The GCP divides the system clock to generate a clock for the CPs of the channels. The main clock signal is prescaled by the value defined in *Table 671* according to bits GPRE[16:23] in the EMIOSMCR. The global prescaler is enabled by setting the GPREN bit in the EMIOSMCR and can be stopped at any time by clearing this bit, thereby stopping the internal counters in all the channels.

In order to ensure safe working and avoid glitches the following steps must be performed whenever any update in the prescaling rate is desired:

1. Write ‘0’ at GPREN bit in EMIOSMCR, thus disabling global prescaler;
2. Write the desired value for prescaling rate at GPRE[16:23] bits in EMIOSMCR;
3. Enable global prescaler by writing ‘1’ at GPREN bit in EMIOSMCR.

The prescaler is not disabled during either freeze state or negated GTBE input.

46.4.3.1 Effect of Freeze on the GCP

When the FRZ bit in the EMIOSMCR is set and the module is in debug mode, the operation of GCP submodule is not affected, that is, there is no freeze function in this submodule.

46.5 Initialization/Application information

On resetting the eMIOS the Unified Channels enter GPIO input mode.

46.5.1 Considerations

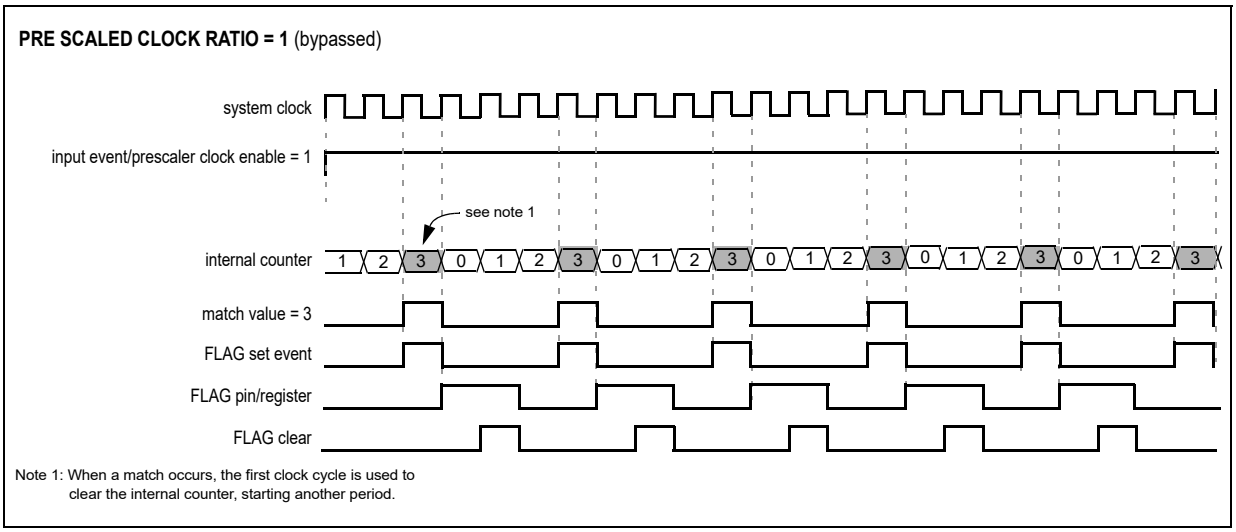
Before changing an operating mode, the UC must be programmed to GPIO mode and EMIOSA*n* and EMIOSB*n* registers must be updated with the correct values for the next operating mode. Then the EMIOSC*n* register can be written with the new operating mode. If a UC is changed from one mode to another without performing this procedure, the first operation cycle of the selected time base can be random, that is, matches can occur in random time if the contents of EMIOSA*n* or EMIOSB*n* were not updated with the correct value before the time base matches the previous contents of EMIOSA*n* or EMIOSB*n*.

When interrupts are enabled, the software must clear the FLAG bits before exiting the interrupt service routine.

46.5.2 Application information

Correlated output signals can be generated by all output operation modes. Bits OU*n* of the EMIOSOUDIS register can be used to control the update of these output signals.

In order to guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global



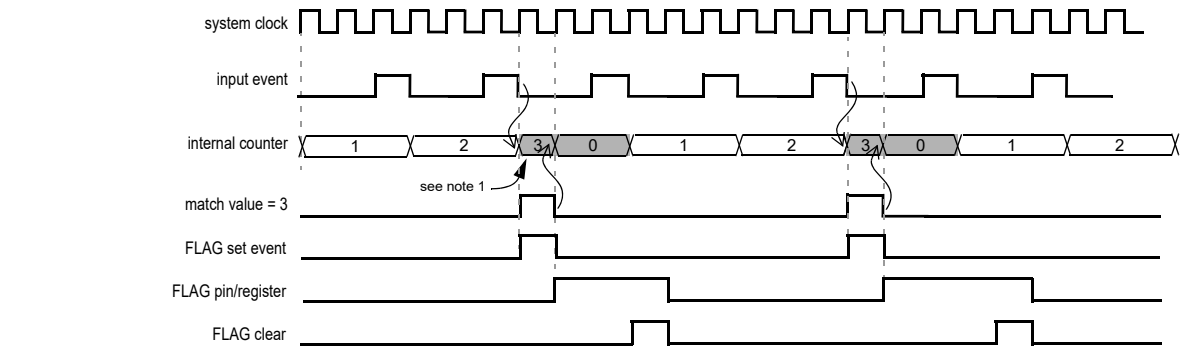
prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters may increment in the same ratio, but at a different clock cycle.

46.5.2.1 Time base generation

For MC with internal clock source operation modes, the internal counter rate can be modified by configuring the clock prescaler ratio. *Figure 580* shows an example of a time base with prescaler ratio equal to one.

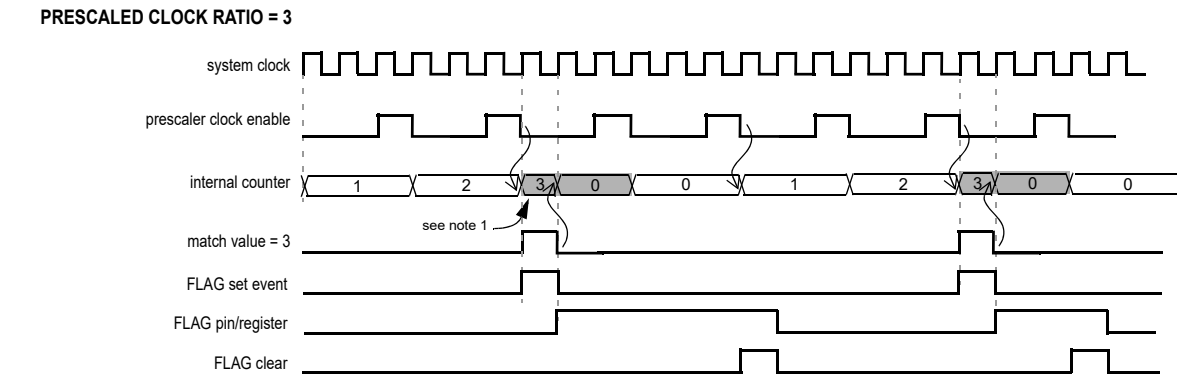
Note: MCB and OPWFMB modes have a different behavior.

Figure 580. Time base period when running in the fastest prescaler ratio



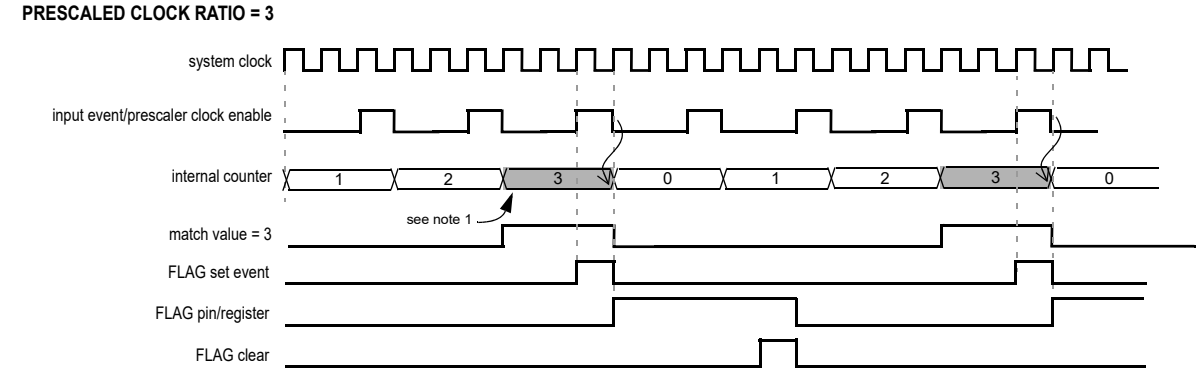
If the prescaler ratio is greater than one or external clock is selected, the counter may behave in three different ways depending on the channel mode:

- If MC mode and Clear on Match Start and External Clock source are selected the internal counter behaves as described in *Figure 581*.
- If MC mode and Clear on Match Start and Internal Clock source are selected the internal counter behaves as described in *Figure 582*.
- If MC mode and Clear on Match End are selected the internal counter behaves as described in *Figure 583*.



Note: MCB and OPWFMB modes have a different behavior.

Figure 581. Time base generation with external clock and clear on match start



Note 1: When a match occurs, the first system clock cycle is used to clear the internal counter, and at the next edge of prescaler clock enable the counter will start counting.

Figure 582. Time base generation with internal clock and clear on match start

Note 1: When a match occurs, the first clock cycle is used to clear the internal counter, and only after a second edge of pre scaled clock the counter will start counting.

Figure 583. Time base generation with clear on match end

Note 1: The match occurs only when the input event/prescaler clock enable is active. Then, the internal counter is immediately cleared.

46.5.2.2 Coherent accesses

It is highly recommended that the software waits for a new FLAG set event before starting to read the EMIOSA*n* and EMIOSB*n* registers to get a new measurement. The FLAG indicates that new data has been captured and it is the only way to assure data coherency.

The FLAG set event can be detected by polling the FLAG bit or by enabling the interrupt request or CTU trigger generation.

Reading the EMIOSA*n* register again in the same period of the last read of EMIOSB*n* register may lead to incoherent results. This will occur if the last read of EMIOSB*n* register occurred after a disabled B2 to B1 transfer.

46.5.2.3 Channel/Modes initialization

The following basic steps summarize basic output mode startup, assuming the channels are initially in GPIO mode:

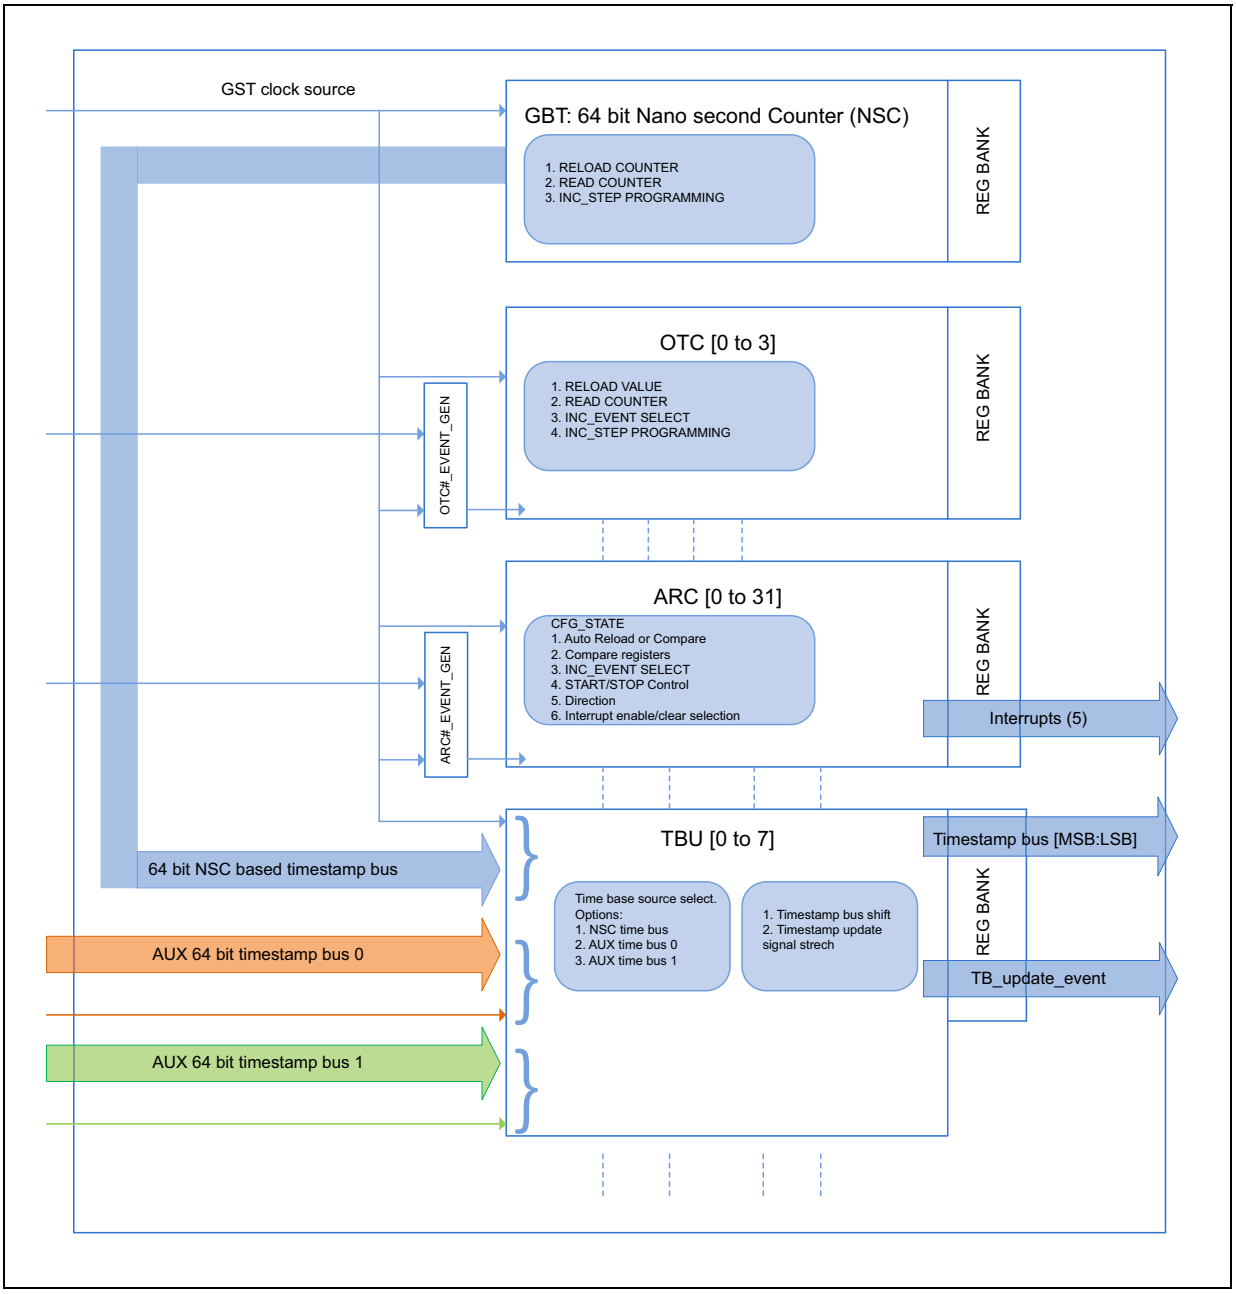
1. *[global]* Disable Global Prescaler.
2. *[timebase channel]* Disable Channel Prescaler.
3. *[timebase channel]* Write initial value at internal counter.
4. *[timebase channel]* Set A/B register.
5. *[timebase channel]* Set channel to MC(B) Up mode.
6. *[timebase channel]* Set prescaler ratio.
7. *[timebase channel]* Enable Channel Prescaler.
8. *[output channel]* Disable Channel Prescaler.
9. *[output channel]* Set A/B register.
10. *[output channel]* Select timebase input through bits BSL[21:22].
11. *[output channel]* Enter output mode.
12. *[output channel]* Set prescaler ratio (same ratio as timebase channel).
13. *[output channel]* Enable Channel Prescaler.
14. *[global]* Enable Global Prescaler.
15. *[global]* Enable Global Time Base.

The timebase channel and the output channel may be the same for some applications such as in OPWFM(B) mode or whenever the output channel is intended to run the timebase itself.

The flags can be configured at any time.

47 Global System Timer (GST)

47.1 Introduction



The key goal of Global System Timer (GST) design is to provide a common counter clock for all the device internal timing tasks. The GST design is composed of the following building blocks.

- Global Base Time unit (GBT)
  - Nano Second Counter
    - For device-internal time base requirements a 64-bit Nano Second Counter or NSC is implemented in GST.
    - NSC is updated on GST_CLOCK.
- Generic Event Generator (xxx_EVENT_GEN)
  - Event generator can be programmed to generate an update event for corresponding module based on GST clock or an auxiliary input.
  - Event generator can prescale GST_CLOCK to generate an update event.
  - Event generator can create an update event from auxiliary input. Update event is always synchronized to GST CLOCK.
  - Multiple modules inside GST have an associated instance of Generic event generator which is called by the sub module name. For example, event generator with ARC module instance number 5 is called ARC5_EVENT_GENERATOR.
- Operation Time Counter (OTC)
  - Operation time counter is composed of free running 64-bit counters to record operation life time for any application. The operating system will regularly store the value of these counters in EEPROM and after power-on reset de-assertion, these values will be restored in the OTC counter by the software.
  - Operation time counter is updated either on GST clock or OTC# event generator output.
- Auto-Reload / Compare (ARC)
  - GST has bank of configurable counters which can be set in either of the two modes, Auto Reload counter or One time counter. The aim of these counters is to enable periodic interrupt generation or variable timing events. Below is a small description of different modes.
  - Auto reload mode: In auto reload mode, the counter once started, keeps running from Reload value till Expiry value. After Expiry value the counter is automatically updated with the Reload value and the counter keeps running.
    - Classic compare mode: If a classic COMPARE counter is required, then the software can set ARC in Auto reload mode with Reload value as 32’h0000_0000 and Expiry value as 32’hFFFF_FFFF (if the counter is incrementing on each valid counting event). This is equivalent to a free running counter.
  - One time mode: In one time mode the counter once started, counts from reload value till the expiry value. It will then go back to reload value and stop counting until another ‘start counter’ request is made.
  - Each ARC counter instance consist of a 32-bit counter, four compare registers, interrupt enable and status registers. Interrupt events are generated based on compare register and counter expiry.

  - Counter in Auto Reload (AR) mode is used to generate periodic interrupts. The counter starts from a programmable ‘reload value’, counts to a programmable ‘expiry value’ and expires. At expiry the counter is reloaded with ‘reload value’. Once configured to start, the counter in auto-reload mode runs continuously unless stopped by a software intervention. Interrupts can be programmed to indicate counter expiry event.
  - Counter in One time mode is used to generate variable timing events. The counter starts from a programmable ‘reload value’ and counts till ‘expiry value’ and expires. At expiry the counter is loaded with ‘reload value’ and stops counting. To restart counter a software intervention is required.
  - Direction of count, counting event, counter start and counter stop are programmable.
- Time Base Unit (TBU)
  - Channel can derive timestamp value from the NSC counter value or an external bus. This is implementation dependent feature and based on instantiation of timestamp channel in the device.
  - Timestamp bus is accompanied with a timestamp update signal. The timestamp update signal can be stretched for multiple clock period. This can be used by peripheral devices to synchronize the timestamp value.
  - Each channel can be configured to select a part of 64-bit input bus value based on requirement of timestamp resolution and update frequency. This is implementation dependent feature and based on instantiation of timestamp channel in the device.

Only GBT.NSC module, OTC0, ARC0 and TBU Channel 0 are fixed in GST. Rest sub modules presence and number of instances are device implementation dependent. (Indexing of OTC, ARC and TBU sub modules starts with 0).

Figure 584. GST block diagram

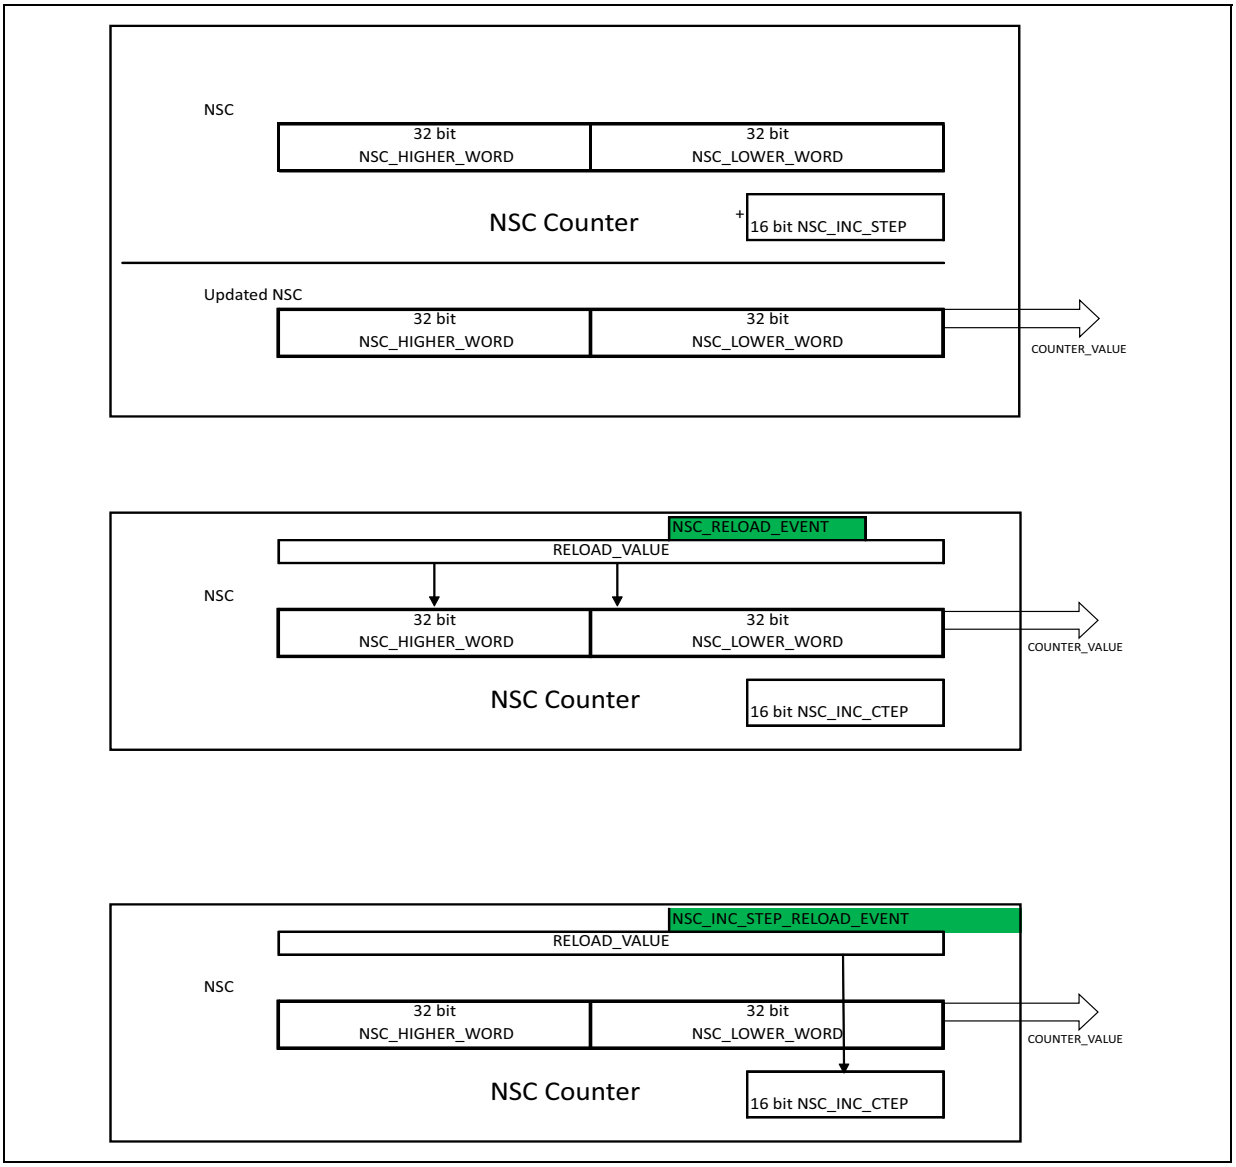
47.2 Feature description

- Nano Second Counter (NSC) with granularity of 1 nano second. The accuracy/precision of NSC is based on GST CLOCK frequency.
- Operational time counters to record lifetime of applications on device.
- Periodic interrupt generation is supported based on software defined timeouts in auto reload mode.
- Interrupt generation based on comparison mode with free running counters is supported.
- Timestamp buses are implemented and can be configured to use Nano Second Counter (NSC) value or external bus value as timestamps.
- Timestamp buses width is configurable.
- Timestamp bus supports synchronization blocks which can be configured to interface with peripherals running on different clock frequencies.

47.3 Functional description

Figure 584 illustrates the sub modules present in GST design. Details of each subsection is described below.

47.3.1 Global Base Time unit (GBT)



47.3.1.1 Overview

GST module consists of one global base time unit. Global base time unit consists of:

- Nano-Second Counter (NSC). This is a 64-bit free running counter.

These features are described in detail below.

Figure 585. 64-bit Nano Second Counter (NSC)

47.3.1.2 Nano second counter (NSC)

A 64-bit wide counter is implemented in GBT module. This counter can be incremented in programmable steps per clock event. The ‘increment step’ register programming should ensure that a single bit of counter reflects a nano-second time period. NSC is a free-running counter. Thus, after reaching its maximum value, it rolls back to the default value of 64'd0.

This counter provides features described in the following sub-sections.

47.3.1.3 Nano second counter debug mode (NSC_DEBUG_CFG)

The default mode of counter in RUN mode and it starts counting as soon as it is out of reset. NSC Counter can be programmed to freeze in Debug mode.

47.3.1.4 Nano second counter reset behavior

The NSC counter default value at power on reset is 0x0000_0000_0000_0000.

Any other reset except Power-on Reset does not stop NSC counter, and it counts as usual on the available GST clock.

47.3.1.5 Nano second counter reload (NSC_L/HWORD_RELOAD)

The counter can be reloaded with any 64-bit value which is programmed in RELOAD registers. This function is available both when the counter is running as well as when the counter is frozen (either due to DEBUG mode or low power Stop mode).

64 bits of NSC counter Reload Value are accessible in [63:32] or NSC_HWORD_RELOAD and [31:0] or NSC_LWORD_RELOAD format.

Any order of write operation NSC_LWORD_RELOAD first or NSC_HWORD_RELOAD first is allowed.

NSC Reload event is defined by NSC_CFG and NSC_CTRL registers.

Software can choose to force reload value on NSC counter either automatically when both the reload registers are updated or wait for application to update NSC counter with reload register explicitly.

Note: When software chooses to force the reload of the NSC counter automatically then, both reload registers should be updated by the software. If a reload register is updated multiple times then the last updated value is considered. Each individual reload register has to be updated at least once for the automatic reload to take place.

In case of automatic reload, once software has accessed both NSC_L/HWORD_RELOAD registers, there is a delay associated with synchronizing the RELOAD value from register interface clock domain to GST clock domain. Thus, the software must not access both these registers again, until the synchronization from previous software access to this register has completed, else the new data can be lost.

47.3.1.6 Nano second counter read (NSC_L/HWORD_READ)

The NSC counter value can be read from register interface in any mode. 64-bit counter is accessible in [63:32] or NSC HIGHER WORD and [31:0] or NSC LOWER WORD format.

A read access to any of the two registers latches the 64-bit value of NSC on NSC_HIGHER_WORD and NSC_LOWER_WORD registers. When both the registers are read by software the latched values are cleared. A status register (NSC_STATUS) shows whether registers are reflecting a latched value based on last read access or current value of NSC. It is also possible to force clear the latched values (NSC_CTRL).

47.3.1.7 Nano second counter increment step (NSC_INCSTEP_CFG)

NSC has an associated increment step value which should be programmed by software based on the GST clock source frequency. At each GST_CLOCK the NSC value is incremented by NSC_INCSTEP_VAL. Increment step value should be chosen so that single bit precision on counter remains 1 nanosecond. The NSC Counter rolls over at 64'hFFFF_FFFF_FFFF_FFFF to 64'h0000_0000_0000_0000.

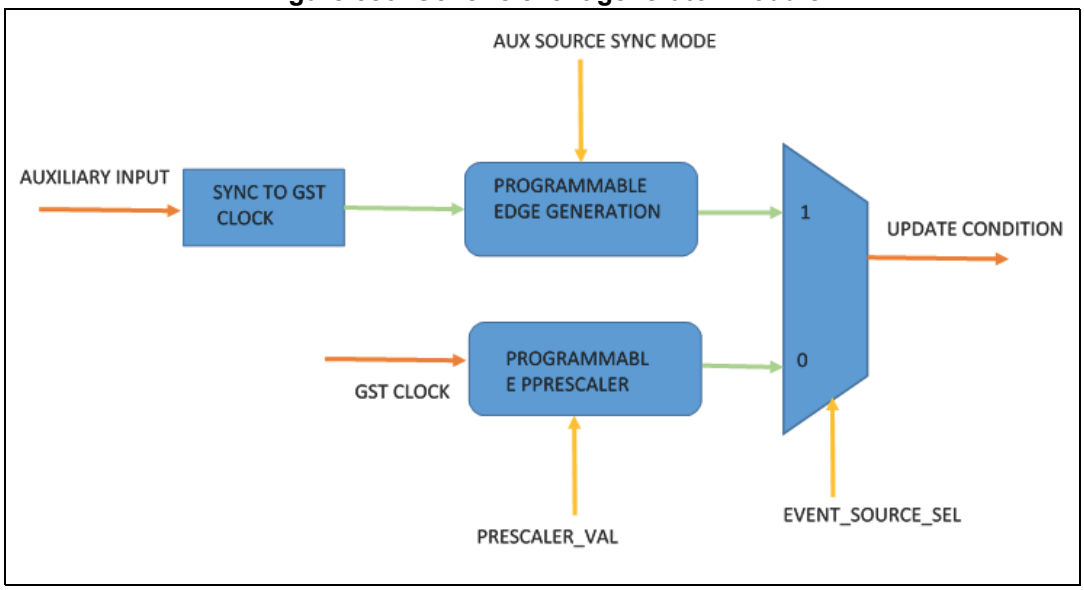
For example if selected clock source frequency = 100 MHz then GST_CLOCK= 100 MHz and then increment step = (10e8/100e6) = 10 or 0x0A.

47.3.1.8 Nano second counter secondary read channel

The value of NSC counter may be required by two separate applications. In order to provide independent read access to two applications a second read channel is present. The second read channel has two registers for the read value of NSC counter and a status and control register to identify and clear latch condition on read registers.

47.3.2 Generic event generator module (xxx_EVENT_GEN)

An event generator module is linked to each instance of OCT and ARC counters. The software can program GST to use the output of event generator module as “update condition” for updating associated counters.



An event generator module can work in two modes: prescaler mode or auxiliary mode.

In prescaler mode the “update condition” is generated by dividing GST clock using a prescaler. The prescaler value is programmable. When “update condition” is high, the associated counter updates on GST clock.

In auxiliary mode the “update condition” is based on an auxiliary input synchronized to GST clock. When “update condition” is high, the associated counter updates on GST clock. Auxiliary input is first synchronized on GST_CLK, and then depending on the software configuration, either of the following can be used as “update condition”:

1. Pulse of 1 GST clock cycle corresponding to rising edge of the auxiliary input.
2. Pulse of 1 GST clock cycle corresponding to falling edge of the auxiliary input.
3. 2 pulses of 1 GST clock cycle each, corresponding to both rising and falling edges of the auxiliary input.
4. Auxiliary input completely synchronized to GST clock.

Figure 586. Generic event generator module

47.3.3 Operation Time Counter (OTC)

Operation time counters are free running 64-bit counters. They can count on either GST clock or dedicated OTC#_EVENT_GEN. OTC are used to maintain operation lifetime

information of any application. Number of OTC counter instances in GST is dependent on implementation parameter. At least one and maximum four OTC instances are supported.

47.3.3.1 OTC mode

OTC counters have two modes of operation, RUN mode and DEBUG mode. The default mode of counter in RUN mode and it starts counting as soon as it is out of power-on-reset. OTC counters can be programmed to freeze in debug mode.

47.3.3.2 OTC reset behavior

The default value of counter on power-on-reset is 64'h0000_0000_0000_0000.

Any other reset except Power-on Reset does not stop OTC counter, and it counts as usual on the available update clock.

47.3.3.3 OTC reload (OTCn_RELOAD_H/L)

The OTC counter can be reloaded with any 64-bit value which is programmed in RELOAD registers. This function is available both when the counter is running as well as when the counter is frozen (either due to DEBUG mode, low power Stop mode or due to a STOP request by software).

64 bits of OTC counter Reload Value are accessible via two registers; [63:32] bits as OTC_HWORD_RELOAD and [31:0] bits as OTC_LWORD_RELOAD.

Any order of write operation within two registers is allowed.

Application may choose to reload OTC counters after updating one or two reload registers of counter. Any reload on OTC counter would force the current value of both reload registers at the OTC counter.

The software can choose to force reload value on OTC counter either automatically when both the reload registers are updated or wait for application to update OTC counter with reload register explicitly.

Note: In case of automatic reload, once the software has accessed both OTC_L/HWORD_RELOAD registers, there is a delay associated with synchronizing the RELOAD value from register interface clock domain to GST clock domain. Thus, the software must not access both these registers again, until the synchronization from previous software access to this register has completed, else the new data can be lost.

47.3.3.4 OTC counter read (OTCn_L/HWORD_READ)

The counter value can be read from register interface in any operating state. 64-bit counter is accessible in [63:32] or HIGHER WORD and [31:0] or LOWER WORD format.

Application may choose to read any of the two registers in any order. As soon as a read access to any of the two registers is made, both registers latches the current value of OTC. The latched value is not cleared until both register locations are accessed. A bit captures whether the registers are in latched state or not. A software write can also force to clear the latched values without reading both registers.

47.3.3.5 OTC default update event

The OTC counters are updated at GST_CLOCK.

47.3.3.6 OTC optional update event

OTC counter can be alternatively updated on output of OTCn_EVENT_GEN module. OTCn_EVENT_GEN can be programmed to generate an update event in multiples of GST_CLOCK or use an auxiliary input source.

47.3.3.7 OTC counter increment step (OTCn_INCSTEP_CFG)

OTC counter has an associated increment step value which should be programmed by software based on update event frequency. At each update event the timer is incremented by OTC_INCSTEP_VAL.

OTC increment step value should be chosen so that single bit precision on counter remains 1 nanosecond.

For example, if selected clock source frequency is 100 MHz, then the increment step equals: ($10^8/100^6$) = 10 or 0x0A.

47.3.3.8 OTC start stop control

OTC counter starts running as soon as they are out of reset. Software can stop a running OTC counter and start an idle counter by OTC_CTRL register.

A start request on already running OTC counter or a stop request on idle OTC counter will have no impact. Software should not request to start and stop the OTC counter simultaneously. If both start and stop requests are launched by the software then only the stop request is considered valid.

A bit in the OTC_STATUS register indicates the start status of OTC counter. '1' indicates that OTC counter has not received a valid 'STOP request' from the software. Based on debug mode/low Power Stop mode configuration, the state of the counter (running or frozen) should be determined. '0' indicates that OTC counter has received a valid 'STOP request' from the software and is frozen due to this stop request.

47.3.4 Auto Reload or Compare (ARC) module

ARC counter is general purpose 32-bit counter. Number of ARC counters in GST is dependent on implementation parameter. GST supports minimum 1 and maximum 32 ARC instances. An ARC event can be configured either to trigger an interrupt or to provide a HW trigger event (pulse) to another peripheral module.

47.3.4.1 ARC module reload value

An ARC module has a programmable 32-bit reload value. The counter starts from its reload value.

47.3.4.2 ARC module expiry value

An ARC module has a programmable 32-bit expiry value. The counter starts from its reload value and updates on valid ‘update event’. On reaching the expiry value, the ARC expiry event is generated. On next update event counter rolls back to reload value.

47.3.4.3 ARC module reset behavior

The ARC counter default value after destructive reset is 0x00000000. After the de-assertion of the reset, the ARC counter goes to its reload value on the next available GST clock edge, and stays at its reload value until start request from software starts the counter.

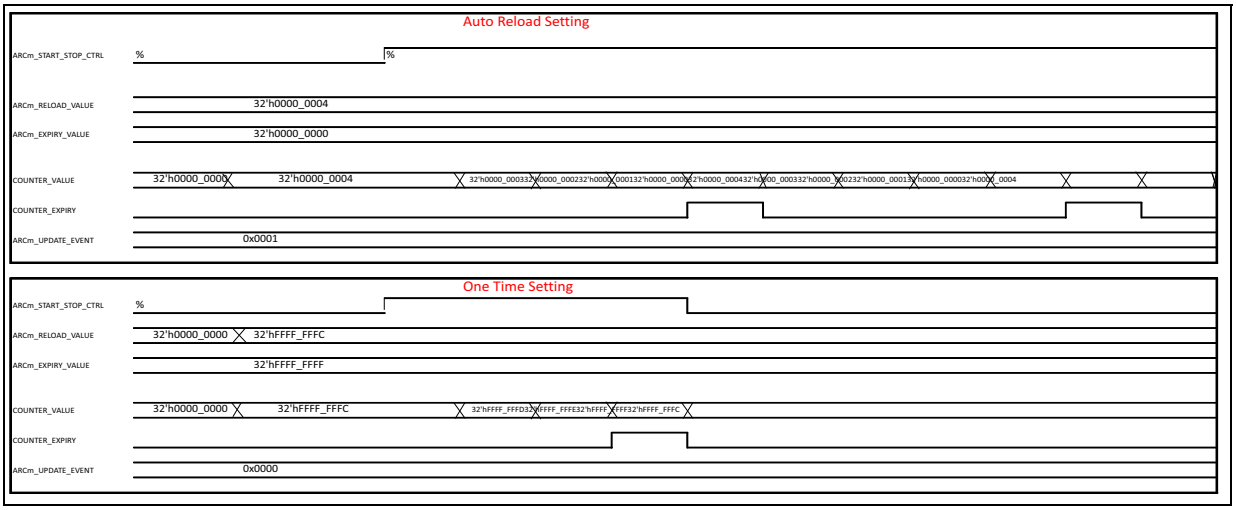
47.3.4.4 ARC module start stop (ARCm_CTRL)

By default the ARC module remains static (or in stop condition). The software can control the ARC counter to start and stop by setting counter start request to 1 or counter stop request to 1 in ARCm_CTRL register. If an ARC counter is forced to stop, it will go to reload value and wait for a start event.

A start request on already running ARC counter or a stop request on idle ARC counter will have no impact. Software should not request to start and stop the ARC counter simultaneously. If both start and stop requests are launched by the software then only the stop request is considered to be valid.

A bit in the ARC_STATUS register holds the start status of ARC counter. '1' indicates that ARC counter has received a valid 'START request' from the software. Based on debug mode/low Power Stop mode configuration, the state of the counter (running or frozen) should be determined. '0' indicates that ARC counter has not received a valid 'START request', due to which it is not counting.

47.3.4.5 ARC module operation mode (ARCm_CFG)



ARC module behavior depends on ARC operational mode.

In Auto reload mode, ARC counter updates from reload value to expiry value and then roll back to reload value and keep on counting. In auto reload mode, an ARC counter once started does not stop until a software request is received to explicitly stop the counter. Counter start request once set is not auto cleared.

A classic Compare mode can be achieved by setting counter in Auto reload mode and setting Reload value to 32’h0000_0000 and Expiry value to 32’hFFFF_FFFF. (Counter is set for increment on each counting event). With these setting counter acts as a free running 32-bit counter.

In One time mode, ARC counter updates from reload value to expiry value and then roll back to reload value and stops. The counter start request is also cleared.

Figure 587. ARC waveforms - Auto reload and compare modes

47.3.4.6 ARC module update event (ARC_UPDATE_EVENT)

An ARC module can be programmed to update counter either at GST CLOCK, ARCm_EVENT_GEN output or based on combination of these two. Following is the list of options which software can program to define the count direction and counting event for ARC.

Table 687. ARC update event configuration

ARCm_CONFIG: ARC_UPDATE_EVENT	Update event source [Posedge only]	Update condition	Direction
0000	GST CLOCK	NONE	UP/ INCREMENT
0001	GST_CLOCK	NONE	DOWN/ DECREMENT
0010	GST_CLOCK	ARCm_EVENT_GEN output = 1	UP/ INCREMENT
0011	GST_CLOCK	ARCm_EVENT_GEN output = 1	DOWN/ DECREMENT
0100(1)	ARCm_EVENT_GEN	NONE	UP/ INCREMENT
0101(2)	ARCm_EVENT_GEN	NONE	DOWN/ DECREMENT
0110(3)	GST_CLOCK	ARCm_EVENT_GEN output = 1	UP/ INCREMENT
		ARCm_EVENT_GEN output = 0	DOWN/ DECREMENT
0111(3)	GST_CLOCK	ARCm_EVENT_GEN output = 1	DOWN/ DECREMENT
		ARCm_EVENT_GEN output = 0	UP/ INCREMENT

1. ARCm_CONFIG = 0100 is the same as 0010. It is due to the generation of ARCm_EVENT_GEN on GST_CLOCK. Refer description in *Section 47.1*: “Event generator can create an update event from auxiliary input. Update event is always synchronized to GST CLOCK”.
2. ARCm_CONFIG = 0101 is the same as 0011. It is due to the generation of ARCm_EVENT_GEN on GST_CLOCK. Refer description in *Section 47.1*: “Event generator can create an update event from auxiliary input. Update event is always synchronized to GST CLOCK”.
3. ARCm_CONFIG = 0110/0111 are not required and software should avoid programming these values.

ARC module has two modes of operation, RUN mode and DEBUG mode. ARC counter updates counter value in run mode. ARC module can be programmed to freeze in debug mode.

47.3.4.7 ARC module compare register bank

Each ARC module has a set of four compare registers. ARC module counter value is compared against compare registers and corresponding interrupt or hardware trigger (pulse) is generated if comparison result is positive.

47.3.4.8 ARC module interrupts

Each ARC module features five maskable interrupts. Four interrupts are driven by comparison results and the last one indicates counter expiry. The interrupts are cleared on arrival of the Power-on reset.

47.3.4.9 ARC module trigger pulses

Each ARC module can be configured to generate a hardware trigger (pulse) instead of an interrupt. Four of these triggers are driven by comparison results and the last one indicates counter expiry.

47.3.5 Time Base Unit (TBU)

The time base unit provides several configurable time counter buses to platform, debugging and peripheral modules to enable them to access the global time base information either by local counter value access or by local capture event. This implementation avoids long latency SW accesses to GST registers interface and enables global time stamping directly in the peripheral modules.

Time base unit consists of timestamp channels. Number of timestamp channels, width of each timestamp channel, and source of timestamps are dependent on implementation parameters of GST.

Timestamp sources can either be NSC counter or any of the two input auxiliary timestamp buses which are selected using TS_SOURCE_SEL field of TSk_SOURCE_SEL_CFG register. Since each timestamp is derived from 64-bit wide bus the timestamp field width can be any subset of [63:0].

NSC counter value is already in GST clock domain. Timestamp buses from auxiliary sources have to be synchronized to GST clock, if the auxiliary source clock is asynchronous to GST clock.

The following table contains an example of a few timestamp channel configurations and associated frequencies.

