: All-x words and ECC*: – Added sentence starting with “Memories that include addresses in the ECC...” – Reworked the paragraph starting with “In case of not valid codeword...” *Section 6.4.4.3: ECC failure handling*, *Section 6.4.4.4: Memory Error Management Unit (MEMU)* and *Section 6.4.4.4.1: Interface to ECC units*: Added “with same (optional) syndrome” *Table 17: Module classification*: – Added STANDBY SAR ADC in NoSaMos Classification – Moved Concentrator DMA from NoSaMos to ViMos – Moved Concentrator HSM to ViMos classification (was NoSaMos) *Section 6.4.1.5.1: BIST during boot (off-line)*: Updated Logic BIST bullet *Table 18: FCCU failure inputs*; – set “Not testable” as Error reaction path for Failures LVD_ERROR and HVD_ERROR – Replaced Failure descriptions for FCCU channel 93, 99, 104 - 109 – Replaced PRAM with “FLASH controller internal RAM” in FCU channel 115 – Updated the table. – Added table footnote in description of failure channel 64. *Section 6.4.4.1: ECC for storage*: Changed introduction *Table 19: ECC RAM implementations*: Replaced all JTAG occurrences by ITAG *Section 6.4.4.4: Memory Error Management Unit (MEMU)*: Rephrased the first paragraph. *Figure 6: Simplified view of E2E ECC*: Updated this picture. Updated *Chapter 7: Device configuration*

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 26: Dual PLL Digital Interface (PLLDIG)* *Section 26.1: Introduction*: Added note with a cross-reference to Clocking chapter for chip-specific implementation details. *Table 338: PLL0DV field descriptions* and *Table 341: PLL1DV field descriptions*: Updated division factors of RFDPHI. *Section 26.4: Modes of operation*: – Changed "the operating modes" by "the operating mode" – Changed "The various modes of operation for the PLL are" by "The mode of operation for the PLL is defined below" *Section 26.6.3: Frequency modulation*, replaced PLLnCR[MFD] with PLL1DV[MFD]. *Section 26.7: Initialization information*: added footnote linked to "procedure" *Table 336: PLL0CR field descriptions*: EXPEDIE bitfield description enhanced Changed "MC_ME_<mode>" by "<ME_mode>, "MC_ME_" or "ME" by "<ME>" and "MC_CGM_ACn" by "<CGM_ACn>" throughout all this chapter. *Figure 230: Dual PLL Digital Interface block diagram*: updated this figure by adding a divider by 2 in PLL0 block. *Chapter 27: Clock Monitor Unit (CMU)* *Table 350: CMU_CSR field descriptions* – SFM: added sentences "MDR[MD] ... CSR[SFM]=1" and "Software ... bit" – RCDIV: added sentence "Ensure ... [RCDIV]" – CME: added sentence "CMU_HFREF ... (CSR[CME=1])" *Section 27.5.2: CLKMN0_RMT supervisor*: deleted Note "f_{CLKMN0_RMT} ... monitoring" *Chapter 29: OSC digital interface (XOSC)* *Figure 320: XOSC Control register (XOSC_CTL)*: Changed I_OSC field access type to R/w1c (was RW). *Chapter 32: Flash memory controller* *Section 32.5.14.1.1: e2eECC and Flash accesses*: added the latest sentence. *Section 32.5.15: e2eECC on data Flash accesses*: added the latest sentence. *Chapter 33: Embedded Flash Memory* *Table 455: UTEST block memory map*: Updated size of customer OTP area *Table 461: MCRE field descriptions*: Updated description of fields N64KL and N16KL. *Table 458: MCR field descriptions*: Improved wording of DWEE, both for code and data memory. *Table 472: MCR2 field descriptions*: Same done for PDWEE but only for code memory *Table 474: ADR field descriptions*: Updated wording for bitfield ADDR *Table 509: ADR2 field descriptions*: Updated wording for bitfield PADR Added *Section 33.4.4.2.2: EEPROM emulation*

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	Added warning description in *Section 33.2.1.4: RWR1_UTEST virtual block memory map* *Section 33.3.2.14: Module Configuration Register 2 (MCR2)*: – Removed MCR2.PRRE bit, and related description. – Updated the description of PDWEE, PSBC1 and PSBC. *Figure 345: Flash memory module structure*: Updated to depict RWR0 and RWR1 Flash arrays *Section 33.3.2.3: Extended Module Configuration Register (MCRE)*: Bitfield "HT" replaced by Reserved bitfield *Section 33.4.4.1: Read While Read*: Removed lines "RWW P6" and "RWW P7" Updated *Table 451: Flash memory partition 5 memory map* *Section 33.3.2.24: Parallel Address register (ADR2)*: Added the sentence "For the address mapping, refer to *Section 33.3.2.16: Address register (ADR)* description." Added *Section 33.4.4.2.1: Multi-bits error management (more than 3 bits error >=4)* *Section 33.3.2.1: Module Configuration Register (MCR)*: – Updated description of bitfield EEE. – Updated PEEE field description. *Table 458: MCR field descriptions*: add sentence "Note that EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash" at EEE field description. *Section 33.4.4.2: Error correction code*: add sentence "EDC post ECC reporting is suppressed for Data Flash and HSM Data Flash" at the end of the fourth sentence.

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 36: Analog-to-Digital Converters (ADC) Configuration* *Section 36.2.1.10: Parallel side interface to programmable decimation filter*: updated the first paragraph. *Chapter 41: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* Throughout the chapter, renamed all occurrences of – AN[x] to AIN[x] – EMDATA to BSEXT – EMCLK to CLKEXT *Figure 437: Converted Data Register (SDADC_CDR)*: Changed register access type to Read (was RW). *Section 37.6.12: Latest Data Register (SDADC_LDREG)*: Renamed this register (was SDADC_LDR) and set its access type to Read (was RW). *Section 37.6.13: Latest Time-Stamp Register (SDADC_LTREG)*: Renamed this register (was SDADC_LTR) and set its access type to Read (was RW). *Table 606: SDADC memory map*, *Section 37.7.15: Global Gating* and *Section 37.7.16: Timestamp*: Changed register name LDR by LDREG and LTR by LTREG. *Section 41.7.11: Gain calibration support*: Added additional notes at the end of this section. *Table 555: SDADC_PSICR field descriptions*: – Updated DEST field description – Removed Destination Address of Decimation Filter table. *Section 41.7.11: Gain calibration support*: – Removed the second sentence of the listed point 7 and point 10. – Rewrote the note with a new table name. *Section 37.7.7: SD ADC Internal Filter Selection*: Added the latest sentence of the latest paragraph. *Chapter 38: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Table 559: MCR field descriptions*: – Replaced SDADC by SARADC in FRZ bitfield description (was a typo). – Added note to NSTART, JSTART and PWDN field descriptions. *Table 556: CTU modes*: Replaced JABORT by JABORTCHAIN field name.