Figure 588. GST TBU concept

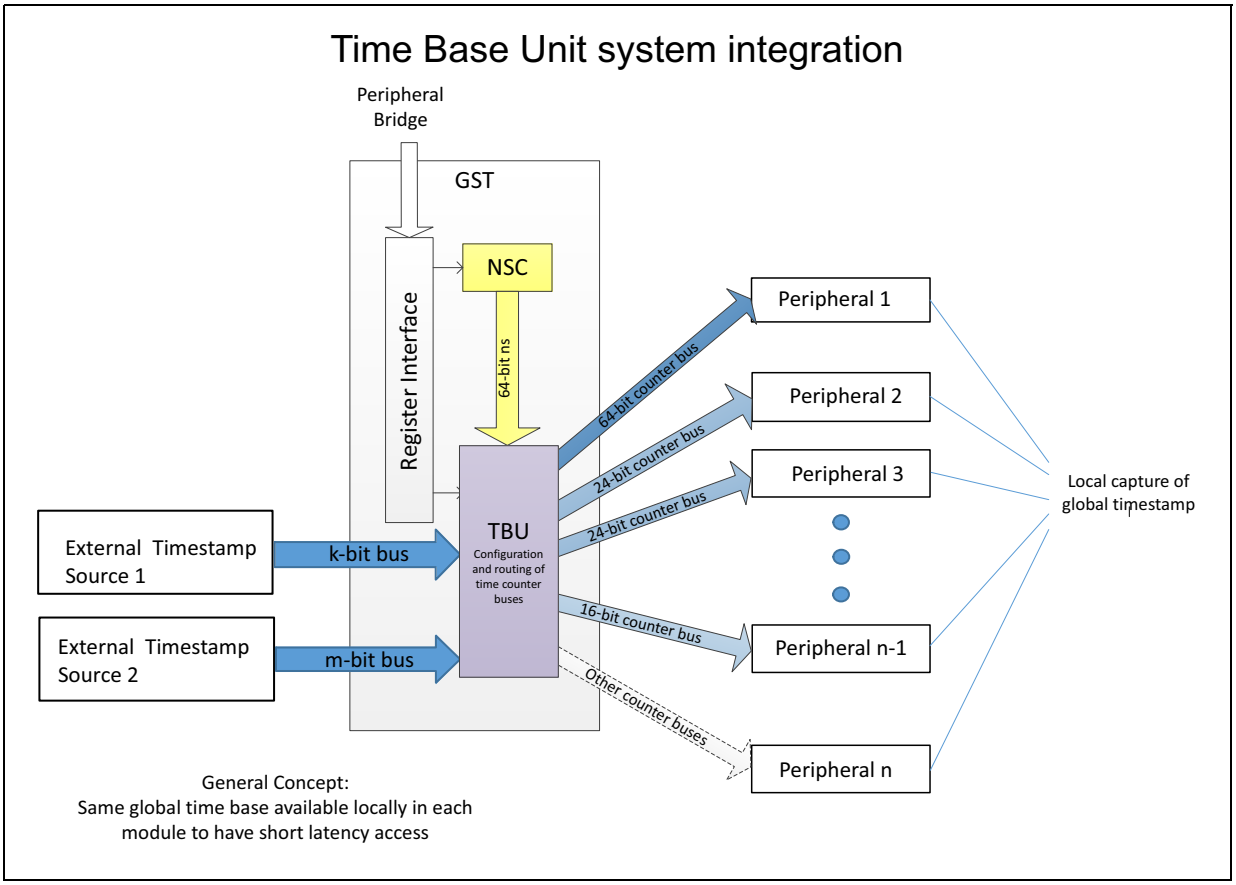


Table 688. Time Base Unit example configurations

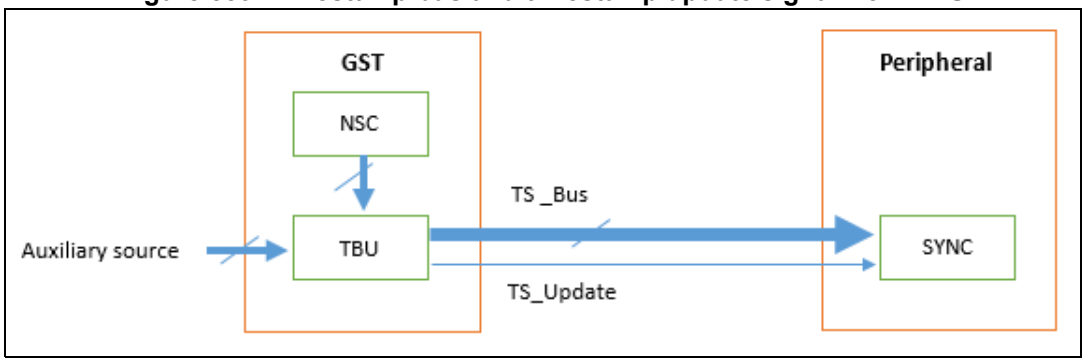
Output resolution (implementation parameter)	Timestamp tick	Source select (register config.)	Counter bit select (register config.)	Count range Min.	Count range Max.
16 bit	According to selected ETB bits	ETB 0, 1	[2:17]	According to selected ETB Bits	
			[4:19]		
			[6:21]		
			[8:23]		
	1 micro second	64 NSC	[9:24]	0.512 micro second	33.554 milli seconds
	10 micro second		[13:28]	8.192 micro second	536.870 milli seconds
24 bit	According to selected ETB bit	ETB 0, 1	[0:23]	According to selected ETB bits	
	10 nano second	64 bit NSC	[3:26]	8 nano second	134.217 milli seconds
	100 nano second		[6:29]	64 nano second	1073.741 milli seconds
	1 micro second		[9:32]	0.512 micro second	8.589 seconds

Table 688. Time Base Unit example configurations (continued)

Output resolution (implementation parameter)	Timestamp tick	Source select (register config.)	Counter bit select (register config.)	Count range Min.	Count range Max.
32 bit	According to selected ETB bit	ETB 0, 1	[0:31]	According to selected ETB Bits	
	10 nano second	64 bit NSC	[3:34]	8 nano second	34.359 seconds
	100 nano second		[6:37]	64 nano second	4.564 minutes
	1 micro second		[9:40]	0.512 micro second	36.65 minutes
64 bit	According to selected ETB bit	ETB0, 1	[0:63]	According to selected ETB bits	
	Same timestamp tick as NSC	64 bit NSC		1 nano second	584.942 years

47.3.5.1 Timestamp bus shift



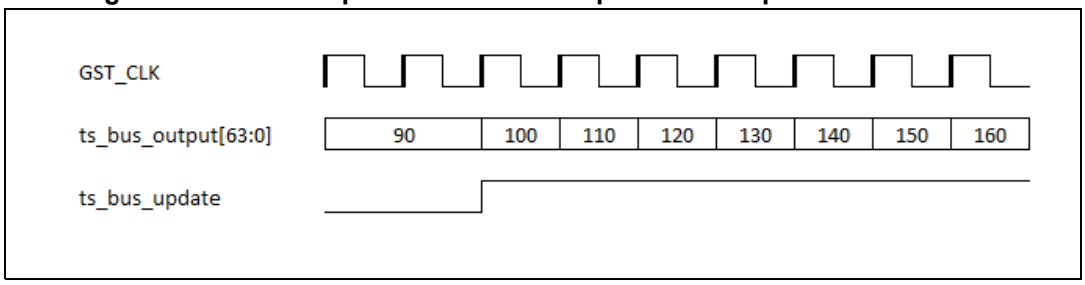
The selected timestamp source can be right-shifted by as many number of bits as the value programmed in the TSk_SOURCE_LSB field of the TSk_BIT_SEL_CFG register (let us call this value TS_BUS_SHIFT). This field should be programmed according to the desired resolution of the TS_Bus. Refer to *Table 688: Time Base Unit example configurations* to see some example of configurations.

47.3.5.2 Timestamp update event generation

Along with every timestamp channel, TBU outputs an associated update event which can be used by a peripheral to capture the timestamp in its own clock domain. Timestamp update event is generated, when the timestamp bus value is different from its value in previous GST clock cycle. At every GST clock cycle, the value of the shifted time-stamp is compared to its value in the previous cycle. If the two values are different, a “time-stamp update” is said to happen and the update event signal is asserted for that GST clock cycle. Note that, if the TS bus has been right-shifted to meet resolution requirement of the peripheral, the update signal is generated with the shifted timestamp bus.

See the figure below, where TS_Bus refers to the timestamp channel output of TBU and TS_Update refers to the associated Timestamp update event signal.

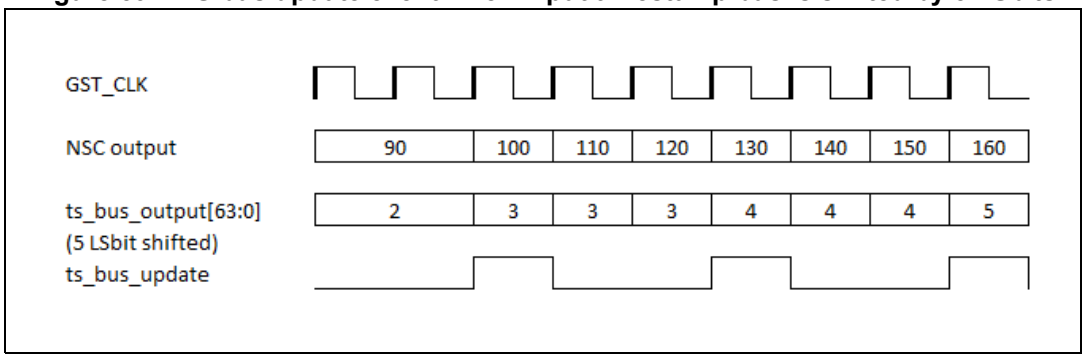
Figure 589. Timestamp bus and timestamp update signal from TBU



47.3.5.3 Timestamp update event stretch

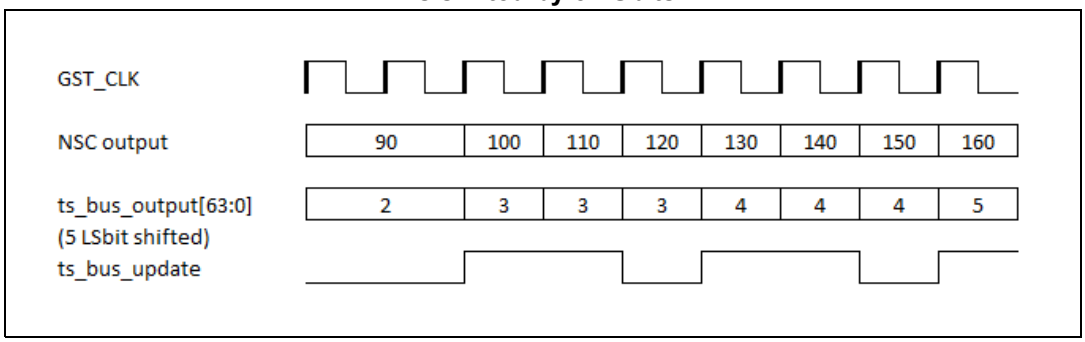
Timestamp channel can be programmed to stretch the timestamp_update event. This allows each channel to have an associated update event which can be used to synchronize timestamp to any clock domain.Timestamp update event is generated on comparing the timestamp value with its value in the previous clock. An updated event is generated when timestamp values are different.

As stated in the above section -Time Base Unit (TBU), timestamp sources can either be NSC counter or any of the two input auxiliary timestamp buses which are selected using TSk_SOURCE_SEL_CFG.TS_SOURCE_SEL register. The auxiliary timestamp buses are first synchronized to bring these into GST clock domain, while NSC value is already in GST clock domain.



Below waveform shows the scenario when 64-bit NSC bus is selected as timestamp source. Here 64-bit NSC value is changing in each GST clock.

Figure 590. TS bus update event when input timestamp bus is not shifted



A continuous high update event cannot be used to synchronize output timestamp to slower peripheral clock domain, for this purpose a pulse is required. To create a pulse of update event, the least significant bits of input timestamp bus can be shifted as per the value programmed in the TSk_BIT_SEL_CFG register. On programming a proper value in the TSk_BIT_SEL_CFG register, the right shifted timestamp bus may have constant value for multiple GST_CLK cycles which on comparing generate pulse of update event signal. For example, below waveform shows a case when 64-bit NSC bus is shifted by 5 LSbits.

Figure 591. TS bus update event when input timestamp bus is shifted by 5 LSbits

Update event signals can be stretched for multiple GST clock period by programming into TSk_UPDATE_EVENT_STRETCH_CFG register. For example in the below figure, update signal shown in above waveform gets stretched by 2 cycles on programming 2 in the TS_UPDATE_EVENT_STRETCH_CYCLE field of TSk_UPDATE_EVENT_STRETCH_CFG register.

Figure 592. Stretched TS bus update event when input timestamp bus is shifted by 5 LSbits

Below relationships should be followed for generation of update event when it is used for the sampling of timestamp bus in slower clock domain of other peripherals for example SAR/SD ADC, M_CAN/M_TTCAN or SPIQ.

Equation 30 TS Update Stretch (cycles) >= GST Freq/Peripheral Freq*1.5 (TSk_UPDATE_EVENT_STRETCH_CFG register value)

Equation 31 TS Bus Constant (cycles) >= 2*Ts Update Stretch

TSk_BIT_SEL_CFG register value should be calculated based on TS Bus Constant (cycles).

For example, in case the peripheral which receives timestamp input from GST is working on 16 MHz clock, then timestamp update signal should be high for more than 100/16 * 1.5 that is 10 clock cycles of GST clock. To generate timestamp update signal, the input timestamp bus should remain constant for more than 20 cycles before input to comparator. It allows to detect an edge in peripheral. To generate constant input timestamp bus for 20 cycles, the TSk_BIT_SEL_CFG register should be programmed to 8 which will shift the bus by 8 bits.

Note: In case, the input AUX timestamp bus is already configured at its source to generate constant value for multiple clock cycles then only stretching should be programmed in GST to allow proper sampling of output timestamp bus.

Note: ts_bus_update is not used.

- *TBU_0 connectivity to Ethernet is synchronous.*
- *TBU_1 connectivity to CAN: change in TBU_1 bus is detected and synchronized in the target domain (CAN clock in this case). So TBU_1 bus should be stable for 3*CAN clock period (PFBRIDGE) + 6*GST clock period.*

47.3.6 Stop mode

Global system timer uses two clocks. Bus interface clock for register management and GST clock for updating all the internal counters/timers.

Stop mode is supported on bus interface clock which means that once the stop mode request is acknowledged, the interface clock can be switched off. The purpose of this signal is to allow GST IP to enter in low power mode. This mode has been referred to as ‘Low power stop mode’ at some places.

47.4 Memory map and register description

This section details all registers in the module.

47.4.1 Memory map

All the GST module registers of SPC58xHx are listed in *Table 689*.

Note: Any access to reserved registers will result in bus error.

Note: The register interface clock domain and the GST counter-clock domain can be completely asynchronous to each other. There is a delay involved in the synchronization of signals from one domain to another.

For example, if the software reads the NSC_LWORD_READ register, it shall get a past value of the lower word of NSC counter, which has been synchronized to the register interface clock domain after some delay. Thus, the value read by software is not "current" in GST clock domain, but "current" in register interface clock domain.

For example, if the software writes to the NSC_LWORD_RELOAD/NSC_HWORD_RELOAD registers, it will take some amount of delay for the Reload value to get synchronized to the GST clock domain. Thus, the actual reload of the NSC counter is expected to be delayed in time, compare to when the software accessed the reload registers.

Figure 594. NSC configuration register (NSC_CFG)

Table 691. NSC_CFG field descriptions

Field	Description
31 NSC_RELOAD_CTRL	NSC Reload Control NSC_RELOAD_CTRL field is used to define which event forces the reload value on NSC current value. NSC current value can be updated either automatically when both reload registers are written or it can be reloaded when a software write 0x1 on NSC_CTRL.FORCE_RELOAD field. 1 NSC is updated with Reload value, as soon as the reload registers are written/updated or when software writes 0x1 on NSC_CTRL.FORCE_RELOAD. 0 NSC is updated with Reload value only when software writes 0x1 on NSC_CTRL.FORCE_RELOAD register. **Note:** NSC_RELOAD_CTRL = 0x1 updates the Reload value on NSC current value as soon as a write access to the two reload registers is finished. The Reload register may or may not be updated with a different value. This option should be used if NSC current value needs to be updated immediately without waiting for another software access. to NSC_CTRL register.

47.4.2.3 NSC status register (NSC_STATUS)

This register contains NSC status.

Offset: 0x0008 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 596. NSC control register (NSC_CTRL)

Table 693. NSC_CTRL field descriptions

Field	Description
23 CLR_READ_REG	NSC Clear Read Register from latched values When software writes 1 on this field, the latch on NSC counter read registers is cleared. A new read access will reflect the new counter value. In order to ensure whether the READ Register hold latched value or current value NSC_STATUS register should be checked. This is a self clearing bit.
31 FORCE_RELOAD	NSC Force Reload NSC current value can be reloaded with RELOAD register values using this control bit. Writing 1 to FORCE_RELOAD updates NSC current value to Reload value. This is a self clearing bit. **Note:** There is a delay associated with synchronizing the reload value from register interface clock domain to GST clock domain. Thus, software must not set this field, until the synchronization from previous software access to this field has completed.

47.4.2.5 NSC lower word read register (NSC_LWORD_READ)

This register value holds NSC lower word [31:0].

Offset: 0x0010 Access: Read-only

Figure 597. NSC lower word read register (NSC_LWORD_READ)

Table 694. NSC_LWORD_READ field descriptions

Field	Description
0:31 NSC_READ_ DATA31_0	NSC Lower Word Read register NSC value is accessible via two registers, NSC_LWORD_READ for NSC current value [31:0] and NSC_HWORD_READ for NSC current value [63:32]. When first read access to any of the two registers is made, NSC current value is latched in both the read registers. The latch is cleared by writing 1 either on NSC_CTRL.CLR_READ_REG or GLBL_LATCH_CLR.NSC_LATCH_CLR register bit. It also gets cleared by completing read accesses on both the Read registers. NSC_STATUS.NSC_READ_REG_STATUS bit holds the status of read register, whether they hold current value or a previously latched value of counter. **Note:** Here “current value” refers to the latest value of the NSC counter in the register interface clock domain.

47.4.2.6 NSC HWORD read register (NSC_HWORD_READ)

This register value holds NSC higher word [63:32].

Offset: 0x0014 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 598. NSC higher word read register (NSC_HWORD_READ)

Table 695. NSC_HWORD_READ field descriptions

Field	Description
0:31 NSC_READ_ DATA63_32	NSC Higher Word Read register NSC value is accessible via two registers, NSC_LWORD_READ for NSC current value [31:0] and NSC_HWORD_READ for NSC current value [63:32]. When first read access to any of the two registers is made, NSC current value is latched in both the read registers. The latch is cleared by writing 1 either on NSC_CTRL.CLR_READ_REG or GLBL_LATCH_CLR.NSC_LATCH_CLR register bit. It also gets cleared by completing read accesses on both the Read registers. NSC_STATUS.NSC_READ_REG_STATUS bit holds the status of read register, whether they hold current value or a previously latched value of counter. **Note:** Here “current value” refers to the latest value of the NSC counter in the register interface clock domain.

47.4.2.7 NSC lower word [31:0] reload register (NSC_LWORD_RELOAD)

This register value is reloaded on NSC current value lower word [31:0]. Reload event is defined by NSC_CFG and NSC_CTRL registers.

Offset: 0x0018 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 604. NSC lower word read register for channel 2 (NSC_LWORD_READ_CH2)

Table 701. NSC_LWORD_READ_CH2 field descriptions

Field	Description
0:31 NSC_READ_CH2_DATA31_0	NSC Lower Word Read register for channel 2 NSC value is accessible via two registers, NSC_LWORD_READ for NSC current value [31:0] and NSC_HWORD_READ for NSC current value [63:32]. When first read access to any of the two registers is made, NSC current value is latched in both the read registers. The latch is cleared either by writing 1 on NSC_CTRL.CLR_READ_REG or by completing read access on both the Read registers. NSC_STATUS.NSC_READ_REG_STATUS bit holds the status of read register, whether they hold current value or a previously latched value of counter.

47.4.2.13 NSC higher word read register for channel 2 (NSC_HWORD_READ_CH2)

This register value holds NSC higher word [63:32].

Offset: 0x0030 Access: Read-only

Figure 607. OTCn config register (OTCn_CFG)

Table 704. OTCn_CFG field descriptions

Field	Description
31 OTC_RELOAD_CTRL	OTCn Reload Control OTC_RELOAD_CTRL field is used to define which event forces the reload value on OTCn current value. OTCn current value can be updated either automatically when two reload registers are written or it can be reloaded when a software write 0x1 on OTC_CTRL.FORCE_RELOAD field. 1 OTC is updated with Reload value, as soon as the two reload registers are written/updated or when software writes 0x1 on OTCn_CTRL.FORCE_RELOAD. 0 OTCn is updated with Reload value only when software writes 0x1 on OTCn_CTRL.FORCE_RELOAD register. **Note:** OTC_RELOAD_CTRL = 0x1 updates the Reload value on OTC current value as soon as a write access to the two reload registers is finished. The Reload register may or may not be updated with a different value. This option should be used if OTCn current value needs to be updated immediately without waiting for another software access. to OTCn_CTRL register.
19 OTC_UPDATE_ EVENT_SEL	OTCn Update Event Selection 0 OTCn is incremented on the positive edge of GST CLOCK. 1 OTCn is incremented on the positive edge of GST CLOCK, only if the update condition output of the OTCn_EVENT_GEN is high. **Note:** Before setting this field to “1”, software should program OTCn_EVENT_GEN_CFG register.

47.4.2.16 OTCn status register (OTCn_STATUS)

This register contains OTCn status.

Offset: 0x0148 + n*0x40 (n= 0 to 0) Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 608. OTCn status register (OTCn_STATUS)

Table 705. OTCn_STATUS field descriptions

Field	Description
23 OTC_READ_ REG_STATUS	OTC Current Value Read Register Status This field reflects the OTCn_LWORD_READ and OTCn_HWORD_READ register status. 0 OTCn Value read registers are not latched. A new read access will reflect current value. 1 OTCn Value read registers are latched due to a previous read access.
15 OTC_RUN_STATUS	OTC RUN Status This field reflects the OTCn counter start status. 0 OTCn counter has received a valid STOP request from software and it is not running due to this request. 1 OTCn counter has not received a valid 'STOP' request from software. Based on the debug mode/low power STOP mode configuration, the state of the counter (running or frozen) should be determined.

47.4.2.17 OTCn control register (OTCn_CTRL)

This register controls the OTCn current value and read register latch status.

Offset: 0x014C + n*0x40 (n= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 609. OTCn control register (OTCn_CTRL)

Table 706. OTCn_CTRL field descriptions

Field	Description
31 FORCE_RELOAD	OTCn Force Reload OTCn current value can be reloaded with RELOAD register values using this control bit. Writing 1 to FORCE_RELOAD updates OTCn current value to Reload value. This is a self clearing bit. **Note:** There is a delay associated with synchronizing the reload value from register interface clock domain to GST clock domain. Thus, software must not set this field, until the synchronization from previous software access to this field has completed.
23 CLR_READ_REG	OTCn Clear Read Register from latched values When software writes 1 on this field, the latch on OTCn counter read registers is cleared. A new read access will reflect the new counter value. In order to ensure whether the READ register hold latched value or current value OTCn_STATUS register should be checked. This is a self clearing bit.
15 OTC_FORCE_START	OTCn Force start An idle (stop) OTCn counter is forced to start by writing 1 on this field. Writing 1 has no impact if OTC counter was already running/incrementing. This is a self clearing bit.
11 OTC_FORCE_STOP	OTCn Force stop A running OTCn counter is forced to stop by writing 1 on this field. Writing 1 has no impact if OTC counter was already stopped. This is a self clearing bit.

47.4.2.18 OTCn lower word read register (OTCn_LWORD_READ)

This register value holds OTCn lower word [31:0].

Offset: 0x0150 + n*0x40 (n= 0 to 0) Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 610. OTCn lower word read register (OTCn_LWORD_READ)

Table 707. OTCn_LWORD_READ field descriptions

Field	Description
0:31 OTC_READ_DATA31_0	OTCn Lower Word Read register OTCn value is accessible via two registers, OTCn_LWORD_READ for OTCn current value [31:0] and OTCn_HWORD_READ for OTCn current value [63:32]. When first read access to any of the two registers is made, OTCn current value is latched in both the read registers. The latch is cleared either by writing 1 on OTCn_CTRL.CLR_READ_REG or by completing read access on both the Read registers. OTCn_STATUS.OTC_READ_REG_STATUS bit holds the status of read register, whether they hold current value or a previously latched value of counter. **Note:** Here “current value” refers to the latest value of the OTC counter in the register interface clock domain.

47.4.2.19 OTCn higher word read register (OTCn_HWORD_READ)

This register value holds OTCn higher word [63:32].

Offset: 0x0154 +n*0x40 (n= 0 to 0) Access: Read-only

Figure 612. OTCn lower word [31:0] reload register (OTCn_LWORD_RELOAD)

Table 709. OTCn_LWORD_RELOAD field descriptions

Field	Description
0:31 OTC_RELOAD_ DATA31_0	OTCn Lower Word Reload value OTCn lower word [31:0] is updated with OTCn LWORD Reload value when an OTCn Reload event occurs. Reload event is defined by OTCn_CFG and OTCn_CTRL registers. **Note:** If the software has accessed both OTC_LWORD_RELOAD and OTC_HWORD_RELOAD registers (in no particular order), and a write access to either OTC_LWORD_RELOAD/OTC_HWORD_RELOAD registers appears on the input of GST in the very next cycle, an IPS write-transfer error will be generated. **Note:** Only word write access is allowed on this register. Any other access apart from word access shall be treated as invalid and will generate bus-transfer error on the IPS register interface.

47.4.2.21 OTCn higher word [63:32] reload register (OTCn_HWORD_RELOAD)

This register value is reloaded on OTCn current value higher word [63:32]. Reload event is defined by OTCn_CFG and OTCn_CTRL registers

Offset: 0x015C + n*0x40 (n= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
19 ARC_START_STATUS	ARCm Start Status 0 ARC counter has not received a valid 'START' request from software. It is not counting. 1 ARC counter has received a valid 'START' request from software. Based on the debug mode/low power STOP mode configuration, the state of the counter (running or frozen) should be determined.

47.4.2.27 ARCm control register (ARCm_CTRL)

This register controls the ARCm. An ARCm counter can be started or stopped using this register.

Offset: 0x024C + m*0x40 (m= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 619. ARCm control register (ARCm_CTRL)

Table 716. ARCm_CTRL field descriptions

Field	Description
15 ARC_START_REQ	ARCm Start request An idle (stop) ARC counter starts if software writes 1 on this field. This is a self clearing bit.
11 ARC_STOP_REQ	ARCm Stop request A running (counting) ARC counter stops if software writes 1 on this field. This is a self clearing bit.

47.4.2.28 ARCm reload config register (ARCm_RELOAD_VALUE)

This register holds the ARCm counter reload value.

Offset: 0x0250 + m*0x40 (m= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 620. ARCm reload config register (ARCm_RELOAD_VALUE)

Table 717. ARCm_RELOAD_VALUE field descriptions

Field	Description
0:31 ARC_RELOAD_VALUE	ARCm Reload Value ARC Reload Value is the default value to which the counter goes after expiry or ARC stop event. An ARC counter starts from RELOAD value and counts till Expiry Value. **Note:** Only word write access is allowed. Any other write access will result in register transfer error.

47.4.2.29 ARCm expiry config register (ARCm_EXPIRY_CFG)

This register holds ARCm counter expiry value.

Offset: 0x0254 +m*0x40 (m= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 621. ARCm expiry config register (ARCm_EXPIRY_CFG)

Table 718. ARCm_EXPIRY_CFG field descriptions

Field	Description
0:31 ARC_EXPIRY_VALUE	ARCm Expiry Value This register holds the Expiry value of ARCm counter. A running counter is updated with RELOAD Value once the Expiry Value is reached. ARCm EXPIRY event is raised when counter reaches the Expiry Value. **Note:** Only word write access is allowed. Any other write access will result in register transfer error.

47.4.2.30 ARCm compare 1 config register (ARCm_COMPARE_1_CFG)

Each ARC counter comes with four compare registers. ARCm_COMPARE_#_CFG register holds the compare values. Each register is associated with its individual interrupt which is raised based on comparison result and interrupt enables.

Offset: 0x0258 + m* 0x40 (m= 0 to 0) Access: Read/Write

47.4.2.34 ARCm interrupt or pulse enable configuration register (ARCm_INT_PULSE_EN_CFG)

ARCm counter can generate up to five interrupts or HW events (pulse generation). Interrupts/pulse are generated either when counter value equals any of the compare register values or at counter expiry. ARCm_INT_PULSE_EN_CFG register enables the individual compare registers or expiry event and defines the behavior of output as either interrupt or pulse.

Offset: 0x0268 + m*0x40 (m= 0 to 0) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

30:31 ARC_INT_ PULSE_C1_EN	ARCm counter interrupt or pulse on compare 1 result Enable 01 The interrupt corresponding compare register 1 on ARCm is enabled. 10 The pulse corresponding compare register 1 on ARCm is enabled. 00 Neither interrupt nor pulse is generated based on Compare register 1 and current ARC counter value. 11 Neither interrupt nor pulse is generated based on Compare register 1 and current ARC counter value.
28:29 ARC_INT_ PULSE_C2_EN	ARCm counter interrupt or pulse on compare 2 result Enable 01 The interrupt corresponding compare register 2 on ARCm is enabled. 10 The pulse corresponding compare register 2 on ARCm is enabled. 00 Neither interrupt nor pulse is generated based on Compare register 2 and current ARC counter value. 11 Neither interrupt nor pulse is generated based on Compare register 2 and current ARC counter value.
26:27 ARC_INT_ PULSE_C3_EN	ARCm counter interrupt or pulse on compare 3 result Enable 01 The interrupt corresponding compare register 3 on ARCm is enabled. 10 The pulse corresponding compare register 3 on ARCm is enabled. 00 Neither interrupt nor pulse is generated based on Compare register 3 and current ARC counter value. 11 Neither interrupt nor pulse is generated based on Compare register 3 and current ARC counter value.
24:25 ARC_INT_ PULSE_C4_EN	ARCm counter interrupt or pulse on compare 4 result Enable 01 The interrupt corresponding compare register 4 on ARCm is enabled. 10 The pulse corresponding compare register 4 on ARCm is enabled. 00 Neither interrupt nor pulse is generated based on Compare register 4 and current ARC counter value. 11 Neither interrupt nor pulse is generated based on Compare register 4 and current ARC counter value.
22:23 ARC_INT_ PULSE_EXPIRY_EN	ARCm counter interrupt or pulse on Counter Expiry Enable 01 The interrupt corresponding counter expiry is enabled. 10 The pulse corresponding counter expiry is enabled. 00 Neither interrupt nor pulse is generated based on counter expiry event. 11 Neither interrupt nor pulse is generated based on counter expiry event.

47.4.2.35 ARCm interrupt status register (ARCm_INT_STATUS)

ARCm counter generates a set of five interrupts. Interrupts are generated either when counter value equals any of the compare register values or at counter expiry. ARCm_INT_STATUS register holds current status of individual interrupt sources.

Note: If the Interrupt generation is not enabled for any of the compare register or expiry event then the corresponding status bit value follows the synchronized value of output ports. If interrupt generation is disabled and output ports are generating pulse then this register is not of much use.

Offset: 0x026C + m*0x40 (m= 0 to 0) Access: Read-only

27 ARC_INT_EXPIRY	ARCm counter interrupt on Expiry status 0 The interrupt corresponding to ARCm Expiry is not asserted/cleared 1 The interrupt corresponding to ARCm Expiry is asserted

47.4.2.36 ARCm interrupt clear register (ARCm_INT_CLR)

ARCm counter generates a set of five interrupts. Interrupts are generated either when counter value equals any of the compare register values or at counter expiry. ARCm_INT_CLR register clears the individual interrupt raised by ARCm.

Note: If the Interrupt behavior is not set for any of the compare register or expiry event, then the corresponding status bit should not be used.

Offset: 0x0270 + m*0x40 (m= 0 to 0) Access: Read/Write

27 ARC_INT_EXPIRY_CLR	ARCm counter clear interrupt on Expiry 1 Writing to this bit clears ARCm_INT_STATUS[ARC_INT_EXPIRY]

47.4.2.37 ARCm event generator config register (ARCm_EVENT_GEN_CFG)

This register controls the ARCm Event Generator. Event generator is a programmable submodule. The application may choose GST clock or an auxiliary event source to drive the Event Generator output.

While programming this register, the register field ARCm_CFG[ARC_UPDATE_EVENT] should be '00'.

Offset: 0x0274 + m*0x40 (m= 0 to 0) Access: Read/Write

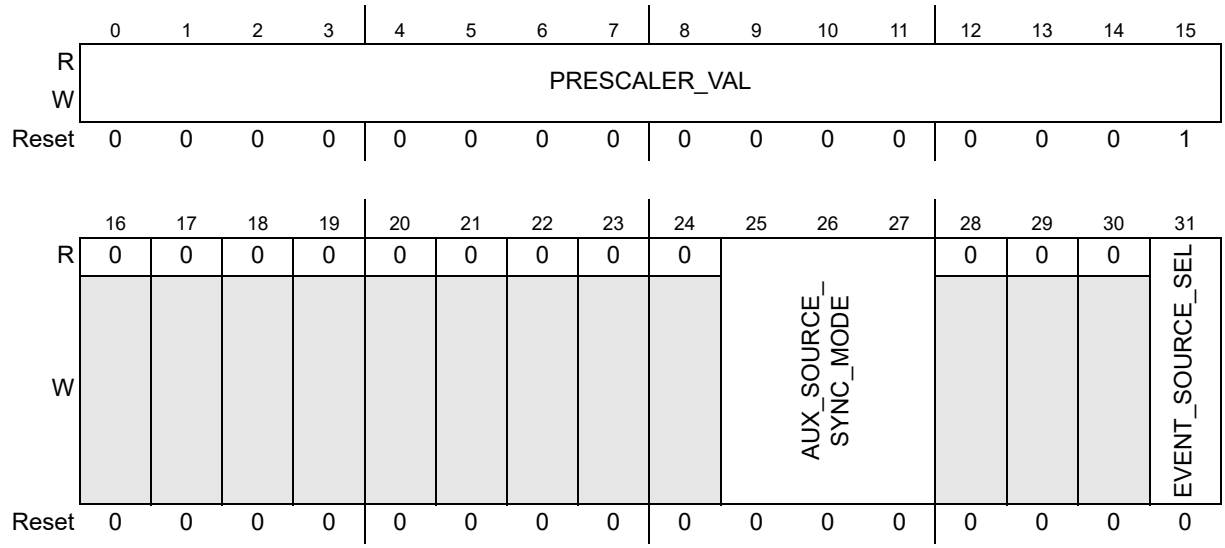

Figure 629. ARCm event generator config register (ARCm_EVENT_GEN_CFG)

Table 726. ARCm_EVENT_GEN_CFG field descriptions

Field	Description
31 EVENT_SOURCE_SEL	ARCm Event Generator Source Selection 0 GST Clock is selected as source for ARCm EVENT GEN output. The Output would be derived by prescaling the GST Clock with ARCm_EVENT_GEN_CFG.PRESCALER _VALUE. 1 Auxiliary source is selected as source for ARCm EVENT GEN output. The output would be derived by Aux source based on ARCm_EVENT_GEN_CFG.AUX_SOURCE_SYNC_MODE.
25:27 AUX_SOURCE_ SYNC_MODE	ARCm Event Generator AUX Source Sync Mode 000 Positive edge of Aux source (synchronized to GST clock) used to create a pulse of 1 GST clock cycle. 001 Negative edge of Aux source (synchronized to GST clock) used to create a pulse of 1 GST clock cycle. 010 Both Positive edge and Negative edge of Aux source (synchronized to GST clock) used to create a pulse of 1 GST clock cycle each. 011 AUX source is synchronized to GST clock. 1xx AUX source is synchronized to GST clock.
0:15 PRESCALER_VAL	ARCm Event Generator GST CLOCK Prescaler Value GST Clock is divided by the PRESCALER_VAL+1. **Note:** For PRESCALER_VAL = 0, GST Clock divided by 2.

47.4.2.38 ARCm read register (ARCm_READ)

This register captures the current value of ARCm counter.

Note: Here “current value” refers to the latest value of the ARC counter in the register interface clock domain.

Offset: 0x0278+ m*0x40 (m= 0 to 0) Access: Read-only

Field	Description
30:31 TS_SOURCE_SEL	Timestamp Channel k Source Select 00 TBU or timestamp channel is based on NSC bus 01 TBU or timestamp channel is based on External time bus 0 10 TBU or timestamp channel is based on External time bus 1 11 TBU or timestamp channel is based on NSC bus

47.4.2.41 Timestamp channel k bit select register (TSk_BIT_SEL_CFG)

This register defines the source bus bits which are used to drive timestamp channel.

Bus width selection starts from the programmed value of TS_SOURCE_LSB field till the implementation parameter TBU_WIDTH_n of each TBU Channel.

The number of bits or the value programmed in TS_SOURCE_LSB field is mapped on bit 0 of output timestamp bus of each channel.

Offset: 0x0A48+ k*0x10 (k= 0 to 1) Access: Read/Write

Figure 633. Timestamp channel k bit select register (TSk_BIT_SEL_CFG)

Table 730. TSk_BIT_SEL_CFG field descriptions

Field	Description
24:31 TS_SOURCE_LSB	Timestamp Channel k Source LSB The value programmed in this field determines the number of bits by which the time-stamp should be right-shifted, before being outputted by TBU. For example, if the selected source of TBU time-stamp is NSC and this field is programmed to be 3, then the NSC time-stamp will be right shifted by 3 bits before being outputted by the TBU. **Note:** This field must be programmed keeping in mind the minimum number of clock cycles for which the TS bus needs to be stable. It may be required to right shift the bus by a given number of bits, so that the Timestamp bus remains stable for a time, long enough to synchronize the Timestamp to the peripheral clock domain. The cost of right shifting the bus by a large value is reducing timestamp resolution. GST has limitation to support some resolutions shown in *Table 688: Time Base Unit example configurations*, because for some of these resolutions, the Timestamp will not remain stable for the required number of GST clock cycles.

47.4.2.42 Global freeze in debug 1 config register (GLBL_FRZ_IN_DBG_1_CFG)

This is part 1 of 2 global registers which controls the debug mode behavior of GST modules.

Offset: 0x0AC0 Access: Read/Write

48 CAN Subsystem

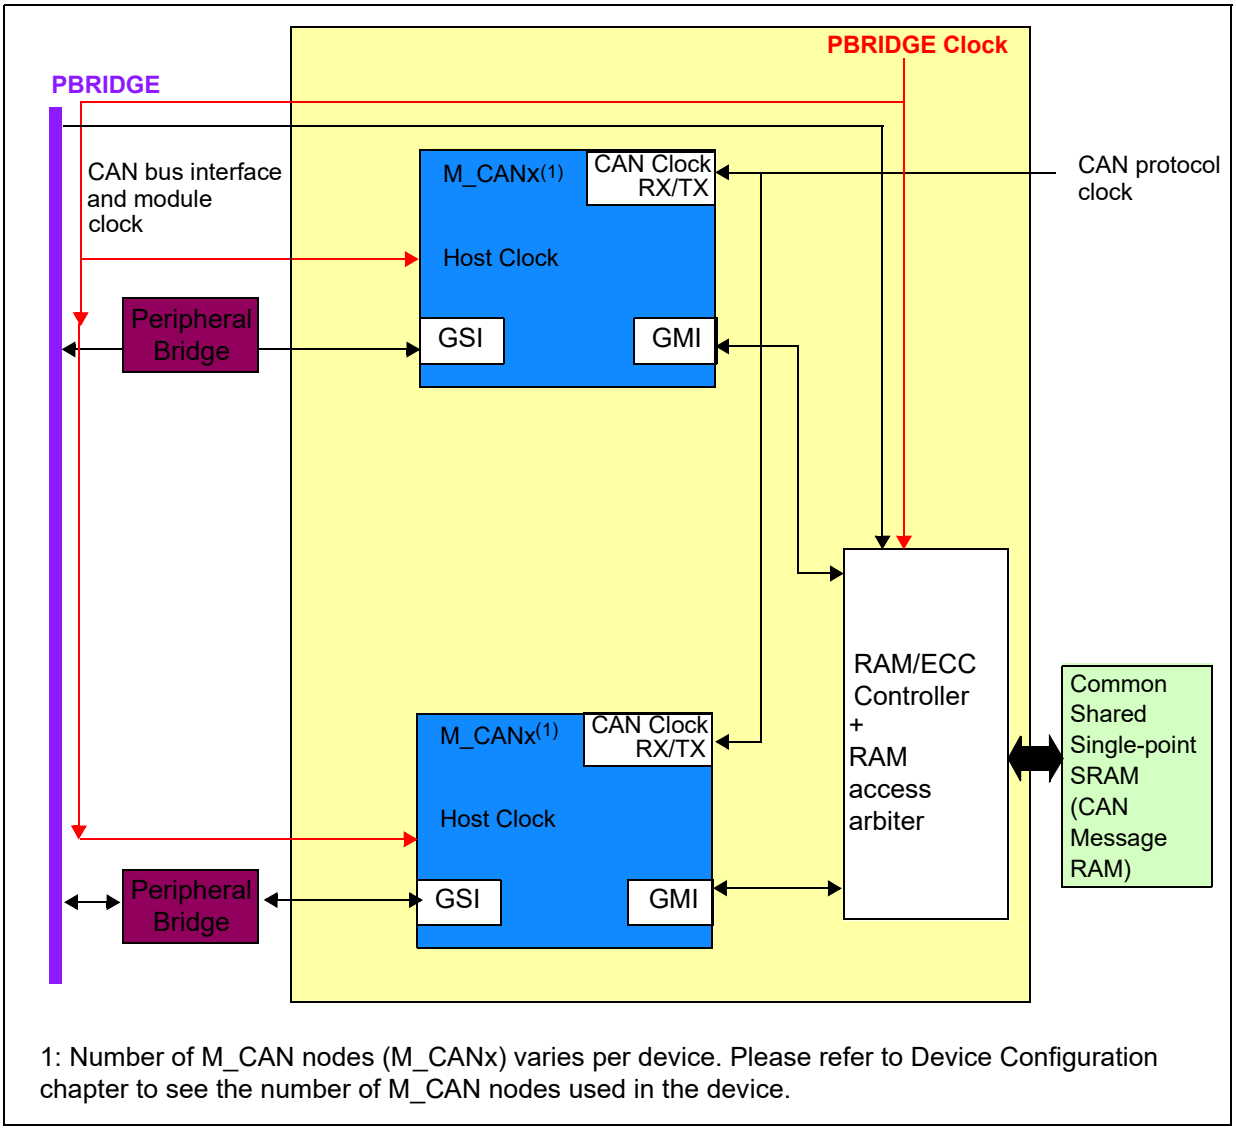
48.1 Introduction

SPC58xHx has below CAN subsystems implemented:

- CAN Subsystem 0
- CAN Subsystem 1
- CAN Subsystem 2
- CAN Subsystem 3

Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the subsystems implementation.

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection from CPU write access. The subsystem follows the little endian format.



Note: Refer to Section 7.8.2: CAN subsystem configuration in Chapter 7: Device configuration to see the number of CAN nodes used in the device.

Table 735. IP user manual versions

IP Name	Version
M_CAN IP	Revision 3.2.3

The general CAN subsystem implementation is shown in *Section 48.2*. It interfaces with the Host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.

Figure 638. CAN subsystem generic block diagram

1: Number of M_CAN nodes (M_CANx) varies per device. Please refer to Device Configuration chapter to see the number of M_CAN nodes used in the device.

48.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller

48.3 Modular CAN (M_CAN) cores

M_CAN functionality conforms to CAN specification V2.0B active for each M_CAN node. The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0.Flexible assignment of Message Objects to nodes.
The bit rate can be programmed to values up to 1 Mbit/s for standard CAN frames. High bit rates are possible in CAN FD mode. Additional transceiver hardware is required for connection to the physical layer.

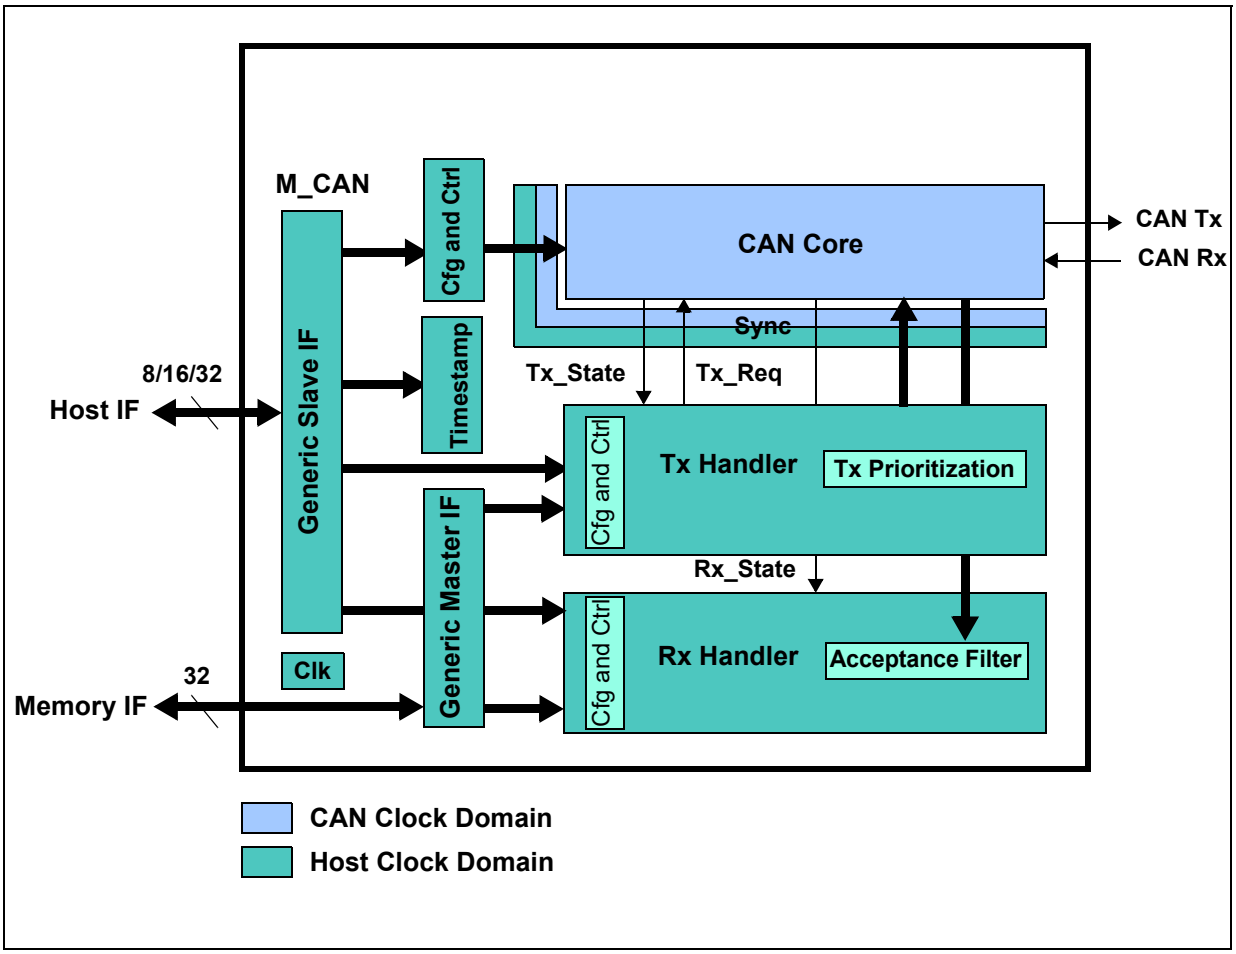
Note: Implemented CAN nodes are fully compliant to ISO CAN FD specification ISO 11898-1: 2015.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.



48.3.1 Features

The following are the features of Modular CAN cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015
- CAN Flexible data-rate (ISO CAN FD) protocol with 64 data bytes on M_CAN is supported
- Bit rates up to 1 Mbit/s in standard CAN mode
- Bit rates up to 8 Mbit/s in ISO CAN FD mode
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bits Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN

48.3.2 Block diagram

Figure 639. M_CAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.
- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored

together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable of connecting to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bits.

48.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

48.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to EINT0 or to EINT1. By default all interrupts are routed to interrupt line EINT0. By programming EINT0 and EINT1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

48.3.5 Memory map and register descriptions

48.3.5.1 Hardware reset description

After hardware reset, the registers of the M_CAN hold the reset values listed in *Table 736*. Additionally the *Bus_Off* state is reset and the M_CAN Tx output is set to *recessive* (HIGH). The value 0x0001 (bit 0 [INIT] of the CCCR register = ‘1’) in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets bit 0 [INIT] of the CCCR register = ‘0’.

48.3.5.2 Register map

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR register is set to ‘1’.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

Caution: Any write access to reserved or not implemented registers in the 16 KB slot assigned by the peripherals bridge to the M_CAN IP will not generate any bus access error.

48.3.5.2.3 Data Bit Timing and Prescaler Register (DBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_CAN clock periods. tq = (FBRP + 1) M_CAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (programmed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning that the data for the next bit is available at the first clock edge after the sample point.

Offset: 0x000C Access: Read Protected

W																
Reset	0	0	0	0	1	0	1	0	0	0	1	1	0	0	1	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 642. Data Bit Timing and Prescaler Register (DBTP)

Table 739. DBTP field descriptions

Field	Description
8 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
11:15 DBRP	Data Baud Rate Prescaler (0x00–0x1F) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. When TDC = ‘1’, the range is limited to 0,1. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
19:23 DTSEG1	Data time segment before sample point (0x0–0x1F) Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

Table 739. DBTP field descriptions (continued)

Field	Description
24:27 DTSEG2	Data time segment after sample point (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 DSJW	Data (Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via DBTP must be higher than or equal to the bit rate configured for the arbitration phase via NBTP.

To achieve high bit rates in CAN FD mode for the data phase up to 8 Mbit/s the number of time quanta bits per CAN bit can be chosen down to 4 time quanta per bit time.

48.3.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting CCCR[TEST] to ‘1’. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back mode and software control of M_CAN Tx pin are hardware test modes. Programming of **TX** ≠ ‘00’ may disturb the message transfer on the CAN bus.

Table 740. TEST field descriptions

Field	Description
24 RX	Receive Pin Monitors the actual value of CAN Rx pin. 0 The CAN bus is dominant (CAN Rx input = ‘0’) 1 The CAN bus is recessive (CAN Rx input = ‘1’)
25:26 TX	Control of Transmit Pin 00 Reset value, CAN Tx output is controlled by the CAN core, updated at the end of the CAN bit time. 01 Sample Point can be monitored at pin CAN Tx output 10 Dominant (‘0’) level at pin CAN Tx output 11 Recessive (‘1’) at pin CAN Tx output
27 LBCK	Loop Back mode 0 Reset value, Loop Back mode is disabled 1 Loop Back mode is enabled (refer to *Section 48.3.7.9: Test modes*)

48.3.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR is set. The RAM Watchdog Counter is clocked by the Host clock.

Offset: 0x0014 Access: Read Protected

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 644. RAM Watchdog Register (RWD)

Table 741. RWD field descriptions

Field	Description
16:23 WDV	Watchdog Value Actual Message RAM Watchdog Counter Value.
24:31 WDC	Watchdog Configuration Start value of the Message RAM Watchdog Counter. With the reset value of '00' the counter is disabled.

48.3.5.2.6 CC Control Register (CCCR)

The following section shows the CAN Control register. For details about setting and resetting of single bits refer to *Section 48.3.7.1.1: Software initialization*.

Offset: 0x0018 Access: Read Protected

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NISO(1)	TXP(1)	EFBI(1)	PXHD(1)	0	0	BRSE(1)	FDOE(1)	TEST(2)	DAR(1)	MON(2)	CSR	CSA	ASM(2)	CCE(1)	INIT
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to '1'.
2. These are protected set (p) bits.

Figure 645. CC Control register (CCCR)

Table 742. CCCR field descriptions

Field	Description
16 NISO	Non ISO Operation If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0 CAN FD frame format according to ISO11898-1 1 CAN FD frame format according to Bosch CAN FD Specification V1.0
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame. 0 Transmit pause disabled 1 Transmit pause enabled
18 EFBI	Edge Filtering during Bus Integration 0 Edge filtering disabled 1 Two consecutive dominant tq required to detect an edge for hard synchronization

Table 742. CCCR field descriptions (continued)

Field	Description
19 PXHD	Protocol Exception Handling Disable 0 Protocol exception handling enabled 1 Protocol exception handling disabled **Note:** When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
22 BRSE	Bit Rate Switch Enable 0 Bit rate switching for transmissions disabled 1 Bit rate switching for transmissions enabled **Note:** When CAN FD operation is disabled FDOE = ‘0’, BRSE is not evaluated.
23 FDOE	FD Operation Enable 0 FD operation disabled 1 FD operation enabled
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to ‘1’. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping Host clock and core clock
29 ASM	Restricted Operation Mode Bit ASM is only set by the Host when both CCE and INIT are set to ‘1’. The bit is reset by the Host at any time. 0 Normal CAN operation 1 Restricted Operation Mode active

Table 742. CCCR field descriptions (continued)

Field	Description
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started **Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

48.3.5.2.7 Nominal Bit Timing and Prescaler Register (NBTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of [4…385] time quanta. The CAN time quantum may be programmed in the range of [1…512] M_CAN clock periods.

Equation 32 tq = (NBRP + 1) M_CAN clock period

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (prog rammed values) [NTSEG1 + NTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Offset: 0x001C Access: Read Protected

Figure 646. Nominal Bit Timing and Prescaler Register (NBTP)

Table 743. NBTP field descriptions

Field	Description
0:6 NSJW	(Re) Synchronization Jump Width (0x00–0x7F) Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
7:15 NBRP	Baud Rate Prescaler (0x000–0x1FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16:23 NTSEG1	Time segment before sample point (0x01–0xFF) Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
25:31 NTSEG2	The time segment after the sample point (0x01–0x7F) Valid values are 1 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the M_CAN for a bit rate of 500 kbit/s.

48.3.5.2.8 Timestamp Counter Configuration Register (TSCC)

Offset: 0x0020 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 648. Timestamp Counter Value Register (TSCV)

Table 745. TSCV field descriptions

Field	Description
16:31 TSC	Timestamp Counter The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = '01', the Timestamp Counter is incremented in multiples of CAN bit times [1 to 16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero. When TSCC.TSS = '10', TSC reflects the external Timestamp Counter value. A write access has no impact.

Note: A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

48.3.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter, refer to *Section 48.3.9*.

Offset: 0x0028 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Figure 651. Error Counter Register (ECR)

Table 748. ECR field descriptions

Field	Description
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR register.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127.
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255.

Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

48.3.5.2.13 Protocol Status Register (PSR)

Offset: 0x0044 Access: RXS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0	PXE(1)	RFDF(1)	RBRS(1)	RESI(1)	DLEC(2)			BO	EW	EP	ACT		LEC(2)		
W																
Reset	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

1. Access type is RX: reset on read.
2. Access type is RS: set on read.

Figure 652. Protocol Status Register (PSR)

Table 749. PSR field descriptions

Field	Description
9:15 TDCV	Transmitter Delay Compensation Value (0x00-0x7F) Position of the secondary sample point, defined by the sum of the measured delay from CAN Tx to CAN Rx and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
17 PXE	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred
18 RFDF	Received CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 DLEC	Data Phase Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state

Table 749. PSR field descriptions (continued)

Field	Description
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing – node is synchronizing on CAN communication 01 Idle-node is neither receiver nor transmitter 10 Receiver-node is operating as receiver 11 Transmitter-node is operating as transmitter
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

The Bus_Off recovery sequence (refer to CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT.] If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

48.3.5.2.14 Transmitter Delay compensation Register (TDCR)

Offset: 0x0048 Access: RP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0	TDCO(1)							0	TDCF(1)						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to ‘1’.

Figure 653. Transmitter Delay compensation Register (TDCR)

Table 750. TDCR field descriptions

Field	Description
17:23 TDCO	Transmitter Delay Compensation Offset (0x00-0x7F) Offset value defining the distance between the measured delay from CAN Tx to CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.
25:31 TDCF	Transmitter Delay Compensation Filter Window Length (0x00-0x7F) Defines the minimum value for the SSP position, dominant edges on CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq.

48.3.5.2.15 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a ‘1’ to the corresponding bit position. Writing a ‘0’ has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Table 751. IR field descriptions (continued)

Field	Description
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (for example parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (for example ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure The flag is set, when the Rx Handler – has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. – was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler is not able to read a message from the Message RAM in time. In this case message transmission is aborted. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full

Table 751. IR field descriptions (continued)

Field	Description
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark
19 TEFN	Tx Event FIDO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element
20 TFE	Tx FIFO Empty 0 Tx FIFO non-empty 1 Tx FIFO empty
21 TCF	Transmission Cancellation Finished 0 No transmission cancellation finished 1 Transmission cancellation finished
22 TC	Transmission Completed 0 No transmission completed 1 Transmission completed
23 HPM	High Priority Message 0 No high priority message received 1 High priority message received
24 RF1L	Rx FIFO 1 Message Lost 0 No Rx FIFO 1 message lost 1 Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
25 RF1F	Rx FIFO 1 Full 0 Rx FIFO 1 not full 1 Rx FIFO 1 full
26 RF1W	Rx FIFO 1 Watermark Reached 0 Rx FIFO 1 fill level below watermark 1 Rx FIFO 1 fill level reached watermark
27 RF1N	Rx FIFO 1 New Message 0 No new message written to Rx FIFO 1 1 New message written to Rx FIFO 1
28 RF0L	Rx FIFO 0 Message Lost 0 No Rx FIFO 0 message lost 1 Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
29 RF0F	Rx FIFO 0 Full 0 Rx FIFO 0 not full 1 Rx FIFO 0 full
30 RF0W	Rx FIFO 0 Watermark Reached 0 Rx FIFO 0 fill level below watermark 1 Rx FIFO 0 fill level reached watermark
31 RF0N	Rx FIFO 0 New Message 0 No new message written to Rx FIFO 0 1 New message written to Rx FIFO 0

48.3.5.2.16 Interrupt Enable Register (IE)

The settings in the Interrupt Enable register determine which status changes in the Interrupt register will be signaled on an interrupt line.

Figure 676. Tx Buffer Request Pending Register (TXBRP)

Table 773. TXBRP field descriptions

Field	Description
0:31 TRP[31:0]	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – after successful transmission together with the corresponding TXBTO bit – when the transmission has not yet been started at the point of cancellation – when the transmission has been aborted due to lost arbitration – when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

48.3.5.2.38 Tx Buffer Add Request Register (TXBAR)

Offset: 0x00D0 Access: R/W

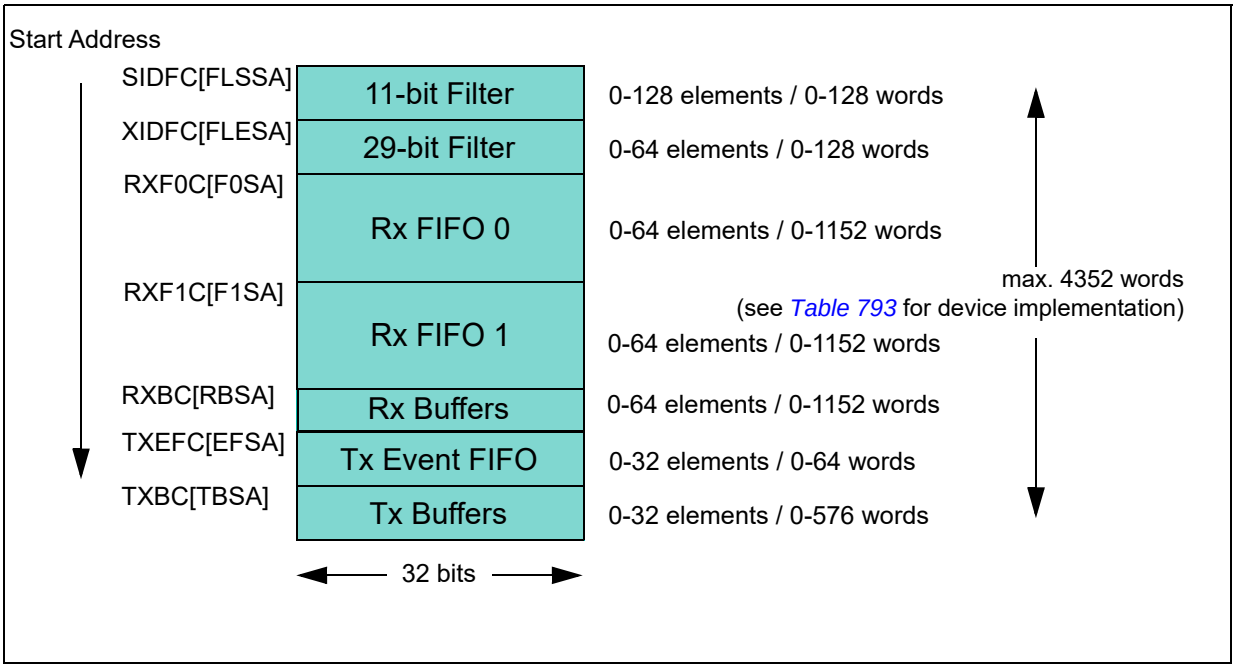
Figure 685. Tx Event FIFO Acknowledge Register (TXEFA)

Table 782. TXEFA field descriptions

Field	Description
27:31 EFAI	Event FIFO Acknowledge Index After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

48.3.6 Message RAM



For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_CAN module.

Note: Because the Message RAM is equipped with ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing, for example, 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 4352 words in the Message RAM (for the chip-specific implementation details of each module's instance, refer to device configuration chapter). It is not necessary to configure each of the sections listed in *Figure 686*, nor is there any restriction with respect to the sequence of the sections.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC.F0DS, RXESC.F1DS, RXESC.RBDS, and TXESC.TBDS.

Figure 686. Message RAM Configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses such as only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Note: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

48.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

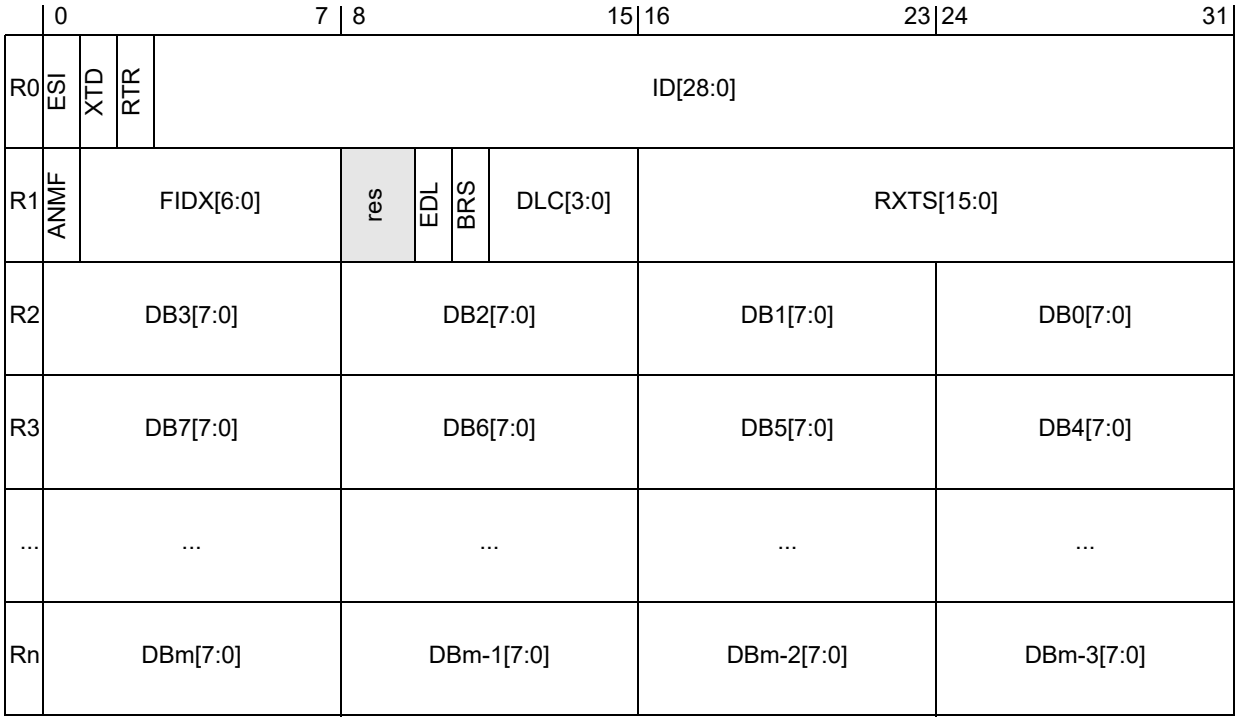


Figure 687. Rx Buffer and FIFO element

Table 783. Rx Buffer and FIFO element descriptions

Field	Description
R0 bit 0 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 bit 1 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 bit 2 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame **Note:** There are no remote frames in CAN FD format. In case a CAN FD frame was received (EDL = '1'), bit RTR reflects the state of the reserved bit r1.
R0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 bit 0 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element

Table 783. Rx Buffer and FIFO element descriptions (continued)

Field	Description
R1 bits 1:7 FIDX[6:0]: Filter Index	0-127=Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 bit 10 EDL: Extended Data Length	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
R1 bit 11 BRS: Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 bits 12:15 DLC[3:0]: Data Length Code	0-8 CAN + CAN FD: Received frame has 0-8 data bytes 9-15 CAN: Received frame has 8 data bytes 9-15 CAN FD: received frame has 12/16/20/24/32/48/64 data bytes
R1 bits 16:31 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 bits 0:7	DB3[7:0]: Data Byte 3
R2 bits 8:15	DB2[7:0]: Data Byte 2
R2 bits 16:23	DB1[7:0]: Data Byte 1
R2 bits 24:31	DB0[7:0]: Data Byte 0
R3 bits 0:7	DB7[7:0]: Data Byte 7
R3 bits 8:15	DB6[7:0]: Data Byte 6
R3 bits 16:23	DB5[7:0]: Data Byte 5
R3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Rn bits 0:7	DBm[7:0]: Data Byte m
Rn bits 8:15	DBm-1[7:0]: Data Byte m-1
Rn bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 to 17) are used for storage of a CAN message's data field.

48.3.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer

configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

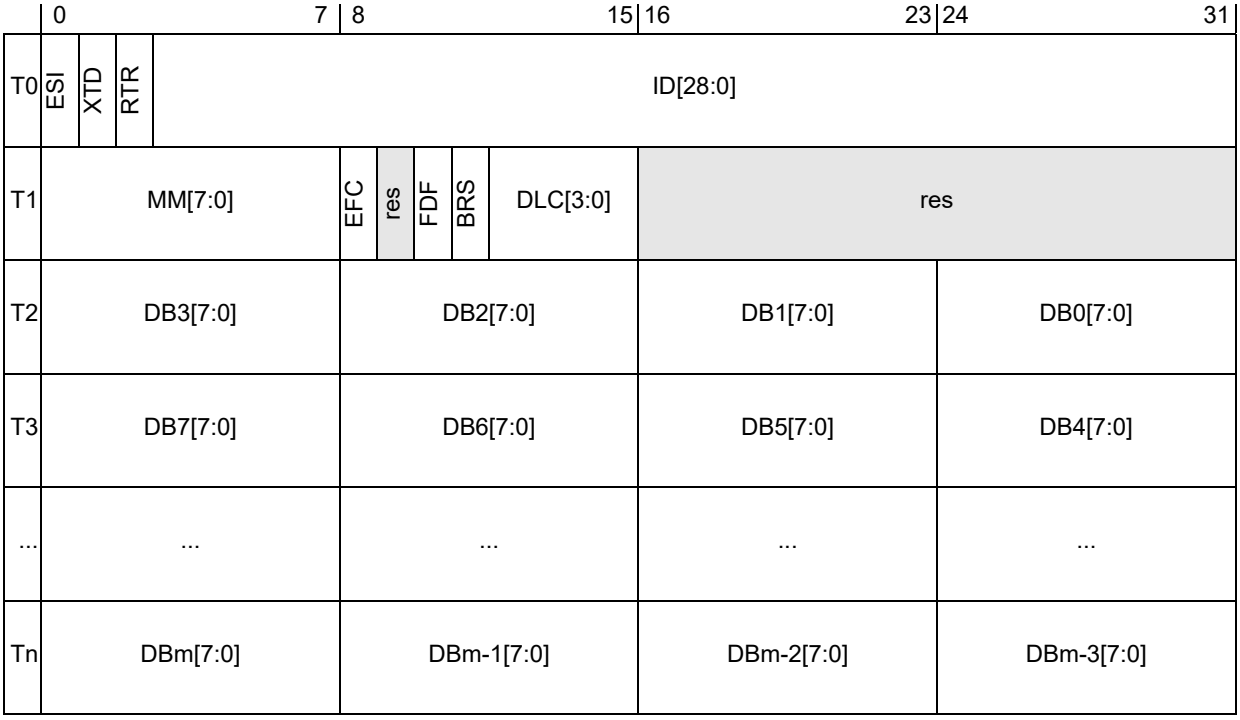

Figure 688. Tx Buffer element

Table 784. Tx Buffer element descriptions

Field	Description
T0 bit 0 ESI: Error State Indicator	0 ESI bit in CAN FD format depends only on error passive flag 1 ESI bit in CAN FD format transmitted recessive **Note:** The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive
T0 bit 1 XTD: Extended Identifier	0 11-bit standard identifier 129-bit extended identifier
T0 bit 2 RTR: Remote Transmission Request	0 Transmit data frame 1 Transmit remote frame **Note:** When RTR = 1, the M_CAN transmits a remote frame according to ISO11898-1, even if CCCR.FDOE enables the transmission in CAN FD format.
T0 bits 3:31 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
T1 bits 0:7 MM[7:0]: Message Marker	Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

Table 784. Tx Buffer element descriptions (continued)

Field	Description
T1 bit 8 EFC **Event FIFO Control**	0 Don't store Tx events 1 Store Tx events
T1 bit 10 FDF **FD Format**	0 Frame transmitted in Classic CAN format 1 Frame transmitted in CAN FD format
T1 bit 11 BRS **Bit Rat Switching**	0 CAN FD frames transmitted without bit rate switching 1 CAN FD frames transmitted with bit rate switching
T1 bits 12:15 DLC[3:0] **Data Length Code**	0-8 Transmit frame with 0-8 data bytes 9-15 Transmit frame with 8 data bytes 9-15 CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes
T2 bits 0:7	DB3[7:0]: Data Byte 3
T2 bits 8:15	DB2[7:0]: Data Byte 2
T2 bits 16:23	DB1[7:0]: Data Byte 1
T2 bits 24:31	DB0[7:0]: Data Byte 0
T3 bits 0:7	DB7[7:0]: Data Byte 7
T3 bits 8:15	DB6[7:0]: Data Byte 6
T3 bits 16:23	DB5[7:0]: Data Byte 5
T3 bits 24:31	DB4[7:0]: Data Byte 4
...	...
Tn bits 0:7	DBm[7:0]: Data Byte m
Tn bits 8:15	DBm-1[7:0]: Data Byte m-1
Tn bits 16:23	DBm-2[7:0]: Data Byte m-2
Tn bits 24:31	DBm-3[7:0]: Data Byte m-3

Note: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 to 17) are used for storage of a CAN message's data field.

48.3.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

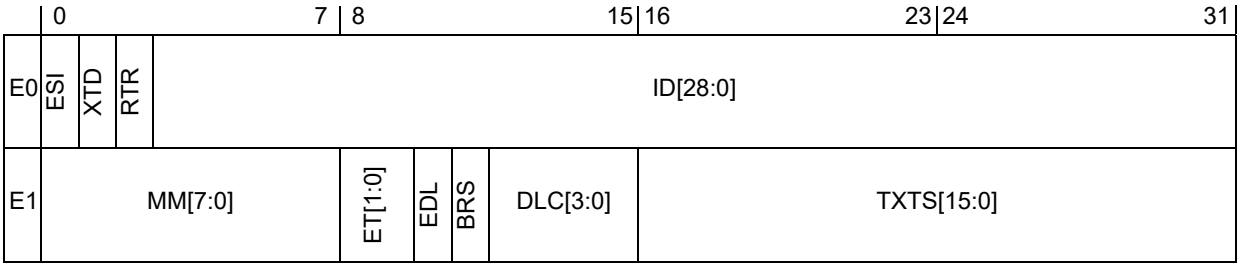

Figure 689. Tx Event FIFO element

Table 785. Tx Event FIFO element descriptions

Field	Description
E0 bit 0 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 bit 1 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.
E1 bit 8:9 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching

Table 785. Tx Event FIFO element descriptions (continued)

Field	Description
E1 bits 12:15 DLC[3:0]	Data Length Code 0-8 CAN + CAN FD: frame with 0-8 data bytes transmitted 9-15 CAN: frame with 8 data bytes transmitted 9-15 CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted
E1 bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

48.3.6.4 Standard Message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0 to 127).

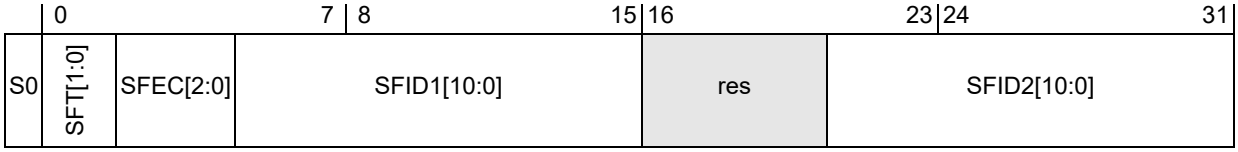

Figure 690. Standard Message ID Filter element

Table 786. Standard Message ID Filter element descriptions

Field	Description
Bits 0:1 SFT[1:0]	Standard Filter Type 00 Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1) 01 Dual ID filter for SFID1 or SFID2 10 Classic filter: SFID1 = filter, SFID2 = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = ‘100’, ‘101’, or ‘110’ a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored

Table 786. Standard Message ID Filter element descriptions (continued)

Field	Description
Bits 5:15 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31 SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: 1) SFEC = '001'...'110' Second ID of standard ID filter element 2) SFEC = '111' Filter for Rx Buffers or for debug messages
	SFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN Host clock period in case the filter matches.
	SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

48.3.6.5 Extended Message ID Filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0 to 63).

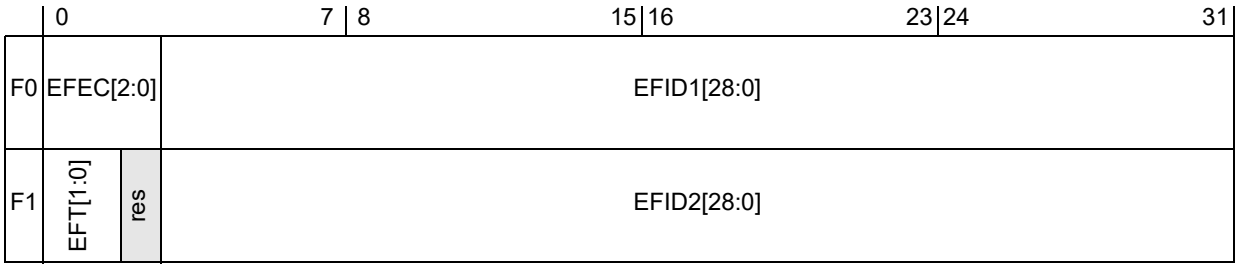

Figure 691. Extended Message ID Filter element

Table 787. Extended Message ID Filter element description

Field	Description
F0 bits 0:2 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = '100', '101', or '110' a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 bits 3:31 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (refer to *Section 48.3.10.1.5*) is used.
F1 bits 0:1 EFT[1:0]	Extended Filter Type 00 Range filter from EFID1 to EFID1 (EFID2 ≥ EFID1) 01 Dual ID filter for EFID1 or EFID2 10 Classic filter: EFID1 = filter, EFID2 = mask 11 Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied
F1 bits 3:31 EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = '001'...'110' Second ID of extended ID filter element 2) EFEC = '111' Filter for Rx Buffers or for debug messages EFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6] is used to control the filter event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

48.3.7 M_CAN functional description

48.3.7.1 Operating modes

48.3.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = ‘1’. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS–High Priority Message Status
- RXF0S–Rx FIFO 0 Status
- RXF1S–Rx FIFO 1 Status
- TXFQS–Tx FIFO/Queue Status
- TXBRP–Tx Buffer Request Pending
- TXBTO–Tx Buffer Transmission Occurred
- TXBCF–Tx Buffer Cancellation Finished
- TXEFS–Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writable while CCCR[CCE] = ‘0’

- TXBAR–Tx Buffer Add Request
- TXBCR–Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

The following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
     while (read_data != 0x003){
        write(M_CAN0,0xF,driver.regs.can0_cccr.addr,0x003);
           read_data = read(M_CAN0,0xF,driver.regs.can0_cccr.addr);
     };
```

```
-- Configuring the time stamp and timeout registers
     write(M_CAN0,0xF,driver.regs.can0_tscc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_tocc.addr,0x000);

-- Configuring the interrupt registers
     write(M_CAN0,0xF,driver.regs.can0_ie.addr,0xFFFFFFFF);
     write(M_CAN0,0xF,driver.regs.can0_ils.addr,0x00000002);
     write(M_CAN0,0xF,driver.regs.can0_ile.addr,0x00000003);

     write(M_CAN0,0xF,driver.regs.can0_gfc.addr,0x000);
     write(M_CAN0,0xF,driver.regs.can0_xidam.addr,0x00FFFFFF);

-- Writing the start addresses of all the M_CAN Buffers
     generate and drive M_CAN0 can0_rxf0c keeping {
                                          .f0sa == 0x100;
                                          .f0s  == 0x03;

48.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, the received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers or a Tx FIFO, or both, or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

48.3.7.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = *recessive* signifies a CAN FD frame, FDF = *dominant* signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = *dominant* and BRS = *recessive*. The coding of res = *recessive* is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = *recessive* and res = *recessive*, it will signal a Protocol Exception Event by setting bit PSR.PXE. When Protocol Exception Handling is enabled (CCCR.PXHD = ‘0’), this causes the operation state to change from Receiver (PSR.ACT = “10”) to Integrating (PSR.ACT = “00”) at the next sample point. In case Protocol Exception Handling is disabled (CCCR.PXHD = ‘1’), the M_CAN will treat a *recessive* res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR.FDOE. In case CCCR.FDOE = ‘1’, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = ‘0’, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set. CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

With CCCR.FDOE = ‘0’, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘0’, only bit FDF of a Tx Buffer element is evaluated. With CCCR.FDOE = ‘1’ and CCCR.BRSE = ‘1’, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to *Table 788*.

Table 788. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is *recessive*. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing & Prescaler Register NBTP. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing & Prescaler Register DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (CAN clock). Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit ESI (Error Status Indicator) is determined by the transmitter’s error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted *recessive*, else it is transmitted *dominant*.

48.3.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via CAN Tx output pin the M_CAN the transmitted data from its local CAN transceiver via CAN Rx input pin. The received data is delayed by the transmitter delay. In case this delay is greater than NTSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is

introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

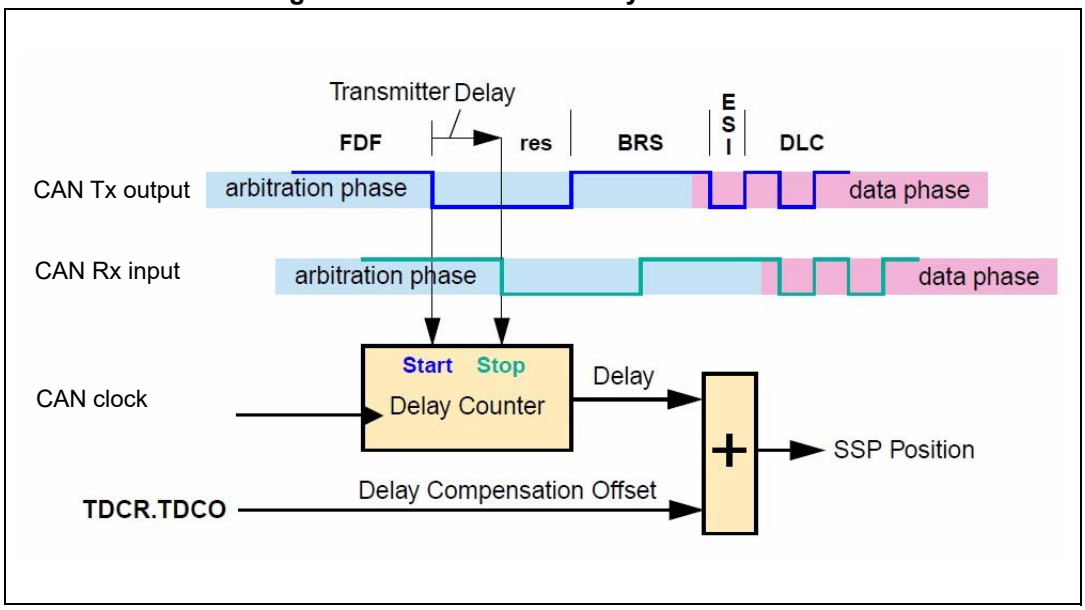
48.3.7.4.1 Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration the transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP.TDC.phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M_CAN's Tx output through the transceiver to the CAN Rx input plus the transmitter delay compensation offset as configured by TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR.TDCV shows the actual transmitter delay compensation value. PSR.TDCV is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.



The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than 6 bit times in the data phase
- The sum of the measured delay from CAN Tx output to CAN Rx input and the configured transmitter delay compensation offset TDCR.TDCO has to be less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs

Figure 692 below describes how the Transceiver Delay Compensation measurement.

If transmitter delay compensation is enabled by programming DBTP.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input CAN Rx input of the transmitter. The resolution of this measurement is one mtq.

Figure 692. Transceiver Delay measurement

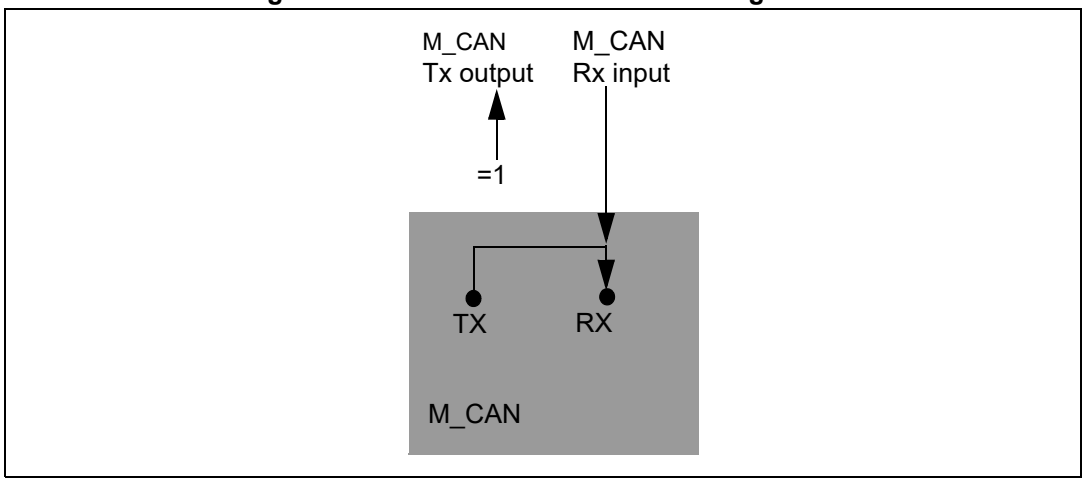
To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on CAN Rx input, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF AND CAN Rx input is low.

48.3.7.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCR.ASM. The bit can only be set by the Host when both CCCR.CCE and CCCR.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.



48.3.7.6 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (refer to ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN

monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

Figure 693 shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

Figure 693. Pin control in Bus Monitoring mode

48.3.7.7 Disabled automatic retransmission

According to the CAN Specification (refer to ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

48.3.7.7.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = '10' (transmission in spite of cancellation).

48.3.7.8 Power down (Sleep mode)

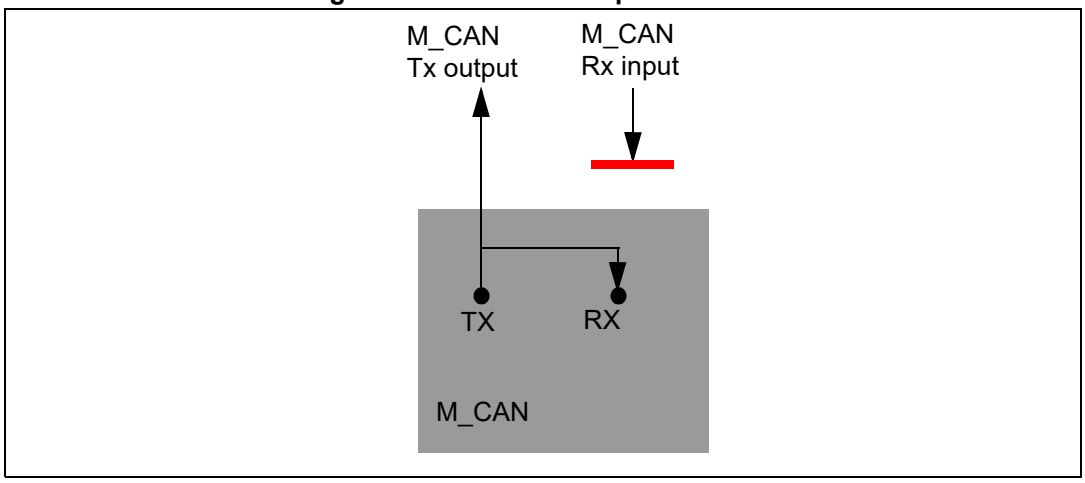
The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and Host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

48.3.7.9 Test modes

To enable write access to register TEST (refer to *Section 48.3.5.2.4: Test Register (TEST)*), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN Tx output pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at M_CAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].



Note: Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

48.3.7.9.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. *Figure 694* shows the connection of Tx and Rx signals to the M_CAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the CAN Tx output pin.

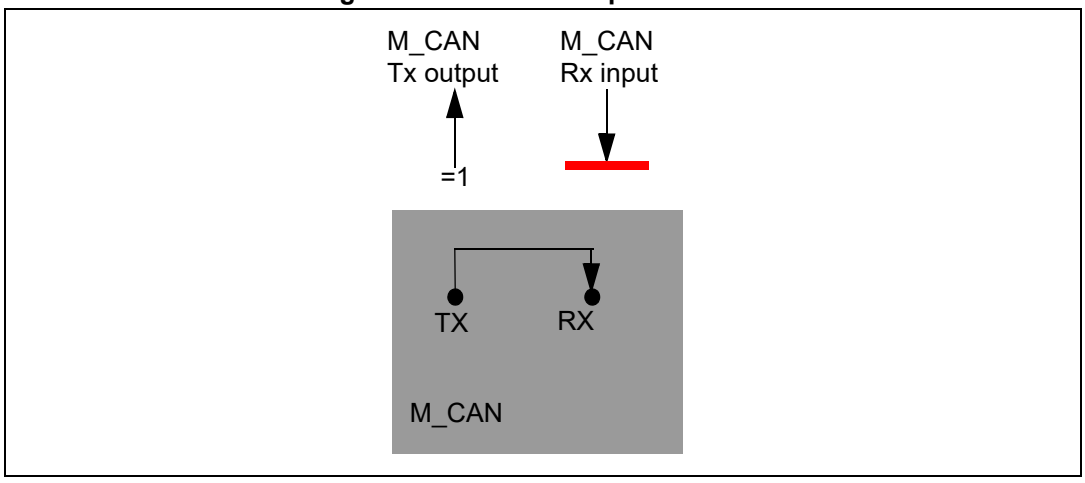


Figure 694. External Loop Back mode

48.3.7.9.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the CAN Tx output and Rx input pins. In this mode M_CAN Tx pin is disconnected from the M_CAN and M_CAN Tx pin is held recessive. *Figure 695* shows the connection of M_CAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

Figure 695. Internal loop back mode

48.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer /Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

48.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = '0'. It is stopped when CCCR[INIT] = '1', for example when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

48.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indexes.

48.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (such as CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC.

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC respectively PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Section 48.3.10.2.2: Rx FIFO Overwrite Mode* have to be considered.

Note: When an accepted message is written to one of the two Rx FIFOs, or into a Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process strongly depends on the sequence of configured filter elements.

48.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SFID1/SFID2 resp. EFID1/EFID2. There are two possibilities when range filtering is used together with extended frames:

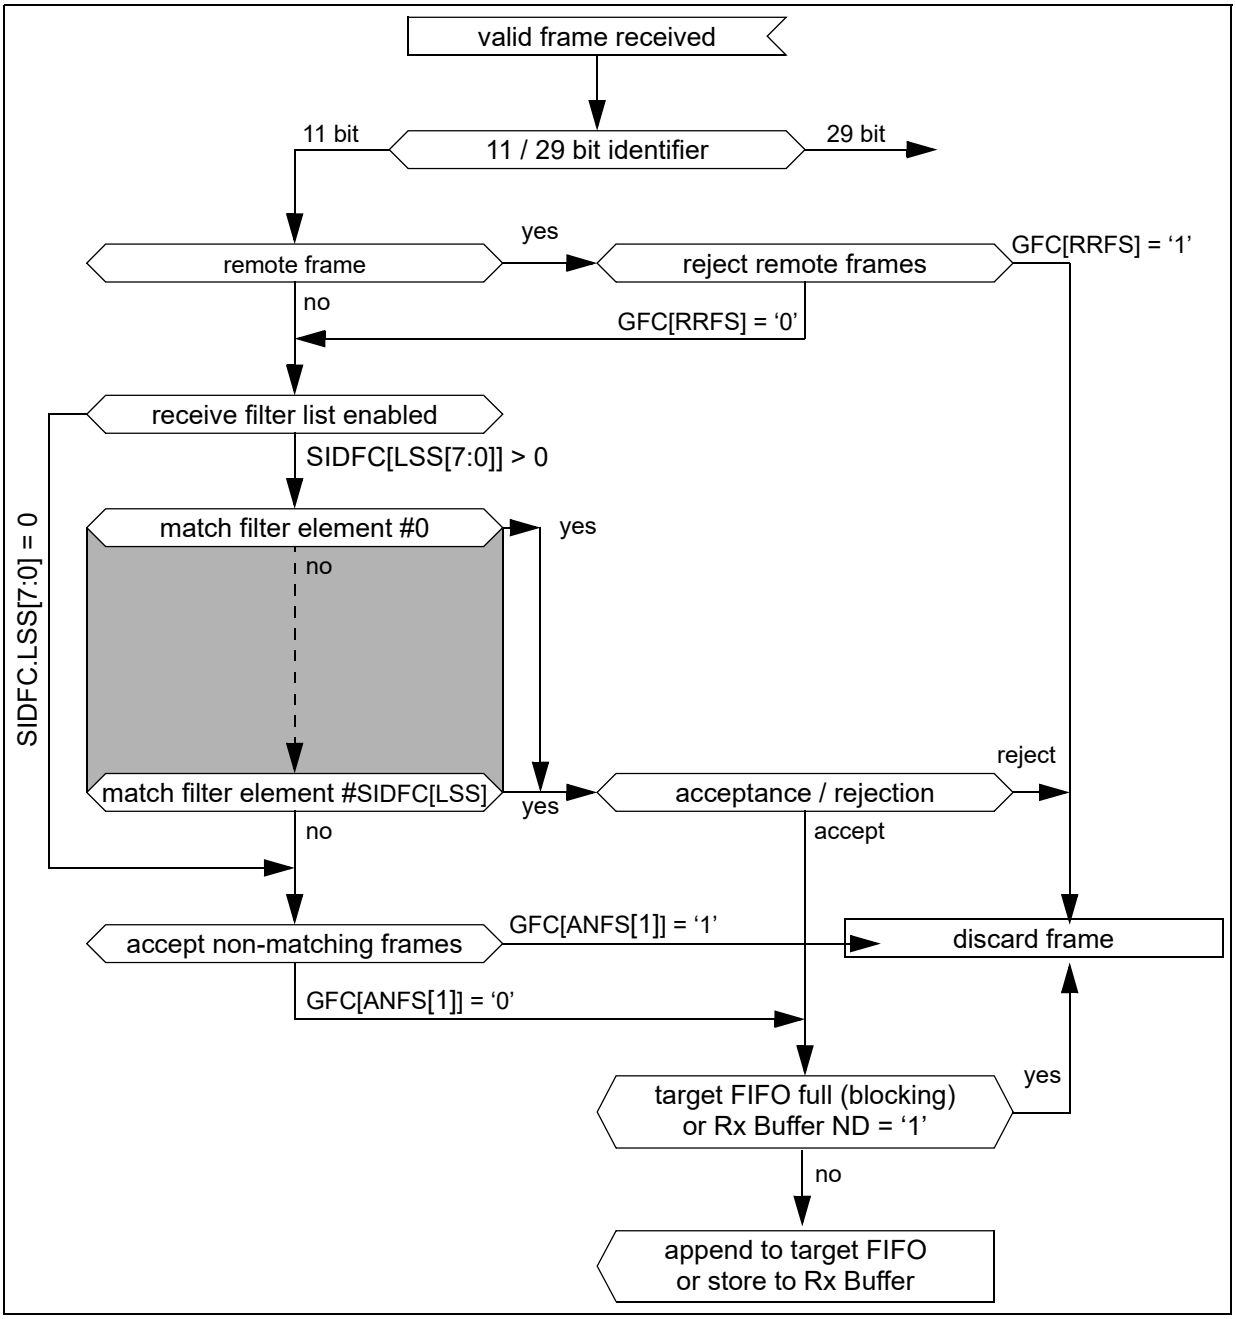
- EFT = ‘00’: The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = ‘11’: The Extended ID AND Mask (XIDAM) is not used for range filtering

48.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1 = SFID2 resp. EFID1 =EFID2.

48.3.10.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1/EFID2 is used as Message ID filter, while SFID2/EFID2 is used as filter mask.