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Section 38.4.8: Programmable analog watchdog*: Added the latest sentence with 2 bullets and *Figure 458: Edge/Level Triggered signal generated during Watchdog Crossover Event* *Table 558: SARADC digital interface register map*: Removed "Register classification" column. Removed *section "CrossTriggering Unit (CTU) interface"* *Table 560: MSR field descriptions*: removed bitfield CTUSTART *Table 561: ISR field descriptions*: removed bit field CTsUTRGERR and EOCTU *Table 564: IMR field descriptions*: removed bitfield MSKEOCTU *Section 38.7: Initialization Information*: – Removed text "and required CTU mode..." in the first bullet and text "To initiate CTU mode..." in the bullet 8 – Added sub-bullets a, b, c in the bullet 8 Added *Section 38.4.5: ADCQ interface* *Section 38.4.4.1: Conversion timings*: changed SAMPSEL by CTSEL field name. *Table 578: PDEDR field descriptions*: added latest paragraph in PDED field description. *Chapter 39: SARADC Queued digital interface (ADCQ)* *Section 39.3.14: Timestamp*: Removed the first paragraph "The timestamp feature is present only when...(GLBL_Qn_CONFIG)". *Section 39.4.9: Global Output register (GLBL_OUTPUT)*: Reworked the first paragraph with a note that refer to Device configuration chapter. Removed the sentence "In a device having multiple instances of ADCQ, only one instance will have this register.". *Figure 534: Global module Configuration register (GLBL_CONFIG)* and *Figure 535: Global Queue Config register (GLBL_Qn_CONFIG)*: Updated figure note with reference to ADCQ parameters table in the Device Configuration chapter. *Figure 534: Global module Configuration register (GLBL_CONFIG)*: Set reset value of NUM_OF_ADC_CFG field to 0x4. *Figure 519: Queue status interrupts*: Updated this figure. *Figure 551: CMDQ PUSH register (Qn_CMDQ_PUSH)*: Changed Reserved and Read as 0 to Reserved at bits 8 and 9. *Chapter 40: Decimation Filter (DECFILTER)* *Section 40.1.3.4: PSI Output Mixed mode*: changed eQADC by SDADC name in the second sentence. *Section 40.4.3: Input buffer description*: updated the sixth paragraph. *Section 40.4.12.1: Input buffer DMA request*: reworked the second and the third paragraphs. *Chapter 44: Periodic Interrupt Timer (PIT)* *Section 44.2.1.6: PIT RTI Timer Control Register (RTI_TCTRL)*: Removed bitfield CHN

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 48: CAN subsystem* *Section 48.9: External Time Stamp*: Added this section and updated figure. *Chapter 49: Serial Interprocessor Interface (SIPI)* *Section 1.11.3: Maximum count reached error*: Updated blank cross reference to SIPI_ACR. *Chapter 51: LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications* Removed *section "Line Driver digital connections"* *Table 986: PLLCR field descriptions*: Updated description of FBDIV. *Table 976: TMCR field descriptions*: Updated description of bitfields CLKTST and LPON *Table 981: PICR field descriptions*: Updated description of bitfield PNGREQ *Table 988: UNSTCR field descriptions*: Updated description of bitfield USNDRQ *Chapter 53: FlexRay communication controller (FlexRay)* *Equation 42*: changed parameter FR_RFSIDX[X] to FR_RFSIR[SIDX]. *Equation 44*: changed parameter FR_RFSYMBADR[SMBA] to FR_SYMBADR[SMBA]. *Table 1291: FlexRay memory map*: Added Strobe Port Control Register (FR_STBPCR) at 0x000A offset. *Table 1306: FR_GIFER field descriptions*: Added note to FAFBIF field. *Section 53.5.2.7: Strobe Port Control Register (FR_STBPCR)*: Added this register. *Figure 1310: Stop Watch Count High Register (FR_STPWHR)* and *Figure 1311: Stop Watch Count Low Register (FR_STPWLR)*: Changed register and STPW field accesses to Read-only (was Read-write). *Chapter 55: SENT Receiver (SRX)* *Table 1455: CHNL_EN field descriptions*, *Table 1457: FMSG_RDY field descriptions*, *Table 1458: SMSG_RDY field descriptions*, *Table 1461: FDMA_CTRL field descriptions*, *Table 1462: SDMA_CTRL field descriptions* and *Table 1463: FRDY_IE field descriptions*: Changed <field>[15:0] to <field>[(CH-1):0] *Table 1455: CHNL_EN field descriptions*, *Table 1457: FMSG_RDY field descriptions*, *Table 1458: SMSG_RDY field descriptions*, *Table 1461: FDMA_CTRL field descriptions*, *Table 1462: SDMA_CTRL field descriptions* and *Table 1463: FRDY_IE field descriptions* and *Table 1464: SRDY_IE field descriptions*: Changed bit position 16:31 to (32-CH):31. *Chapter 56: Peripheral Sensor Interface (PSI5)* *Table 1487: PSI5 memory map*: Removed "Register classification" column. *Figure 1443: PSI5 Channel Control Register (PSI5_CH0_PCCR)*: Updated the access of bit 16 from "Read only" to "RW" and added a note "This is a redundant bit and RW will not have any effect".

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 57: Peripheral Sensor Interface-Support module (PSI5-S)* *Figure 1527: PSI5-S global control register (PS_GCR)*: Changed field accesses of bit 21:23 to write-only and always read as 0. *Figure 1546: PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)*: Changed field access of bit 28 to write-only and always read as 0. *Figure 1549: PSI5-S channel message configuration register A (PS_MSGA_CHn)*: Changed field access of bit 28 to write-only and always read as 0. *Figure 1552: PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)*: Changed field access of bit 4 to read-write. *Table 1575: PS_WD_CFGR_CHn field descriptions*: Removed text "This bit is one shot. it is always read as 0." at bit 4. *Figure 1555: PSI5-S ECU to sensor control register (PS_E2SCR_CHn)*: Changed field access of bit 18 to write-only and always read as 0. *Figure 1558: PSI5-S channel1 ECU to sensor downstream data shift register low (PS_DDSR_L_CHn)* and *Table 1581: PS_DDSR_L_CHn field descriptions*: Changed field names to DDSR_L1 for bits 0:7 and DDSR_L0 for bits 8:31. *Chapter 58: Deserial Serial Peripheral Interface (DSPI)* *Section 58.1.2: Features*: Removed "edge sensitive hardware trigger" in Transfer initiation conditions feature. *Section 58.2: DSPI signal description*: Removed HT signal. *Section 58.2: DSPI signal description*: Removed HT - Hardware Trigger section. *Chapter 59: LINFlexD* *Figure 1668: Master node: DMA Tx FSM (concept scheme)* and *Figure 1672: Slave node: DMA Tx FSM (concept scheme)*: Added note "DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.". *Figure 1689: LIN Time-Out Control Register (LINTOCR)*: Updated HTO reset value by adding a note (1) on bits 26:27. *Figure 1693: LIN Control Register 2 (LINCR2)*: Updated IOPE reset value note (3). *Table 1654: LINFlexD memory map*: Removed "Register classification" column. *Chapter 60: Reset Generation Module (MC_RGM)* *Table 1683: RGM_DES field descriptions*: Updated F_SUF field description. *Chapter 61: Boot Assist Flash (BAF)* *Section 61.1: Introduction*: Updated the fourth paragraph. *Section 61.2: Memory map*: Added a note (removed from the PASS chapter's Clock Jitter activation section and copied here) *Section 61.3.8: Optionally perform a serial boot*: Updated introduction. *Figure 1770: Production Disable callback function flow chart*: Replaced "PIT" by "Periodic Timer"

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 62: System Status and Configuration Module (SSCM)* *Section 62.3.7: Life Cycle*: – Changed the sentence starting with "The LC is written into 5 slots, 128 bits each,..." by "The LC is written into 5 slots, 256 bits each,..." – Updated *Table 1738: Life Cycle slots*, *Table 1739: Life Cycle Slots in Memory*, and *Table 1740: Resulting Life Cycle* Updated *Figure 1787: Appending DCF records* Removed *section "Glossary"* *Figure 1780: HSM and User Option Status Register (UOPS)* and *Table 1733: UOPS field descriptions*: – Added fields FL_RUN and BAF_FA and their respective descriptions. – Changed HSB bit field length to 3 bits and updated its description. *Chapter 63: Power management controller digital interface (PMC_Dig)* *Section 63.3: IPS bus interface*: Updated the section. *Section 63.5: Registers description*: Replaced "Access: User read/write" with "Access: User read/write, Supervisor read/write, Test read/write" in all the relevant register figures. *Figure 1793: Reset Event Enable Register (REE_LV0)*: Updated the access of all the fields as read/write. *Figure 1795: Interrupt Enable Register (IE_LV0)*: Updated the access of all the fields as read/write. *Figure 1814: Global Interrupt Enable Register (IE_G)*: Updated the access of all the fields as read/write. *Table 1764: GR_S field descriptions*: Updated the description of fields "TEMP_2", "TEMP_1", and "TEMP_0". *Section 63.1: Introduction*: Updated the text "The PMU digital block generates a transfer error event...." *Section 63.3: IPS bus interface*: Updated the bullet point "The PMU digital block generates a transfer error event....." *Table 1778: BIST_FLAGS_PHASE1 field descriptions*, *Table 1779: BIST_FLAGS_PHASE2 field descriptions* and *Table 1784: BIST_DEBUG field description*: Replaced "Status will be ignored" by "Status should be ignored" *Section 63.5.37: User BIST Time1 and Time0 register (BIST_TIME10)*,*Section 63.5.38: User BIST Time3 and Time2 register (BIST_TIME32)* and *Section 63.5.39: User BIST Time6 and Time5 register (BIST_TIME65)*: Added a cross-reference to Voltage monitor BIST programming section. *Table 1769: HPREG_SMPS_SEL_S field descriptions*: Updated SMPS_ENB field description.

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Table 1745: REE_LV0 field descriptions* and *Table 1755: REE_HV0 field descriptions*: – Changed "REE" by "RES" in REE_XX field descriptions. – Changed "RES" by "REE" in RES_XX field descriptions *Section 63.9: Flash interface (DCF client usage)*: added 2 paragraphs relative to monitors reactions. *Section 63.10: Voltage monitor BIST programming*: updated this section. *Chapter 71: Sequence Processing Unit (SPU)* *Figure 1957: CPU2 processor exception vector prefix (C2PEVP)*: Renamed bitfield CPU1 into CPU2 For each occurrence of "Calibration and Debug" in the chapter, added "(or Debug and Trace)" *Chapter 75: LVDS Fast Asynchronous Serial Transmission – High Speed Debug* Removed section "Line Driver digital connections" *Table 1939: TMCR field descriptions*: Updated description of bitfields CLKTST and LPON *Table 1943: PICR field descriptions*: updated description of bitfield PNGREQ *Table 1945: UNSTCR field descriptions*: updated description of bitfield USNDRQ. *Chapter 81: Memory Error Management Unit (MEMU)* *Section 81.6.2.14: Flash memory correctable error reporting table status register (FLASH_CERR_STSn)* changed boundary from 64bit to 128 bit. *Figure 2186: MEMU reporting table uniqueness check flow chart*. Added arrow from [Error dropped] *Section 81.1: Introduction*: Replaced "Peripheral System RAM" by "Peripheral RAM" in the second bullet. *Table 2088: SYS_RAM_UNCERR_ADDR field descriptions*, *Table 2093: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 2098: FLASH_UNCERR_ADDR field descriptions*: Added the sentence "This register must be READ ONLY when its corresponding valid bit is not asserted" to ERR_ADD field description. *Table 2095: FLASH_CERR_STSn register field descriptions*: Updated description of bitfield BAD_BIT to replace 0xFF by 0xFFFF. *Figure 2201: Flash memory correctable error reporting table address register (FLASH_CERR_ADDRn)* and *Table 2096: FLASH_CERR_ADDRn register field descriptions*: – Added SDE field and its description at bit 0. – Reduced ERR_ADD bit length to 31 bits (was 32) and updated its field description. *Chapter 82: Indirect Memory Access (IMA)* *Table 2102: E2EECSR0 field descriptions*: Corrected register name in title.