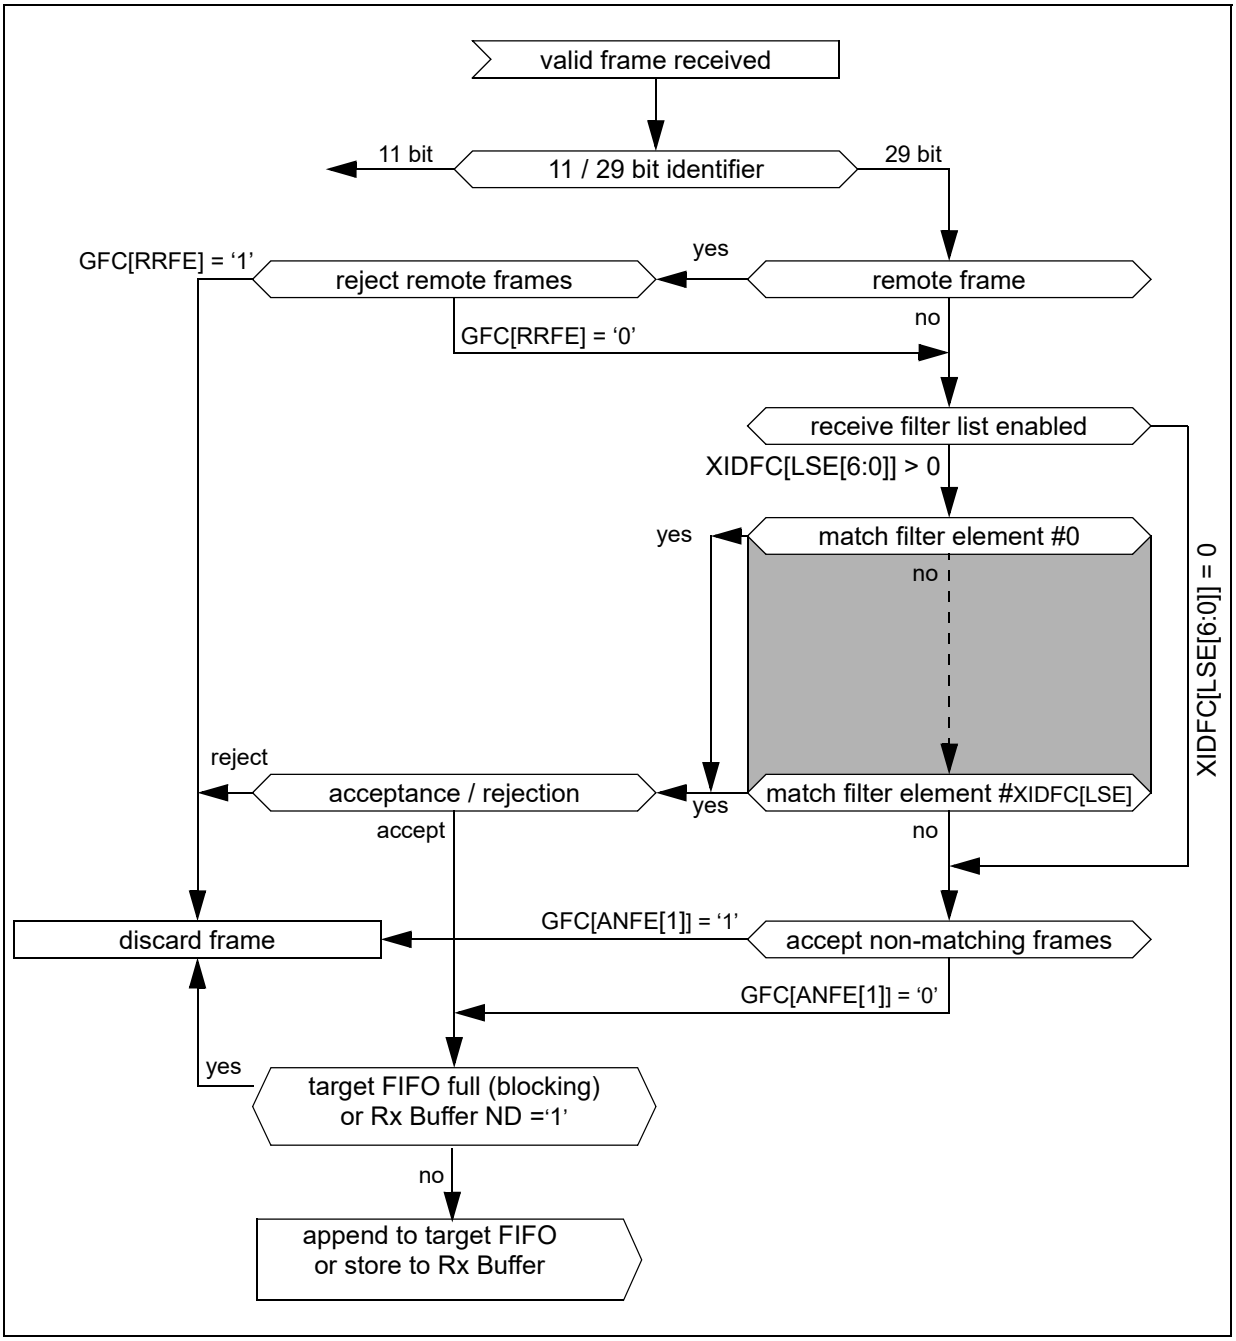
A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

48.3.10.1.4 Standard message ID filtering

Figure 690 shows the flow for standard message ID (11-bit Identifier) filtering.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 696. Standard Message ID Filter Path



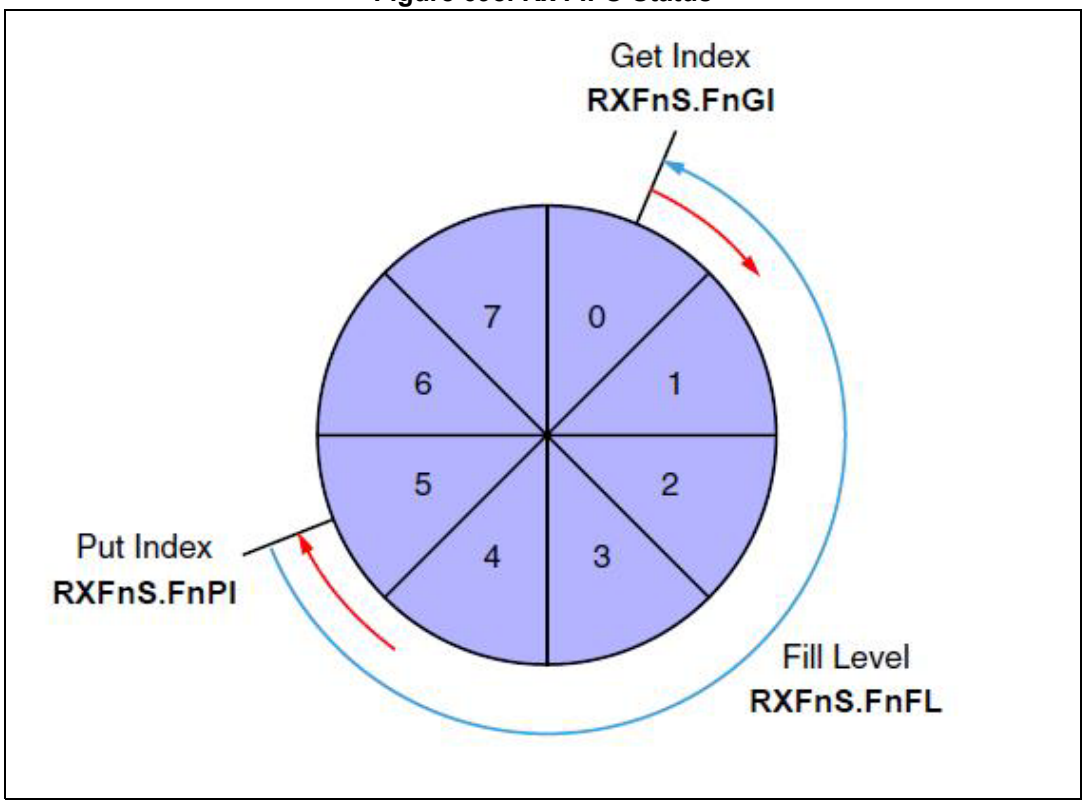
48.3.10.1.5 Extended message ID filtering

Figure 697 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in *Section 48.3.5.2.21: Extended ID Filter Configuration Register (XIDFC)*.

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the

Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 697. Extended Message ID Filter Path



48.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 refer to *Section 48.3.10.1: Acceptance filtering*. The Rx FIFO element is described in *Section 48.3.6.1: Rx Buffer and FIFO element*.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IR.RFnW is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag IR.RFnF is set.

Figure 698. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI × FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 789. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10

Table 789. Rx Buffer / FIFO Element Size (continued)

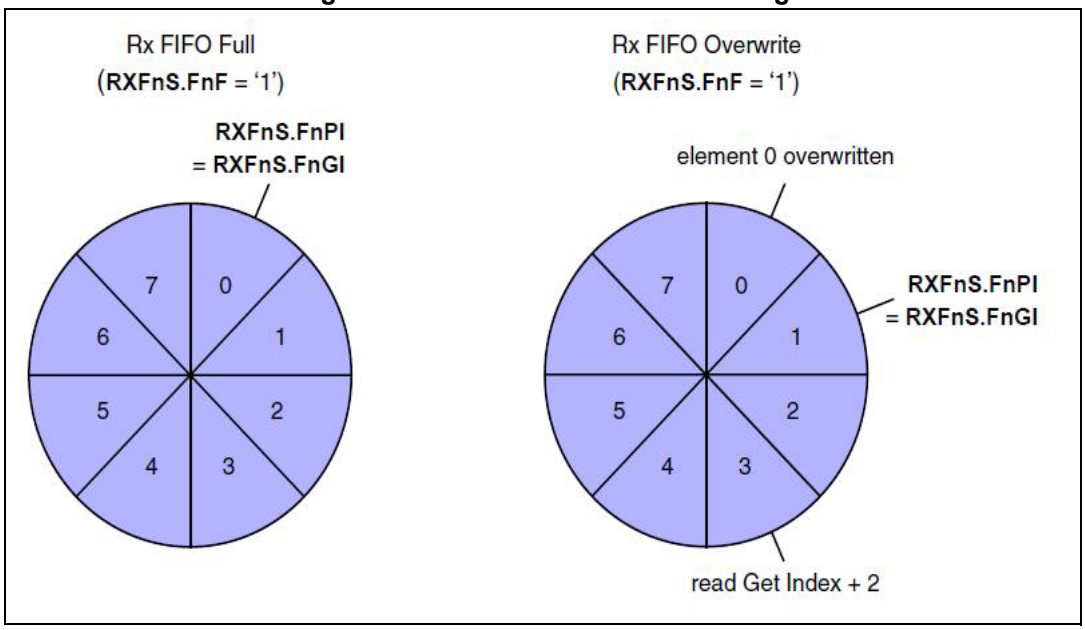
RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
110	48	14
111	64	18

48.3.10.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IR.RFnL is set.



48.3.10.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. *Figure 699* shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 699. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = '0').

48.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = '111' and SFID2 / EFID2[10:9] = '00' has to be configured (refer to *Section 48.3.6.4: Standard Message ID Filter element* and *Section 48.3.6.5: Extended Message ID Filter element*).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 790. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set,

the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a ‘1’ to the respective bit position.

While an Rx Buffer’s New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

48.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

48.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (for example #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (refer to *Section 48.3.6.1: Rx Buffer and FIFO element*).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = ‘111’ have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while DMA request output is activated. The behavior is similar to that of an Rx Buffers with its New Data flag set.

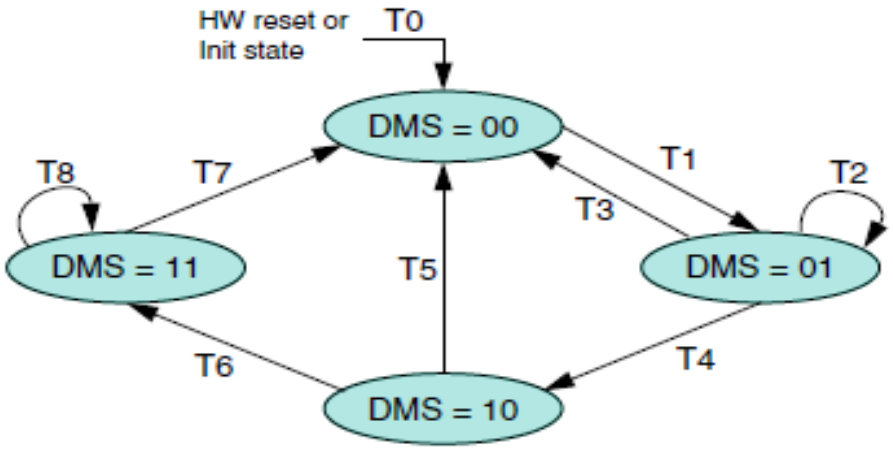
After the DMA has completed the DMA unit sets the DMA acknowledge input. This resets the DMA request output. Now the M_CAN is prepared to receive the next set of debug messages.

48.3.12.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to ‘111’. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 /EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 791. Example Filter Configuration for debug messages



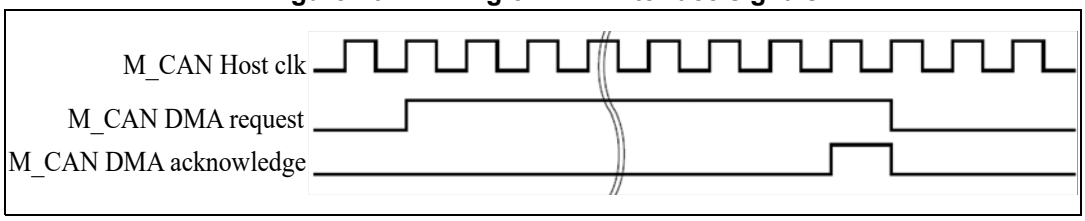
Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

48.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S.DMS.

Figure 700. Debug Message Handling State Machine



T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C
T1: reception of debug message A
T2: reception of debug message A
T3: reception of debug message C
T4: reception of debug message B
T5: reception of debug messages A, B
T6: reception of debug message C
T7: DMA transfer completed
T8: reception of debug message A,B,C (message rejected)

48.3.12.3 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message handling state machine enters idle state (DMS = ‘00’) and waits for reception of the next debug messages.

Figure 701. Timing of DMA interface signals

Note: If the DMA unit activates input M_CAN DMA acknowledge signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

48.3.13 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indexes, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in the *Note: on page 1240*.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

48.3.13.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU’s CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If for example CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR.TXP = ‘0’).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

48.3.13.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 792*). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

Table 792. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

48.3.13.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to ‘0’. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = ‘1’) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

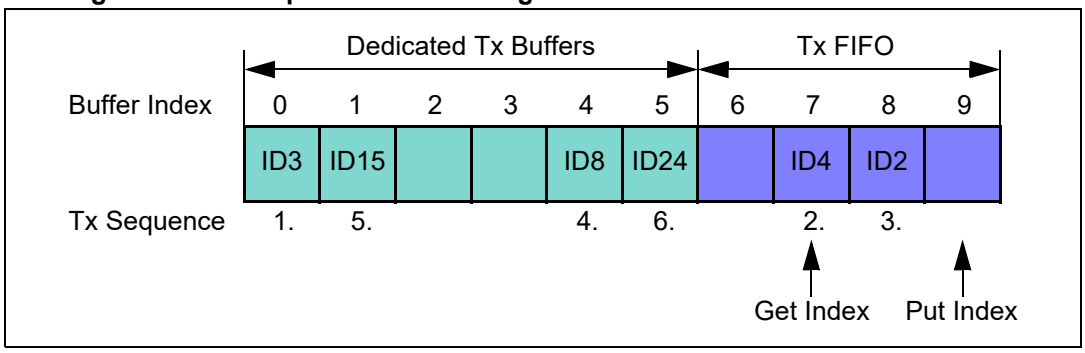
When a single message is added to the Tx FIFO, the transmission is requested by writing a ‘1’ to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level. When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (refer to *Table 792*). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

48.3.13.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to ‘1’. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = ‘1’), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.



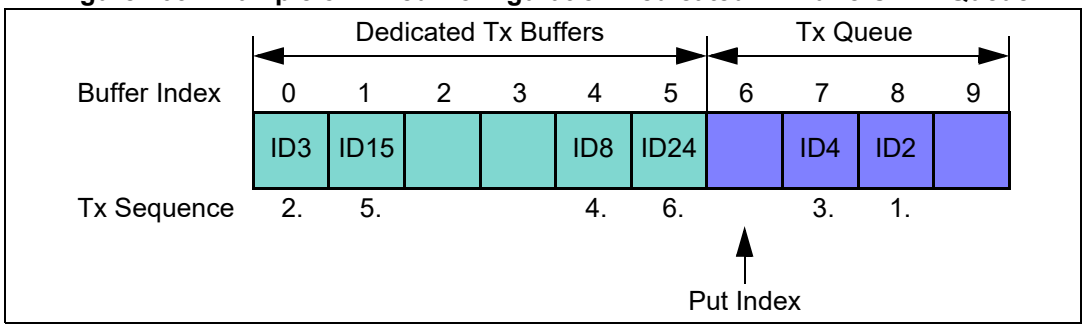
The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (refer to *Table 792*). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) × Element Size to the Tx Buffer Start Address TXBC.TBSA.

48.3.13.5 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 702. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO



Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.13.6 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 703. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.13.7 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a ‘1’ to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to ‘1’.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits

are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

48.3.13.8 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in the Note *Note: on page 1242*. When a Tx Event FIFO full condition is signaled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

48.3.14 FIFO acknowledge handling

The Get Indexes of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (refer to *Section 48.3.5.2.28: Rx FIFO 0 Acknowledge Register (RXF0A)* and *Section 48.3.5.2.46: Tx Event FIFO Acknowledge Register (TXEFA)*). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

48.4 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note: From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

48.4.1 Features

- Active low asynchronous reset
- 1–CPU + up to 5–CAN arbiter
- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth
- Time slot is defined as one peripheral clock cycle

48.4.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
  - CPU obtains every 2nd slot
  - CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
  - CPU obtains no time slots
  - CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains every 2nd time slot
  - Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains no time slots
  - Active CAN 1/2 obtains every 2nd time slot

48.5 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are detailed in *Section 48.7: Shared memory map*.

48.5.1 ECC controller

The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access. The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2 bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors displays the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

48.5.1.1 Features

The ECC module supports the following:

- ecc_error = ‘00’ No error is detected in the read data from memory
- ecc_error = ‘01’ This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.
- ecc_error = ‘10’ This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- ecc_error = ‘11’ This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

48.6 External signal description

The CAN subsystem has the following external pins.

- M_CAN_x_RX: M_CAN x receive input
- M_CAN_x_TX: M_CAN x transmit output
- M_CAN_x_RXFD: M_CAN_x Receive Fast Data control signal
- M_CAN_x_TXFD: M_CAN_x Transmit Fast Data control signal

48.7 Shared memory map

Table 793 shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 793. Shared memory map versus CAN transmit, receive and filters elements

Start Address Offset (byte)	End Address Offset (byte)	CAN block/sub block		Comment
CAN Subsystem_0 - PBRIDGE_2				
0x0000	0x3DFF	CAN_SUB_0_M_CAN_0 CAN_SUB_0_M_CAN_1 CAN_SUB_0_M_CAN_2 CAN_SUB_0_M_CAN_3	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 1	
			Rx Buffer	
			Tx Event FIFO	
			Tx Buffers	
			Reserved	
CAN Subsystem_1 - PBRIDGE_1				

Table 793. Shared memory map versus CAN transmit, receive and filters elements (continued)

Start Address Offset (byte)	End Address Offset (byte)	CAN block/sub block		Comment
0x0000	0x3DFF	CAN_SUB_1_M_CAN_1 CAN_SUB_1_M_CAN_2 CAN_SUB_1_M_CAN_3 CAN_SUB_1_M_CAN_4	Standard Filters Extended Filters Rx FIFO 0 Rx FIFO 2 Rx Buffer Tx Event FIFO Tx Buffers Reserved	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
CAN Subsystem_2 - PBRIDGE_0				
0x0000	0x3DFF	CAN_SUB_2_M_CAN_1 CAN_SUB_2_M_CAN_2 CAN_SUB_2_M_CAN_3 CAN_SUB_2_M_CAN_4	Standard Filters Extended Filters Rx FIFO 0 Rx FIFO 2 Rx Buffer Tx Event FIFO Tx Buffers Reserved	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.
CAN Subsystem_3 - PBRIDGE_0				
0x0000	0x3DFF	CAN_SUB_3_M_CAN_1 CAN_SUB_3_M_CAN_2 CAN_SUB_3_M_CAN_3 CAN_SUB_3_M_CAN_4	Standard Filters Extended Filters Rx FIFO 0 Rx FIFO 2 Rx Buffer Tx Event FIFO Tx Buffers Reserved	This available physical memory space could be configured for Filters/ FIFO/Buffer. This memory space can be flexible, assigned to any of the implemented M_CAN modules.

Note: There is no write access protection from a CAN module to the message memory space.

The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters and the Tx/Rx buffers used, it is mandatory for the user to configure the start address registers, specified in Table 794, in order to fit the memory mapping specified in Table 793.

The CPU uses the peripheral interface to access the memory locations. It must be noted that there is no transfer error reported to the CPU in case of access to reserved memory locations.

Table 794. Detailed mapping in CAN sub-blocks

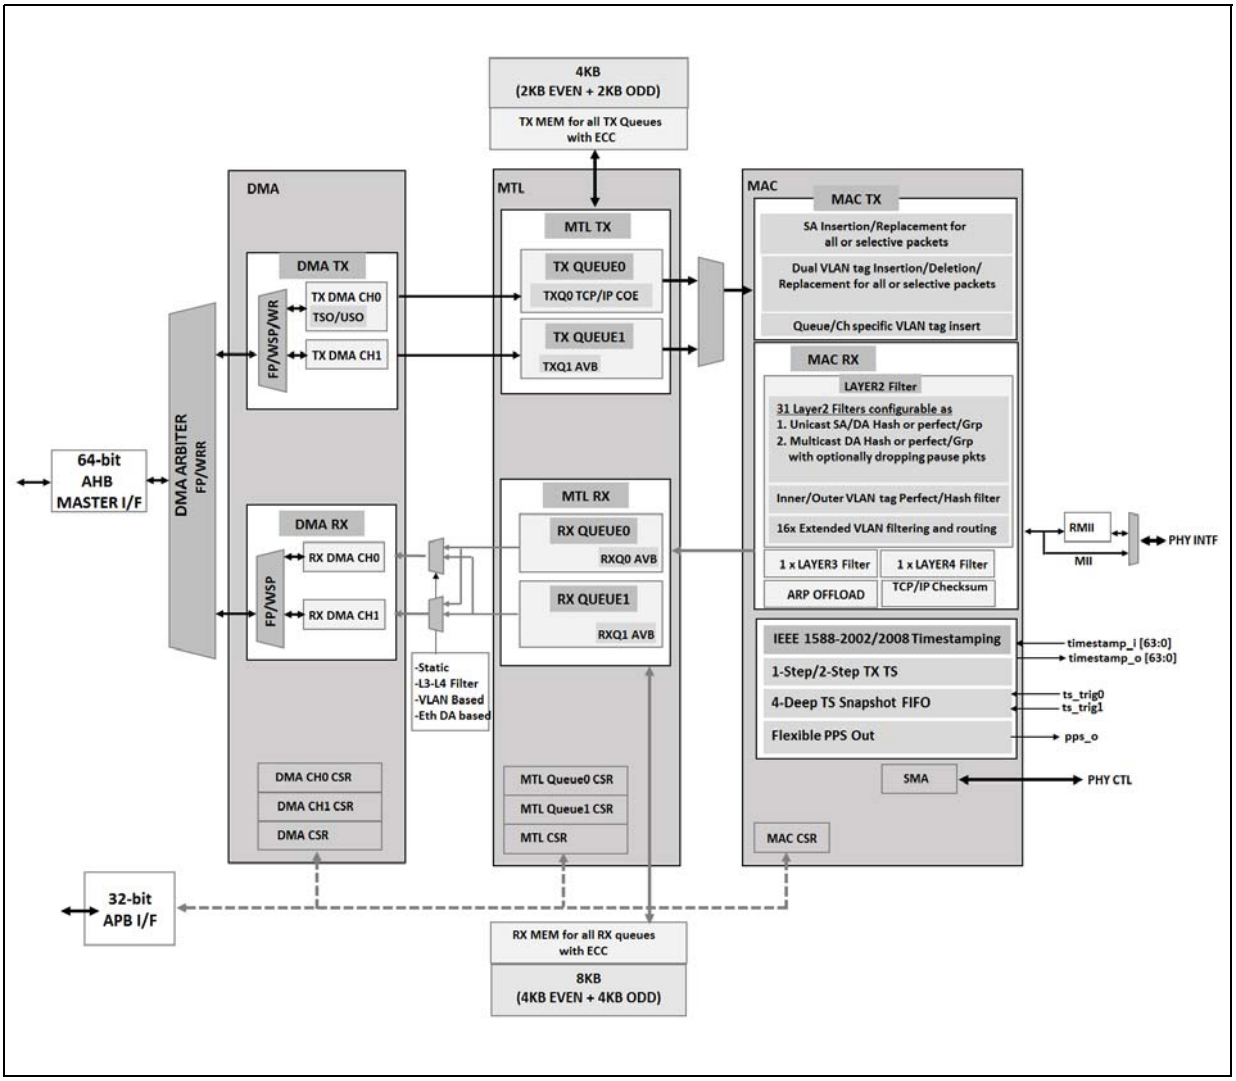
CAN sub-block	Element name	Comment
Standard Filters	Standard Message ID filter 0 ... Standard Message ID filter 127	address configured in SIDFC [FLSSA]
Extended Filters	Extended Message ID filter 0 ... Extended Message ID filter 63	address configured in XIDFC [FLESA]
Rx FIFO0	Rx FIFO0 element 0 ... Rx FIFO0 element 63	address configured in RXF0C[F0SA]
Rx FIFO1	Rx FIFO1 element 0 ... Rx FIFO1 element 63	address configured in RXF1C[F1SA]
Rx Buffer	Rx Buffer element 0 ... Rx Buffer element 63	address configured in RXBC[RBSA]
Tx Event FIFO	Tx event FIFO element 0 ... Tx event FIFO element 31	address configured in TXEFC[EFSA]
Tx Buffers	Tx Buffer element 0 ... Tx Buffer element 31	address configured in TXBC[TBSA]

49 Ethernet 10 Mbps/100 Mbps

49.1 Overview

The Ethernet module enables a host to transmit and receive data over the Ethernet in compliance with the IEEE 802.3-2015. *Figure 704* shows a block diagram of the Ethernet module.

As shown in *Figure 704*, the Ethernet module uses a 64-bit AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through AHB master interface. One AHB master interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all the paths (Transmit and Receive) in all channels.



As shown in *Figure 704*, the Ethernet module uses a 32-bit APB interface to program the Control and Status registers (CSR). Each channel has a separate set of Control and Status registers (CSR) for managing the Transmit and Receive functions, descriptor handling, and interrupt handling.

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the Ethernet module. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are one-ported RAM of 68-bit width for 64 data bus widths. The extra bits are used for storing the byte-enable information.

For multiple queues, all Tx queue share the Tx FIFO memory and all Rx queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue. The Ethernet module provides a direct read or write access to the FIFO memories in Debug mode.

The Ethernet module can be programmed to use one of the multiple PHY interfaces.

Figure 704. Module block diagram

49.1.1 Ethernet module features

For Ethernet features, refer to the Ethernet Configuration section of the Device Configuration chapter.

49.2 Memory map and registers description

This section provides a detailed description of all registers accessible in this module.

49.2.1 Memory map

Table 795. Ethernet memory map

Address offset (hex)	Register	Location
0x0000	MAC Configuration register (MAC_CONFIGURATION)	*Section 49.2.2.1*
0x0004	MAC Extended Configuration register (MAC_EXT_CONFIGURATION)	*Section 49.2.2.2*
0x0008	MAC Packet Filter register (MAC_PACKET_FILTER)	*Section 49.2.2.3*
0x000C	MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)	*Section 49.2.2.4*
0x0010	MAC Hash Table register 0 (MAC_HASH_TABLE_REG0)	*Section 49.2.2.5*
0x0014	MAC Hash Table register 1 (MAC_HASH_TABLE_REG1)	*Section 49.2.2.6*
0x0018–0x004F	Reserved	
0x0050	MAC VLAN Tag Control register (MAC_VLAN_TAG_CTRL)	*Section 49.2.2.7*
0x0054	MAC VLAN Tag Data register (MAC_VLAN_TAG_DATA)	*Section 49.2.2.8*
0x0054	MAC VLAN Tag Filter n register (MAC_VLAN_TAG_FILTERn) for n = 0 to 15	*Section 49.2.2.9*
0x0058	MAC VLAN Hash Table register (MAC_VLAN_HASH_TABLE)	*Section 49.2.2.10*
0x0060	MAC VLAN Tag Inclusion register (MAC_VLAN_INCL)	*Section 49.2.2.11*
0x0060	MAC VLAN Tag Inclusion register n (MAC_VLAN_INCLn) for n = 0 to 1	*Section 49.2.2.12*
0x0064	MAC Inner VLAN Tag Inclusion register (MAC_INNER_VLAN_INCL)	*Section 49.2.2.13*
0x0070	MAC Q0 TX Flow Control register (MAC_Q0_TX_FLOW_CTRL)	*Section 49.2.2.14*
0x0090	MAC Receive Flow Control register (MAC_RX_FLOW_CTRL)	*Section 49.2.2.15*
0x0094	MAC Receive Queue Control 4 register (MAC_RXQ_CTRL4)	*Section 49.2.2.16*
0x0098–0x009F	Reserved	
0x00A0	MAC Receive Queue Control 0 register (MAC_RXQ_CTRL0)	*Section 49.2.2.17*
0x00A4	MAC Receive Queue Control 1 register (MAC_RXQ_CTRL1)	*Section 49.2.2.18*
0x00A8	MAC Receive Queue Control 2 register (MAC_RXQ_CTRL2)	*Section 49.2.2.19*
0x00AC–0x00AF	Reserved	
0x00B0	MAC Interrupt Status register (MAC_INTERRUPT_STATUS)	*Section 49.2.2.20*
0x00B4	MAC Interrupt Enable register (MAC_INTERRUPT_ENABLE)	*Section 49.2.2.21*
0x00B8	MAC Receive Transmit Status register (MAC_RX_TX_STATUS)	*Section 49.2.2.22*
0x00BC–0x00BF	Reserved	
0x00C0	MAC PMT Control and Status register (MAC_PMT_CONTROL_STATUS)	*Section 49.2.2.23*
0x00C4	Wake-up Packet Filter registers	*Section 49.2.2.24*
0x00C8–0x00CF	Reserved	
0x00D0	MAC LPI Control and Status register (MAC_LPI_CONTROL_STATUS)	*Section 49.2.2.25*
0x00D4	MAC LPI Timers Control register (MAC_LPI_TIMERS_CONTROL)	*Section 49.2.2.26*
0x00D8	MAC LPI Entry Timer register (MAC_LPI_ENTRY_TIMER)	*Section 49.2.2.27*

Table 795. Ethernet memory map (continued)

Address offset (hex)	Register	Location
0x00DC	MAC 1US Tic Counter register (MAC_1US_TIC_COUNTER)	Section 49.2.2.28
0x00E0–0x010F	Reserved

49.2.2 Registers definition

49.2.2.1 MAC configuration register (MAC_CONFIGURATION)

The MAC configuration register establishes the operating mode of the MAC.

Offset 0x0000 Access: User Read/Write

Figure 705. MAC configuration register (MAC_CONFIGURATION)

Table 796. MAC_CONFIGURATION field descriptions

Field	Description
0 ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.
1:3 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 1 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[2:3]: 0x If TDES3[SAIC] = 3'b000 then the application provides the correct SA field else insertion logic will work according to the setting of TDES3[SAIC]. 10 If Bit 1 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 11 If Bit 1 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. **Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

Table 796. MAC_CONFIGURATION field descriptions (continued)

Field	Description
4 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. Always set this bit when Layer 3 and Layer 4 Packet Filter is enabled or Split Header is enabled.
5:7 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. Values: 0x0 (IPG96): 96 bit times IPG 0x1 (IPG88): 88 bit times IPG 0x2 (IPG80): 80 bit times IPG 0x3 (IPG72): 72 bit times IPG 0x4 (IPG64): 64 bit times IPG 0x5 (IPG56): 56 bit times IPG 0x6 (IPG48): 48 bit times IPG 0x7 (IPG40): 40 bit times IPG
8 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1518 bytes. Otherwise, the MAC considers 1518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9018 bytes (9022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.
9 S2KP	IEEE 802.3 as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1518 bytes (1522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, refer to Giant Packet Status based on S2KP and JE Bits. **Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.

Table 796. MAC_CONFIGURATION field descriptions (continued)

Field	Description
10 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. This function is valid when Type 2 Checksum Offload Engine is enabled. **Note:** For information about how the settings of the ACS bit and this bit impact the packet length, refer to *Table 797*.
11 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1536 bytes. All received packets with length field greater than or equal to 1536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. For more details refer to *Table 797*. **Note:** For information about how the settings of CST bit and this bit impact the packet length, refer to *Table 797*.
12 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16383 bytes. When this bit is reset, the MAC does not allow more than 2048 bytes (10240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2048 bytes.
14 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16383 bytes. When this bit is reset, if the application sends more than 2048 bytes of data (10240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.
15 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9018 bytes (9022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
16 PS	Port Select 0 Reserved 1 For 10 or 100 Mbps operations
17 FES	Speed This bit selects the speed in the 10/100 Mbps mode: 0 10 Mbps 1 100 Mbps
18 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously.
19 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Table 796. MAC_CONFIGURATION field descriptions (continued)

Field	Description
20 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal.
21 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the MII_TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode.
22 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.
23 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode.
25:26 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. 00 k = min (n, 10) 01 k = min (n, 8) 10 k = min (n, 4) 11 k = min (n, 1) where - = retransmission attempt The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode.

Table 796. MAC_CONFIGURATION field descriptions (continued)

Field	Description
27 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24288 bit times in 10 or 100 Mbps mode. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII. The defer time is not cumulative. For example, if the transmitter defers for 10000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.
28:29 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 7 bytes of preamble 01 5 bytes of preamble 10 3 bytes of preamble 11 Reserved
30 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the selected interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.
31 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the selected interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the selected interface.

Table 797. Packet length based on the CST and ACS bits

Receive checksum offload engine	Receive packet length	CST	ACS	FCS stripping done
IPCKSUM_EN = 0 and IPC_FULL_OFFLOAD = 0 or IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 1	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	0	x	No
		1	x	Yes (for Type packets)
IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 0	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	x	x	No

49.2.2.2 MAC extended configuration register (MAC_EXT_CONFIGURATION)

The MAC extended configuration register establishes the operating mode of the MAC.

Table 798. MAC_EXT_CONFIGURATION field descriptions

Field	Description
2:6 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
7 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. **Note:** The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode.
9:11 HDSMS	Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet: The following values are valid only: 000 64 bytes 001 128 bytes 010 256 bytes 011 512 bytes 100 1024 bytes

Table 798. MAC_EXT_CONFIGURATION field descriptions (continued)

Field	Description
12 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_Address *n*_High register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of MAC_Address *n*_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value.
13 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
14 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.
15 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.
18:31 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1518 bytes. Any other programmed value is considered as 1518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

49.2.2.3 MAC packet filter register (MAC_PACKET_FILTER)

The MAC packet filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Figure 707. MAC packet filter register (MAC_PACKET_FILTER)

Table 799. MAC_PACKET_FILTER field descriptions

Field	Description
0 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.
10 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
11 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.
15 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.
21 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Table 799. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
22 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. **Note:** According to the IEEE specification, Bit 47 of the SA is reserved. However, in the Ethernet module, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.
23 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.
24:25 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 The MAC filters all control packets from reaching the application. 01 The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 10 The MAC forwards all control packets to the application even if they fail the Address filter. 11 The MAC forwards the control packets that pass the Address filter.
26 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets.
27 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
28 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
29 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Table 799. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
30 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.
31 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

49.2.2.4 MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

Offset 0x000C — Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 708. MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)

Table 800. MAC_WATCHDOG_TIMEOUT field descriptions

Field	Description
23 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register.
28:31 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Encoding is as follows: 0x0: 2 KB 0x1: 3 KB 0x2: 4 KB 0x3: 5 KB ... 0xC: 14 KB 0xD: 15 KB 0xE: 16383 Bytes 0xF: Reserved **Note:** When the PWE bit is set, the value in this field should be more than 1522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

49.2.2.5 MAC Hash table register 0 (MAC_HASH_TABLE_REG0)

The Hash table register 0 contains the first 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

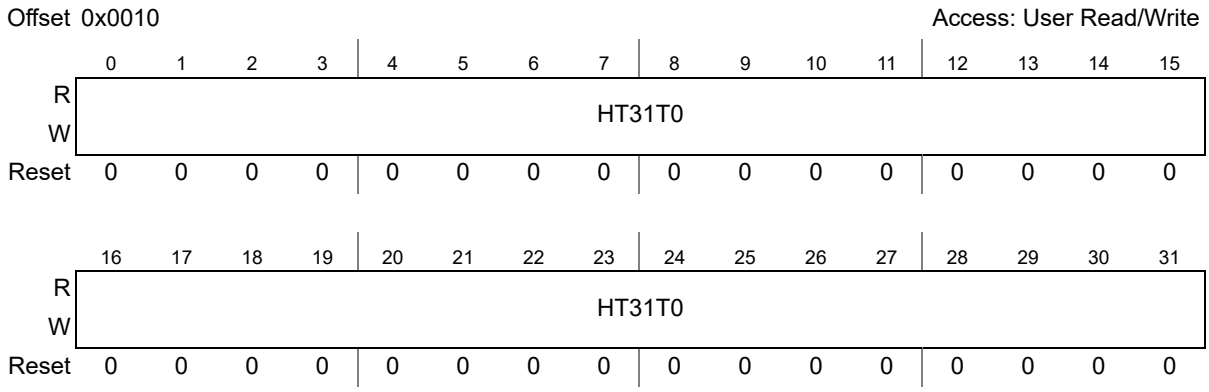

Figure 709. MAC Hash Table Reg0 register (MAC_HASH_TABLE_REG0)

Table 801. MAC_HASH_TABLE_REG0 field descriptions

Field	Description
0:31 HT31T0	This field contains the first 32 bits [0:31] of the MAC Hash table.

49.2.2.6 MAC Hash Table register 1 (MAC_HASH_TABLE_REG1)

The Hash table register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 711. MAC VLAN tag control register (MAC_VLAN_TAG_CTRL)

Table 803. MAC_VLAN_TAG_CTRL field descriptions

Field	Description
0 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.
2:3 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
4 ERIVLT	Enable Inner VLAN Tag When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
5 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).
6 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed.
7 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.
9:10 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
13 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.
14 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Table 803. MAC_VLAN_TAG_CTRL field descriptions (continued)

Field	Description
25:29 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
30 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicates a read operation. When reset, it indicates a write operation.
31 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the MAC_VLAN_Tag_Data register only after this bit is reset.

49.2.2.8 MAC VLAN tag data register (MAC_VLAN_TAG_DATA)

This register holds the read/write data for Indirect Access of the Per VLAN tag registers.

During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_TAG_CTRL register.

Table 804. MAC_VLAN_TAG_DATA field descriptions

Field	Description
6 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
7 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing.
11 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present).
12 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
13 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit.
14 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet.
15 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields.
16:31 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

Field	Description
6 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field needs not be programmed.
7 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing.
11 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present).
12 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
13 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit.

Table 805. MAC_VLAN_TAG_FILTERn field descriptions (continued)

Field	Description
14 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet.
15 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields.
16:31 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

49.2.2.10 MAC VLAN hash table register (MAC_VLAN_HASH_TABLE)

When the VTHM bit of MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4’b1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, refer to Section 3.2.8 of IEEE 802.3 - 2008).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 715. MAC VLAN tag inclusion register (MAC_VLAN_INCL)

Table 807. MAC_VLAN_INCL field descriptions

Field	Description
0 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register.
1 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset.
7 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
10 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register.
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet to be taken from the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
13 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored.

Table 807. MAC_VLAN_INCL field descriptions (continued)

Field	Description
14:15 VLC	VLAN Tag Control in Transmit Packets – 2'b00: No VLAN tag deletion, insertion, or replacement – 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. – 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. – 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

49.2.2.12 MAC VLAN tag inclusion register *n* (MAC_VLAN_INCL*n*)

The Tx Queue VLAN tag inclusion register contains the VLAN tag for insertion in the transmit packets from Tx Queue *n*. It also contains the VLAN tag insertion controls.

Offset 0x0060 (n = 0 to 1) Access: User Read/Write

Table 809. MAC_INNER_VLAN_INCL field descriptions

Field	Description
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

Table 809. MAC_INNER_VLAN_INCL field descriptions (continued)

Field	Description
13 VLP	VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.
14:15 VLC	VLAN Tag Control in Transmit Packets 00 No VLAN tag deletion, insertion, or replacement 01 VLAN tag deletion. The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. 10 VLAN tag insertion. The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11 VLAN tag replacement. The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

49.2.2.14 MAC Q0 TX flow control register (MAC_Q0_TX_FLOW_CTRL)

The Flow control register controls the generation and reception of the control (Pause command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

Figure 718. MAC Q0 TX flow control register (MAC_Q0_TX_FLOW_CTRL)

Table 810. MAC_Q0_TX_FLOW_CTRL field descriptions

Field	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Table 810. MAC_Q0_TX_FLOW_CTRL field descriptions (continued)

Field	Description
30 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.
31 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.15 MAC receive flow control register (MAC_RX_FLOW_CTRL)

The Receive flow control register controls the pausing of MAC Transmit based on the received Pause packet.

Offset 0x0090 Access: User Read/Write

Figure 719. MAC receive flow control register (MAC_RX_FLOW_CTRL)

Table 811. MAC_RX_FLOW_CTRL field descriptions

Field	Description
30 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. **Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.
31 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

49.2.2.16 MAC Receive queue control 4 register (MAC_RXQ_CTRL4)

The Receive queue control 4 register controls the routing of unicast and multicast packets that fail the destination or source address filter to the Rx queues.

Field	Description
14 VFFQ	VLAN Tag Filter Fail Packets Queue This field holds the Rx queue number to which the tagged packets failing the Destination or Source Address filter (and UFFQE/MFFQE not enabled) or failing the VLAN tag filter must be routed to. This field is valid only when the VFFQE bit is set.
15 VFFQE	VLAN Tag Filter Fail Packets Queuing Enable When this bit is set, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter, are routed to the Rx Queue Number programmed in the VFFQ. When this bit is reset, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set.
22 MFFQ	Multicast Address Filter Fail Packets Queue This field holds the Rx queue number to which the Multicast packets failing the Destination or Source Address filter are routed to. This field is valid only when the MFFQE bit is set.
23 MFFQE	Multicast Address Filter Fail Packets Queuing Enable When this bit is set, the Multicast packets which fail the Destination or Source address filter is routed to the Rx Queue Number programmed in the MFFQ. When this bit is reset, the Multicast packets which fail the Destination or Source address filter is routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set.
30 UFFQ	Unicast Address Filter Fail Packets Queue This field holds the Rx queue number to which the Unicast packets failing the Destination or Source Address filter are routed to. This field is valid only when the UFFQE bit is set.
31 UFFQE	Unicast Address Filter Fail Packets Queuing Enable When this bit is set, the Unicast packets which fail the Destination or Source address filter is routed to the Rx Queue Number programmed in the UFFQ. When this bit is reset, the Unicast packets which fail the Destination or Source address filter is routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set.

49.2.2.17 MAC Receive queue control 0 register (MAC_RXQ_CTRL0)

The Receive queue control 0 register controls the queue management in the MAC Receiver.

Figure 724. MAC Interrupt status register (MAC_INTERRUPT_STATUS)

Table 816. MAC_INTERRUPT_STATUS field descriptions

Field	Description
13 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of MAC_CSR_SW_Ctrl register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
17 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.
18 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: – Excessive Collision (EXCOL) – Late Collision (LCOL) – Excessive Deferral (EXDEF) – Loss of Carrier (LCARR) – No Carrier (NCARR) – Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.
19 TSIS	Timestamp Interrupt Status This bit is set when any of the following conditions is true: – The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. – There is an overflow in the Seconds register. – The Target Time Error occurred, that is, programmed target time already elapsed. – When the auxiliary snapshot trigger is asserted. – When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register.
20 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
21 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.

Table 816. MAC_INTERRUPT_STATUS field descriptions (continued)

Field	Description
22 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
23 MMCIS	MMC Interrupt Status This bit is set high when Bit 20, Bit 21, or Bit 22 is set high. This bit is cleared only when all these bits are low.
26 LPIIS	LPI Interrupt Status This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set).
27 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when Bits [25:26] are cleared because of a Read operation to the MAC_PMT_Control_Status register (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
28 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).

49.2.2.21 MAC Interrupt enable register (MAC_INTERRUPT_ENABLE)

The Interrupt enable register contains the masks for generating the interrupts.

Offset 0x00B4 Access: User Read/Write

Figure 725. MAC Interrupt enable register (MAC_INTERRUPT_ENABLE)

Table 817. MAC_INTERRUPT_ENABLE field descriptions

Field	Description
13 MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_INTERRUPT_STATUS register.
17 RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the MAC_INTERRUPT_STATUS register.
18 TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the MAC_INTERRUPT_STATUS register.
19 TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in MAC_INTERRUPT_STATUS register.
26 LPIIE	LPI Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in MAC_INTERRUPT_STATUS register.
27 PMTIE	PMT Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in MAC_INTERRUPT_STATUS register.
28 PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in MAC_INTERRUPT_STATUS register.

49.2.2.22 MAC Receive transmit status register (MAC_RX_TX_STATUS)

The Receive transmit status register contains the Receive and Transmit Error status.

Offset 0x00B8 Access: User Read-only

Figure 726. MAC Receive transmit status register (MAC_RX_TX_STATUS)

Table 818. MAC_RX_TX_STATUS field descriptions

Field	Description
23 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2048 bytes is received (10240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
26 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
27 LCOL	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
28 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24288 bit times (155680 when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
29 LCARR	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
30 NCARR	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
31 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2048 bytes (10240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

49.2.2.23 MAC PMT control and status register (MAC_PMT_CONTROL_STATUS)

This register captures the remote wakeup control and status.

Offset 0x00C0 Access: User Read/Write

Figure 727. MAC PMT control and status register (MAC_PMT_CONTROL_STATUS)

Table 819. MAC_PMT_CONTROL_STATUS field descriptions

Field	Description
0 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
5:7 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.

Table 819. MAC_PMT_CONTROL_STATUS field descriptions (continued)

Field	Description
21 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. **Note:** If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
22 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.
25 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
26 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
29 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.

Table 819. MAC_PMT_CONTROL_STATUS field descriptions (continued)

Field	Description
30 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet.
31 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.24 Wake-up packet filter registers

The wkuppktfilter_reg register at address 0x00C4 loads the Wake-up packet filter register.

To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight register values in address (0x00C4) for wkuppktfilter_reg0, wkuppktfilter_reg1, …, wkuppktfilter_reg7, respectively. The wkuppktfilter_reg register is read in a similar way.

The Ethernet module updates the wkuppktfilter_reg register current pointer value in Bits[5:7] of MAC_PMT_Control_Status register.

- Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3) to determine whether or not a packet is a wake-up packet.
  - The MSB (bit 0) must be zero.
  - Bit j[1:31] is the byte mask.
  - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.
- Filter i Command: The 4-bit filter i command controls the filter i operation.
  - Bit 28 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.
  - Bit 29 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.
  - Bit 29, along with Bit 30, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”.
  - Bit 30 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three,

or four filters. This depends on the number of filters that have the And_Previous bit set.