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Chapter 83: Fault Collection and Control Unit (FCCU)* *Table 2144: F2A_STATUS field descriptions*: – Changed the table title from F2AF_STATUS to F2A_STATUS – Description of value 0xFF of bitfield FAFS: replaced word "critical" by word "recoverable" *Figure 2237: FCCU RF Configuration Register n (FCCU_RF_CFGn)*: Removed "Refer to for the errors description" from table footnote 1. *Table 2140: FCCU_STAT field descriptions*: Added a note to PhysicErrorPin field description. *Section 83.7: FCCU Output Supervision Unit*: updated this section. *Table 2121: FCCU memory map*: Removed "Register classification" column. *Figure 2234: FCCU Control Register (FCCU_CTRL)*, *Figure 2245: FCCU IO Control Register (FCCU_EINOUT)* and *Figure 2255: FCCU MCS Register (FCCU_MCS)*: Changed some reset bit values to "0/1" with a cross-reference to the Device configuration chapter. *Table 2122: FCCU_CTRL field descriptions*: – Added field numbers. – Updated description of DEBUG field. – Updated description of OPR field *Figure 2235: FCCU CTRL Key Register (FCCU_CTRLK)* and *Table 2123: FCCU_CTRLK field descriptions*: Changed CTRLK field name to CTRLK_VAL. *Figure 2240: FCCU RF Key register (FCCU_RFK)* and *Table 2131: FCCU_RFK field descriptions*: Changed RFK field name to RFK_VAL. *Figure 2254: FCCU XTMR Register (FCCU_XTMR)* and *Table 2148: FCCU_XTMR field descriptions*: Changed XTMR field name to XTMR_VAL. *Figure 2258: FCCU Delta T Register (FCCU_DELTA_T)* and *Table 2153: FCCU_DELTA_T field descriptions*: Changed XTMR field name to XTMR_VAL. *Section 83.5.6: NMI/WKPU interface*: Removed bullet about of Wake-up indication *Table 2124: FCCU_CFG field descriptions*: Updated description of bitfield FCCU_SET_CLEAR *Section 83.6.2: FCCU CTRL Key Register (FCCU_CTRLK)*: Updated Note *Chapter 84: Self-Test Control Unit (STCU2)* *Table 2166: STCU_WDG field descriptions*: Added table note "STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE clock frequency value." *Section 84.4.2.1: Offline reset generation*: Added sentence "In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module." *Table 2160: STCU2 memory map*: Renamed table title (was register set). *Section 84.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Removed equation number. *Section 84.5.11: STCU2 Error FM Register (STCU_ERR_FM)*: Set reset value of bits 0:15 to all 0. Removed section "Register map." *Section 84.4.6: Interrupt interface*: added "there are two interrupt sources:" and a bullet "One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1)".

Table 2389. Document revision history (continued)

Date	Revision	Changes
06-Dec-2018	3 (cont'd)	*Section 84.4.2: Reset management*: added a third sentence. *Section 84.4.8.1: Initialization sequence*: updated second bullet with a second sentence. *Table 2164: STCU_CFG field descriptions*: changed note in LB_DELAY field description. *Table 2193: STCU_LB_CTRLn field descriptions*: updated CWS field description at enumerated value 0x0. *Table 2205: STCU_MB_CTRLk field descriptions*: updated PTR field description. *Chapter 86: Password and Device Security Module (PASS)* *Table 2222: Debug Interface Enable Truth Table*: Added a column and row relation to clock jitter. *Table 2211: LCSTAT register field descriptions*: Updated description of LIFE bitfield with value 110 (ST production). *Figure 2325: Password Group n - Lock 0 Status register (LOCK0_PGn)*: Added ATSL field at bit 1 and set undefined reset with figure note. *Table 2216: LOCK0_PGn register field descriptions*: Added ATSL field and its description at bit 1. *Section 86.3.1.4: Challenge Input register (CINn)*: Added the following sentence "Valid password criteria is that it should not be all Zeros or all Ones". *Table 2211: LCSTAT register field descriptions*: Added note to all RLx field descriptions. *Table 2225: Flash Memory Read Protection truth table*: Removed the second table. *Section 86.5.6.2.4: Fuse Bypass Password compare*: Removed text "of the Flash page contain different data not related to Fuse Bypass" at the end of the first sentence. *Chapter 93: Tamper Detection Module (TDM)* *Section 93.6.3: Diary*: Replaced "is 8 bytes" with "depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector." *Section 93.6.4: Specifying the diary base address*: Replaced "is 8 bytes" with "depends on the Flash sector, 8 bytes for Data sector and 16 bytes for the remaining sector." Deleted "Therefore the diary can hold a maximum of 256 × 8 byte entries." *Section 93.6.5.1: Diary management*, replaced "64-bit double word "with "record". *Table 2346: TDM_STO_KEYn field descriptions*, added text "See the section..." *Figure 2446: Diary implementation*; changed Diary_TDR0 size from 256x64 to 256x128 bits. *Chapter 88: ASC Modeling Unit version 2 (AMU2)* *Figure 2366: AMU P8 Channel n Register (AMU2_P8CHn)*: Changed register and fields accesses to Read (was Read/Write). *Figure 2363: AMU V Pointer Channel n Register (AMU2_VPTRCHn)*: Changed register and fields accesses to Read/Write (was Read).

Table 2389. Document revision history (continued)

Date	Revision	Changes
03-Jul-2020	4	Following are the changes in this version of the document: *Chapter 3: Embedded memories* *Section 3.2.1: System SRAM*: Updated the text from, “The SRAM can be configured....PFCR1.....controller.” to “The SRAM can be configured... PRCR1.....controller.” *Chapter 5: Memory Map* *Table 14: UTest memory map*: Added a footnote, “Factory could program.....find it” to the “UTest DCF records” for Start offset of 0x0360. *Chapter 6: Functional safety* *Table 17: Module classification* – Changed SEMA4 by SEMA42. Below Modules have been moved Vimos to NoSaMoS: – Performance Core (Core_1), – D-Cache Performance Core (Core_1), – I-Cache Performance Core (Core_1), – other local memories of Performance Core (Core_1) – Overlay RAM – PIT Below Module to be moved from PeMoS to ViMoS: – PBRIDGEn Below Module to be moved from ViMoS to SuMoS – STCU2 *Table 6.4.4.4: Memory Error Management Unit (MEMU)*: Removed MEMU connections figure. *Table 18: FCCU failure inputs*: – Added note to “COMPENSATION CELLS” in “Failure description” column. – Removed FCCU channel 109 – Updated failure description and Error reaction path check for FCCU channel 17-20. – Updated failure description for FCCU channel 30 – Updated column Reference Manual related information for FCCU channel 58, 60, 63, 64 and 66 to Section: Safety considerations Updated *Section 6.4.4.1: ECC for storage* *Table 19: ECC RAM implementations*: – Updated column-head from memory classification to MEMU classification – Added footnote for column-headed ECC for System RAM for location Platform – Added footnote for column-headed ECC in location Core0, Core1 and Core2 for all I-Dem and D-Mem – Updated MEMU Classification for Location HSM for devices

Table 2389. Document revision history (continued)

Date	Revision	Changes
03-Jul-2020	4 (cont'd)	*Chapter 7: Device configuration* Made changes throughout this chapter. *Chapter 8: Reset and Boot* *Table 120: Module status during reset phases*: Removed note from Module "System watchdog" *Section 8.3.1: Power-on and the Reset Generation Module*: Updated the text from, "The STCU is reset on any power-on.....(external reset in this case is ESR0)". to "The STCU is reset and offline self-test (if enabled) is triggered on any power-on.....(external reset in this case is ESR0)". *Section 8.3.5: PHASE2[DEST] Phase: flash initial configuration*: Updated the note. *Chapter 9: Device Configuration Format (DCF) Records* *Table 130: DCF client list*: – Removed STCU rows from STCU_MB_CTRL_92 to STCU_MB_CTRL_101. – Changed UTEST Miscellaneous reset value to 0x00049E01. *Figure 47: UTEST Miscellaneous DCF Client*: refer to DCF client list for reset value. *Chapter 10: Power management* *Table 141: Device power management controller external signals*: Updated the name VDD_HV_IO_MAIN to VDD_HV_IO. *Table 143: Voltage monitors configurability*: Updated this table. *Chapter 14: Core (z4256n3) description* *Table 174: Exceptions and conditions*: Deleted TBD line *Figure 96: DMEM Configuration Register 0 (DMEMCFG0)*: Updated DMSIZE. Added note *Section 14.10.1.1: End-to-End ECC Control Register 0 (E2ECTL0)* Updated *Figure 74: Core (z4256n3) Supervisor Mode Programmer's Model DCRs and PMRs* Updated *Section 14.9.2.1: DMEM Configuration Register 0 (DMEMCFG0)* Updated row-headed DMEM BASE ADDR *Table 199: DMEMCFG0 Field Descriptions* Updated row-headed IMEM BASE ADDR *Table 202: IMEMCFG0 Field Descriptions*. *Chapter 15: System Integration Unit Lite2 (SIUL2)* *Figure 105: SIUL2 MCU ID Register #1 (SIUL2_MIDR1)*: Updated the Reset value from 588800XX to 589800XX.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Chapter 16: Crossbar switch (XBAR)* *Table 230: XBAR_CRSn field descriptions*: Updated the note of PARK field from "Only select master.....behavior may occur." to "Only select master.....parking configuration." *Table 228: XBAR memory map*: added MASTER channel n (n = 0 to 7) title and XBAR_MGPCRn registers at 0x0800 +n*0x100 address offsets. *Section 16.3.3: Master General Purpose Control Register (XBAR_MGPCRn)*: added this section. *Table 229: XBAR_PRSn field descriptions*: added description of bitfield M3. *Chapter 17: Crossbar Integrity Checker (XBIC)* *Table 234: XBIC_EIR field descriptions*: In the second note, replaced "SMPU logical bus master assignments" with "AHB Master ID Assignments". *Chapter 21: Semaphores2 (SEMA42)* *Table 261: Memory map/register definition*: – Updated register name for 0x0040 – Deleted line for 0x0042 – Updated Address offset for Reserved line *Section 21.2.2: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: Replaced all occurrences of SEMA4_RSTGT_W by SEMA4_RSTGT – *Figure 155: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: added RSTGSM and RSTGMS. – *Table 263: SEMA4_RSTGT field descriptions*: added RSTGSM and RSTGMS. Deleted the section, Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT_R). *Chapter 23: Enhanced Direct Memory Access (eDMA)* *Figure 172: Control Register (eDMA_CR)*: – Changed GRP3PRI and GRP2PRI field access type to RW. – Updated register reset value with a specific figure footnote. *Table 277: eDMA_CR field descriptions*: Added note to GRP3PRI and GRP2PRI field descriptions. *Chapter 25: Clocking* *Figure 219: Clock generation (part 1 of 2)*: Updated. *Table 327: MC_CGM relationship to clocks*: SEM4 replaced by SEMA42. *Section 25.1: Introduction*: Deleted text "as a backup clock" *Section 25.8.1: Loss of PLL/XOSC clock*: Updated this section. Updated *Section 25.1: Introduction* "The internal 16 MHz...chapter for details." Updated *Section 25.8.2: Loss of IRCOSC clock* *Section 25.5.1.6: Loss of clock detection*: Deleted the last sentence "Software may enable or disable an optional backup clock in the PLL".

Table 2389. Document revision history (continued)