– Bit 31 is the enable for filter i. If Bit 31 is not set, filter i is disabled.

- Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.
  – This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
  – The minimum allowed offset is 12, which refers to the 13th byte of the packet.
  – The offset value 0 refers to the first byte of the packet.
- Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.
  – The 16-bit CRC calculation uses the following polynomial:
  $G(x) = x^{16} + x^{15} + x^2 + 1$
  Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  – 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.
  – 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.

The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.

Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).

When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).

49.2.2.24.1 Notes on And_Previous bit setting

The And_Previous bit setting is applicable within a set of 4 filters.

- Setting of And_Previous bit of filter that is not enabled has no effect. In other words, setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.
- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example:

  If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set) but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered.

  If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 2 is not enabled (bit 0 of in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. If filters chained by And_Previous bit setting have complementary programming, then a frame may never

pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 of Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 of Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Table 825. RWK_FILTER0123_COMMAND field descriptions

Field	Description
4:7 Filter3_Command	Filter${l} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”. – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
12:15 Filter2_Command	Filter${k} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”. – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.

Table 825. RWK_FILTER0123_COMMAND field descriptions (continued)

Field	Description
20:23 Filter1_Command	Filter${j} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”. – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
28:31 Filter0_Command	Filter${i} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2”. – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.

49.2.2.24.8 Wakeup filter 0123 offset register (RWK_FILTER0123_OFFSET)

Corresponds to registers wkuppktfilter_reg5 described in *Figure 728*.

Offset 0x00C4 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 738. MAC LPI control and status register (MAC_LPI_CONTROL_STATUS)

Table 829. MAC_LPI_CONTROL_STATUS field descriptions

Field	Description
10 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. 0 LPI Tx Clock Stop is disabled 1 LPI Tx Clock Stop is enabled
11 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions. 0 LPI Timer is disabled 1 LPI Timer is enabled
12 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of the MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0 LPI Tx Automate is disabled 1 LPI Tx Automate is enabled
14 PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. 0 Link is down 1 Link is okay

Table 829. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
15 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0 LPI state is disabled 1 LPI state is enabled
22 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface. 0 Receive LPI state not detected 1 Receive LPI state detected
23 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface. 0 Transmit LPI state not detected 1 Transmit LPI state detected
28 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 Receive LPI exit not detected 1 Receive LPI exit detected
29 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 Receive LPI entry not detected 1 Receive LPI entry detected

Table 829. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
30 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0 Transmit LPI exit not detected 1 Transmit LPI exit detected
31 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0 Transmit LPI entry not detected 1 Transmit LPI entry detected

49.2.2.26 MAC LPI timers control register (MAC_LPI_TIMERS_CONTROL)

The LPI timers control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Offset 0x00D4 Access: User Read/Write

Figure 739. MAC LPI timers control register (MAC_LPI_TIMERS_CONTROL)

Table 830. MAC_LPI_TIMERS_CONTROL field descriptions

Field	Description
6:15 LST	LPI LS TIMER This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
16:31 TWT	LPI TW TIMER This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

49.2.2.27 MAC LPI entry timer register (MAC_LPI_ENTRY_TIMER)

This register controls the Tx LPI entry timer. This counter is enabled only when bit[11](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Offset 0x00D8 Access: User Read/Write

Figure 740. MAC LPI entry timer register (MAC_LPI_ENTRY_TIMER)

Table 831. MAC_LPI_ENTRY_TIMER field descriptions

Field	Description
12:28 LPIET	LPI Entry Timer This field specifies the time in microseconds the MAC will wait to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [29:31] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

49.2.2.28 MAC 1US Tic counter register (MAC_1US_TIC_COUNTER)

This register controls the generation of the reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

Offset 0x00DC Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 741. MAC 1US Tic counter register (MAC_1US_TIC_COUNTER)

Table 832. MAC_1US_TIC_COUNTER field descriptions

Field	Description
20:31 TIC_1US_CNTR	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100 MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

49.2.2.29 MAC Version register (MAC_VERSION)

The version register identifies the version of the Ethernet module.

Figure 751. MAC MDIO address register (MAC_MDIO_ADDRESS)

Table 842. MAC_MDIO_ADDRESS field description

Field	Description
4 PSE	Preamble Suppression Enable When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.
5 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0.
6:10 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
11:15 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
17:19 NTC	Number of Training Clocks This field controls the number of trailing clock cycles generated on sma_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.

Table 842. MAC_MDIO_ADDRESS field description (continued)

Field	Description
20:23 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0000 CSR clock = 60-100 MHz; MDC clock = CSR clock/42 0001 CSR clock = 100-150 MHz; MDC clock = CSR clock/62 0010 CSR clock = 20-35 MHz; MDC clock = CSR clock/16 0011 CSR clock = 35-60 MHz; MDC clock = CSR clock/26 0100 CSR clock = 150-250 MHz; MDC clock = CSR clock/102 0101 CSR clock = 250-300 MHz; MDC clock = CSR clock/124 0110 CSR clock = 300-500 MHz; MDC clock = CSR clock/204 0111 CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 20 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 20 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000 CSR clock/4 1001 CSR clock/6 1010 CSR clock/8 1011 CSR clock/10 1100 CSR clock/12 1101 CSR clock/14 1110 CSR clock/16 1111 CSR clock/18
27 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
28:29 GOC	PHY SMA interface Operation Command This field indicates the operation command to the PHY: 00 Reserved 01 Write 10 Post Read Increment Address for Clause 45 PHY 11 Read When Clause 22 PHY is enabled, only Write (01) and Read (11) commands are valid.

Table 842. MAC_MDIO_ADDRESS field description (continued)

Field	Description
30 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
31 GB	PHY SMA interface Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.39 MAC MDIO data register (MAC_MDIO_DATA)

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Figure 753. MAC GPIO control register (MAC_GPIO_CONTROL)

Table 844. MAC_GPIO_CONTROL field descriptions

Field	Description
0:15 GPIT	GPI Type When this bit is set, it indicates that the corresponding GPIS bit in MAC_GPIO_Status register is of latched-low (LL) type. When this bit is reset, it indicates that the corresponding GPIS is of latched-high (LH) type. The number of bits available in this field depends on the GP Input Signal Width option. Other bits are not used (reserved and always reset).
28:31 GPIE	GPI Interrupt Enable When this bit is set and the programmed event (LL or LH) occurs on the corresponding GPIS bit of MAC_GPIO_Status register, the GPIIS bit of DMA_Interrupt_Status register is set and an interrupt is generated on the mci_intr_o or sbd_intr_o signal. The GPIIS bit is cleared when the application reads the Bits[7:0] of MAC_GPIO_Status register. When this bit is reset, the GPIIS bit is not set when any event occurs on the corresponding GPIS bits.

49.2.2.41 MAC GPIO status register (MAC_GPIO_STATUS)

The General Purpose IO register provides the control to drive the following: up to 16 bits of output ports (GPO) and status of up to 16 input ports (GPIS).

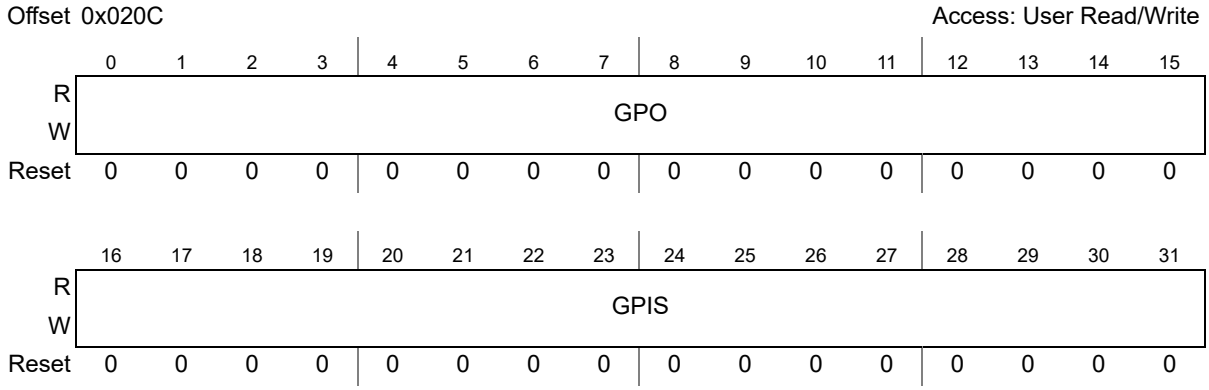

Figure 754. MAC GPIO status register (MAC_GPIO_STATUS)

Table 845. MAC_GPIO_STATUS field descriptions

Field	Description
0:15 GPO	General Purpose Output When this bit is set, it directly drives the gpo_o output ports. When this bit is reset, it does not directly drive the gpo_o output ports.
16:31 GPIS	General Purpose Input Status This field gives the status of the signals connected to the gpi_i port. This field is of the following types based on the setting of the corresponding GPIT field of MAC_GPIO_Control register: Latched-low (LL): this field is cleared when the corresponding gpi_i input becomes low. This field remains low until the application reads this field after which this field reflects the current value of gpi_i input. Latched-high (LH): this field is set when the corresponding gpi_i input becomes high. This field remains high until the application reads this field after which this field reflects the current value of gpi_i input.

49.2.2.42 MAC ARP address register (MAC_ARP_ADDRESS)

The ARP address register contains the IPv4 Destination Address of the MAC.

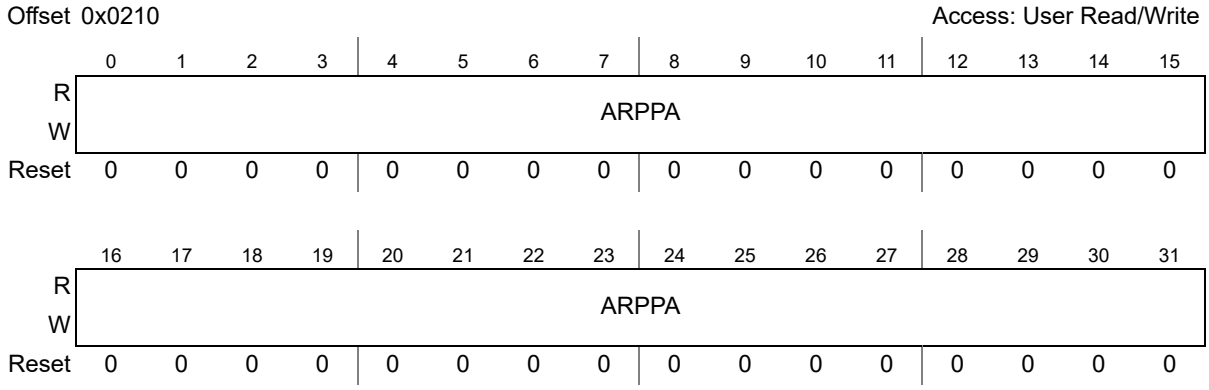

Figure 755. MAC ARP address register (MAC_ARP_ADDRESS)

Table 846. MAC_ARP_ADDRESS field descriptions

Field	Description
0:31 ARPPA	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

49.2.2.43 MAC CSR SW control register (MAC_CSR_SW_CTRL)

This register contains software programmable controls for changing the CSR access response and status bits clearing.

Field	Description
0:31 MPTN	MAC 1722 Presentation Time in ns These bits indicate the value of the 32-bit binary rollover equivalent time of the PTP System Time in ns.

49.2.2.46 MAC Presentation Time Update register (MAC_PRESN_TIME_UPDT)

This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSUPDT are defined in *Section 49.2.2.148: Timestamp control register (MAC_TIMESTAMP_CONTROL)*).

Figure 759. MAC Presentation time update register (MAC_PRESN_TIME_UPDT)

Table 850. MAC_PRESN_TIME_UPDT field descriptions

Field	Description
0:31 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSUPDT defined in *Section 49.2.2.148: Timestamp control register (MAC_TIMESTAMP_CONTROL)*). When ADDSUB field of MAC_System_Time_Nanoseconds_Update is set, this value is directly used for subtraction.

49.2.2.47 MAC address 0 high register (MAC_ADDRESS0_HIGH)

The MAC Address 0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [24:31]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MAC Address 0 Register [0:47] is compared with 0x665544332211.

Clock domain synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Figure 760. MAC address 0 high register (MAC_ADDRESS0_HIGH)

Table 851. MAC_ADDRESS0_HIGH field descriptions

Field	Description
0 AE	Address Enable This bit is always set to 1.
14:15 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: this field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. If the PDC bit of MAC_Ext_Configuration register is set: this field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address0 content is routed.
16:31 ADDRHI	MAC Address0[0:15] This field contains the upper 16 bits [0:15] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

49.2.2.48 MAC address 0 low register (MAC_ADDRESS0_LOW)

The MAC address 0 low register holds the lower 32 bits of the 6-byte first MAC address of the station.

Figure 761. MAC address 0 low register (MAC_ADDRESS0_LOW)

Table 852. MAC_ADDRESS0_LOW field descriptions

Field	Description
0:31 ADDRLO	MAC address 0 [16:47] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

49.2.2.49 MAC address *n* High register (MAC_ADDRESS*n*_HIGH)

The MAC address *n* high register holds the upper 16 bits of the second 6-byte MAC address of the station.

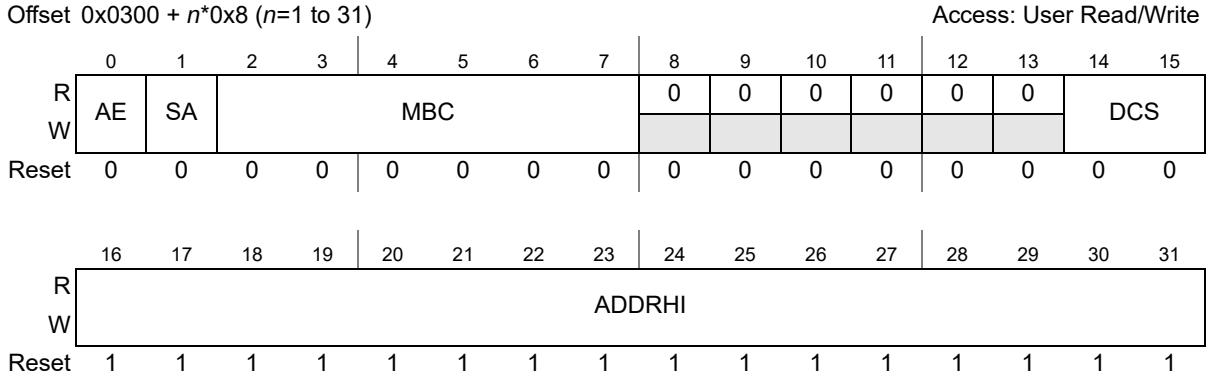

Figure 762. MAC address *n* high register (MAC_ADDRESS*n*_HIGH)

Table 853. MAC_ADDRESS*n*_HIGH field descriptions

Field	Description
0 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.
1 SA	Source Address When this bit is set, the MAC Address1[0:47] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[0:47] is used to compare with the DA fields of the received packet.
2:7 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: Bit 2: Register 194 [16:23] Bit 3: Register 194 [24:31] Bit 4: Register 195 [0:7] … Bit 7: Register 195 [24:31] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
14:15 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: this field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address *n* content is routed. If the PDC bit of MAC_Ext_Configuration register is set: this field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address *n* content is routed.
16:31 ADDRHI	MAC Address *n* [0:15] This field contains the upper 16 bits [0:15] of the second 6-byte MAC address.

49.2.2.50 MAC address *n* low register (MAC_ADDRESS*n*_LOW)

The MAC address *n* low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Figure 763. MAC address *n* low register (MAC_ADDRESS*n*_LOW)

Table 854. MAC_ADDRESS*n*_LOW field descriptions

Field	Description
0:31 ADDRLO	MAC Address *n* [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

49.2.2.51 MMC control register (MMC_CONTROL)

The MMC control register establishes the operating mode of the management counters.

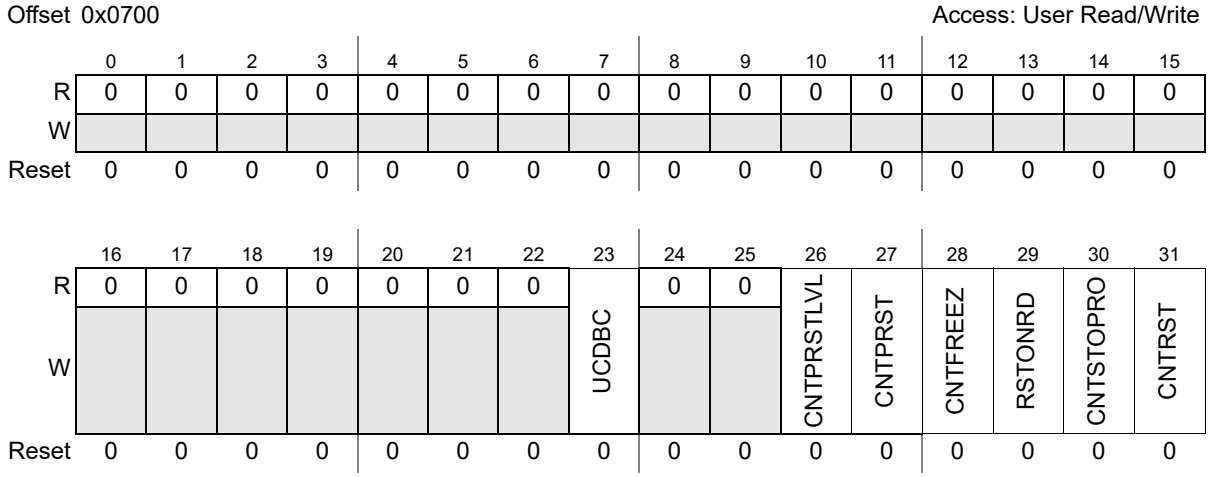

Figure 764. MMC control register (MMC_CONTROL)

Table 855. MMC_CONTROL field descriptions

Field	Description
23 UCDBC	Update MMC Counters for Dropped Broadcast Packets When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets.
26 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16).
27 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.
28 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
29 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[0:7]) is read.
30 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value.
31 CNTRST	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

49.2.2.52 MMC receive interrupt register (MMC_RX_INTERRUPT)

The MMC receive interrupt register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values, that is 0x8000_0000.
- Receive statistic counters cross their maximum values, that is 0xFFFF_FFFF.
- When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Field	Description
4 RXLPITRCIM	MMC Receive LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 RXLPIUSCIM	MMC Receive LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.
6 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value.
7 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.
8 RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value.
9 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value.
10 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxfifooverflow counter reaches half of the maximum value or the maximum value.
11 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpausepackets counter reaches half of the maximum value or the maximum value.
12 RXORANGEPIM	MMC Receive Out Of Range Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value.
13 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value.
14 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.
15 RX1024TMAXOCTGBPIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
16 RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value.

Table 858. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
17 RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value.
18 RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value.
19 RX65T127OCTGBPIM	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value.
20 RX64OCTGBPIM	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value.
21 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value.
22 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value.
23 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value.
24 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value.
25 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value.
26 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value.
27 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value.
28 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
29 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value.

Table 858. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
30 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value.
31 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value.

49.2.2.55 MMC Tx interrupt mask register (MMC_TX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Transmit statistics counters.

Table 859. MMC_TX_INTERRUPT_MASK field descriptions

Field	Description
4 TXLPITRCIM	MMC Transmit LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when TX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 TXLPIUSCIM	MMC Transmit LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when TX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.

Table 859. MMC_TX_INTERRUPT_MASK field descriptions (continued)

Field	Description
6 TXOSIZEGPIM	MMC Transmit Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
7 TXVLANGPIM	MMC Transmit VLAN Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txvlanpackets_g counter reaches half of the maximum value or the maximum value.
8 TXPAUSPIM	MMC Transmit Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpausepackets counter reaches half of the maximum value or the maximum value.
9 TXEXDEFPIM	MMC Transmit Excessive Deferral Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value.
10 TXGPKTIM	MMC Transmit Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_g counter reaches half of the maximum value or the maximum value.
11 TXGOCTIM	MMC Transmit Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value.
12 TXCARERPIM	MMC Transmit Carrier Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value.
13 TXEXCOLPIM	MMC Transmit Excessive Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value.
14 TXLATCOLPIM	MMC Transmit Late Collision Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value.
15 TXDEFPIM	MMC Transmit Deferred Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value.
16 TXMCOLGPIM	MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value.
17 TXSCOLGPIM	MMC Transmit Single Collision Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value.
18 TXUFLOWERPIM	MMC Transmit Underflow Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value.
19 TXBCGBPIM	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value.

Table 859. MMC_TX_INTERRUPT_MASK field descriptions (continued)

Field	Description
20 TXMCGBPIM	MMC Transmit Multicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value.
21 TXUCGBPIM	MMC Transmit Unicast Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value.
22 TX1024TMAXOCTGBPIM	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
23 TX512T1023OCTGBPIM	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value.
24 TX256T511OCTGBPIM	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value.
25 TX128T255OCTGBPIM	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value.
26 TX65T127OCTGBPIM	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value.
27 TX64OCTGBPIM	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value.
28 TXMCGPIM	MMC Transmit Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value.
29 TXBCGPIM	MMC Transmit Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
30 TXGBPKTIM	MMC Transmit Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the txpacketcount_gb counter reaches half of the maximum value or the maximum value.
31 TXGBOCTIM	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value.

49.2.2.56 Transmit octet count good bad register (TX_OCTET_COUNT_GOOD_BAD)

This register provides the number of bytes transmitted by the Ethernet module, exclusive of preamble and retried bytes, in good and bad packets.

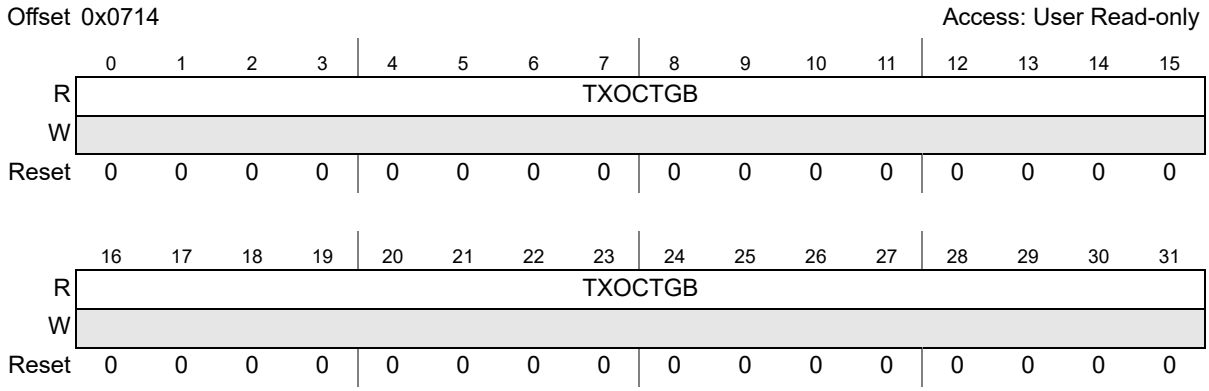

Figure 769. Transmit octet count good bad register (TX_OCTET_COUNT_GOOD_BAD)

Table 860. TX_OCTET_COUNT_GOOD_BAD field descriptions

Field	Description
0:31 TXOCTGB	This field indicates the number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad packets.

49.2.2.57 Transmit packet count good bad register (TX_PACKET_COUNT_GOOD_BAD)

This register provides the number of good and bad packets transmitted by the Ethernet module, exclusive of retried packets.

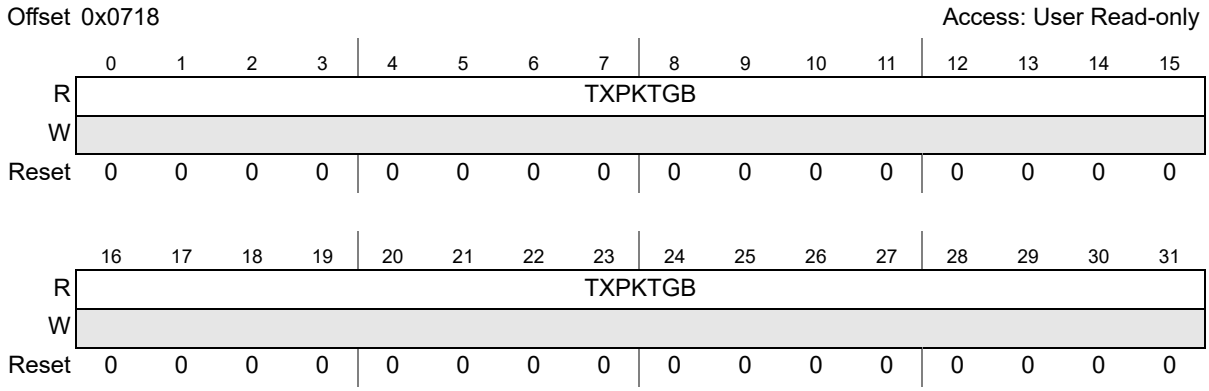

Figure 770. Transmit packet count good bad register (TX_PACKET_COUNT_GOOD_BAD)

Table 904. RX_LENGTH_ERROR_PACKETS field descriptions

Field	Description
0:31 RXLENERR	This field indicates the number of packets received with length error (Length Type field not equal to packet size), for all packets with valid length field.

49.2.2.101 Receive out of range type packets (RX_OUT_OF_RANGE_TYPE_PACKETS)

This register provides the number of packets received by the Ethernet module with length field not equal to the valid packet size (greater than 1500 but less than 1536).

Offset 0x07CC Access: User Read-only

49.2.2.112 MMC IPC receive interrupt mask register (MMC_IPC_RX_INTERRUPT_MASK)

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Offload Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Offload) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32-bit wide.

4 RXTCPEROIM	MMC Receive TCP Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_octets counter reaches half of the maximum value or the maximum value.
5 RXTCPGOIM	MMC Receive TCP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_octets counter reaches half of the maximum value or the maximum value.
6 RXUDPEROIM	MMC Receive UDP Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_octets counter reaches half of the maximum value or the maximum value.
7 RXUDPGOIM	MMC Receive IPV6 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_octets counter reaches half of the maximum value or the maximum value.
8 RXIPV6NOPAYOIM	MMC Receive IPV6 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_octets counter reaches half of the maximum value or the maximum value.

Table 916. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
9 RXIPV6HEROIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_octets counter reaches half of the maximum value or the maximum value.
10 RXIPV6GOIM	MMC Receive IPV6 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half of the maximum value or the maximum value.
11 RXIPV4UDSBLOIM	MMC Receive IPV4 UDP Checksum Disabled Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half of the maximum value or the maximum value.
12 RXIPV4FRAGOIM	MMC Receive IPV4 Fragmented Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half of the maximum value or the maximum value.
13 RXIPV4NOPAYOIM	MMC Receive IPV4 No Payload Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value.
14 RXIPV4HEROIM	MMC Receive IPV4 Header Error Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value.
15 RXIPV4GOIM	MMC Receive IPV4 Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value.
18 RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_pkts counter reaches half of the maximum value or the maximum value.
19 RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_pkts counter reaches half of the maximum value or the maximum value.
20 RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_pkts counter reaches half of the maximum value or the maximum value.
21 RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_pkts counter reaches half of the maximum value or the maximum value.
22 RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_pkts counter reaches half of the maximum value or the maximum value.
23 RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_pkts counter reaches half of the maximum value or the maximum value.
24 RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_pkts counter reaches half of the maximum value or the maximum value.

Table 916. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
25 RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
26 RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value.
27 RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value.
28 RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value.
29 RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value.
30 RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
31 RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value.

49.2.2.113 MMC IPC receive interrupt register (MMC_IPC_RX_INTERRUPT)

This register maintains the interrupt that the receive IPC statistic counters generate.

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

49.2.2.142 Layer 3 and Layer 4 control 0 register (MAC_L3_L4_CONTROL0)

The Layer 3 and Layer 4 control register controls the operations of filter 0 of Layer 3 and Layer 4.

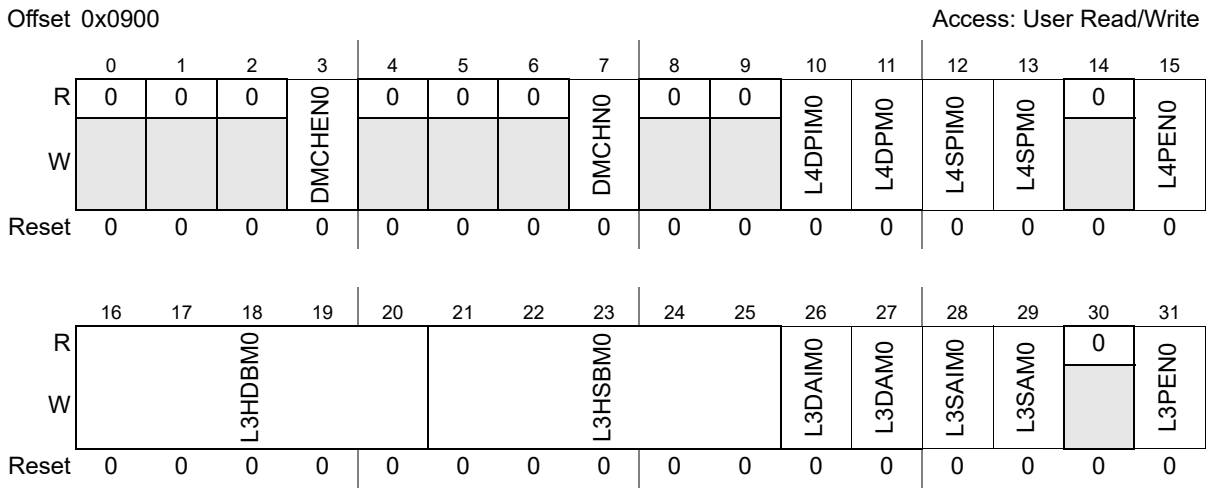

Figure 855. Layer 3 and Layer 4 control 0 register (MAC_L3_L4_CONTROL0)

Table 946. MAC_L3_L4_CONTROL0 field descriptions

Field	Description
3 DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter.
7 DMCHN0	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. 0 Packet is passed by this filter to DMA CH 0 1 Packet is passed by this filter to DMA CH 1
10 L4DPIM0	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high.
11 L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
12 L4SPIM0	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high.
13 L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
15 L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.

Table 946. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
16:20 L3HDBM0	Layer 3 IP DA Higher Bits Match **IPv4 Packets:** This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: 0x00: No bits are masked. 0x01: 1 LSb is masked 0x02: Two LSbs are masked ... 0x1F: All bits except MSb are masked. **IPv6 Packets:** Bits[29:30] of this field correspond to Bits[25:26] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[30:31] and L3HSBM0 bits: - 0x00: No bits are masked. - 0x01: 1 LSb is masked. - 0x02:Two LSbs are masked - ... - 0x7F: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
21:25 L3HSBM0	Layer 3 IP SA Higher Bits Match **IPv4 Packets:** This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: 0x00: No bits are masked. 0x01: 1 LSb is masked 0x02: Two LSbs are masked ... 0x1F: All bits except MSb are masked. **IPv6 Packets:** This field contains Bits[27:31] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
26 L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.
27 L3DAM0	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Table 946. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
28 L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
29 L3SAM0	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
31 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

49.2.2.143 Layer 4 address 0 register (MAC_LAYER4_ADDRESS0)

This register holds the TCP source and destination port numbers against which a match is performed.

Offset 0x0904 Access: User Read/Write

Figure 856. Layer4 address 0 register (MAC_LAYER4_ADDRESS0)

Table 947. MAC_LAYER4_ADDRESS0 field descriptions

Field	Description
0:15 L4DP0	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
16:31 L4SP0	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4SPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

49.2.2.144 Layer 3 address 0 register 0 register (MAC_LAYER3_ADDR0_REG0)

For IPv4 packets, the Layer 3 address 0 register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[96:127] of the 128-bit IP Source Address or Destination Address field.

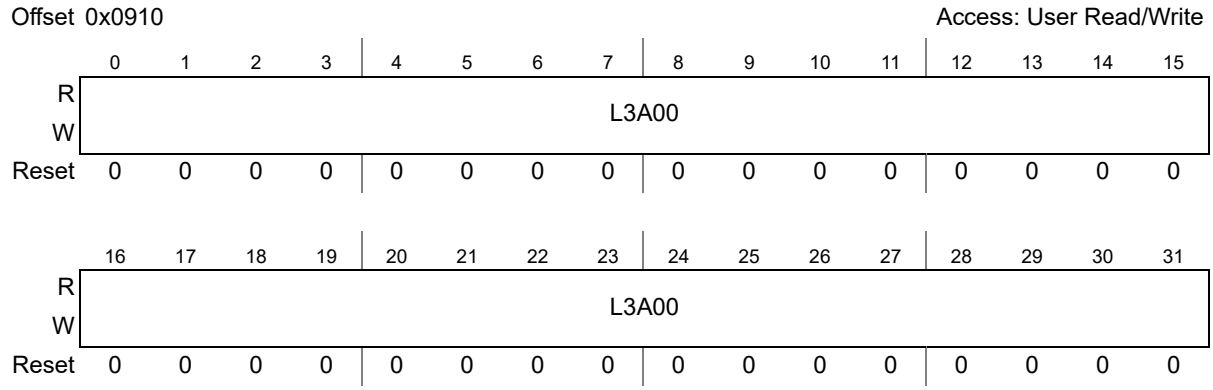

Figure 857. Layer 3 address 0 register 0 register (MAC_LAYER3_ADDR0_REG0)

Table 948. MAC_LAYER3_ADDR0_REG0 field descriptions

Field	Description
0:31 L3A00	Layer 3 Address 0 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

49.2.2.145 Layer3 address1 register 0 register (MAC_LAYER3_ADDR1_REG0)

For IPv4 packets, the Layer 3 address 1 register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[64:95] of the 128-bit IP Source Address or Destination Address field.

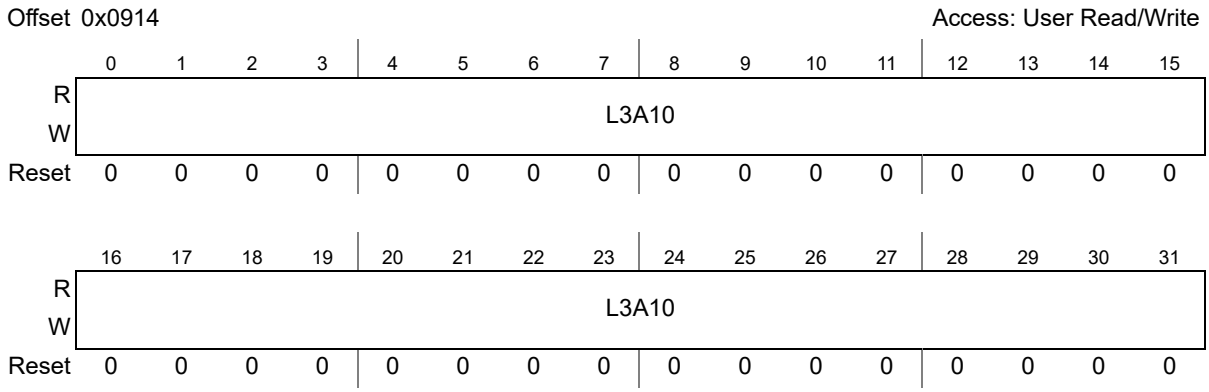

Figure 858. Layer3 address1 register 0 register (MAC_LAYER3_ADDR1_REG0)

Table 949. MAC_LAYER3_ADDR1_REG0 field descriptions

Field	Description
0:31 L3A10	Layer 3 Address 1 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[64:95] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[64:95] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

49.2.2.146 Layer3 address2 register 0 register (MAC_LAYER3_ADDR2_REG0)

The Layer 3 address 2 register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[32:63] of 128-bit IP Source Address or Destination Address field.

Offset 0x0918 Access: User Read/Write

Figure 859. Layer3 address2 register 0 register (MAC_LAYER3_ADDR2_REG0)

Table 950. MAC_LAYER3_ADDR2_REG0 field descriptions

Field	Description
0:31 L3A20	Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

49.2.2.147 Layer3 address3 register 0 register (MAC_LAYER3_ADDR3_REG0)

The Layer 3 address 3 register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[0:31] of 128-bit IP Source Address or Destination Address field.

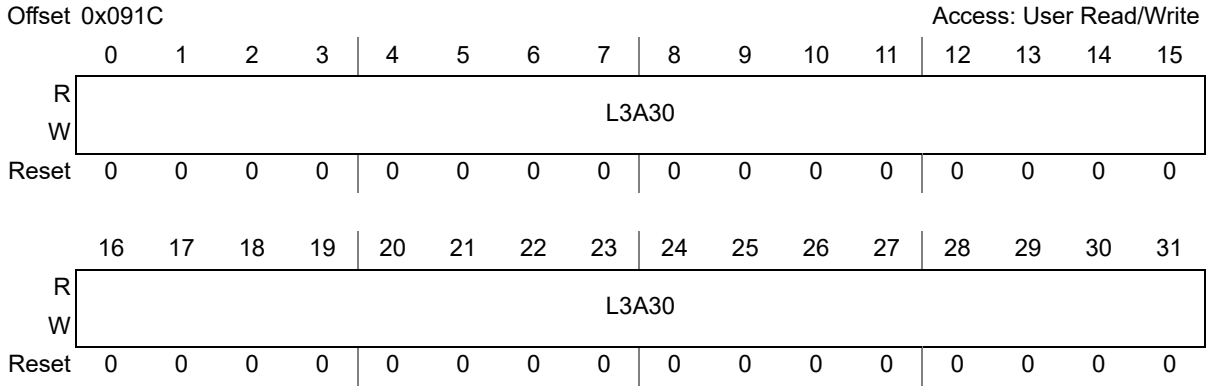

Figure 860. Layer3 Address3 Register 0 register (MAC_LAYER3_ADDR3_REG0)

Table 951. MAC_LAYER3_ADDR3_REG0 field descriptions

Field	Description
0:31 L3A30	Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

49.2.2.148 Timestamp control register (MAC_TIMESTAMP_CONTROL)

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Offset 0x0B00 Access: User Read/Write

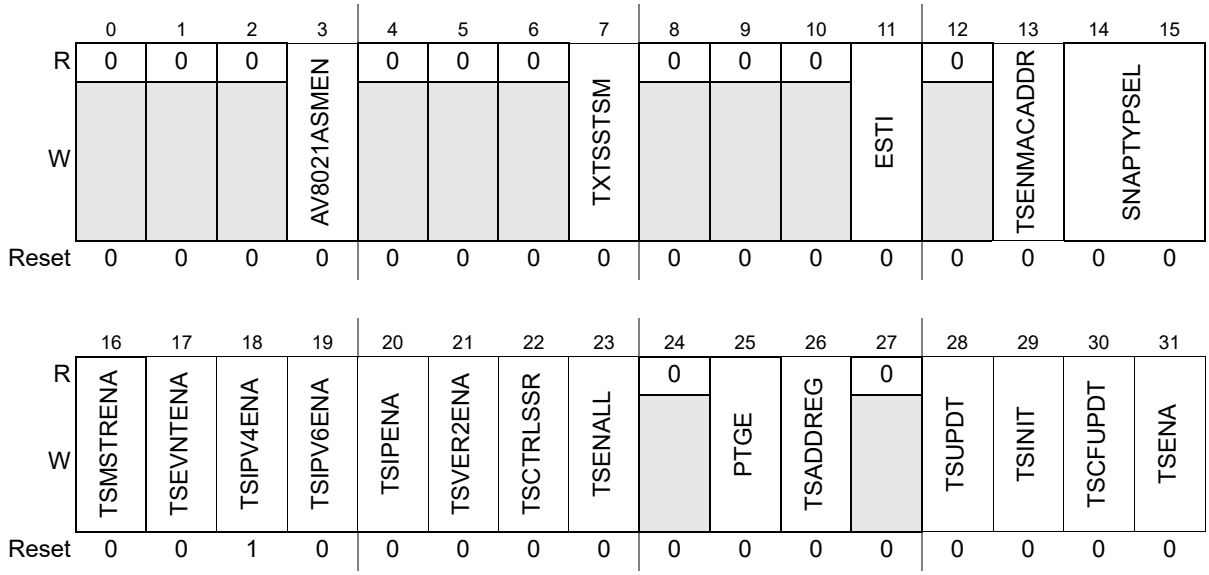

Figure 861. Timestamp control register (MAC_TIMESTAMP_CONTROL)

Table 952. MAC_TIMESTAMP_CONTROL field descriptions

Field	Description
3 AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation.
7 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the MAC_TxTimestamp_Status_Seconds register.
11 ESTI	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: – to take the timestamp provided as status – to insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled When this bit is reset, the MAC uses the internal reference System Time.

Table 952. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
13 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. MAC address registers 0 to 31 is considered for unicast destination address matching.
14:15 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 16 and 17, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
16 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.
17 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, refer to Timestamp Snapshot Dependency on Register Bits Table.
18 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.
19 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.
20 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
21 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.
22 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Table 952. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
23 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.
25 PTGE	Presentation Time Generation Enable When this bit is set the Presentation Time generation will be enabled.
26 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
28 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
29 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
30 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.
31 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set.

49.2.2.149 Sub second increment register (MAC_SUB_SECOND_INCREMENT)

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref clock.

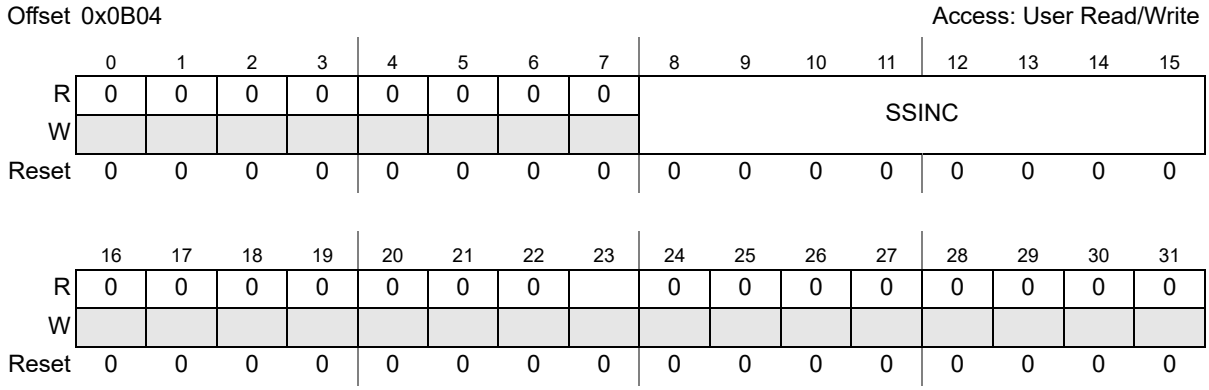

Figure 862. Sub second increment register (MAC_SUB_SECOND_INCREMENT)

Table 953. MAC_SUB_SECOND_INCREMENT field descriptions

Field	Description
8:15 SSINC	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 22 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

49.2.2.150 System time seconds register (MAC_SYSTEM_TIME_SECONDS)

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

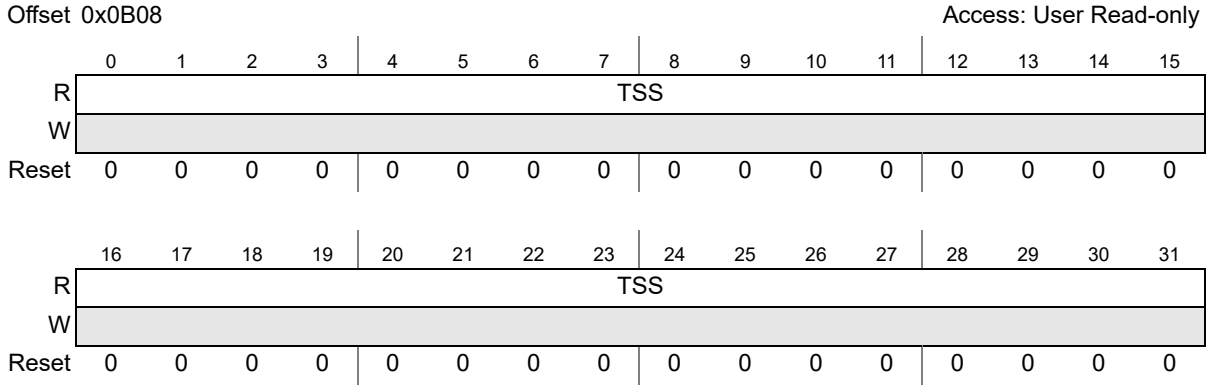

Figure 863. System time seconds register (MAC_SYSTEM_TIME_SECONDS)

Table 954. MAC_SYSTEM_TIME_SECONDS field descriptions

Field	Description
0:31 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

49.2.2.151 System time nanoseconds register (MAC_SYSTEM_TIME_NANOSECONDS)

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Offset 0x0B0C Access: User Read-only

Figure 864. System time nanoseconds register (MAC_SYSTEM_TIME_NANOSECONDS)

Table 955. MAC_SYSTEM_TIME_NANOSECONDS field descriptions

Field	Description
1:31 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 22 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

49.2.2.152 System time seconds update register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in MAC_Timestamp_Control.

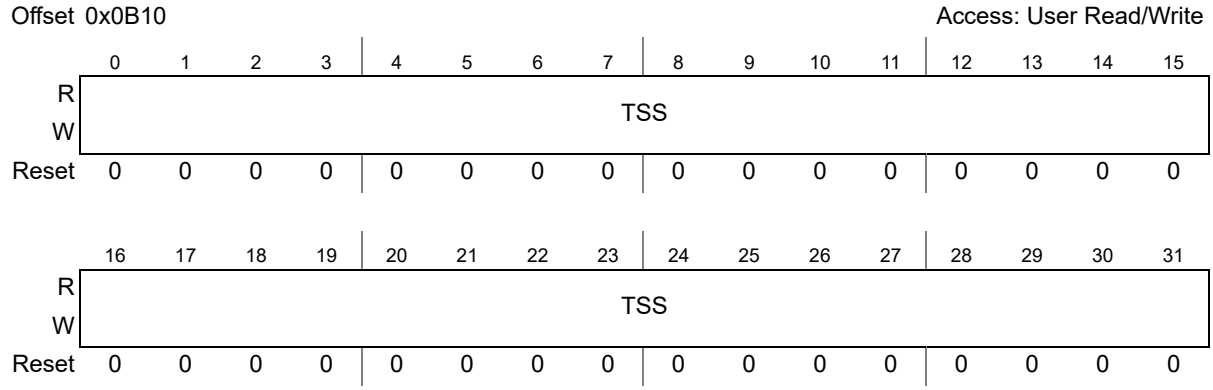

Figure 865. System time seconds update register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

Table 956. MAC_SYSTEM_TIME_SECONDS_UPDATE field descriptions

Field	Description
0:31 TSS	Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, then this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSS field in the MAC_Timestamp Seconds update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

49.2.2.153 System time nanoseconds update register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

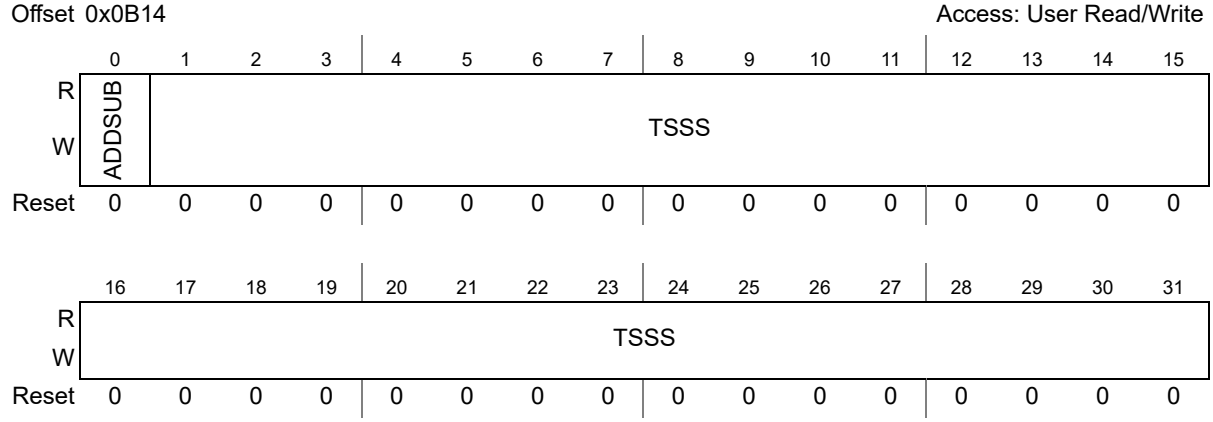

Figure 866. System time nanoseconds update register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

Table 957. MAC_SYSTEM_TIME_NANOSECONDS_UPDATE field descriptions

Field	Description
0 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.
1:31 TSSS	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_Timestamp_Control is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_Timestamp_Control is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

49.2.2.154 Timestamp addend register (MAC_TIMESTAMP_ADDEND)

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Figure 869. Timestamp status register (MAC_TIMESTAMP_STATUS)

Table 960. MAC_TIMESTAMP_STATUS field descriptions

Field	Description
2:6 ATSNS	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. value equal to 4 indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.
7 ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.
14:15 ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. Bit 15: Auxiliary trigger 0 Bit 14: Auxiliary trigger 1 The software can read this register to find the triggers that are set when the timestamp is taken. Access restriction applies. Clears on read. Self-set to 1 on internal event.
16 TXTSSIS	Tx Timestamp Status Interrupt Status When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set).

Table 960. MAC_TIMESTAMP_STATUS field descriptions (continued)

Field	Description
28 TSTRGTERR0	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
29 AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
30 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
31 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

49.2.2.157 Transmit timestamp status nanoseconds register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

This register contains the nanosecond part of timestamp captured for Transmit when Tx status is disabled.

The MAC_TxTimestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TxTimestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits [31:24] are read; in big-endian mode, bits [7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [16] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

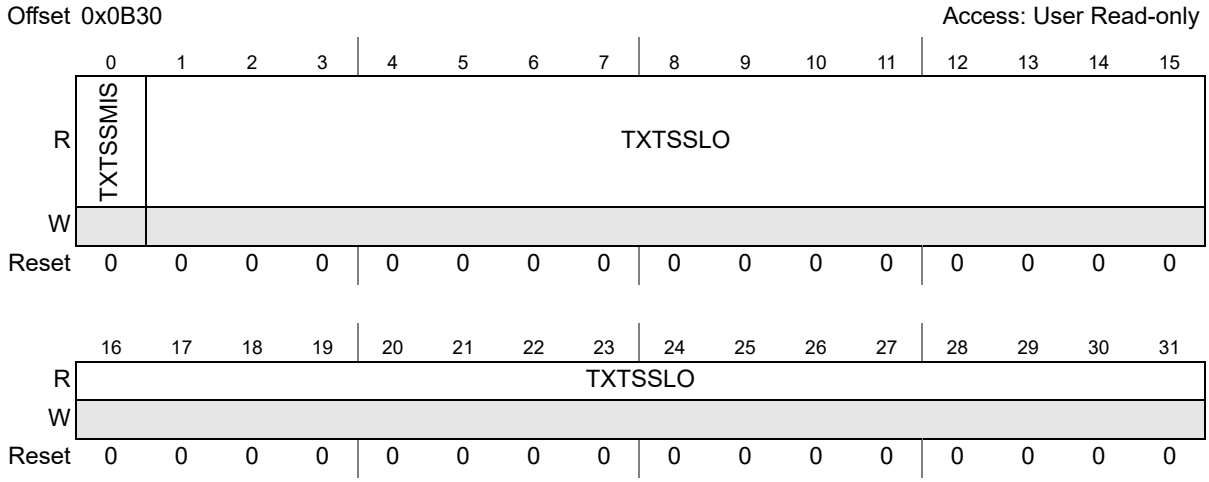

Figure 870. Transmit timestamp status nanoseconds register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

Table 961. MAC_TX_TIMESTAMP_STATUS_NANOSECONDS field descriptions

Field	Description
0 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event.
1:31 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

49.2.2.158 Transmit timestamp status seconds register (MAC_TX_TIMESTAMP_STATUS_SECONDS)

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

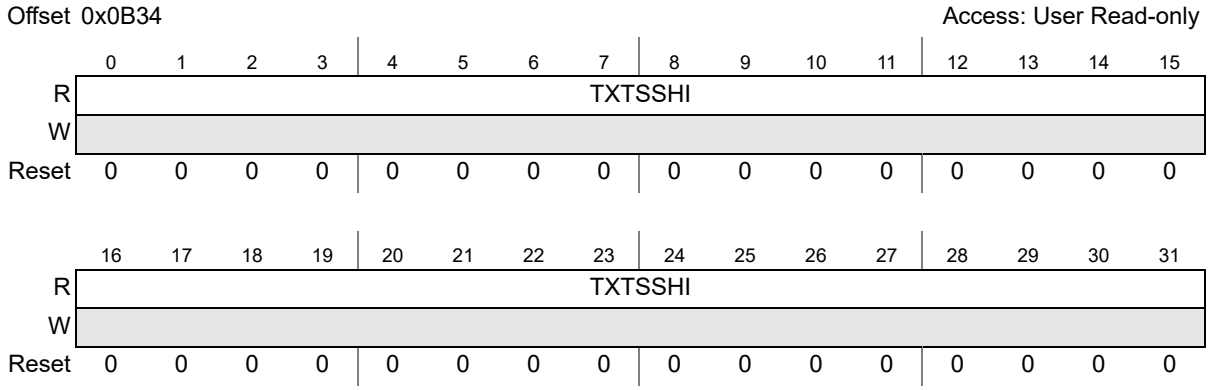

Figure 871. Transmit timestamp status seconds register (MAC_TX_TIMESTAMP_STATUS_SECONDS)

Table 962. MAC_TX_TIMESTAMP_STATUS_SECONDS field descriptions

Field	Description
0:31 TXTSSHI	Transmit Timestamp Status High This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

49.2.2.159 Auxiliary control register (MAC_AUXILIARY_CONTROL)

The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot.

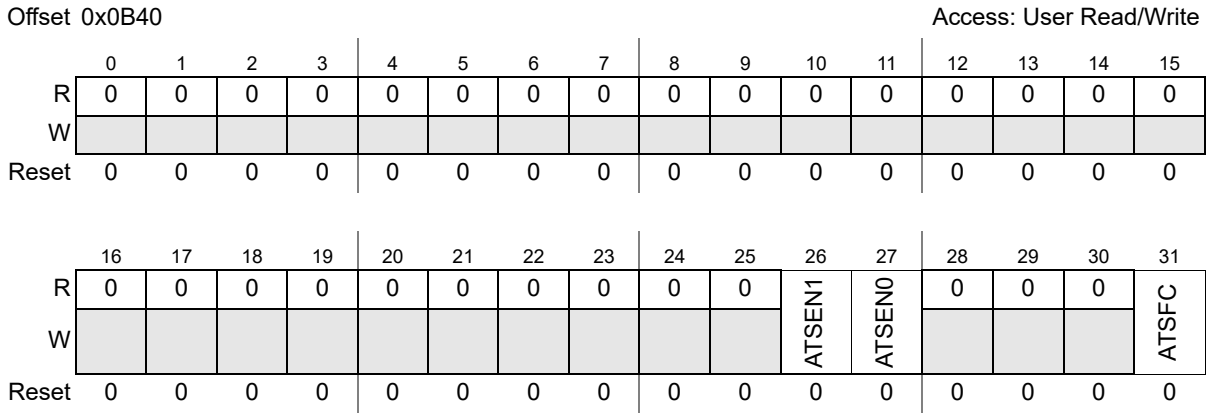

Figure 872. Auxiliary control register (MAC_AUXILIARY_CONTROL)

Table 963. MAC_AUXILIARY_CONTROL field descriptions

Field	Description
26 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored.
27 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored.
31 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.160 Auxiliary timestamp nanoseconds register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4.

You can store multiple snapshots in this FIFO. Bits[2:6] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

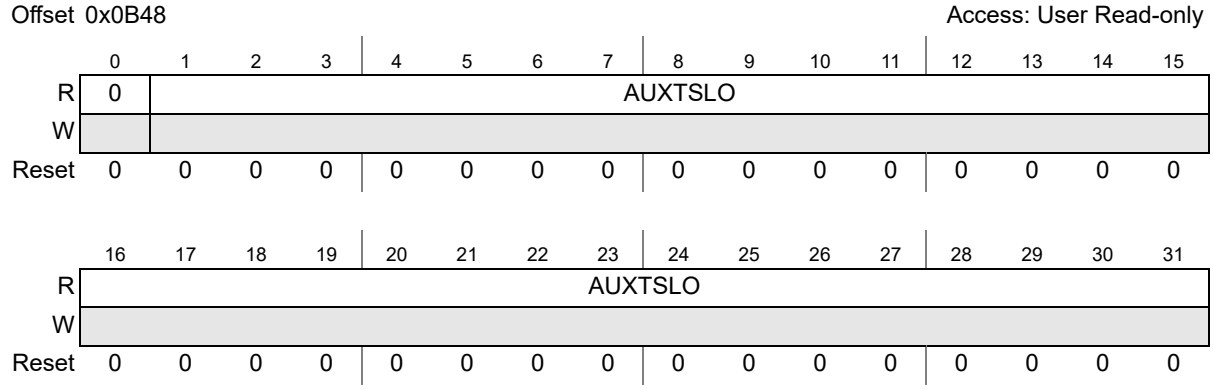

Figure 873. Auxiliary timestamp nanoseconds register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

Figure 875. Timestamp ingress asymmetry correction register (MAC_TIMESTAMP_INGRESS_ASYM_CORR)

Table 966. MAC_TIMESTAMP_INGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 0 representing the sign bit.

49.2.2.163 Timestamp egress asymmetry correction register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

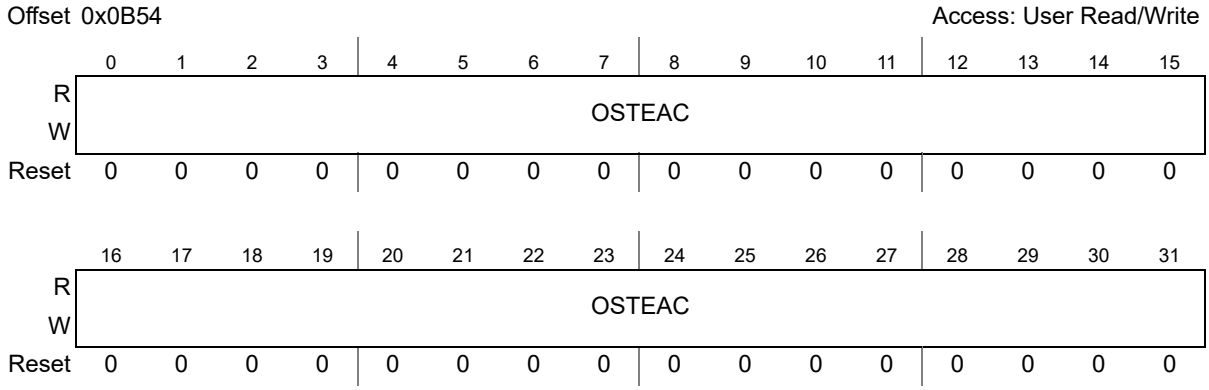

Figure 876. Timestamp egress asymmetry correction register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

Table 967. MAC_TIMESTAMP_EGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000 (2.5 × 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 × 216).

49.2.2.164 Timestamp ingress correction nanosecond register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

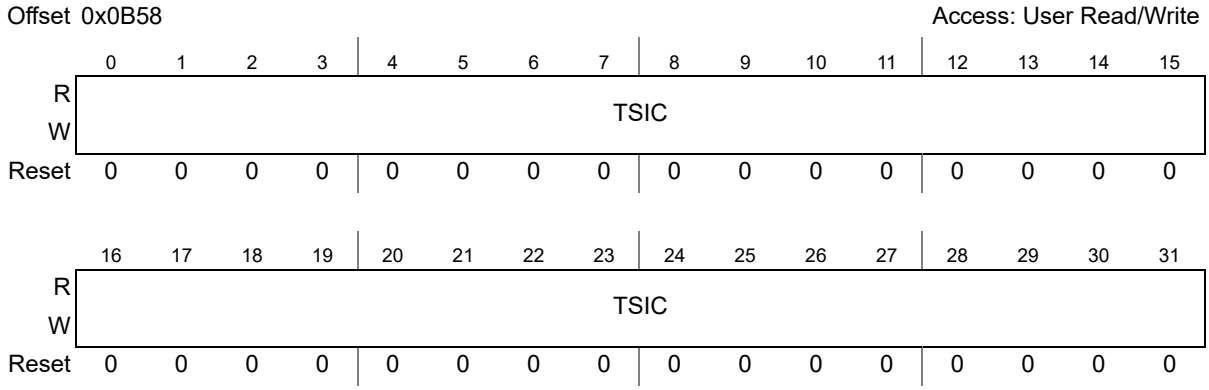

Figure 877. Timestamp ingress correction nanosecond register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

Table 968. MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND field descriptions

Field	Description
0:31 TSIC	Timestamp Ingress Correction This field contains the ingress path correction value as defined by the Ingress Correction expression.

49.2.2.165 Timestamp egress correction nanosecond register (MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

Figure 881. MAC PPS control register (MAC_PPS_CONTROL)

Table 972. MAC_PPS_CONTROL field descriptions

Field	Description
24 MCGREN0	MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0 0^{th} PPS instance is enabled to operate in PPS mode 1 0^{th} PPS instance is enabled to operate in MCGR mode
25:26 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS0 output signal: 00 Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01 Reserved 10 Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11 Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.

Table 972. MAC_PPS_CONTROL field descriptions (continued)

Field	Description
27 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[28:31] function as PPSCMD. When this bit is reset, Bits[28:31] function as PPSCTRL (Fixed PPS mode).
28:31 PPSCTRL_ PPSCMD	**PPS Output Frequency Control** This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 0001 The binary rollover is 2 Hz, and the digital rollover is 1 Hz 0010 The binary rollover is 4 Hz, and the digital rollover is 2 Hz 0011 The binary rollover is 8 Hz, and the digital rollover is 4 Hz 0100 The binary rollover is 16 Hz, and the digital rollover is 8 Hz ... 1111 The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz **Note:** In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second.(1) or **Flexible PPS Output (ptp_pps_o[0]) Control** Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: 0000 No Command 0001 START Single Pulse. This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. 0010 START Pulse Train. This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. 0011 Cancel START. This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. 0100 STOP Pulse train at time. This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. 0101 STOP Pulse Train immediately. This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). 0110 Cancel STOP Pulse train. This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. 0111–1111 Reserved Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

1. For example:
When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and 537 ms period. Second clock of 463 ms period (268 ms low and 195 ms high)
When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and 268 ms period. Fourth clock of 195 ms period (134 ms low and 61 ms high)
This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

49.2.2.169 MAC PPS0 target time seconds register (MAC_PPS0_TARGET_TIME_SECONDS)

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 30 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Figure 883. MAC PPS0 target time nanoseconds register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

Table 974. MAC_PPS0_TARGET_TIME_NANOSECONDS field descriptions

Field	Description
0 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.
1:31 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [25:26]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.171 MAC PPS0 interval register (MAC_PPS0_INTERVAL)

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B88 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	PPSINT0

Figure 884. MAC PPS0 interval register (MAC_PPS0_INTERVAL)

Table 975. MAC_PPS0_INTERVAL field descriptions

Field	Description
0:31 PPSINT0	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

49.2.2.172 MAC PPS0 width register (MAC_PPS0_WIDTH)

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B8C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 885. MAC PPS0 width register (MAC_PPS0_WIDTH)

Table 976. MAC_PPS0_WIDTH field descriptions

Field	Description
0:31 PPSWIDTH0	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. **Note:** The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

49.2.2.173 MTL operation mode register (MTL_OPERATION_MODE)

The Operation mode register establishes the Transmit and Receive operating modes and commands.

Offset 0x0C00 Access: User Read/Write

Figure 886. MTL operation mode register (MTL_OPERATION_MODE)

Table 977. MTL_OPERATION_MODE field descriptions

Field	Description
22 CNTCLR	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 Counters are not reset 1 All counters are reset
23 CNTPRST	Counters Preset When this bit is set: – MTL_TxQ[0-7]_Underflow register is initialized/preset to 12'h7F0. – Missed Packet and Overflow Packet counters in MTL_RxQ[0-7]_Missed_Packet_Overflow_Cnt register is initialized/preset to 12'h7F0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 Counters Preset is disabled 1 Counters Preset is enabled
25:26 SCHALG	Tx Scheduling Algorithm This field indicates the algorithm for Tx scheduling: 00 WRR algorithm 01 WFQ algorithm when DCB feature is selected 10 DWRR algorithm when DCB feature is selected 11 Strict priority algorithm
29 RAA	Receive Arbitration Algorithm This field is used to select the arbitration algorithm for the Rx side. 0 Strict priority (SP) Queue 0 has the lowest priority and the last queue has the highest priority. 1 Weighted Strict Priority (WSP)
30 DTXSTS	Drop Transmit Status When this bit is set, the Tx packet status received from the MAC is dropped in the MTL. When this bit is reset, the Tx packet status received from the MAC is forwarded to the application. 0 Drop Transmit Status is disabled 1 Drop Transmit Status is enabled

49.2.2.174 MTL debug access control register (MTL_DBG_CTL)

The FIFO Debug Access Control and Status register controls the operation mode of FIFO debug access.

Offset 0x0C08 Access: User Read/Write

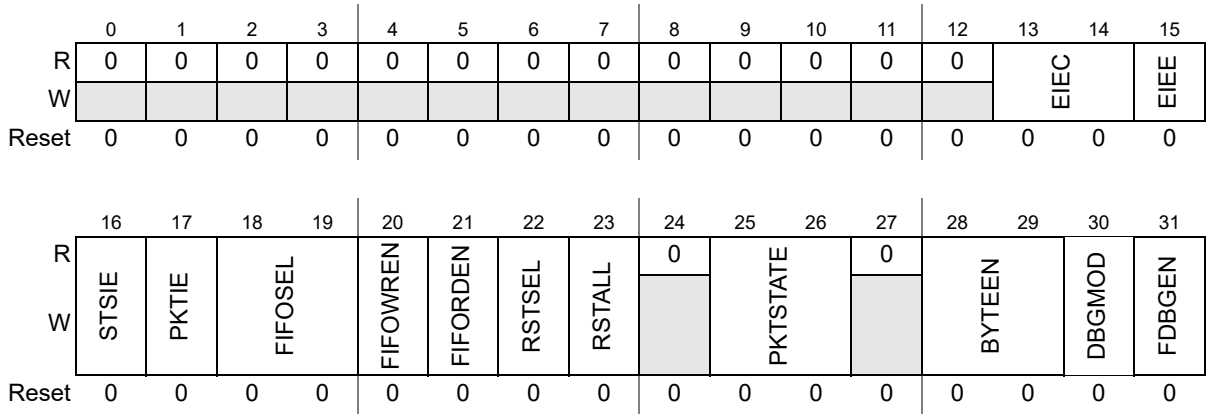

Figure 887. MTL debug access control register (MTL_DBG_CTL)

Table 978. MTL_DBG_CTL field descriptions

Field	Description
13:14 EIEC	ECC Inject Error Control for Tx, Rx and TSO memories When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. 00 Insert 1 bit error 01 Insert 2 bit errors 10 Insert 3 bit errors 11 Insert 1 bit error in address field
15 EIEE	ECC Inject Error Enable for Tx, Rx and TSO memories When set, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0 ECC Inject Error for Tx, Rx and TSO memories is disabled 1 ECC Inject Error for Tx, Rx and TSO memories is enabled
16 STSIE	Transmit Status Available Interrupt Status Enable When this bit is set, an interrupt is generated when Transmit status is available in slave mode. 0 Transmit Packet Available Interrupt Status is disabled 1 Packet Available Interrupt Status is enabled
17 PKTIE	Receive Packet Available Interrupt Status Enable When this bit is set, an interrupt is generated when EOP of received packet is written to the Rx FIFO. 0 Receive Packet Available Interrupt Status is disabled 1 Receive Packet Available Interrupt Status is enabled
18:19 FIFOSEL	FIFO Selected for Access This field indicates the FIFO selected for debug access: 00 Tx FIFO 01 Tx Status FIFO (only read access when SLVMOD is set) 10 TSO FIFO (cannot be accessed when SLVMOD is set) 11 Rx FIFO

Table 978. MTL_DBG_CTL field descriptions (continued)

Field	Description
20 FIFOWREN	FIFO Write Enable When this bit is set, it enables the Write operation on selected FIFO, when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 FIFO Write is disabled 1 FIFO Write is enabled
21 FIFORDEN	FIFO Read Enable When this bit is set, it enables the Read operation on selected FIFO, when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 FIFO Read is disabled 1 FIFO Read is enabled
22 RSTSEL	Reset Pointers of Selected FIFO When this bit is set, the pointers of the currently-selected FIFO are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 Reset Pointers of Selected FIFO is disabled 1 Reset Pointers of Selected FIFO is enabled
23 RSTALL	Reset All Pointers When this bit is set, the pointers of all FIFOs are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 Reset All Pointers is disabled 1 Reset All Pointers is enabled
25:26 PKTSTATE	Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO / Rx FIFO: 00 Tx Packet Data / Rx Packet Data 01 Tx Control Word / Rx Normal Status 10 Tx SOP Data / Rx Last Status 11 Tx EOP Data / Rx EOP
28:29 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid

Table 978. MTL_DBG_CTL field descriptions (continued)

Field	Description
30 DBGMOD	Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: – Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO – Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: – Write access to the Tx FIFO – Read access to the Rx FIFO and Tx Status FIFO 0 Debug Mode Access to FIFO is disabled 1 Debug Mode Access to FIFO is enabled
31 FDBGEN	FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface. 0 FIFO Debug Access is disabled 1 FIFO Debug Access is enabled

49.2.2.175 MTL debug status register (MTL_DBG_STS)

The FIFO Debug status register contains the status of FIFO debug access.

Offset 0x0C0C — Access: User Read/Write

Table 979. MTL_DBG_STS field descriptions

Field	Description
0:16 LOCR	Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively.
22 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit.
23 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit.
27:28 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid
29:30 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. This field is applicable only for Tx FIFO and Rx FIFO during Read operation. Tx FIFO / Rx FIFO: 00 Tx Packet Data / Rx Packet Data 01 Tx Control Word / Rx Normal Status 10 Tx SOP Data / Rx Last Status 11 Tx EOP Data / Rx EOP
31 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: All other fields of this register All fields of the MTL_FIFO_Debug_Data register

49.2.2.176 MTL FIFO debug data register (MTL_FIFO_DEBUG_DATA)

The FIFO debug data register contains the data to be written to or read from the FIFOs.

Field	Description
26 CUES	Clear Uncorrectable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the respective memory‘s uncorrectable error address and uncorrectable error count values will be cleared upon reading. Hardware resets this bit when all the error status values are cleared. 0 Clear Uncorrectable Error Status not detected 1 Clear Uncorrectable Error Status detected
27 CCES	Clear Correctable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the respective memory‘s correctable error address and correctable error count values will be cleared upon reading. Hardware resets this bit when all the error status values are cleared. 0 Clear Correctable Error Status not detected 1 Clear Correctable Error Status detected

Table 987. MTL_ECC_Err_Sts_Rctl field descriptions (continued)

Field	Description
28:30 EMS	MTL ECC Memory Selection When EESRE bit of this register is set, this field indicates which memory's error status value to be read. The memory selection encoding is as described below. 000 MTL Tx memory 001 MTL Rx memory 010 MTL EST memory 011 MTL Rx Parser memory 100 DMA TSO memory
31 EESRE	MTL ECC Error Status Read Enable When this bit is set, based on the EMS field of this register, the respective memory's error status values will be captured as described below: – The correctable and uncorrectable error count values will be captured into MTL_ECC_Err_Cnt_Status register – The address location's of correctable and uncorrectable errors will be captured into MTL_ECC_Err_Addr_Status register Hardware resets this bit when all the status values are captured into the MTL_ECC_Err_Cnt_Status and MTL_ECC_Err_Addr_Status registers. 0 MTL ECC Error Status Read is disabled 1 MTL ECC Error Status Read is enabled

49.2.2.184 MTL ECC Error Address Status register (MTL_ECC_ERR_ADDR_STATUS)

This register provides the memory addresses for the correctable and uncorrectable errors.

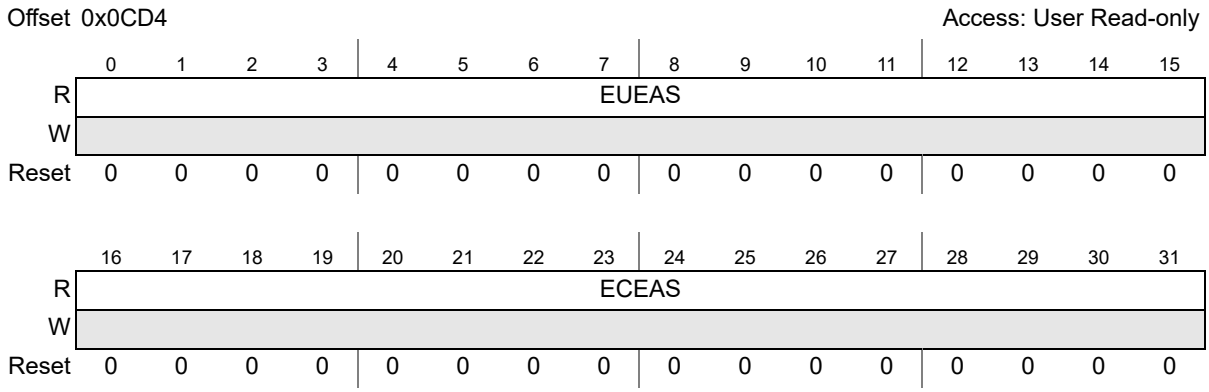

Figure 897. MTL ECC Error Address Status register (MTL_ECC_Err_Addr_Status)

Table 988. MTL_ECC_Err_Addr_Status field descriptions

Field	Description
0:15 EUEAS	MTL ECC Uncorrectable Error Address Status Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory‘s address locations for which an uncorrectable error or address mismatch is detected. When MEEAO bit of MTL_ECC_Control register is set, this field holds the last valid address of memory for which either an uncorrectable error or an address mismatch is detected. When MEEAO bit of MTL_ECC_Control register is reset, this field holds the first address of the memory for which either an uncorrectable error or address mismatch is detected.
16:31 ECEAS	MTL ECC Correctable Error Address Status Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory‘s address locations for which a correctable error is detected. When MEEAO bit of MTL_ECC_Control register is set, this field holds the last valid address of memory for which correctable error or address mismatch is detected. When MEEAO bit of MTL_ECC_Control register is reset, this field holds the first address of the memory for which correctable error is detected.

49.2.2.185 MTL ECC Error Counter Status register (MTL_ECC_ERR_CNTR_STATUS)

This register provides ECC error count for correctable and uncorrectable errors.

Figure 899. MTL Data Parity Protection Control register (MTL_DPP_CONTROL)

Table 990. MTL_DPP_Control field descriptions

Field	Description
20 IPERD	Insert Parity error in Rx write-back Descriptor parity generator When set to 1, parity bit of first valid data generated by the DMA Rx write-back descriptor parity generator (or at PG8 as shown in *Figure 980: Receive Datapath Parity Protection*) is flipped. 0 Insert Parity error in Rx write-back Descriptor parity generator is disabled 1 Insert Parity error in Rx write-back Descriptor parity generator is enabled
21 IPETD	Insert Parity error in Tx write-back Descriptor parity generator When set to 1, parity bit of first valid data generated by the DMA Tx write-back descriptor parity generator (or at PG4 as shown in *Figure 979: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. Values: 0 Insert Parity error in Tx write-back Descriptor parity generator is disabled 1 Insert Parity error in Tx write-back Descriptor parity generator is enabled
22 IPETSO	Insert Parity Error in DMA TSO parity generator When set to 1, parity bit of first valid data generated by the DMA TSO parity generator is (or at PG3 as shown in *Figure 979: Transmit Datapath Parity Protection*) flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in DMA TSO parity generator is disabled 1 Insert Parity Error in DMA TSO parity generator is enabled

Table 990. MTL_DPP_Control field descriptions (continued)

Field	Description
23 IPEDDC	Insert Parity Error in DMA DTX Control word parity generator When set to 1, parity bit of first valid data generated by the DMA DTX Control word parity generator (or at PG2 as shown in *Figure 979: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in DMA DTX Control word parity generator is disabled 1 Insert Parity Error in DMA DTX Control word parity generator is enabled
24 IPEMRF	Insert Parity Error in MTL Rx FIFO read control parity generator When set to 1, parity bit of first valid data generated by the MTL Rx FIFO read control parity generator (or at PG7 as shown in *Figure 980: Receive Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in MTL Rx FIFO read control parity generator is disabled 1 Insert Parity Error in MTL Rx FIFO read control parity generator is enabled
25 IPEMTS	Insert Parity Error in MTL Tx Status parity generator When set to 1, parity bit of first valid data generated by the MTL Tx Status parity generator (or at PG6 as shown in *Figure 979: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in MTL Tx Status parity generator is disabled 1 Insert Parity Error in MTL Tx Status parity generator is enabled
26 IPEMC	Insert Parity Error in MTL checksum parity generator When set to 1, parity bit of first valid data generated by the MTL checksum parity generator (or at PG5 as shown in *Figure 979: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once the respective parity bit is flipped. 0 Insert Parity Error in MTL checksum parity generator is disabled 1 Insert Parity Error in MTL checksum parity generator is enabled
27 IPEID	Insert Parity Error in Interface Data parity generator When set to 1, parity bit of first valid input data generated by the Interface data parity generator (or at PG1 as shown in *Figure 979: Transmit Datapath Parity Protection*) is flipped. Following is the input data bus on which parity bits are generated based on configuration selected: AHB hrdata_i Hardware will clear this bit once the respective parity bit is flipped. 0 Insert Parity Error in Interface Data parity generator is disabled 1 Insert Parity Error in Interface Data parity generator is enabled
29 EPSI	Enable Parity on Slave Interface port When set to 1, enables the parity check for the slave interface ports and disables the internal generation of parity for the input slave data port. When set to 0, disables the parity check for the slave interface ports and enables the internal parity generation for the input slave data port. 0 Parity on Slave Interface port is disabled 1 Parity on Slave Interface port is enabled

Table 990. MTL_DPP_Control field descriptions (continued)

Field	Description
30 OPE	Odd Parity Enable When set to 1, enables odd parity protection on all the external interfaces and when set to 0, enables even parity protection on all the external interfaces. 0 Odd Parity is disabled 1 Odd Parity is enabled
31 EDPP	Enable Data path Parity Protection When set to 1, enables the parity protection for EQOS datapath by generating and checking the parity on EQOS datapath. When set to 0, disables the parity protection for EQOS datapath. 0 Data path Parity Protection is disabled 1 Data path Parity Protection is enabled

49.2.2.187 MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)

The Queue 0 transmit operation mode register establishes the Transmit queue operating modes and commands.

Figure 900. Queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)

Table 991. MTL_TXQ0_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. A value of 0 indicates 256 bytes.
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 00 Not enabled 01 Reserved 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.188 MTL queue 0 underflow counter register (MTL_TXQ0_UNDERFLOW)

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 901. Queue 0 underflow counter register (MTL_TXQ0_UNDERFLOW)

Table 992. MTL_TXQ0_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

49.2.2.189 MTL queue 0 transmit debug register (MTL_TXQ0_DEBUG)

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 902. Queue 0 transmit debug register (MTL_TXQ0_DEBUG)

Table 993. MTL_TXQ0_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 993. MTL_TXQ0_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled. Reception of 802.3x Pause packet when PFC is disabled.

49.2.2.190 MTL queue 0 ETS status register (MTL_TXQ0_ETS_STATUS)

The Queue 0 ETS status register provides the average traffic transmitted in Queue 0.

Offset 0x0D14 Access: User Read-only

Figure 905. MTL interrupt control status register (MTL_Q0_INTERRUPT_CONTROL_STATUS)

Table 996. MTL_Q0_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[10]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

49.2.2.193 MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)

The Queue 0 receive operation mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 Access: User Read/Write

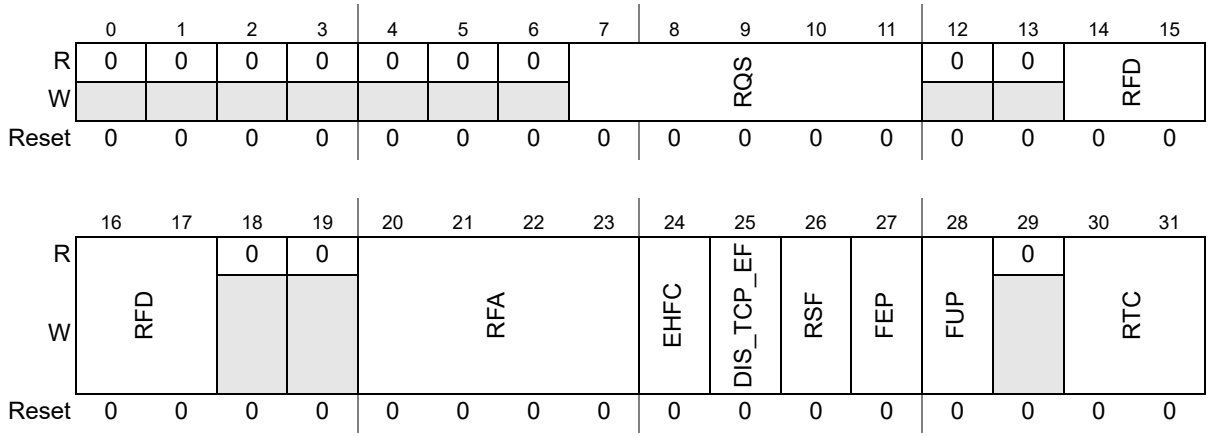

Figure 906. MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)

Table 997. MTL_RXQ0_OPERATION_MODE field descriptions

Field	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes.
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.

Table 997. MTL_RXQ0_OPERATION_MODE field descriptions (continued)

Field	Description
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

49.2.2.194 MTL RX Queue 0 missed packet and overflow counter register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

The Queue 0 missed packet and overflow counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

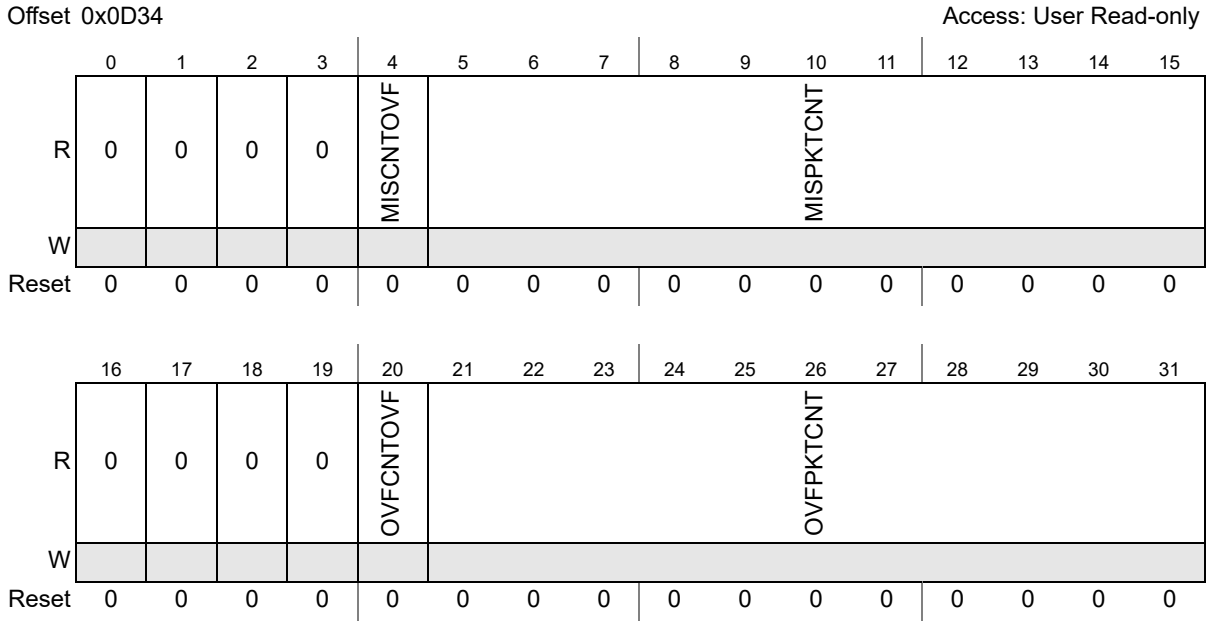

Figure 907. MTL RX Queue 0 missed packet and overflow counter register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

Table 998. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

49.2.2.195 MTL RX Queue 0 receive debug register (MTL_RXQ0_DEBUG)

The Queue 0 receive debug register gives the debug status of various blocks related to the Receive queue.

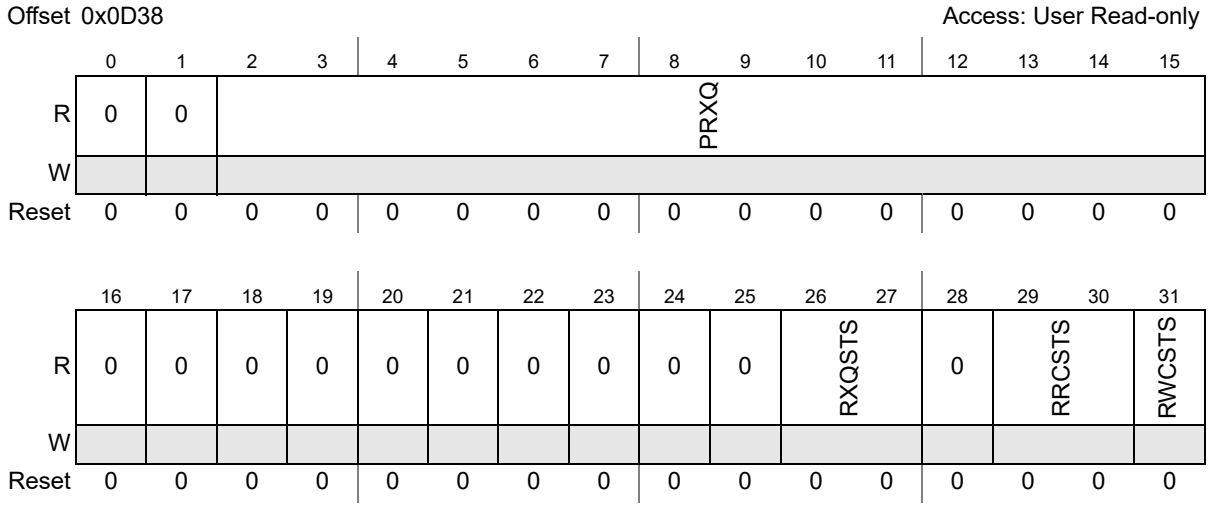

Figure 908. MTL RX Queue 0 receive debug register (MTL_RXQ0_DEBUG)

Table 999. MTL_RXQ0_DEBUG field descriptions

Field	Description
2:15 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
26:27 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00 Rx Queue empty 01 Rx Queue fill-level below flow-control deactivate threshold 10 Rx Queue fill-level above flow-control activate threshold 11 Rx Queue full
29:30 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00 Idle state 01 Reading packet data 10 Reading packet status (or timestamp) 11 Flushing the packet data and status
31 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.

49.2.2.196 MTL RX Queue receive control register (MTL_RXQ0_CONTROL)

The Queue receive control register controls the receive arbitration and passing of received packets to the application.

Offset 0x0D3C Access: User Read/Write

Figure 909. MTL RX Queue receive control register (MTL_RXQ0_CONTROL)

Table 1000. MTL_RXQ0_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL packet requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

49.2.2.197 MTL Transmit Q*n* operation mode register (MTL_TXQ*n*_OPERATION_MODE)

The Queue transmit operation mode register establishes the Transmit queue operating modes and commands.

Offset 0x0D00 + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 910. MTL Transmit Q*n* operation mode register (MTL_TXQ*n*_OPERATION_MODE)

Table 1001. MTL_TXQ*n*_OPERATION_MODE field descriptions

Field	Description
12:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes.
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue n. 00 Not enabled 01 Enable in AV mode 10 Enabled 11 Reserved

Table 1001. MTL_TXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.198 MTL Transmit Q*n* underflow register (MTL_TXQ*n*_UNDERFLOW)

The Queue underflow counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 + *n**0x40 (n = 1 to 1) Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 911. MTL Transmit Q*n* underflow register (MTL_TXQ*n*_UNDERFLOW)

Table 1002. MTL_TXQ*n*_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

49.2.2.199 MTL Transmit Q*n* debug register (MTL_TXQ*n*_DEBUG)

The Queue Transmit debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 + *n**0x40 (n = 1 to 1) Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 912. MTL Transmit Q debug register (MTL_TXQ*n*_DEBUG)

Table 1003. MTL_TXQ*n*_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

49.2.2.200 MTL Transmit Q*n* ETS control register (MTL_TXQ*n*_ETS_CONTROL)

The Queue ETS control register controls the enhanced transmission selection operation.

Offset 0x0D10 + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 913. MTL Transmit Q*n* ETS control register (MTL_TXQ*n*_ETS_CONTROL)

Table 1004. MTL_TXQ*n*_ETS_CONTROL field descriptions

Field	Description
25:27 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CHn_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQn_ETS_Status register, need to be computed for Queue. The encoding is as follows: 000 1 Slot 001 2 Slots 010 4 Slots 011 8 Slots 100 16 Slots 101 Reserved 110 Reserved 111 Reserved
28 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel n. The credit accumulates even when there is no packet waiting in Channel n and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel. When there is no packet waiting in Channel n and other channel is transmitting, no credit is accumulated.
29 AVALG	AV Algorithm When Queue *n* is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue *n* traffic. When reset, strict priority is selected.

49.2.2.201 MTL Transmit Q*n* ETS status register (MTL_TXQ*n*_ETS_STATUS)

The Queue 1 ETS status register provides the average traffic transmitted in Queue 1.

Offset 0x0D14 + *n**0x40 (n = 1 to 1) Access: User Read-only

Figure 914. MTL Transmit Q*n* ETS status register (MTL_TXQ*n*_ETS_STATUS)

Table 1005. MTL_TXQ*n*_ETS_STATUS field descriptions

Field	Description
8:31 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. For AV operation for Queue 1, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ*n*_ETS_CONTROL register. When Enable Slot Interval feature is selected, the maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps. Bits [8:14] are always read as zero.

49.2.2.202 MTL Transmit Q*n* quantum weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

The Queue idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Offset 0x0D18 + *n**0x40 (n = 1 to 1) Access: User Read/Write

Figure 915. MTL Transmit Q*n* quantum weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

Table 1006. MTL_TXQ*n*_QUANTUM_WEIGHT field descriptions

Field	Description
11:31 ISCQW	idleSlopeCredit, Quantum or Weights **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. **Weights** When enabled with WRR algorithm for Queue traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [11:24] must be written to zero.

49.2.2.203 MTL Transmit Q*n* send slope credit register (MTL_TXQ*n*_SENDSLOPECREDIT)

The SendSlopeCredit register contains the SendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D1C + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 916. MTL Transmit Q*n* send slope credit register (MTL_TXQ*n*_SENDSLOPECREDIT)

Table 1007. MTL_TXQ*n*_SENDSPLOPECREDIT field descriptions

Field	Description
18:31 SSC	SendSlopeCredit With AV operation enabled, this field contains the SendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is 0x1000 in 100 Mbps mode. This field should be programmed with absolute SendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel n is selected for transmission.

49.2.2.204 MTL Transmit Q*n* high credit register (MTL_TXQ*n*_HICREDIT)

The HiCredit register contains the HiCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D20 + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 917. MTL Transmit Q*n* high credit register (MTL_TXQ*n*_HICREDIT)

Table 1008. MTL_TXQ*n*_HICREDIT field descriptions

Field	Description
3:31 HC	HiCredit When the AV feature is enabled, this field contains the HiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16384 bytes or 131072 bits). The value to be specified is 131072 × 1024 = 134217728 or 0x0800_0000.

49.2.2.205 MTL Transmit Q*n* low credit register (MTL_TXQ*n*_LOCREDIT)

The LoCredit register contains the LoCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D24 + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 918. MTL Transmit Q*n* low credit register (MTL_TXQ*n*_LOCREDIT)

Table 1009. MTL_TXQ*n*_LOCREDIT field descriptions

Field	Description
3:31 LC	loCredit When AV operation is enabled, this field contains the LoCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value to be programmed corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then $(8192 \times 2) \times 8 \times 1024 = 134217728$ or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

49.2.2.206 MTL Q*n* interrupt control status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue interrupts.

Offset 0x0D2C + *n**0x40 (n = 1 to 1) Access: User Read/Write

Figure 919. MTL Q*n* interrupt control status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

Table 1010. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.