Date	Revision	Changes
03-Jul-2020	4 (cont'd)	*Table 329: Maximum auxiliary level clock frequencies*: – Added note "DSPI_CLK frequency should always be greater than or equal to 1.25 times PBRIDGE_CLK" to DSPI_CLK. – Added note "80 MHz maximum frequency is at aux divider output. The maximum frequency of FRAY_CLK after the multiplexer is 40 MHz" to FRAY_CLK for Aux Clock 2 Selector. *Chapter 26: Dual PLL digital interface (PLLDIG)* *Figure 230: Dual PLL digital interface block diagram*: Backup Clock Selection" block is made blue and note added "Backup Clock Selection" block in blue is not implemented". *Section 26.4.1: Normal mode with reference, PLL0 or both PLLs enabled*: added in Note cross-ref to *Section 26.7: Initialization information*. *Section 26.5.2.1: PLL0 control register (PLL0CR)*, *Section 26.5.2.4: PLL1 control register (PLL1CR)*: Updated note for field LOLIE. *Chapter 27: Clock Monitor Unit (CMU)* *Section 27.4.1.1: CMU Control Status Register (CMU_CSR)*: – Updated the description of RCDIV from, "Ensure clock.....CMU_CSR[RCDIV]." to "Ensure clock.....otherwise the operation can lead to a spurious OLR event." – Updated the descriptions of SFM and CME fields. *Section 27.4.1.5: CMU Interrupt Status Register (CMU_ISR)*: updated Note. *Chapter 29: OSC digital interface (XOSC)* Added *Section 29.2.4.1: Automatic Level Control (ALC)* *Chapter 30: IRCOSC digital interface* *Table 434: IRCOSC_NT field descriptions*: Updated description of bitfields FT_CODE and RCTRIM *Chapter 1: PRAM_E2E_ECC_64 block guidePlatform RAM controller AHB (PRAMC_AHB)* Changed the chapter name. *Chapter 33: Embedded Flash Memory* *Table 461: MCRE field descriptions*: Removed the row of field "N256KH". *Table 455: UTEST block memory map*: Added note to offset 0x140. *Table 462: LOCK0 field descriptions*, *Table 461: LOCK1 field descriptions*, *Table 462: LOCK2 field descriptions*, *Table 463: LOCK3 field descriptions*, *Table 464: LOCK0A field descriptions*, *Table 465: Alternate LOCK1 field descriptions*, *Table 468: SEL0 field descriptions*, *Table 469: SEL1 field descriptions*, *Table 470: SEL2 field descriptions*, *Table 469: SEL3 field descriptions*: Text modified as follows "once an Interlock Write is completed until DONE is set and MCR.EHV gets cleared" in the bit-field description of these registers.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Chapter 34: Flash Memory Programming and Configuration* *Section 34.6.2: Creating the tamper detect diary*: – The maximum size of Diary updated from 2 KB to 4 KB. – Multiplied by 2 KB is updated to 4 KB. Updated the *Example 7: Creating the tamper detect diary* *Example 4: Overriding secure write protection*: Updated paragraph list 2. *Figure 400: Sample DCF record for secure write protection*: Updated the value of the figure. *Chapter 37: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* Removed Table "Destination Address of Decimation Filter". *Chapter 38: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Section 38.4.6: Test channel connection with internal analog channel*: Removed temperature sensor and bandgap from the first sentence of the first paragraph. *Table 563: MCR field descriptions*: Updated the note for NSTART. *Section 38.5.1.11: Watchdog Threshold Register n (WTHRHLRn)*: Replaced in 1st note MSB=0 bits numbers by LSB=0 bit numbers. *Section 38.4.8: Programmable analog watchdog* Updated the content from, "A watchdog.....SD ADC converted....value" to "A watchdog.....SARADC converted....value". User access updated for: – *Section 38.5.1.32: External Channel Interrupt Pending Register n (ECIPRn)* – *Section 38.5.1.39: External Channel Analog Watchdog Out of Range Register n (ECAWORRn)* *Chapter 44: Periodic Interrupt Timer (PIT)* *Section 44.5: Example Configuration for the Lifetime Timer*: Updated *Equation 32:* From, "current_uptime = PIT_LTMR64H << 64" to "current_uptime = PIT_LTMR64H << 32". *Chapter 48: CAN subsystem* *Table 814: TSCC field descriptions*: – TCP: Removed the note, "With CAN FD..... timestamp generation (TSS = '10')." – TSS: Updated the description of TSS field and added a note, "In case of CAN FD.... timestamp generation." *Section 48.3.5.2.3: Data Bit Timing and Prescaler Register (DBTP)*: Corrected time quanta max number in the first sentence. *Table 827: XIDFC field descriptions*: Corrected max enumerated value of LSE field to 0x7F. *Table 832: RXF0C field descriptions*: Corrected max enumerated value of F0WM and FOS fields to 0x7F. *Section 48.3.5.2.9: Timestamp Counter Value Register (TSCV)*: Updated the description of TSC field.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Chapter 49: Serial Interprocessor Interface (SIPI)* *Figure 2: SIPI module*: Updated figure note by removing "Channel 0 has the highest priority for transmission" *Section 1.4.1: Main features*: Updated bullet starting by "Target node contains a set of nine" *Figure 9: Streaming write request format*: Updated the Note below the figure. *Section 1.7.3.2.1: Streaming write transfer*: Added first sentence "The related registers...". *Figure 16: Streaming transfer with data*: Added CR2[0], CR2[1] and CR2[7]. *Section 1.8: Transfer API and flow charts*: Updated Multiple Write Transfer Request generation sequence and Single Read Transfer Request generation sequence. *Figure 31: SIPI data stream model - Target*: Replaced "8-bit data" by "Data". *Figure 32: SIPI data stream with acknowledge trigger*: – Replaced 'Bus Master DMA' by 'Bus Master AHB' – Moved the arrow that was between CRC Checker and ACK Frame Generation so that it is between Bus Master AHB and ACK Frame Generation *Section 1.16.1.1: SIPI Channel Control Register (SIPI_CCRn)*: – Added "streaming command is 9 words long". – Deleted footnote "Only transfers with channel 2..." *Table 12: SIPI_CCRn field descriptions*: Updated DEN field description. *Figure 40: SIPI Channel address Register (SIPI_CARn)*: Deleted figure footnote. *Table 21: SIPI_MCR field descriptions*: Updated description of AID bitfield. *Section 1.6.2: Payload and frame format*: Added Note at the end of the section. *Table 950: Payload size of LFAST channel frame*: Added footnote. *Figure 13: Data allocation*: Added 32-bit data allocation *Table 17: SIPI_CARn field descriptions*: Updated CAR bitfield definition. *Section 1.9: DMA handling in transfer initiator mode*: – Renamed the title. – Added definition of DMA handling of transfer initiator and of transfer target Updated *Section 1.1.1: Scalability* Updated row-headed TE in *Table 22: SIPI_SR field descriptions* Updated the Note in *Section 1.16.1.12: SIPI Address Count Register (SIPI_ACR)* Added a Note and *Table 7: Target Memory content dependent from CAR content* in *Section 1.7.2: Read answer transfer* Updated *5.* in list Multiple Write Transfer Request generation in *Section 1.8: Transfer API and flow charts* *Section 1.11.1: Timeout error*: – Added Note. – Removed Note "In case of timeout...being sent now"