Table 1010. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions (continued)

Field	Description
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

49.2.2.207 MTL Receive Q*n* operation mode register (MTL_RXQ*n*_OPERATION_MODE)

The Queue receive operation mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 + *n**0x40 (n = 1 to 1) Access: User Read/Write

Figure 920. MTL Receive Q*n* operation mode register (MTL_RXQ*n*_OPERATION_MODE)

Table 1011. MTL_RXQ*n*_OPERATION_MODE field descriptions

Field	Description
7:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes.
14:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
20:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, refer to RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Table 1011. MTL_RXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_RX_ERR, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

49.2.2.208 MTL Receive Q*n* missed packet and overflow counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

The Queue Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

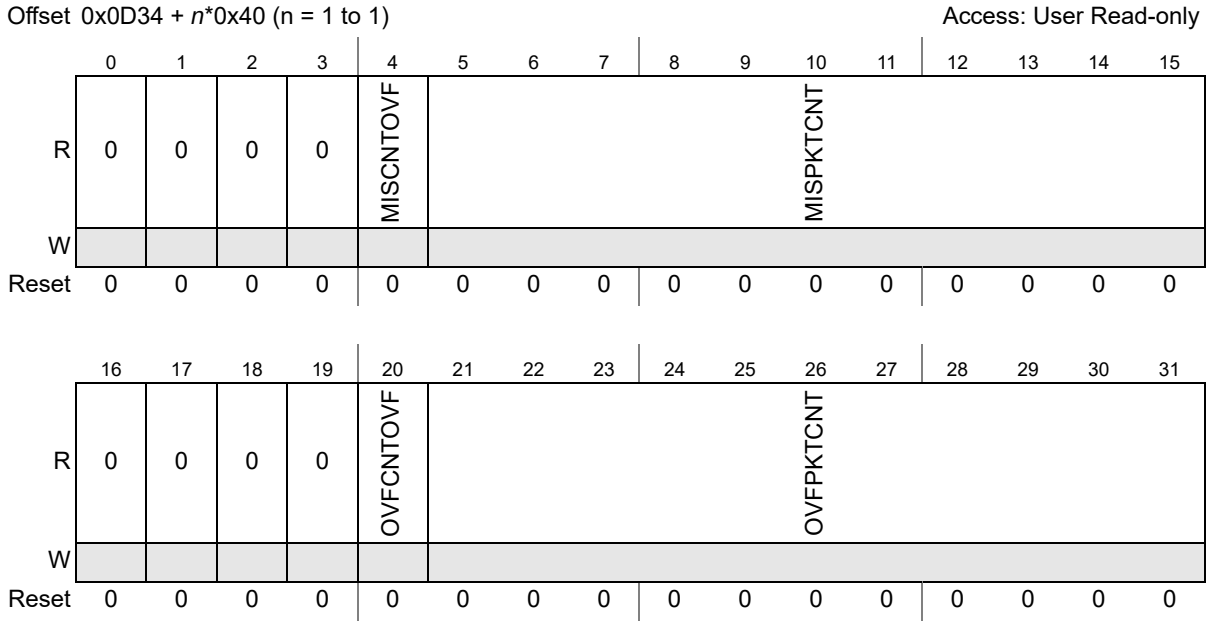

Figure 921. MTL Receive Q*n* missed packet and overflow counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

Table 1012. MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

49.2.2.209 MTL Receive Q*n* debug register (MTL_RXQ*n*_DEBUG)

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 + *n**0x40 (n = 1 to 1) Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 922. MTL Receive Q*n* debug register (MTL_RXQ*n*_DEBUG)

Table 1013. MTL_RXQ*n*_DEBUG field descriptions

Field	Description
2:15 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
26:27 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00 Rx Queue empty 01 Rx Queue fill-level below flow-control deactivate threshold 10 Rx Queue fill-level above flow-control activate threshold 11 Rx Queue full
29:30 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00 Idle state 01 Reading packet data 10 Reading packet status (or timestamp) 11 Flushing the packet data and status
31 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.

49.2.2.210 MTL Receive Q*n* control register (MTL_RXQ*n*_CONTROL)

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

Offset 0x0D3C + *n**0x40 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 923. MTL Receive Q*n* control register (MTL_RXQ*n*_CONTROL)

Table 1014. MTL_RXQ*n*_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL packet requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

49.2.2.211 DMA mode register (DMA_MODE)

The Bus mode register establishes the bus operating modes for the DMA.

Offset 0x1000 Access: User Read/Write

Figure 924. DMA mode register (DMA_MODE)

Table 1015. DMA_MODE field descriptions

Field	Description
14:15 INTM	Interrupt Mode This field defines the interrupt mode of the Ethernet module. The behavior of the following outputs changes depending on the following settings: – sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) – sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) – sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status. 00 sbd_perch_* are pulse signals for each completion events. sbd_intr_o is also asserted and cleared only when software clears the corresponding RI/TI status bits 01 sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these packet transfer completion events. 10 sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these packet transfer completion events. 11 Reserved
17:19 PR	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. 000 The priority ratio is 1:1 001 The priority ratio is 2:1 010 The priority ratio is 3:1 011 The priority ratio is 4:1 100 The priority ratio is 5:1 101 The priority ratio is 6:1 110 The priority ratio is 7:1 111 The priority ratio is 8:1
20 TXPR	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.

Table 1015. DMA_MODE field descriptions (continued)

Field	Description
27:29 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000 Fixed priority In fixed priority, Channel 0 has the lowest priority and the last channel has the highest priority. 001 Weighted Strict Priority (WSP) 010 Weighted Round-Robin (WRR) 011 Reserved ... 111 Reserved
30 DA	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: 0 Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[17:19] and the priority weight is specified in the TXPR bit. 1 Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.
31 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all Ethernet module clock domains. Before reprogramming any Ethernet module register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. **Note:** The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

49.2.2.212 DMA system bus mode register (DMA_SYSBUS_MODE)

The System Bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

Offset 0x1004 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 925. DMA system bus mode register (DMA_SYSBUS_MODE)

Table 1016. DMA_SYSBUS_MODE field descriptions

Field	Description
16 RB	Rebuild INCRx Burst When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.
17 MB	Mixed Burst When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).
19 AAL	Address-Aligned Beats When this bit is set to 1, AHB master performs address-aligned burst transfers on Read and Write channels.
31 FB	Fixed Burst Length When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE). When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.

49.2.2.213 DMA interrupt status register (DMA_INTERRUPT_STATUS)

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Figure 930. DMA channel 0 control register (DMA_CH0_CONTROL)

Table 1021. DMA_CH0_CONTROL field descriptions

Field	Description
7 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload.
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[10:15] in DMA_CH0_Tx_Control and Bits[10:15] in DMA_CH0_Rx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.
18:31 MSS	Maximum Segment Size This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of DMA_CH0_Tx_Control register is set. The value programmed in this field must be greater than the configured data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

49.2.2.218 DMA channel *n* control register (DMA_CH*n*_CONTROL)

The DMA Channel *n* Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Offset 0x1100 + *n**0x80 (n = 1 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 931. DMA channel *n* control register (DMA_CH*n*_CONTROL)

Table 1022. DMA_CH*n*_CONTROL field descriptions

Field	Description
7 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload.
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[10:15] in DMA_CH0_Tx_Control and Bits[10:15] in DMA_CH0_Rx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

49.2.2.219 DMA channel *n* transmit control register (DMA_CH*n*_TX_CONTROL)

The DMA Channel Transmit Control register controls the Tx features such as PBL, and Tx Channel weights.

Offset 0x1104 + *n**0x80 (n = 0 to 1) Access: User Read/Write

Figure 932. DMA channel *n* transmit control register (DMA_CH*n*_TX_CONTROL)

Table 1023. DMA_CH*n*_TX_CONTROL field descriptions

Field	Description
3 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel will use Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes.
10:15 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in DMA_CH0_Control register. – Set the TxPBL. **Note:** The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, the total locations in Tx Queue of size 512 bytes is 64, TxPBL and PBLx8 needs to be programmed to less than or equal to 32.
19 TSE	TCP Segmentation Enabled When this bit is set, the DMA performs the TCP segmentation or UDP Segmentation/Fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/Fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than 4.
27 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Table 1023. DMA_CH*n*_TX_CONTROL field descriptions (continued)

Field	Description
28:30 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
31 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: – The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. – The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.

49.2.2.220 DMA channel *n* receive control register (DMA_CH*n*_RX_CONTROL)

The DMA Channel *n* Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Figure 933. DMA channel *n* receive control register (DMA_CH*n*_RX_CONTROL)

Table 1024. DMA_CH*n*_RX_CONTROL field descriptions

Field	Description
0 RPF	Rx Packet Flush When this bit is set to 1, then Ethernet module automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the Ethernet module will not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue.
10:15 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the PBLx8 mode in the DMA_CH0_Control register. 2. Set the RxPBL. **Note:** The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
17:27 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 K bytes. The buffer size is applicable to payload buffers when split headers are enabled. **Note:** The buffer size must be a multiple of 8 (64-bit AHB bus). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).

Table 1024. DMA_CH*n*_RX_CONTROL field descriptions (continued)

Field	Description
28:30 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration.
31 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

49.2.2.221 DMA channel *n* transmit descriptor list address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

The Channel *n* Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Figure 934. DMA channel *n* transmit descriptor list address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

Table 1025. DMA_CH*n*_TXDESC_LIST_ADDRESS field descriptions

Field	Description
0:28 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the 3 LSB bits for 64-bit data bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

49.2.2.222 DMA channel *n* receive descriptor list address register (DMA_CH*n*_RXDESC_LIST_ADDRESS)

The Channel*n* Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Figure 940. DMA channel *n* interrupt enable register (DMA_CH*n*_INTERRUPT_ENABLE)

Table 1031. DMA_CH*n*_INTERRUPT_ENABLE field descriptions

Field	Description
16 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 31: Transmit Interrupt – Bit 29: Transmit Buffer Unavailable – Bit 25: Receive Interrupt – Bit 20: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled.
17 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 30: Transmit Process Stopped – Bit 24: Rx Buffer Unavailable – Bit 23: Receive Process Stopped – Bit 22: Receive Watchdog Timeout – Bit 21: Early Transmit Interrupt – Bit 19: Fatal Bus Error – Bit 18: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled.
18 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled.
19 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.
20 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.
21 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.
22 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.
23 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.
24 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.
25 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Table 1031. DMA_CH*n*_INTERRUPT_ENABLE field descriptions (continued)

Field	Description
29 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.
30 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.
31 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.

49.2.2.228 DMA channel *n* receive interrupt watchdog timer register (DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER)

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHn_STATUS register.

Offset 0x1138 + *n**0x80 (n = 0 to 1) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 941. DMA channel *n* receive interrupt watchdog timer register (DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER)

Table 1032. DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER field descriptions

Field	Description
14:15 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. 00 256 01 512 10 1024 11 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2x512=1024 system clock cycles.
24:31 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[1]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[1] of any received packet.

49.2.2.229 DMA channel *n* slot function control status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset 0x113C + *n**0x80 (n = 0 to 1) Access: User Read/Write

Figure 942. DMA channel *n* slot function control status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

Table 1033. DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS field descriptions

Field	Description
12:15 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
16:27 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default/reset value is 0x07C which corresponds to slot interval of 125 us.
30 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is – equal to the reference slot number given in the RSN field or – ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set.
31 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is – equal to the reference slot number or – ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. **Note:** The TSO should not be enabled along with TBS/AVB Slot number check. The TSO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for the software to specify a slot number for subsequent packets.

49.2.2.230 DMA channel *n* current application transmit descriptor register (DMA_CH*n*_CURRENT_APP_TXDESC)

The Channel*n* Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Field	Description
10:12 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 10 1'b1: Error during data transfer by Rx DMA 1'b0: No Error during data transfer by Rx DMA Bit 11 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 12 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
13:15 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 13 1'b1: Error during data transfer by Tx DMA 1'b0: No Error during data transfer by Tx DMA Bit 14 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 15 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
16 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 31: Transmit Interrupt Bit 29: Transmit Buffer Unavailable Bit 25: Receive Interrupt Bit 20: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1038. DMA_CHn_STATUS field descriptions (continued)

Field	Description
17 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 30: Transmit Process Stopped Bit 24: Receive Buffer Unavailable Bit 23: Receive Process Stopped Bit 21: Early Transmit Interrupt Bit 19: Fatal Bus Error Bit 18: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
18 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
19 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
20 ERI	Early Receive Interrupt This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
21 ETI	Early Transmit Interrupt This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2048 bytes (10240 bytes when Jumbo Packet mode is enabled) is received.
23 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1038. DMA_CHn_STATUS field descriptions (continued)

Field	Description
24 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
25 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 0 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
29 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 0 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
30 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 0 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

49.2.2.235 DMA channel *n* miss frame counter register (DMA_CH*n*_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in DMA_CH*n*_Rx_Control register.

Offset 0x1164 + *n**0x80 (n = 0 to 1) Access: User Read-only

Field	Description
20:31 ECNT	ERI Counter When ERIC bit of DMA_CH(#i)_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter will get reset at the start of new packet.

49.3 Functional description

49.3.1 AHB master interface

The DMA controller interfaces with the application through the AMBA AHB interface. The AHB master interface converts the internal DMA request cycles into AHB cycles. The AHB master interface has the following features:

- The AHB master interface is AMBA 2.0-compliant AHB master with no restrictions.
- The AHB master interface supports the following burst length modes: fixed, unspecified, and mixed. These modes are explained in *Section 49.3.1.1: AHB burst length modes*.
- The AHB master interface can handle the AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response halts all further transactions for that DMA and indicates the error as fatal through CSR and interrupt. The application can choose to give a hard or soft reset to the module to restart the operation.
- The AHB master interface can handle the AHB 1 K boundary breaking.
- The AHB master interface can handle all 64-bit data transfers except for Descriptor Status Write accesses (which may be 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.
- The AHB master interface can align all AHB burst transfers to an address value. For more information, refer to *Section 49.3.1.2: Aligning AHB burst transfers to an address value*.
- The DMA requests an AHB Burst Read transfer only when it can completely accept the received burst data. The data read from the AHB is always pushed into the DMA without any delay or Busy cycles. However, when multiple channels are selected, there may be some delay and busy cycles may be inserted because of the shared-memory architecture for the channels.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to completely transfer the burst. The AHB interface always assumes that it has the data available to push into the AHB bus. However, the DMA can prematurely indicate end-of-valid data (because of the transfer of EOP of an Ethernet packet) during the burst.
- In Fixed Burst Length mode, the AHB master interface continues the burst with dummy data until the specified length is completed. In INCR mode, it ends the burst transfer prematurely.

49.3.1.1 AHB burst length modes

The AHB master interface supports the following burst length modes:

- Fixed Burst Length: In fixed burst length mode, the AHB master always initiates a burst with SINGLE, INCR4, INCR8, or INCR16 type. However, when such a burst is responded with SPLIT, RETRY, or Early Burst Termination (EBT), by default, the AHB master again initiates the pending transfers of the burst with INCR or SINGLE burst length type. When only one beat is remaining, the AHB master performs a SINGLE transfer. If more than one beat is remaining, the AHB master performs an INCR transfer. The AHB master terminates such INCR bursts when remaining beats of the original requested fixed burst are transferred.
  To ensure that the AHB master always performs the INCRx and SINGLE transfers even when a part of the burst is initiated again after a SPLIT, RETRY, or EBT response, use the RIB bit of the register. However, when you enable this mode, the pending burst may further get split into multiple transfers as per the following rules before any new transfer is initiated:
  - If the DMA requests a burst transfer that is not equal to INCR4, INCR8, or INCR16, the AHB application interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4, and three SINGLE transactions.
  - If the burst length is more than 16, the AHB master interface splits it into multiple burst transfers. For example, if the burst length is 32 and the DMA starts a 32-beat transfer, the AHB master splits the burst into two INCR16.
- Unspecified Burst Length: In unspecified burst mode, the AHB master always initiates a transfer with INCR and completes the DMA requested burst in one transfer.
- Mixed Burst Mode: In mixed burst mode, the AHB master always initiates the bursts with fixed-size (INCRx) when the DMA requests transfers of size less than or equal to 16 beats. When the DMA requests bursts of length more than 16, the AHB master initiates such transfers with INCR and completes the request in one transfer.

To ensure that the pending burst of a transfer is rebuilt only with INCRx transfers when an INCRx transfer is interrupted by RETRY, SPLIT, or EBT response, use the RB bit of the DMA_SysBus_Mode register. However, if an INCR burst initiated in this mode is interrupted, the AHB master rebuilds the burst only with INCR transfers.

You can choose the burst modes by programming the FB bit in the DMA_SysBus_Mode register.

Note: The AHB master does not generate the WRAP bursts.

The AHB master does not generate the locked or protected transfers. Therefore, the Ethernet IP does not have the HLOCK or HPROT output signals.

49.3.1.2 Aligning AHB burst transfers to an address value

The AHB master interface can align all AHB burst transfers to an address value. You can enable this by using the AAL bit in the DMA_SysBus_Mode register. If Bit 31 and Bit 19 of DMA_SysBus_Mode register are set to 1, the AHB interface and the DMA ensure that all initiated beats are aligned to the address, completing the packet transfer in the minimum number of required beats.

The AHB interface and the DMA split unaligned address beats for a 64-bit data bus and initiate INCR16 beats only when the seven least-significant bits of the address have a zero value.

49.3.2 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The DMA supports up to 2 Tx and 2 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. You can control the offset by the DSL field of DMA_CH*n*_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The Ethernet IP supports the ring structure for the DMA descriptor. For more information on the descriptor, refer to *Section 49.3: Functional description* describes the descriptor structure and how the DMA accesses the descriptors.

49.3.2.1 Application bus burst access

When configured through Bit 31 of the DMA_SysBus_Mode register, the DMA attempts to execute the fixed-length burst transfers on the AHB master interface. The PBL field of Transmit Control and Receive Control registers of respective DMA channel indicates and limits the maximum burst length. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 $\times$ 8/bus width) burst length for 16 bytes to be read.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL × bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burs.
- EOP (when it is less than the configured burst length) is detected in the Rx Queue.

The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB Interface is configured for fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the AHB interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise [Bit 31 of DMA_SysBus_Mode register is reset], the DMA transfers the data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AHB is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16) for AHB interface because it does not support more than INCR16.

49.3.2.1.1 Application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 1041. Application data buffer alignment examples

Data buffer	Examples
Buffer Read	If the Tx buffer address is 32’h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32’h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32’h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32’h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

49.3.2.1.2 Buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FS bit of TDES2 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LS bit of TDES2), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FS bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits[17:30] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (FL bits of RDES3[17:31]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

Note: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to have a 0x1002 offset. The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programmed as 1024 bytes, because of the start address offset.

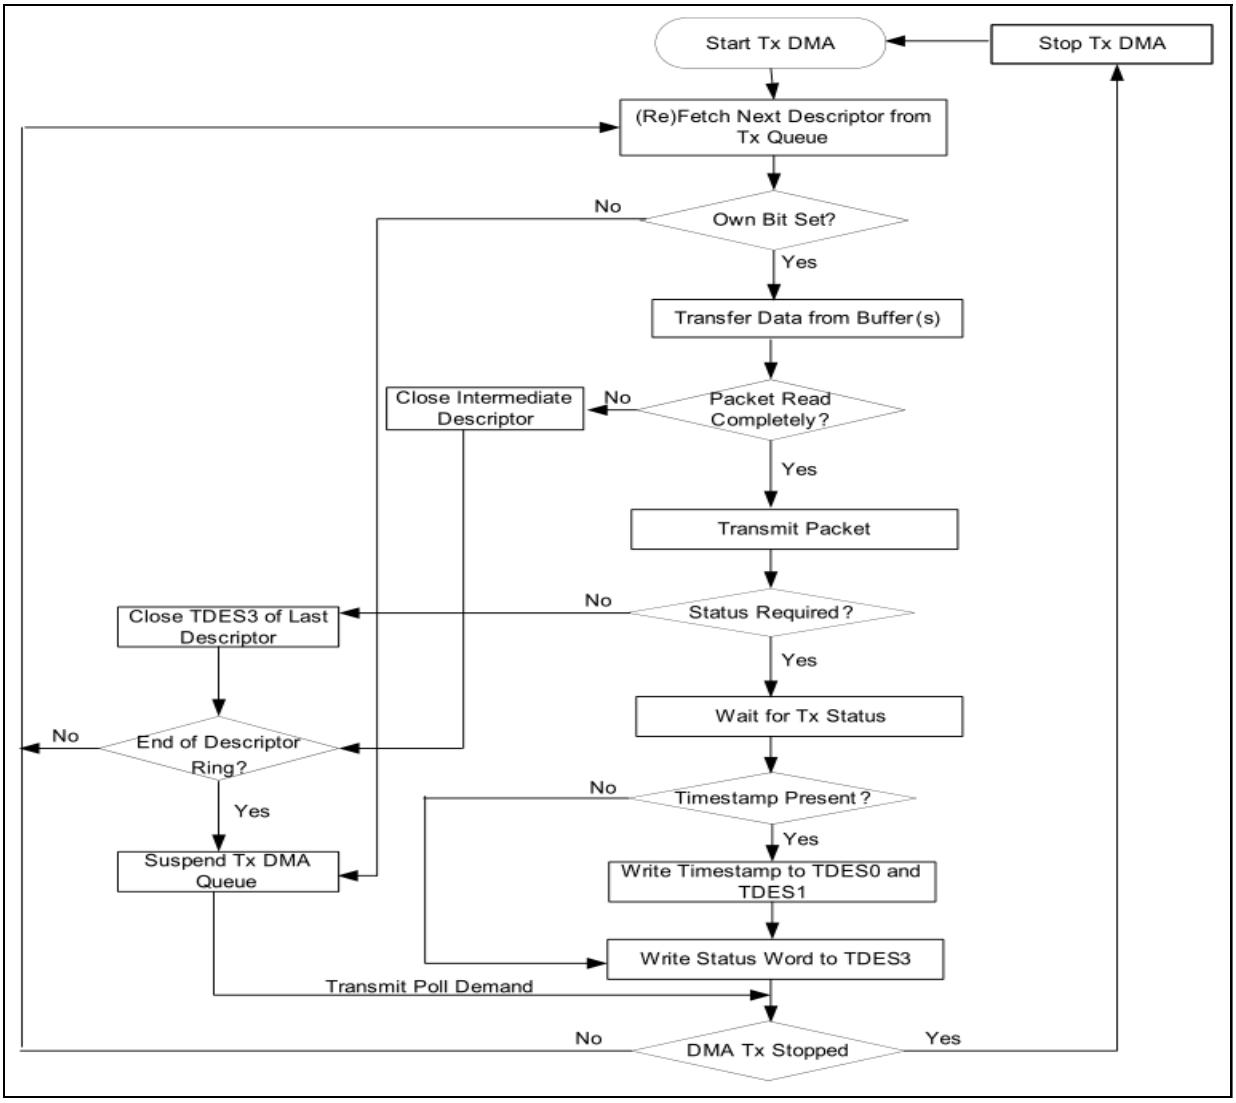
49.3.2.1.3 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface. The following two types of arbitrations are supported:

- Round-Robin Arbitration: When Bit 30 of the DMA_Mode register is reset and both Tx and Rx DMAs are simultaneously requesting for access, the arbiter allocates the data bus in ratio set by Bits[17:19] of DMA_Mode register
- Fixed-Priority Arbitration: When Bit 30 of the DMA_Mode register is set, the Rx DMA always gets priority over the Tx DMA for data access by default. When Bit 20 of DMA_Mode register is also set, the Tx DMA gets priority over the Rx DMA

49.3.2.2 DMA transmission

49.3.2.2.1 TX DMA operation: default (non-OSP) mode



The TX DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[0]) after setting up the corresponding data buffer(s) with Ethernet Packet data
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed

4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and Bit 29 and Bit 15 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to Step *11*:
   a) The descriptor is flagged as owned by the application (TDES3 [0] = 1'b0)
   b) The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   c) An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[0] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Step *3* through Step *7* are repeated until the end-of-Ethernet-packet data is transferred to the MTL
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.
   If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1
10. Bit 31 of Status Register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[0]) set in its Last Descriptor. The DMA engine returns to Step *3*
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to Step *3*). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state

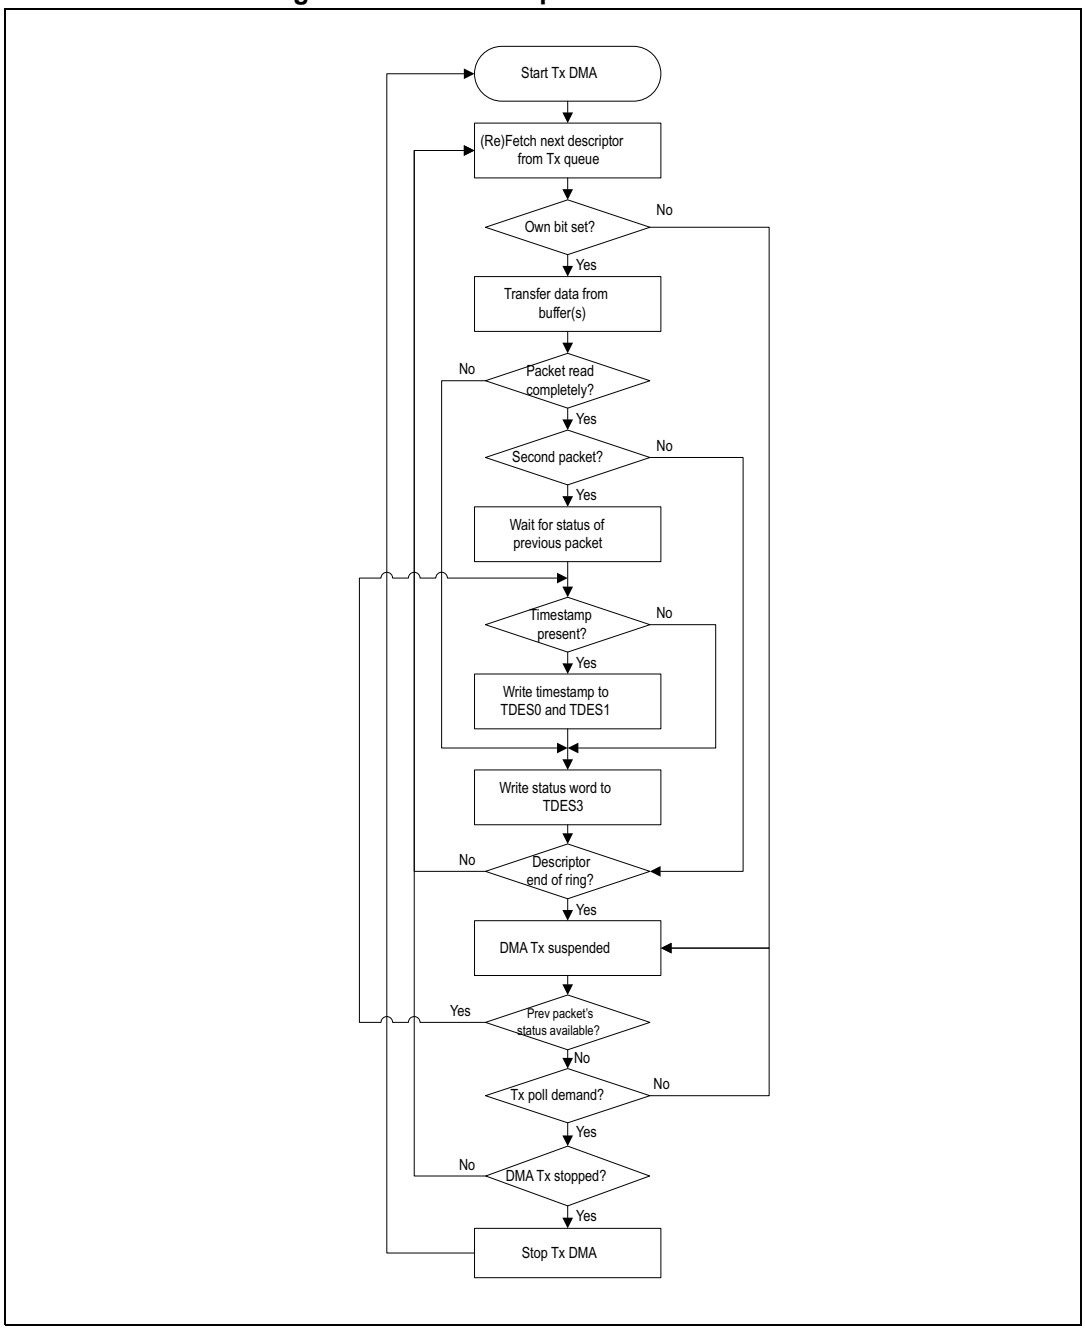
The Tx DMA transmission flow in default mode is shown in *Figure 950*.

Figure 950. TX DMA operation in default mode

49.3.2.2.2 TX DMA operation: OSP mode

In the Run state, if Bit 27 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:



1. The DMA operates as described in Step *1* – Step *7* of the Tx DMA (default mode).
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step *7*.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES0 and TDES1.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to Step *3* (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step *7*).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:
   a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1.
   b) Writes the status to the corresponding TDES3.
   c) Sets relevant interrupts and returns to Suspend mode.

   If no status is pending and the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (goes to Step *1* or Step *2* depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

Note: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. It is recommended to have a minimum descriptor length of four.

The basic flow is described in *Figure 951*.

Figure 951. Tx DMA operation in OSP mode

49.3.2.2.3 Transmit packet processing

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[2]) and the Last Descriptor (TDES3[3]). As transmission starts, the First Descriptor must have TDES3[2] set. When this occurs, the packet data is

transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[3]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[2] clear. If TDES3[3] is clear, it indicates an intermediary buffer. If TDES3[3] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor Bit set in Transmit Descriptor 3 (TDES3[3]). At this time, if Interrupt on Completion (TDES2[0]) is set, Bit 31 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (Bits[25:27] of Transmit Operation Mode register of corresponding MTL Transmit Queue).
- A full packet is contained in the FIFO.

You can also use the store-and-forward mode (Bit 30 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[0] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[3]) set.

49.3.2.2.4 Transmit polling suspended

Transmit polling can be suspended by any of the following conditions:

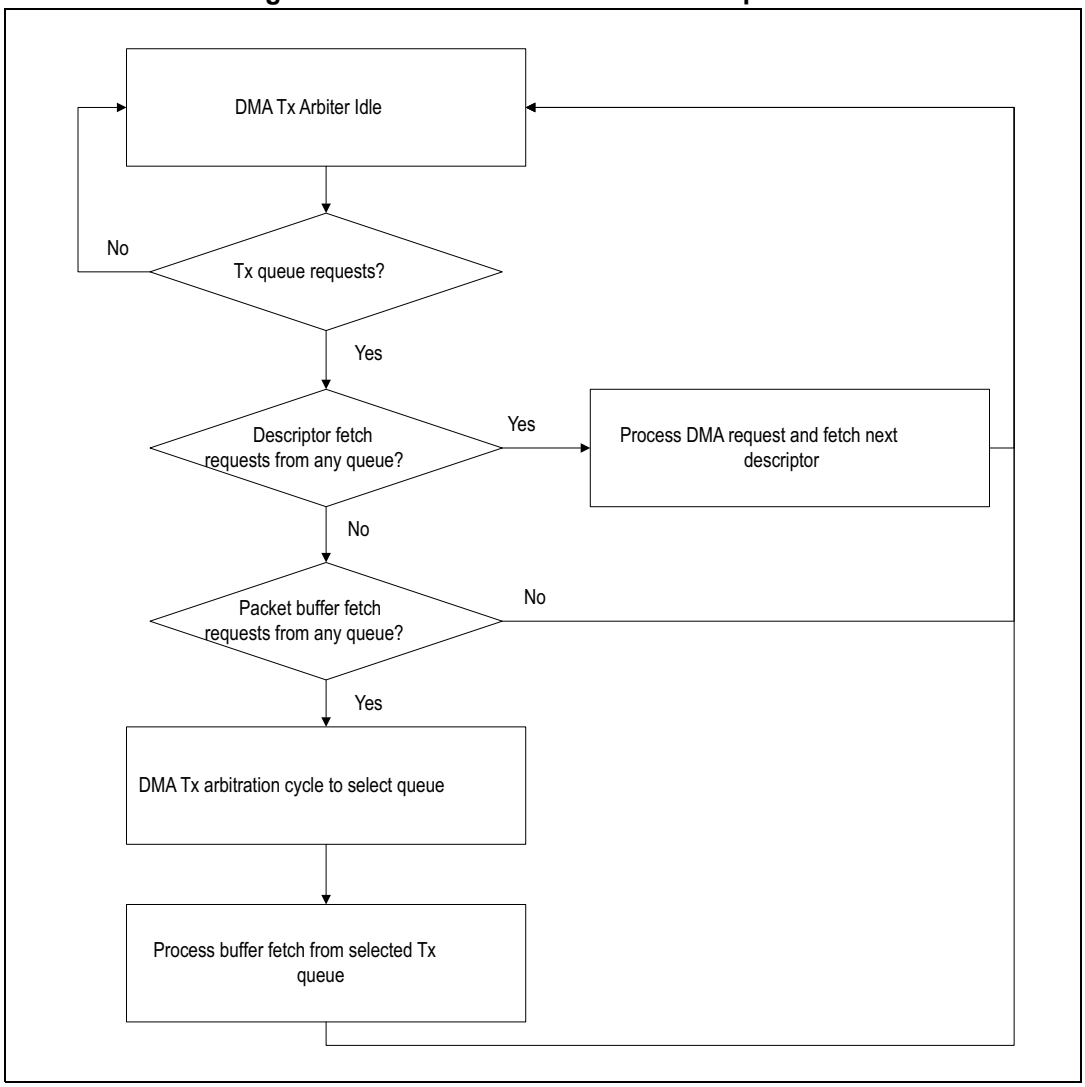
- The DMA detects a descriptor owned by the application (TDES3[0]=0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, Bit 16 and Bit 29 of Status Register of corresponding DMA channel are set.
- A packet transmission is aborted when a Transmit error is detected because of underflow.
  The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 17 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_INTERRUPT_STATUS
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by it.
  To resume, the software driver must modify the Tail Pointer register.

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

49.3.2.2.5 Transmit channel arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). *Figure 952* shows the DMA Tx channel arbitration process.

When there is any request in the Tx queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the



DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 1 (or the last enabled channel) and then Channel 0. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to Channel1 (or last enabled channel). If Channel 1 has no frames to transmit, the remaining weight is assigned to Channel 0.
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit.
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the Transmit Control register of a channel is ignored.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

Figure 952. DMA Tx channel arbitration process

49.3.2.3 DMA reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 953 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[0]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel.
2. When Bit 31 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state.
   The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor

Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to Step *11*.

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the RDES3[CTXT] field.
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to Step *10*.
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set.
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step *3*; otherwise, go to the Suspend state (Step *11*).
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel.

The engine proceeds to Step *2* and re-fetches the next descriptor.

Figure 953. RX DMA operation

49.3.2.3.1 Receive descriptor acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 31 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state.
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA.
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed.
- A Receive poll demand is issued (update of the Tail Pointer register).

49.3.2.3.2 Receive packet processing

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless Bit 0 of MAC_Packet_Filter register is set).
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue.
3. When the DMA application Interface (AHB) becomes ready, it transfers the data and sets the following:
   a) If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[3]) and First Descriptor (RDES3[2]).
   b) If the packet fits into more than one descriptor, the DMA sets the First Descriptor (RDES3[2]) to delimit the packet.
4. The DMA releases the descriptors by resetting the Own (RDES3[0]) bit to 0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor.
5. If Interrupt Enabled on Completion (RDES3[1]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and Bit 25 of Interrupt Enable Register of corresponding DMA channel is set, the DMA sets Bit 25 of Status register of corresponding DMA channel.
   The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if Bit 24 of Interrupt Enable Register of corresponding DMA channel is set, the Receive Process sets Bit 24 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained.

49.3.2.4 DMA error response

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to Ethernet IP or re-initialize the DMA descriptor list and start again. The rest of the DMA

channels are not affected by such errors. In AHB the DMA receives the error response through hresp_i signal.

49.3.3 MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The data path for both directions is 64-bit wide.

49.3.3.1 MTL transmit path

The DMA pushes the Ethernet packets read from the application or system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application. The fill level of the queue is indicated to the internal DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the application or system memory. The following two modes of operation trigger reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode: In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the Queue.
  - The Tx FIFO becomes almost full.
  - The ATI watermark becomes low.

The watermark becomes low when the requested Queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx Queue size.

The application can flush complete content of the Tx Queue by setting Bit 31 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

49.3.3.1.1 Initialization flow

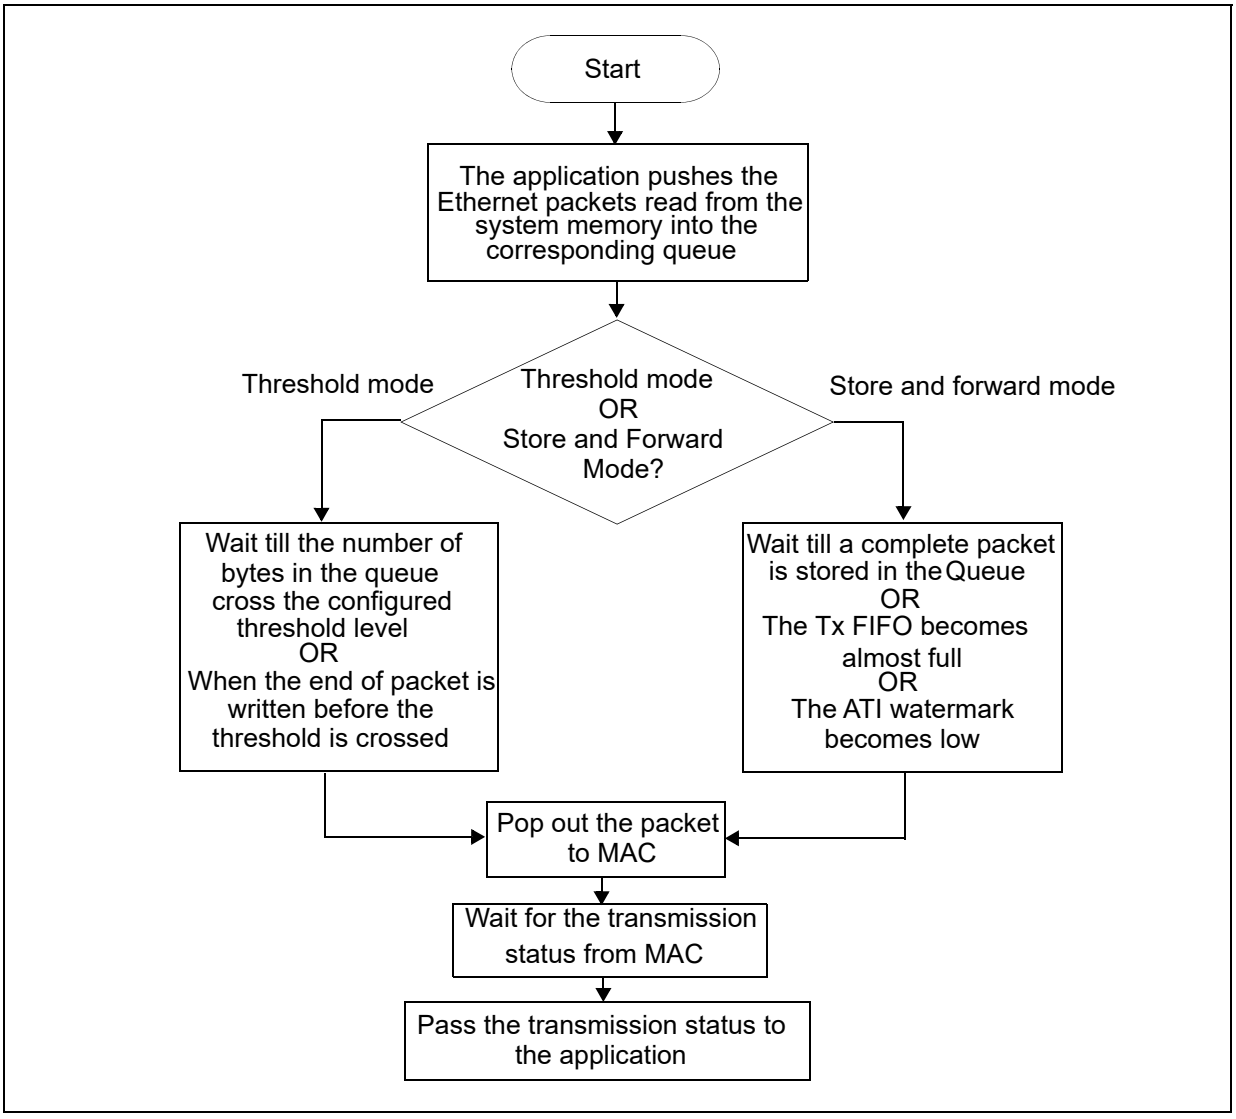
Upon reset, the MTL is ready to manage the flow of data to and from the application or DMA, and MAC.

First you need to initialize the Queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. You also need to initialize the MAC block. The internal DMA controllers must be individually enabled through their respective Cars.

49.3.3.1.2 Data flow between the DMA and the MTL

This section describes the interaction process between the MTL and the DMA.

49.3.3.1.2.1 Single-packet transmit operation



The following flow is valid when the core is operating in non-OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 0.

During a Transmit operation, the MTL block is a slave for the DMA controller. The general sequence of events for a Transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller (if enabled) fetches the data from the application through the AHB master interface and starts forwarding it to the MTL. The DMA descriptor memory contains the information related to packet control which is used to drive the MTL Control Word. The DMA data buffer memory contains the packet data.
2. The MTL pushes the data received from the DMA into the corresponding queue. This process continues until the EOP is transferred.
3. When the threshold level is crossed or a full packet of data is received into the queue, the MTL reads the packet data and drives it to the MAC.
4. The queue controller continues to transfer data from the queue until a complete packet is transferred to the MAC.
5. When the packet transfer is complete, the MTL receives the status from the MAC and notifies the DMA controller.

Figure 954 illustrates the MTL single-packet transmit operation.

Figure 954. MTL single packet transmit flow

Note: When Bit 30 (DTXSTS) of Section 49.2.2.173 register is set, the MTL does not provide any status to the DMA.

49.3.3.1.2.2 Transmit operation: two packets in the buffer

The following flow is valid when the core is operating in OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 1.

The flow is similar to the flow described in Single-Packet Transmit Operation. However after fetching a packet, the DMA instead of waiting for the status, it continues to fetch another packet if available in the system memory. So, MTL can receive the second packet while it is processing the first packet. This flow improves the performance because the DMA can process two packets back to back before waiting for the status of the first packet.

49.3.3.1.2.3 Relationship between the number of TX DMA channels and Tx queues

The number of Tx DMA channels is always equal to the Tx queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Bursts Lengths). However, the Tx queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and Tx queues to maintain the packet-level coherency.

49.3.3.1.2.4 Retransmission during collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a Retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes are read out towards the MAC, the Queue Controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

When a packet transmission is aborted because of underflow and a collision event immediately follows (initiating a retry), retry has higher priority than abort.

Note: Before issuing the Transmit Queue Flush command, make sure that the Tx Queue is not empty, that is, Bit 27 (TXQSTS) of Transmit Debug Register of corresponding queue is reset.

49.3.3.1.2.5 Transmit status word

At the end of transfer of the Ethernet packet to the MAC and after the MAC completes the transmission of the packet, the MTL provides the Transmit status on respective queues. The detailed description of the Transmit Status is the same as for Bits[17:31] of TDES3 normal descriptor in write-back format. If IEEE 1588 Timestamp feature is enabled, the MTL returns 64-bit timestamp of the packet, along with the Transmit status.

If Bit 30 (DTXSTS) of MTL_Operation_Mode register is set then it disables the dependency of the DMA to read the status words from the Status FIFO thus the DMA can push as many packets as possible into the Tx queues because the application or DMA is not required to read the status words from the Status FIFO.

49.3.3.2 MTL Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured Receive threshold (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

49.3.3.2.1 Receive operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. For the 64-bit bus, one additional location is taken.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the below two modes.
7. Threshold mode: In the (default) Threshold mode, the MTL reads the data and indicates its availability to DMA when one of the following happens:
   a) Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue).
   b) A full packet of data is received into the queue.
8. Store-and-forward mode: In the store-and-forward mode (when Bit 26 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 27 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

Note: In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.

49.3.3.2.2 Receive operation multi-packet handling

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

49.3.3.2.3 Error handling

If the MTL Rx queue is full before it receives the EOP data from the MAC, the following happens:

1. An overflow is declared.
2. The whole packet (including the status word) is dropped.
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 27 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such

packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. The MTL then starts the transfer of next packet (if available).