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Section 1.4.1: Main features*: Updated the eleventh feature bullet. *Section 1.6.2.5: Streaming write request*: Updated note. *Section 1.6.2.8: CRC field*: Updated this section. *Table 950: Payload size of LFAST channel frame*: Updated this table. *Table 951: Converted coding of LFAST channel code for SIPI headers*: Updated this table. *Section 1.7.2: Read answer transfer*: Added "big endian" in brackets to the note. *Section 1.7.3.2.1: Streaming write transfer*: Updated the second paragraph. *Section 1.8: Transfer API and flow charts*: Updated this section. *Figure 24: SIPI single write API*: Changed TC name by CPU. *Section 1.9: DMA handling in transfer initiator mode*: Updated single write transfer request generation list. *Section 1.10: Modes of operation*: Updated this section. *Section 1.16.1.1: SIPI Channel Control Register (SIPI_CCRn)*: Updated CHEN and DEN fields. *Section 1.16.1.6: SIPI Channel Address Register (SIPI_CARn)*: Updated this section. *Table 22: SIPI_SR field descriptions*: Updated STATE field. *Section 1.16.1.12: SIPI Address Count Register (SIPI_ACR)*: Updated this section. Updated *Section 1.4.1: Main features* Removed bullet "Target node...commands" Updated Note in *Section 1.6.2.5: Streaming write request* Updated *Section 1.8: Transfer API and flow charts* Updated *Figure 16: Streaming transfer with data* Updated *Figure 26: SIPI multiple write API* Updated *Figure 27: SIPI single read API* Updated *Figure 28: SIPI multiple read API* Updated *Figure 29: SIPI data stream model* Updated *Section 1.10.2: Normal Mode (NM)* removed text "SIPI needs...Register (SIPI_MCR))." Updated Note in *Section 1.16.1.1: SIPI Channel Control Register (SIPI_CCRn)* Updated row-headed TC in *Table 12: SIPI_CCRn field descriptions* Updated row-headed CAR in *Table 17: SIPI_CARn field descriptions* *Table 21: SIPI_MCR field descriptions*: – Updated row-headed AID – Updated AID and SR fields *Chapter 50: Zipwire* Deleted the entire section "Zipwire performance". *Chapter 51: LVDS Fast Asynchronous Serial Transmission – Interprocessor Communications* *Table 986: PLLCR field descriptions*: Updated the description of FBDIV.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Chapter 52: Ethernet* *Figure 1011: MMC Rx Interrupt mask Register (MMC_RX_INTERRUPT_MASK)*: Updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Figure 1012: MMC Tx Interrupt Mask Register (MMC_TX_INTERRUPT_MASK)*: Updated the register access type from User Read to Software read/write. Access type for all the bits ranging from [4:31] changed from Read only to Read Write. *Chapter 53: FlexRay communication controller (FlexRay)* *Table 1291: FlexRay memory map*: Corrected not implemented and reserved spaces. *Figure 1288: Protocol Configuration Register 9 (FR_PCR9)*: Corrected minislot_exists and symbol_window_exists field names. *Figure 1289: Protocol Configuration Register 10 (FR_PCR10)*: Corrected wakeup_channel field name. *Figure 1290: Protocol Configuration Register 11 (FR_PCR11)*: Corrected key_slot_used_for_startup field name. *Section 53.5.2.67.23: Protocol Configuration Register 22 (FR_PCR22)*: updated bit field 'R' by 'Reserved'. *Chapter 55: SENT Receiver (SRX)* *Figure 1428: Channel n Slow Serial Message Time Stamp read register (CHn_SMSG_TS)*, *Figure 1429: Channel n Fast Message Data 2 read register (CHn_FMSG_DATA2)* Added the following footnote and a cross ref to it "The value of the CH is device-specific. Refer to the Device Configuration chapter for details." *Chapter 57: Peripheral Sensor Interface-Support module (PSI5-S)* *Section 57.1.2: Features*: Removed "(big endian)" from the first bullet. *Chapter 58: Deserial Serial Peripheral Interface (DSPI)* *Section 58.3.6: DSPI Status Register (DSPI_SR)*: Changed reset value from 0xDEAD_BEEF to 0x0201_0000. *Table 1587: DSPI_MCR field descriptions*: Added note to HALT field description. *Section 58.4.6.3: Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)*: Added a second note. *Chapter 59: LINFlexD* *Section 59.2.2: UART mode features*: Updated the 3 latest bullets. *Table 1652: TCD setting: UART - Tx mode*: Removed note at DADDR[31:0]. *Table 1653: TCD setting: UART - Rx mode*: Removed note at SADDR[31:0]. *Section 59.4: Memory map and register description*: Added note that refer to the LinFlexD configuration of the Device Configuration chapter. *Table 1654: LINFlexD memory map*: Removed note that refer to the Device Configuration chapter and all cross-references to this note.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Table 1679: DMATXE field descriptions*: Field editorial changes to remove the table note. *Table 1680: DMARXE field descriptions*: Field editorial changes to remove the table note. *Chapter 60: Reset Generation Module (MC_RGM)* *Section 60.4.7: 'Destructive' reset escalation*: Added footnote to "each 'destructive' reset". *Chapter 61: Boot Assist Flash (BAF)* *Section 61.3.8: Optionally perform a serial boot*: Deleted text "All Tx-channels have to be disabled during this phase" *Chapter 62: System Status and Configuration Module (SSCM)* *Section 62.3.3: Boot mode functionality*: Updated Standby-Boot section. *Table 1732: ERROR field descriptions*: Removed "This feature...application code." for row-headed PAE and RAE Updated *Table 1739: Life Cycle Slots in Memory* *Chapter 63: Power management controller digital interface (PMC_Dig)* Updated *Section 63.5.37: User BIST Time1 and Time0 register (BIST_TIME10)*, *Section 63.5.38: User BIST Time3 and Time2 register (BIST_TIME32)*, *Section 63.5.39: User BIST Time6 and Time5 register (BIST_TIME65)*: Size of bitfields, TIME_x are updated to 12 bits from of 13 bits. *Chapter 65: Mode Entry Module (MC_ME)* *Table 1796: ME_<mode>_MC field descriptions*: Removed table footnote in XOSCON field description. *Section 65.4.1: Mode transition request*: Added a second note. *Chapter 67: Debug and Calibration Interface (DCI)* *Section 67.1.3.5: SWT control*: Added note "Debugger should...the SWT." *Chapter 72: JTAG Master (JTAGM)* Updated row-headed IIE in *Table 1924: JTAGM_MCR register field descriptions* Updated *Table 1926: JTAGM_DOR0 register field descriptions* Updated *Table 1927: JTAGM_DOR1 register field descriptions* Updated *Table 1928: JTAGM_DOR2 register field descriptions* Updated *Table 1929: JTAGM_DOR3 register field descriptions* *Chapter 74: Debug Serial Interprocessor Interface (SIPI)* *Section 74.6.2: Frame format*: Added Note at the end of the section. *Table 1936: Payload size of LFAST channel frame*: Added footnote.

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Figure 2021: Data allocation*: Added 32-bit data allocation *Section 74.6.2.7: Payload field*: Updated this section. *Table 1936: Payload size of LFAST channel frame*: Updated this table. *Table 1937: Converted coding of LFAST channel code for Debug SIPI headers*: Updated this table. *Section 74.7.2: Register read answer transfer*: Added "big endian" in brackets to the note. *Table 1940: SIPI_MCR field descriptions*: Updated SR field. Added a Note and *Table 1938: Target Memory content dependent from CAR content* in *Section 74.7.2: Register read answer transfer* *Chapter 80: Cyclic Redundancy Check (CRC) Unit* *Figure 2: CRC Configuration Register n (CRC_CFGn)*: Swapped reset values versus function of n in the figure footnote of POLYG reset. *Chapter 81: Memory Error Management Unit (MEMU)* *Table 2093: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 2098: FLASH_UNCERR_ADDR field descriptions*: Deleted the sentence "This register is not writable when the corresponding VLD bit is zero.)" *Section 81.6.2.13: Peripheral RAM concurrent overflow registers (PERIPH_RAM_OFLWn)*: Updated the "number of system RAM unique error sources" to 113. *Chapter 82: Indirect Memory Access (IMA)* Updated *Figure 2206: Cache Debug Access Control register (CDACNTL)* Updated *Figure 2207: Cache Debug Access Data register (CDADATA)* Updated *Section 82.2.2.1: e2eECC Error Control/Status register 0 (E2EECSR0)*. Updated *Section 82.3: Accessing memory via the IMA module* *Chapter 83: Fault Collection and Control Unit (FCCU)* *Section 83.6.8: FCCU RF Enable Register n (FCCU_RF_En)*: Deleted text "for debugging purposes". Deleted text "This register is for test/ debug purposes" from the following sections: – *Section 83.6.14: FCCU NA Freeze Status Register (N2AF_STATUS)* – *Section 83.6.15: FCCU AF Freeze Status Register (A2FF_STATUS)* – *Section 83.6.16: FCCU NF Freeze Status Register (N2FF_STATUS)* *Section 83.6.17: FCCU FA Freeze Status Register (F2A_STATUS)* *Section 83.6.13: FCCU Status Register (FCCU_STAT)*: Deleted text "for debugging purposes".

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Section 83.6.1: FCCU Control Register (FCCU_CTRL)*: Updated the bullet "configure the glitch filter present on location given by FILTER_POSITION parameter" to "configure the glitch filter present on EIN0 input (FCCU failure input #96)" and replaced text "(FCCU_RF_Sn[RFSx] where y = FILTER_POSTN)" to "FCCU failure input #96". Updated *Figure 2218: FCCU block diagram* Updated row-headed "REG intf" for *Table 2112: FCCU submodules* Updated row-headed OPR for *Table 2122: FCCU_CTRL field descriptions* *Chapter 84: Self-Test Control Unit (STCU2)* *Section 84.6: Use cases and limitations*: Added paragraph: "The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support." *Section 84.5.15: STCU2 Online LBIST End Flag Register (STCU_LBESW)*, *Section 84.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*, *Section 84.5.17: STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)*: Decreased number of fields from 16 to 8. Removed following sections: – STCU2 Offline MBIST 4 Status Register (STCU_MBS4) – STCU2 Offline MBIST 4 End Flag Register (STCU_MBE4) – STCU2 Online MBIST 4 Status Register (STCU_MBS4SW) – STCU2 Online MBIST 4 End Flag Register (STCU_MBE4SW) – STCU2 MBIST 4 Unrecoverable FM Register (STCU_MBUFM4) For all available MBIST registers: – Added note, "Refer to..... number of NMCUT available in this device." – Added note to all fields from 0:30, "The availability of this field is based on.....Device configuration chapter" *Section 84.4.8.2: LBIST and MBIST scheduling*: Removed STCU_MBE4 and STCU_MBE4SW inside this section. *Section 84.6.1: Offline self-test sequence*: Removed STCU_MBS4, STCU_MBS4 and STCU_MBE4 registers inside this section. *Section 84.6.2: Online self-test Sequence*: Removed STCU_MBUFM4, STCU_MBS4SW and STCU_MBE4SW registers inside this section. *Section 84.4.9: CRC*: Added note at the end of the section "The expected value of the CRC depends on multiple internal critical signals and can differ among different samples." *Section 84.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)*: updated description of WDGEOC bitfield *Section 84.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Added the note to "The expected value of the CRC depends on multiple internal critical signals and can differ among different samples." *Section 84.5.5: STCU2 PLL Configuration Register (STCU_PLL_CFG)*: Added a note, "f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz."

Table 2389. Document revision history (continued)

Date	Revision	Changes
02-Jul-2020	4 (cont'd)	*Chapter 86: Password and Device Security Module (PASS)* *Section 86.5.6.2.4: Fuse Bypass Password compare*: Removed "as the most significant 32 bits" in the second sentence. *Table 2224: Debug Interface Enable Truth table*: Updated the table. *Chapter 89: Wakeup unit (WKPU)* *Table 2292: NSR field descriptions*: Added missing fields NIF2 and NOVF2. *Section 89.1.2: Features*: Added a note referring to the Device Configuration chapter.

Table 2389. Document revision history (continued)

Date	Revision	Changes
11-Jan-2021	5 (cont'd)	Following are the changes in this version of the document: *Chapter 6: Functional safety* *Table 18: FCCU failure inputs*: Added note "Refer to....for more details" for FCCU channel 21 and 22. *Chapter 7: Device configuration* Made changes throughout this chapter *Chapter 8: Reset and Boot* Updated row-headed SWT in *Table 120: Module status during reset phases*. Updated *Section 8.3.5: PHASE2[DEST] Phase: flash initial configuration*. *Chapter 9: Device Configuration Format (DCF) Records* *Table 130: DCF client list*: – Added *2.* – Added row STCU_LBUFM. *Chapter 10: Power management* *Figure 60: Voltage monitors functionality*: Updated the figure. *Chapter 16: Crossbar switch (XBAR)* *Section 16.3.1: XBAR Priority Registers Slave (XBAR_PRSn)*: – Added text "Once the RO.....initiating the write" – Added note "No two available.... will not be updated" *Chapter 26: Dual PLL digital interface (PLLDIG)* Removed section "Register classification for safety requirements" *Chapter 31: Platform RAM controller AHB (PRAMC_AHB)* *Section 31.2.1: Registers description*: added this section title. *Chapter 33: Embedded Flash Memory* *Table 458: MCR field descriptions*: updated description of DONE field: removed Tpabt /Teabt parameters *Chapter 34: Flash Memory Programming and Configuration* *Section 34.1: Selection of Flash memory blocks for erase*: Replaced LOCKx with SELx in this section. *Chapter 37: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface* *Section 37.6: Memory map and register descriptions*: added sub-sections titles and updated sections numbering.

Table 2389. Document revision history (continued)

Date	Revision	Changes
11-Jan-2021	5 (cont'd)	*Chapter 43: Software Watchdog Timer (SWT)* Removed section "External signal description" *Chapter 54: Inter-Integrated Circuit (I2C)* Updated *Figure 1400: Flow-Chart of DMA mode master receive* *Section 54.4: Memory map and register definition*: added *Section 54.4.2: Registers definition* sub-section and updated registers sections numbering. *Chapter 55: SENT Receiver (SRX)* Removed section "Register classification for safety". *Chapter 57: Peripheral Sensor Interface-Support module (PSI5-S)* *Table 1556: PS_GLCR field descriptions*: added description for TSCS_A bit field. *Table 1578: PS_E2SCR_CHn field descriptions*: updated description for DDSR_CLK_SEL. *Chapter 58: Deserial Serial Peripheral Interface (DSPI)* Removed section "Register classification for safety" *Section 58.4.12.10: Receive FIFO Drain interrupt or DMA Request*: added 3 notes. *Chapter 63: Power management controller digital interface (PMC_Dig)* Updated *Table 1741: Power Management Controller Memory Map* Removed footnote from *Figure 1814: Global Interrupt Enable Register (IE_G)* Added *Section 63.5.32: ESR0 Configuration Register (ESR0_CFG)* *Chapter 67: Debug and Calibration Interface (DCI)* Updated *Section 67.1.3.5: SWT control* *Chapter 80: Cyclic Redundancy Check (CRC) Unit* *Table 2076: CRC unit memory map*: Removed the "Register classification column" *Chapter 84: Self-Test Control Unit (STCU2)* *Section 84.5.12: STCU2 Offline LBIST Status Register (STCU_LBS)*: Updated the positioning of field LBS and length of this field in table to match the register figure. *Section 84.5.13: STCU2 Offline LBIST End Flag Register (STCU_LBE)*: Updated the positioning of field LBE and length of this field in table to match the register figure. *Section 84.5.14: STCU2 Online LBIST Status Register (STCU_LBSSW)*: Updated the positioning of field LBSSW and length of this field in table to match the register figure.

Table 2389. Document revision history (continued)

Date	Revision	Changes
11-Jan-2021	5 (cont'd)	*Section 84.5.15: STCU2 Online LBIST End Flag Register (STCU_LBESW)*: Updated the positioning of field LBESW and length of this field in table to match the register figure. *Section 84.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*: Updated the positioning of field LBRMSW and length of this field in table to match the register figure. *Section 84.5.17: STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)*: Updated the positioning of field LBUFM and length of this field in table to match the register figure.