49.3.3.2.4 Receive status word format

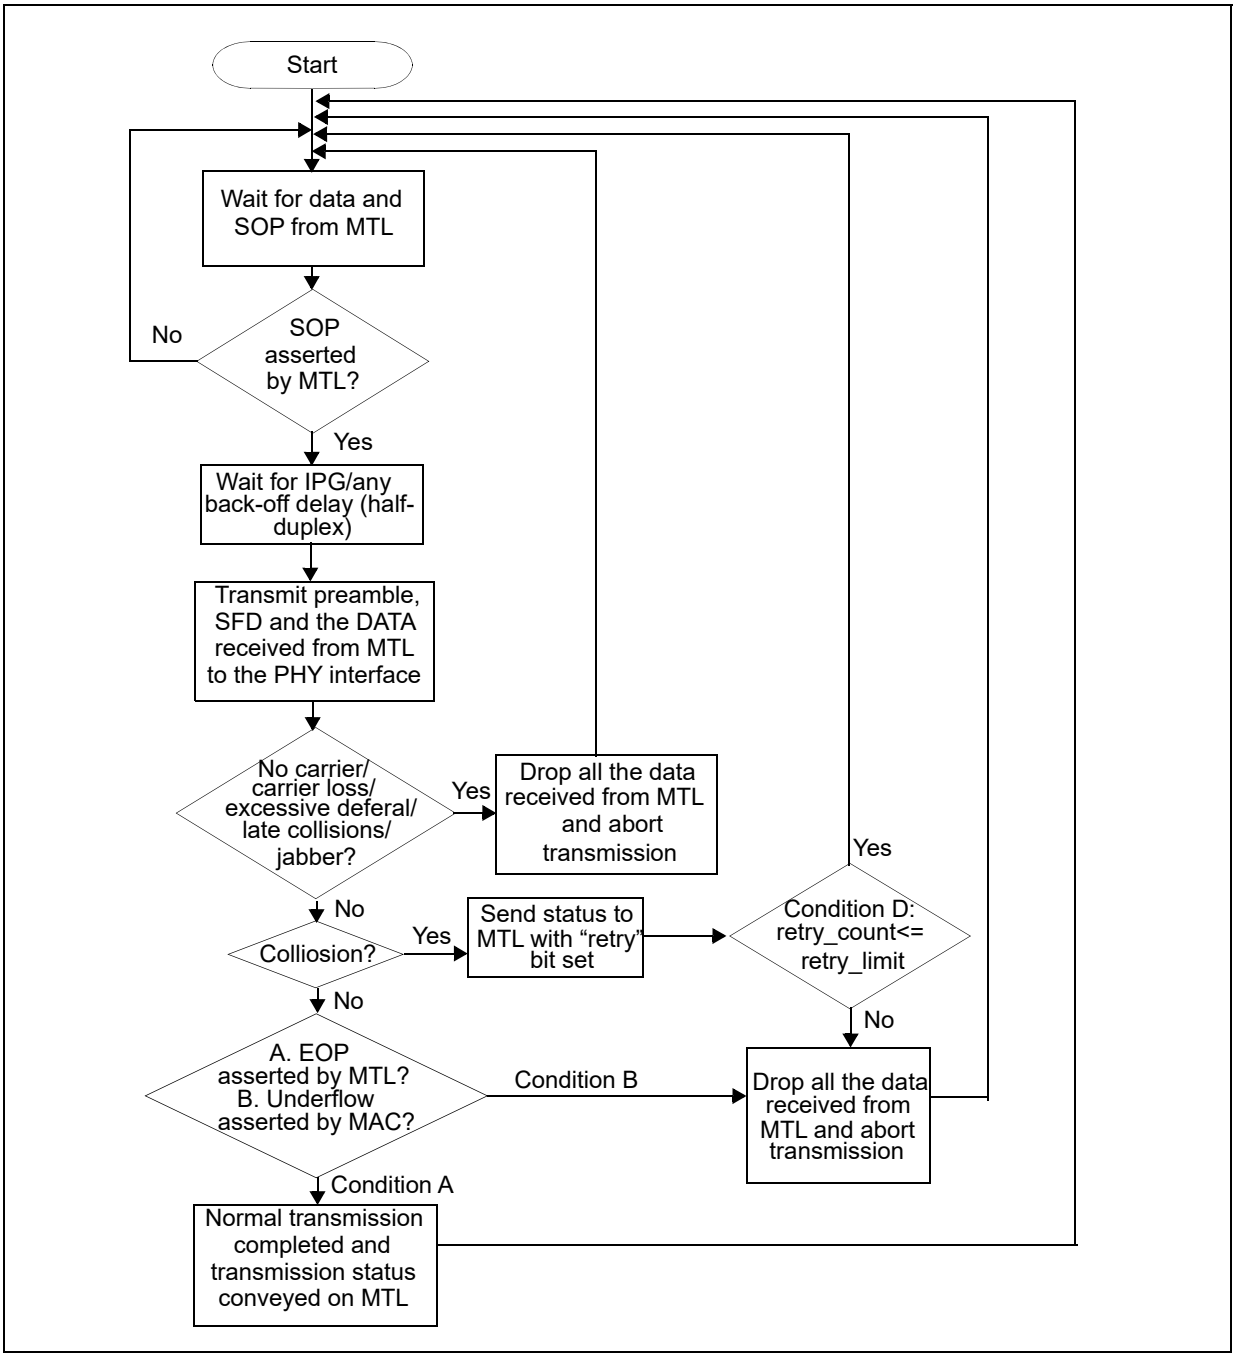
The Rx packet status words are sent to the application after the packet data in Threshold mode and before the packet data in the Store and Forward Mode.

49.3.4 MAC

The MAC supports MII and RMII interfaces towards the PHY chip. The PHY interface can be selected only once after reset.

49.3.4.1 MAC transmission

The transmission process is as follows:



1. Transmission is initiated when the MTL pushes in data with the SOP.
2. When the SOP is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the packet data to the MII after the application initiates the transmission depends on delay factors such as IPG delay, time to transmit preamble or SFD, and any back-off delays for half-duplex mode. While the packets data is being transmitted, the MAC can throttle the MTL.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   a) The MAC completes the normal transmission and gives the transmission status to the MTL.
   b) If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till either the packet is successfully transmitted or maximum retry requests expire.
4. When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.

5. The MAC aborts the packet transmission under the following conditions:
   a) No carrier (half-duplex mode)
   b) Loss of carrier (half-duplex mode)
   c) Excessive deferral (half-duplex mode)
   d) Late collisions (half-duplex mode)
   e) Jabber

   The MAC accepts and drops all further data until the next SOP is received.
6. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
7. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

Figure 955 illustrates the MAC transmission process flow.

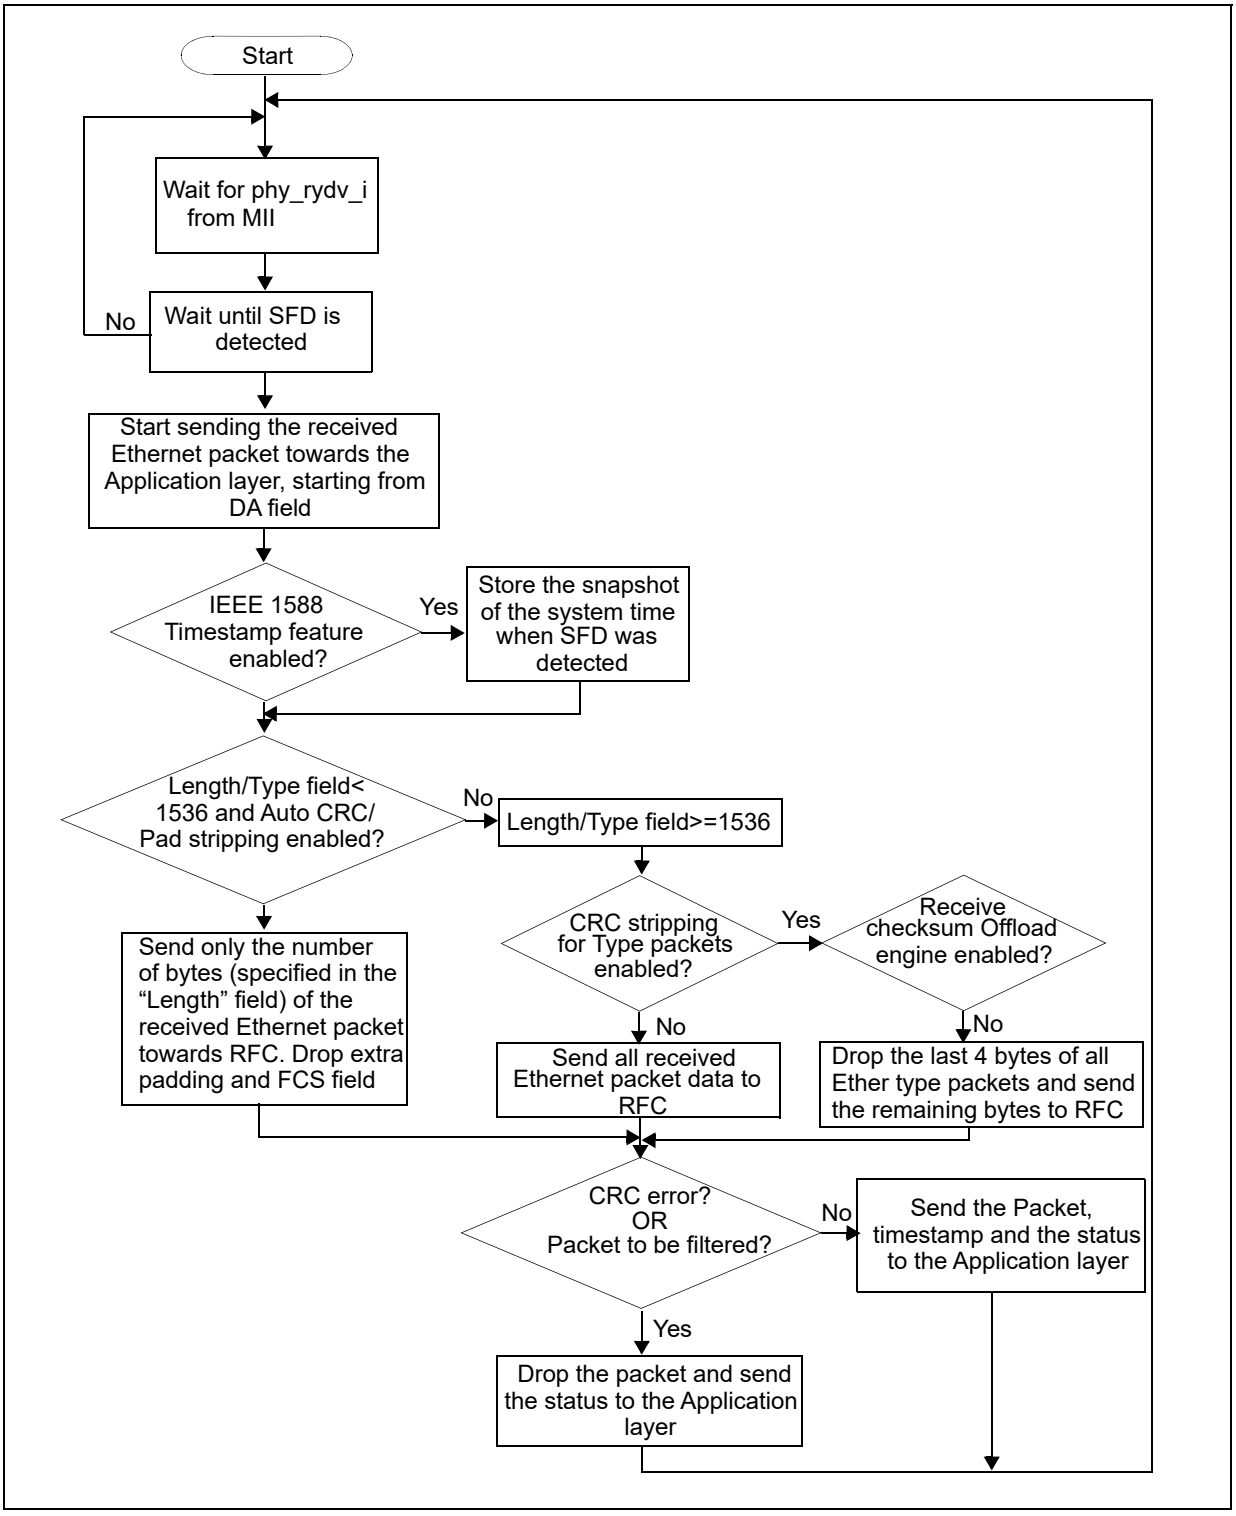


Figure 955. Overview of MAC transmission process flow

49.3.4.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

Figure 956. Overview of MAC RX operation

49.3.5 Multiple channels and queues support

The Ethernet module supports multiple queues and channels on Tx and Rx paths. *Figure 704* shows the architecture of the Ethernet module with multiple queues and channels. This section describes how the Ethernet module supports multiple queues and channels. It contains the following sub-sections:

- DMA with Multiple Channels
- MTL with Multiple Queues

49.3.5.1 DMA with multiple channels

This section describes how multiple queues are supported in the Transmit and Receive DMA paths.

49.3.5.1.1 Multi-channel DMA transmit path

The Ethernet module supports multiple Tx channels with the following priority schemes:

- Fixed Priority Scheme
- Weighted Strict Priority
- Weighted Round Robin

49.3.5.1.1.1 Fixed priority scheme

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. In Fixed Priority Scheme, CH0 has the lowest priority and highest numbered channel has the highest priority.

49.3.5.1.1.2 Weighted strict priority

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. CH0 has lowest priority and the highest numbered channel has highest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

49.3.5.1.1.3 Weighted round robin

In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the DMA_CHn_Tx_Control register provides the weight for each Transmit channel as shown in Weights for DMA Channels.

Table 1042. Weights for DMA channels

TCW field	Transmit channel weight
000	1
001	2

Table 1042. Weights for DMA channels (continued)

TCW field	Transmit channel weight
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

49.3.5.1.2 Multi-channel DMA receive path

The Ethernet module supports multiple Rx channels. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

49.3.5.1.3 Priority scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the register. For round-robin arbitration, you can use the PR field of the register to specify the weighted priority between the Tx DMA and Rx DMA. The table below provides information about the priority scheme between Tx DMA and Rx DMA.

Table 1043. Priority scheme for Tx DMA and Rx DMA

Bit 17(1)	Bit 18(1)	Bit 19(1)	Bit 20(1)	Bit 30(1)	Priority scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table 1043. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 17(1)	Bit 18(1)	Bit 19(1)	Bit 20(1)	Bit 30(1)	Priority scheme
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

1. Bits 17, 18, 19, 20 and 30 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

49.3.5.1.4 Rx queue to DMA RX channel mapping

The packets in the MTL Rx Queues can be routed to any one of the 2-RX DMA channels by programming the MTL_RxQ_DMA_Map0 Register. The following types of Rx Queue to DMA mapping is possible through programming:

- Static mapping
- Dynamic (per packet) mapping
- Broadcast/multicast packet duplication

49.3.5.1.4.1 Static mapping

In this mode, all the packets of an Rx Queue is connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[28:31]) and Q0DDMACH (bit[24] = 0) of the MTL_RxQ_DMA_Map0 register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

49.3.5.1.4.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet being read from an Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx

Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: When the Layer 3 and Layer 4 Packet Filter is enabled, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If the L3-L4 Registers do not give a comparison match, then the Ethernet module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set.
   The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to 0. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.
   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

Broadcast/multicast packet duplication

Broadcast/multicast packet duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

In a virtual system that supports multiple guest OS's (for instance, each OS owning a DMA), where each DMA could act as an independent Ethernet Node, there can be requirement to route the received multicast/broadcast packets to all/multiple DMA channels. This is implemented by having the MTL_RX_FIFO_read_controller to read the packet from the same queue multiple times and route the same packet to the specified multiple DMA channels.

The DCS field of the of MAC_ADDRESS0_HIGH and other optional MAC_ADDRESSn_HIGH (n = 1 to 31) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register)

must be routed.
The DCS field allows more than one DMA channel number to be selected. The DCS field can hold any one of the following values:

- Binary value of the channel number when the PDC bit of the MAC_Ext_Configuration register is set to 0.

- One-hot value of the channel number when PDC bit of the MAC_Ext_Configuration register is set to 1.

To enable the Multicast/Broadcast packets to be routed to multiple DMA channels, use the DA based routing. Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing. In other words, if the destination DMA channel is decided by the VLAN or L3-L4 filter result, it is routed only to the specific channel even if the DA of the packet matches the multicast address in the MAC_Address register.
The Packet Duplication feature is supported only on the highest MTL Queue. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present.

In a packet duplication, the MTL Read Controller sequentially transfers the same packet to all the required RxDMA. This packet is removed from the MTL FIFO only after the packet is transferred to all the selected DMA channels. Therefore this feature is suitable for smaller packet sizes or very low bandwidth traffic; to ensure that the MTL RxQ does not overflow due to the long period for which the packet remains in the queue during the packet duplication.

Note: When more than one bit is set for the DMA channel number, a packet that is not routed to the highest receive queue is routed to only one DMA channel as indicated by the lowest bit set in the dmach_sel.

49.3.5.1.5 Selection of tag priorities assigned Rx queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The setting in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

49.3.5.1.6 Rx side routing from MAC to queues

The MAC routes the Rx packets to the Rx Queues based on following packet types:

- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged IEEE1588 PTP over Ethernet packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for generic through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the AVPTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RXQ_CTRL1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RXQ_CTRL0 register. If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

49.3.5.1.7 Rx side arbitration between DMA and MTL

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

49.3.5.1.8 Tx side arbitration between DMA and MTL

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its

respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX Checksum Engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DM A starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

49.3.5.2 MTL with multiple queues

The Ethernet module supports 2xTx and 2xRx queues. The number of Tx queues is equal to the number of DMA channels. You can control a Tx queue through *Section 49.2.2.187: MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)*. You can control an Rx queue through *Section 49.2.2.193: MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)*.

49.3.5.2.1 Queue memory

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of *Section 49.2.2.187: MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)* and the Rx queue size in the RQS field of the *Section 49.2.2.193: MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)*.

49.3.5.2.2 Queue modes

You can enable a Tx queue for generic, AV, or all types of traffic. Generic Tx queues use WRR or WSP queuing algorithms. AV Tx queue uses CBS or SP queuing algorithms.

You can enable an Rx queue for generic, AV, or all types of traffic. A particular queue enabled for generic or AV based routing is determined by the RXQ*n*EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Generic Rx queues

  All queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. Untagged packets are routed through Queue 0. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.
- Multiple Rx queues with AV feature

  When you select the *Enable Audio Video Bridging* option, AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register.

49.3.5.2.3 AV feature

The Ethernet module supports the AV data transfer in 100 Mbps mode. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

49.3.5.2.3.1 Transmit path functions

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue, as shown in *Figure 704*. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit.
- If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Fixed Priority Scheme for DMA Channels.

49.3.5.2.3.2 Receive path functions

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in *Section 49.4.4: Receive descriptor*. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets

  The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program Bits[16:23] in the Transmit Flow Control Register of the corresponding queue.

- AV control packets

  The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these packets on any other queue, you can program Bits[29:31] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[25:27] of the MAC_RxQ_Ctrl1 register.

49.3.5.2.3.3 Credit-based shaper algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

Credit value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in Credit Value Per Transmit Cycle Example.

Table 1044. Credit value per transmit cycle example

Mode	Values	Description
100 Mbps	– portTransmitRate = 100 Mbps – idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) – sendSlope = 30 Mbps	– credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. – credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The Ethernet module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 30 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, $2.8 \times 1024 = 2867$ and $1.2 \times 1024 = 1229$. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12000 bits and 3036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000×1024 bits and two's complement of 3036×1024, respectively.

Bandwidth status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[25:27] of the CBS control register of the respective queue. For example, if you have

programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

49.3.5.2.3.4 Slot number function

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals. You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels.

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated every 125 µs of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the second's field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program Bit 31 of the Slot Function Control and Status register of the corresponding DMA channel.

You can enable the check for slot number by setting Bit 31 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, Bits [12:15] indicate the value of the reference slot number in DMA.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

49.3.5.3 Overview of time-based scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. This is an optional feature. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and

avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.

- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

49.3.5.3.1 Description of time-based scheduling

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode.
- Link speed is 100 Mbps or higher.
- Configurations in which time-stamping is enabled.
- EST enabled configurations. In these configurations, the ESTM mode bit setting impacts the time-based scheduling feature only when the DUT processes the GCL list.

Note: Time-based scheduling should not be enabled for the channel for which TSO feature is enabled.

The following are the definitions specific to the time-based scheduling feature:

- Launch Time
- Fetch Time
- Expiry Time

49.3.5.3.1.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time is specified in the Enhanced Normal Descriptor in the DMA configurations. For more details, refer to *Section 49.5.15: Programming the launch time in time-based scheduling*.

The launch time can also be specified as a Control Word for each packet in the MTL configurations.

When the launch time is specified in the DMA configuration, it is valid only for the specific frame that is scheduled for transmission. The launch time is reset after the transmission of one frame.

The following are the two formats of the launch time:

- Normal/Absolute Format
- EST/Offset Format

Normal/absolute format

In this format, the Launch time is an absolute time value at which the packet is launched for transmission. This format is supported in all configurations in which Time-Based Scheduling feature (DWC_EQOS_TBS) is enabled.

When both Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec.
- Launch Time is less than current System Time when its value is between “System Time[39:8] + 128sec” and “System Time[39:8] + 256 sec”, because this is a modulo 256 computation.

EST/Offset format

(BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

This format is enabled only when both Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled. For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled).

If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as,
Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

49.3.5.3.1.2 GCL Slot Number (GSN)

When Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled, a modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

49.3.5.3.1.3 Launch expiry time

In the EST mode of operation, if the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:
Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) where,

CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

Note: Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.

49.3.5.3.1.4 Fetch time

In configurations with DMA, the Fetch Time can also be indicated for each packet by the software. This is done by setting FTOV field of DMA_TBS_CTRL register.

If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

Normal mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as “greater” than System Time if the Fetch Time is in the range of “System Time[39:8]” and “System Time[39:8] + 128 sec”. The frame is considered as not-eligible for fetch.
- The Fetch time is defined as “smaller” than the System Time if the Fetch time is in the range of “System Time[39:8] + 128 sec” and “System Time[39:8] + 256 sec”. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

```
If (Launch Time Offset >= FTOS):
Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)
CBFS(CTR Borrow for Fetch Subtraction) = 0
```

```
If (Launch Time Offset < FTOS)
Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)
CBFS (CTR Borrow for Fetch Subtraction) = 1
```

The Fetch GSN is computed as follows:

```
Fetch GSN = Launch GSN - FGOS - CBFS
Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset
```

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

Note: Max value of FGOS is 7. This implies that when FTOV is set, the frame can be fetched at a maximum of <8 GCL loop iterations before it becomes eligible for Launch.

DMA operations sequence

The sequence of operations when FTOV = 1 is as follows.

1. Fetch the first Enhanced Normal Descriptor. (FD is set).
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time. Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

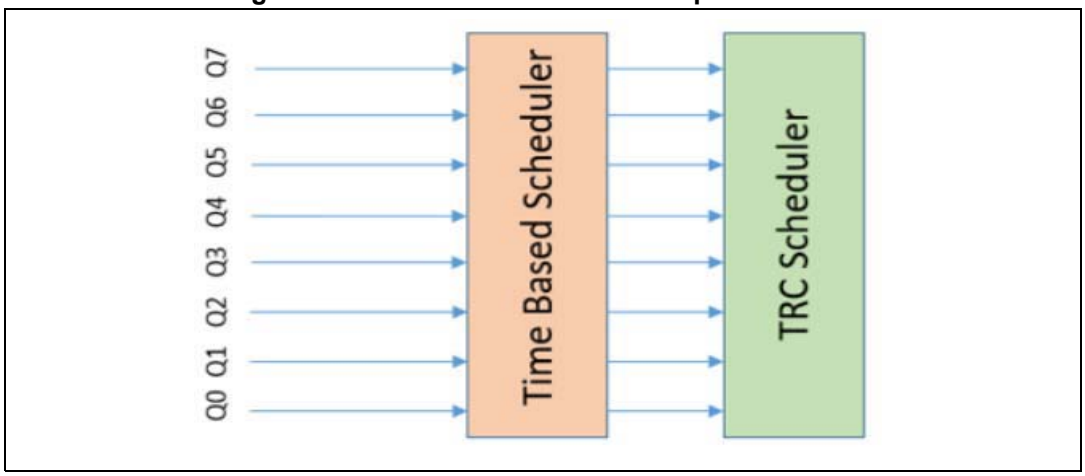
49.3.5.3.2 Control word (MTL configurations)

Time-based scheduling ensures that a Ethernet Frame is allowed to arbitrate for transmission only if the System Time is greater than the Launch Time.

In MTL configuration,

- Launch Time and GSN, use the same field that is used to hold the 64-bit timestamp value for OSTC (One Step Timestamping Correction). If the LTV bit is set and OSTC bit is not set (bit 19 of first control word), the Time Stamp field is interpreted as Launch Time. Launch Time uses the fields meant for OSTC TimeStamp[39:8] and GSN uses OSTC TimeStamp[43:40] field.
- Bit-31 of Control-Word0 is the equivalent of the LTV field, and the last two Control D-Words is used for providing the Launch Time and GST.
- The last two Control D-words is considered to the Time Stamp for OSTC, when bit-19 of Control-Word0 (OSTC) is set.

When the MTL TXFIFO Read Controller reads the first control word, it checks bit-31 to determine if the frame has a valid Launch Time. If bit-31 is set, it reads the subsequent control words to get the Launch Time.



49.3.5.3.3 Impact on transmission selection algorithm

Time-Based Scheduler does not directly influence the Transmission Selection Algorithm but has an indirect influence as it determines if a queue is eligible to participate in the scheduling.

If a frame of a specific queue has a valid Launch Time, the Time Based Scheduler ensures that the frame participates in Transmit Scheduling (TRC Scheduler) only after the Launch time has elapsed.

The gating done by Time-Base scheduler is only for the Scheduling (picking frame for Transmission). It might not alter any other characteristics and behavior of the frame. For example, the Frame waiting for the Launch time to lapse will continue to gain credits in CBS, and the CBS credits will not be lost as the frame is marked as available but not ready. Strict Priority or CBS are recommended Transmit Scheduling algorithms for the TBS implementation because, scheduling for TBS enabled queues are more predictable.

Figure 957. Time based scheduler implementation

49.3.6 VLAN and double VLAN handling

The Ethernet module supports the double VLAN tagging feature in which the MAC can process up to two VLAN tags (inner and outer). The Ethernet module supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.
- Channel/queue based VLAN tag insertion on all transmitted packets.

49.3.6.1 VLAN processing in transmit path

Table 5-2 Double VLAN Processing Features in Tx Path5-2 describes the double VLAN processing features supported by the MAC on the Transmit side.

Table 1045. Double VLAN processing features in Tx path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_Inner_VLAN_Incl registers. The Ethernet module supports processing of any sequence of outer and inner VLAN tags. **Note:** The Ethernet module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: – The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. – The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. – The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. – The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields.
- Insert or replace the VLAN Type and VLAN Tag fields. Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_INCL register as described in *Table 1046*.

Table 1046. VLAN insertion or replacement based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_INCL register) – VLAN Tag field with the Content of the VT field of Transmit context descriptor of the packet.
VLTI bit is reset	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_INCL register) – VLAN Tag field with the VLT field of MAC_VLAN_INCL register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets. To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_INCL register.
- Enabling VLAN insertion, replacement, or deletion for selective packets. To enable this feature for selective packets, Program the VTIR field of TDES2 Normal Descriptor.

49.3.6.2 VLAN processing in receive path

Table 1047 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 1047. Double VLAN processing in Rx path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

49.3.6.3 Queue/channel based VLAN tag insertion on Tx

Ethernet module supports channel/queue based VLAN tag insertion on all transmitted packets.

Queue/Channel specific VLAN tag registers are accessed using indirect addressing via the MAC_VLAN_INCL register. VLAN type and tag value can be independently programmed for each queue/channel.

When the CBTI field is set in the MAC_VLAN_INCL register, the VLAN tag is inserted on every packet that is transmitted from a queue/channel, with the programmed tag value taken from queue/channel specific VLAN tag register.

Refer to *Section 49.5.14: Programming sequence for queue/channel based VLAN inclusion register*.

49.3.7 Source address insertion, replacement, or deletion

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field.
- Replace the content of the SA field with the content of the MAC Address Registers.

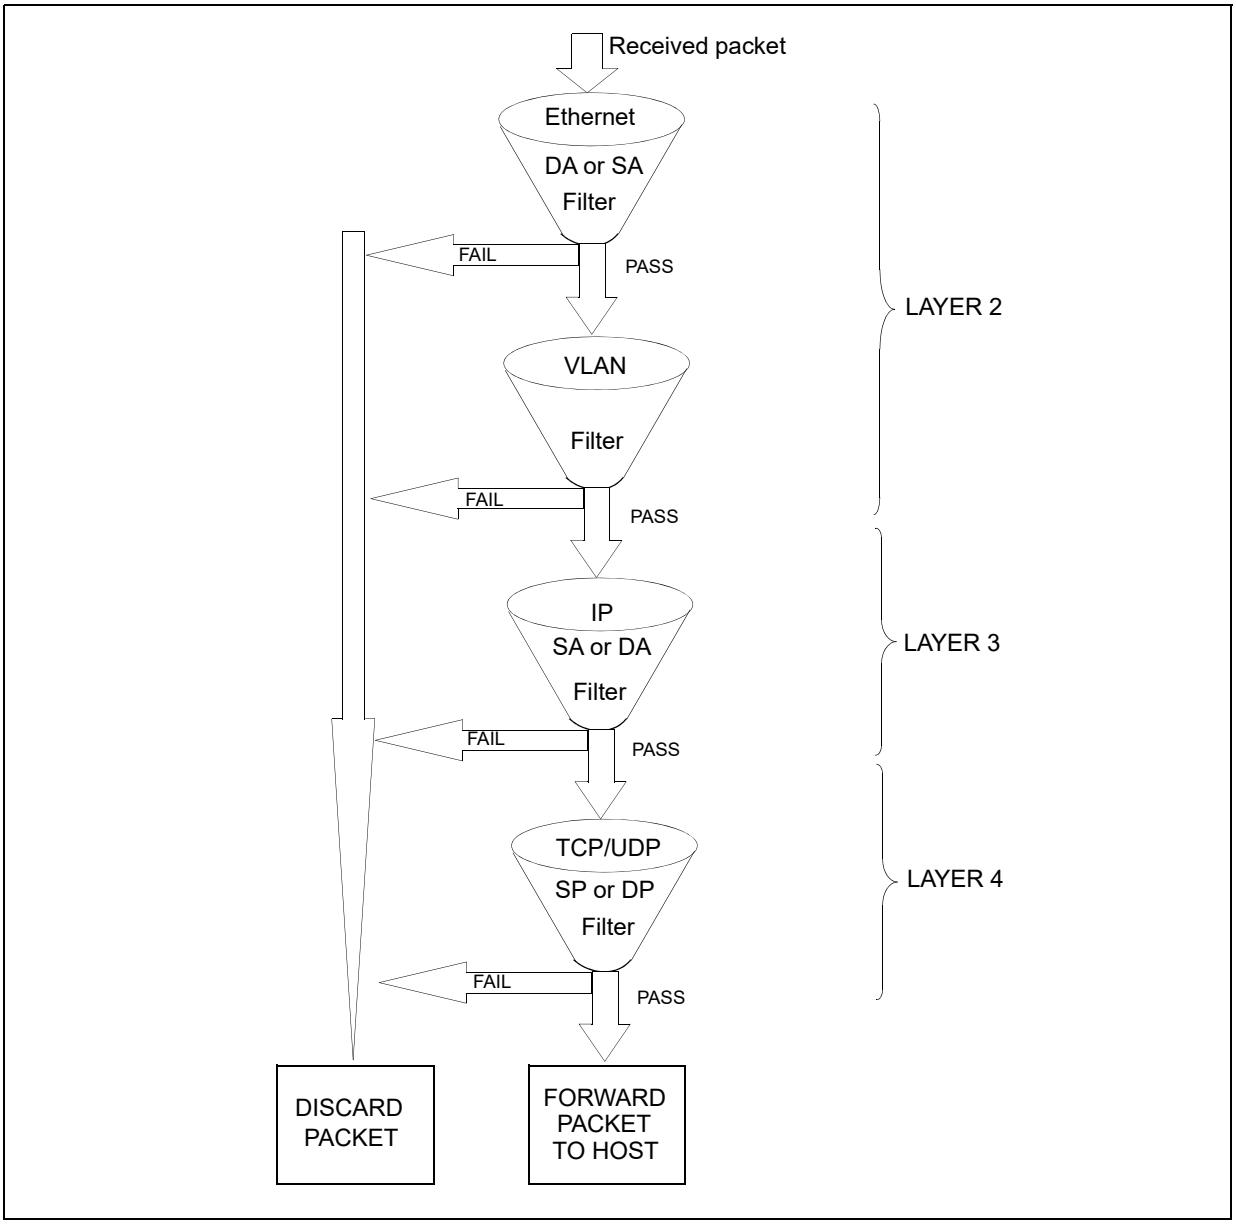
When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- To enable this feature for all packets, program the SARC field of the MAC_Configuration register.
- To enable this feature for selective packets, use the following method:
  Program the SA Insertion Control field (Bits[6:8] of TDES3 Normal Descriptor (Read Format)) in the first Transmit descriptor of the packet. When Bit 6 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 6 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.
- If both MAC_Configuration Register and TDES3 are programmed for SA insertion, then setting of MAC_Configuration register takes precedence.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

49.3.8 Packet filtering



The Ethernet module supports the following types of filtering for Rx packets:

- Source Address or Destination Address Filtering: The Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet.
- VLAN Filtering: The Ethernet module supports the VLAN tag-based and VLAN hash filtering. Handling of VLAN filter fail packets queue. Extended receive VLAN filtering and routing.
- Layer 3 and Layer 4 Filtering: Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering.

Figure 958 shows the filtering sequence for Rx packets.

The sequence shown in *Figure 958* is valid when all the filters (L2, VLAN, L3, L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control. For example, when Bit RA of MAC_Packet_Filter register is set to 1, all discarded packets are forwarded to the host but with its packet status indicating the specific filter-failure. If RA=0, Bits VTFE and IPFE of MAC_Packet_Filter register controls if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.

Figure 958. Packet filtering sequence

49.3.8.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

49.3.8.1.1 Unicast destination address filtering

The MAC supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC of MAC_Packet_Filter register bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects Bit 63 of selected register, and a value of 11111 selects Bit 0 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

49.3.8.1.2 Multicast destination address filtering

To program the MAC to pass all multicast packets, set the PM bit in *Section 49.2.2.3: MAC packet filter register (MAC_PACKET_FILTER)*. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

In Perfect filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bit CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 63 of selected register and a value of 111111 selects Bit 0 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

49.3.8.1.3 Hash or perfect address filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in *Section 49.2.2.3: MAC packet filter register (MAC_PACKET_FILTER)*. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

49.3.8.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

49.3.8.1.5 Unicast source address filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 1 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

49.3.8.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 1048 and *Table 1049* summarize the DA and SA filtering based on the type of packets received.

Table 1048. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 1049. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

49.3.8.2 VLAN filtering

The Ethernet module supports the following types of VLAN filtering:

- VLAN Tag Perfect Filtering
- VLAN Tag Hash Filtering

49.3.8.2.1 VLAN tag perfect filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. The VLAN packet status bit (Bit 21 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

49.3.8.2.2 VLAN tag hash filtering

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered

as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 1050 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of the MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in the MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail. In *Table 1050*, value *X* means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 1050. VLAN match status(1)

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

1. In this table, X represents any value.

Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_Tag register. When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.

49.3.8.3 VLAN filter fail packets queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 and the enable bit (VFFQE) for the queue is set.

1. RA and VTFE bits are implemented in the MAC_Packet_Filter register.
2. VFFQ and VFFQE fields are implemented in the MAC_RxQ_Ctrl4 register.

The packets that pass the VLAN filtering are routed based on the VLAN TAG priority field. The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in

the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA = 0 or VTFE = 1. However when RA = 1 or VTFE = 0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE = 0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

The below table shows the Rx Queue routing table for Unicast tagged packets, with SA Filter enabled.

Table 1051. Rx queue routing table for unicast tagged packets

RA	VFTE	SA/DA filter results	VLAN filter result	VFFQE	Queue routing
X(1)	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ(2)/PSRQ
1	X	FAIL	X	1	UFFQ(2)/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

1. X: Don’t care condition.
2. When UFFQE is enabled else PSRQ.

49.3.8.4 Extended receive VLAN filtering and routing

The MAC Receiver can classify the received packets based on VLAN Tag and steer them to a specific Rx DMA channel. The MAC compares the received frame's VLAN Tag with all the enabled and relevant filters and provides a filtering result. If any of the perfect filters give a pass result and if the respective filter's DMA channel number is enabled, the frame is routed to that DMA channel.

In addition to filtering, routing can also be done. For more details about routing, refer to “Extended VLAN based DMA selection” in *Section 49.3.5.1.4.2: Dynamic (per packet) mapping*.

49.3.8.4.1 Comparison modes

For each VLAN Tag Filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only.

For example, if a filter is enabled for 16-bit comparison, SVLAN Type, and Outer VLAN Tag, any single or double VLAN Tagged frames with Outer SVLAN Tags are compared with this filter, and a pass or fail result is obtained.

Note: The inner VLAN Tag comparison is applicable only if Double VLAN Tag processing is enabled through the MAC VLAN Control Register bit.

49.3.8.4.2 Filtering

When Extended RX VLAN Filtering and Routing feature is enabled, the application can enable both Perfect and Hash Filtering. The overall VLAN Filter Result is based on the perfect filter result and the Hash Filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

49.3.8.4.3 Filter status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions in various configurations. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15: Outer VLAN Tag Filter Status
- Bit 14: Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15: Outer VLAN Tag Filter Status
- Bit 14: Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47: Outer VLAN Tag Filter Status
- Bit 46: Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the framefs Outer VLAN tag has matched one of the VLAN tag filters.
- If this bit is reset, it indicates that the framefs Outer VLAN tag has either failed the relevant Outer VLAN tag filters or bypassed them.
- If none of the filters are enabled for Outer VLAN tag comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the framefs VLAN tag has passed all the relevant VLAN tag filters. If it is reset, then it has failed at least one of or bypassed all the filters programmed for Outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the framefs Inner VLAN tag has matched one of the VLAN tag filters.
- If this bit is reset, it indicates that the framefs Inner VLAN tag has either failed the relevant Inner VLAN tag filters or bypassed them.
- If none of the filters are enabled for Inner VLAN tag comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the framefs VLAN Tag has passed all the relevant VLAN tag filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN tag comparison.
- This bit is valid for only Double VLAN tagged frames, when double VLAN processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Table 1052 and *Table 1053* show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Caption for the table:

- VTIM: VLAN Tag Inverse Match Enable. Bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison. bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison. Bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO: Perfect Filter comparison enabled for Outer VLAN Tag. Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI: Perfect Filter comparison enabled for Inner VLAN Tag. Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS: Outer VLAN Tag Filter Status.
- ITS: Inner VLAN Tag Filter Status.

Table 1052 shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 1052. OTS and ITS bit values with at least one perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 1053 shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 1053. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of *Table 1052* indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame does not pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of *Table 1052* indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

49.3.8.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.
- If the application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if Stripping is enabled for any of the tags, the tag can be put in the status. For this the application will have to enable the respective “VLAN Tag in Status” bit - 24 or 31 in the MAC VLAN Tag Control Register.

49.3.8.4.5 Programming guidelines for extended VLAN filtering and routing on receive

Refer to *Section 49.5.13: Programming guidelines for extended VLAN filtering and routing on Receive*.

49.3.8.5 Layer 3 and Layer 4 filtering

The Ethernet module supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the MAC_Configuration register to enable the Rx Checksum Offload Engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match.
  - At least one of the enabled field matches and other fields are bypassed or disabled.
- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

49.3.8.5.1 Layer 3 and Layer 4 filters register set

The MAC implements a set of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_Control0, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address0
- MAC_Layer3_Address0_Reg0
- MAC_Layer3_Address1_Reg0
- MAC_Layer3_Address2_Reg0
- MAC_Layer3_Address3_Reg0

49.3.8.5.2 Layer 3 filtering

The Ethernet module supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

49.3.8.5.3 Layer 4 filtering

The Ethernet module supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

49.3.9 IEEE 1588 timestamps

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The Ethernet module supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet module provides programmable support for both standards. It supports the following features:

- Supports both timestamp formats.
- Provides an option to take snapshot of all packets or only PTP type packets.
- Provides an option to take snapshot of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent.
- Provides an option to select the node to be a master or slave for ordinary and boundary clock.
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

49.3.9.1 Clock types

The Ethernet module supports the following clock types defined in the IEEE 1588-2008:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

49.3.9.1.1 Ordinary clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or

an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled.
- Maintains the data sets such as timestamp values.

Table 1054 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 1054. Ordinary clock: PTP messages for snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control register.

49.3.9.1.2 Boundary clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

49.3.9.1.3 End-to-End transparent clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in the bullet points below. The snapshot is taken by setting the SNAPTYPSEL bits to ‘10’ in the MAC_Timestamp_Control register.

End to End transparent clock: PTP messages for snapshot:

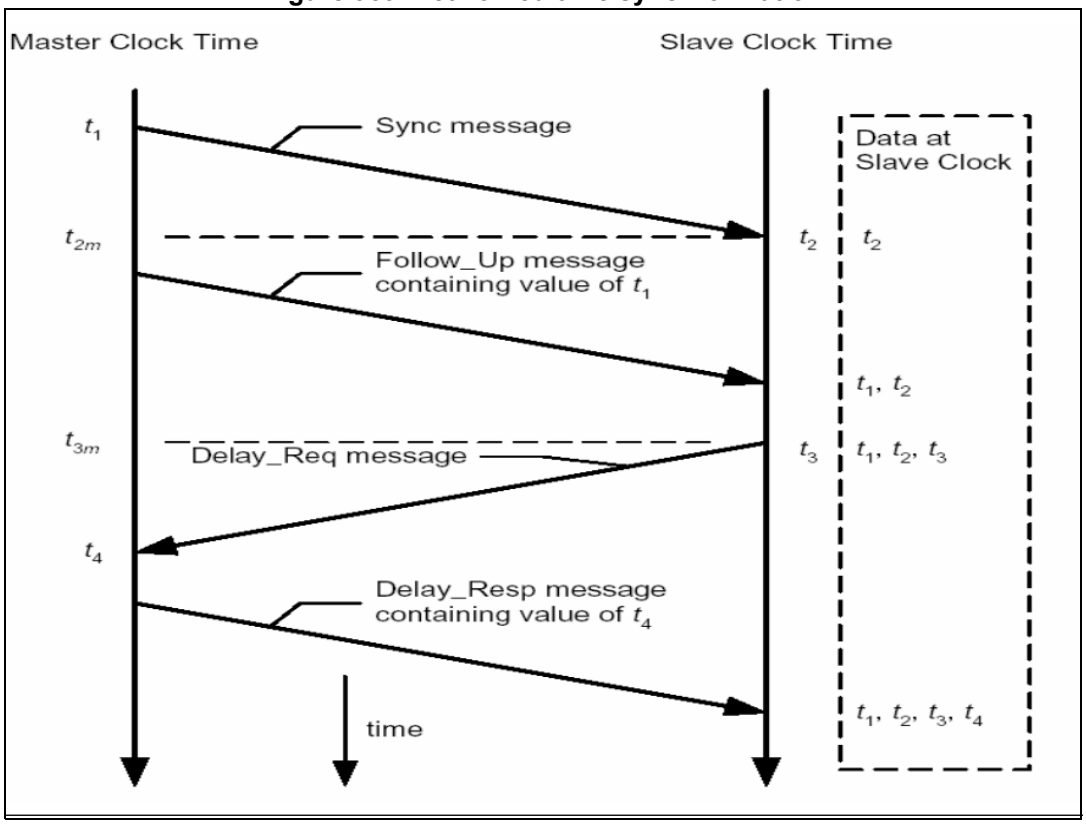
- SYNC
- Delay_Req

49.3.9.1.4 Peer-to-Peer transparent clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as mentioned in the below bullet points.

Peer-to-Peer transparent clock: PTP messages for snapshot



- SYNC
- Pdelay_Req
- Pdelay_Resp

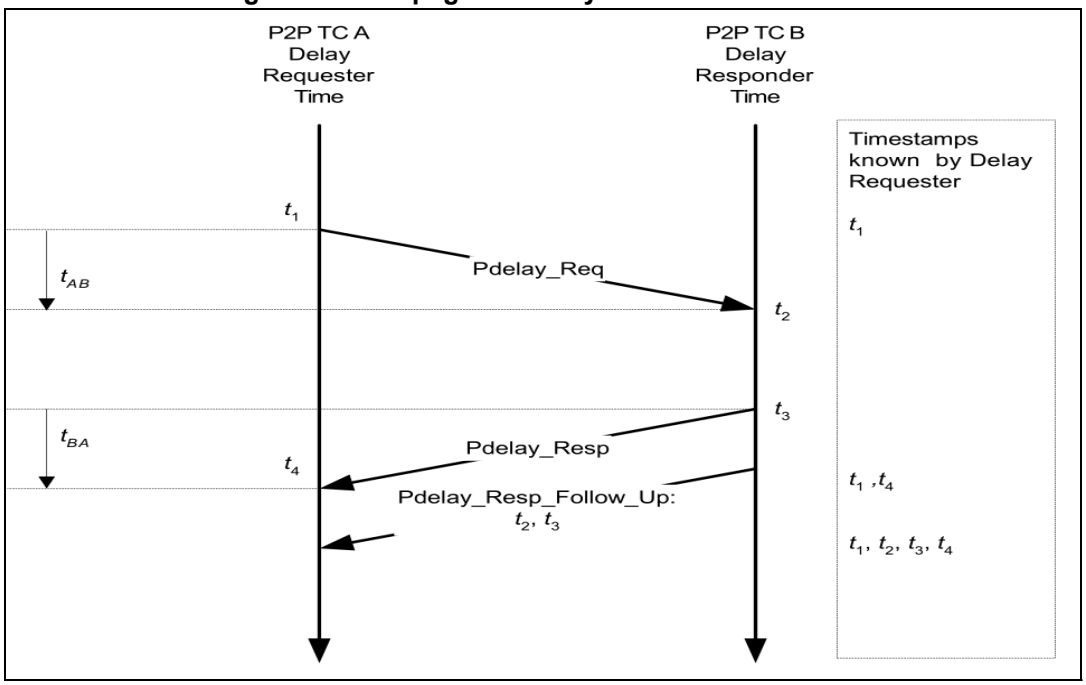
The snapshot is taken by setting the SNAPTYPESEL bit to ‘11’ in MAC_Timestamp_Control register.

49.3.9.2 Delay Request-Response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. *Figure 959*, shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 959. Networked time synchronization

As shown, the PTP uses the following process:



1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

49.3.9.3 Peer-to-Peer PTP Transparent Clock (P2P TC) message support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. *Figure 960* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 960. Propagation delay calculation in clocks

As shown, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.

To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

a) Difference between the timestamps t2 and t3 in the Pdelay_Resp message
b) Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
c) Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

49.3.9.4 Reference timing source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

49.3.9.4.1 Internal reference time

Ethernet module provides the following options for using the reference timing source in a node:

- External Timestamp Input

  This option takes an external 64-bit timing reference and its clock as input. The clock input is used to synchronize the timing reference to the MAC clock domain.
- Internal Reference Time (80-bit)

  This option takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The Ethernet module provides an Internal Reference Time (80-bit). It takes the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

- UInteger48 secondsField: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bit wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002.
- UInteger32 nanosecondsField: The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001.

The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

Note: These modes are set through TSCTRLSSR bit in MAC_Timestamp_Control register.

49.3.9.4.2 External timestamp input

The 64-bit timing reference is split into the following two 32-bit signals:

- Upper 32-bits providing the time in seconds.
- Lower 32-bits providing the time in nanoseconds.

This timing reference is used to timestamp the packets.

49.3.9.4.3 IEEE 1588 higher word register

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. You can read the values of the upper 16-bits of the seconds field from the CSR register.

Note: This Higher Word Register can be invoked only when the "System Time Source" is "Internal".

49.3.9.4.4 Fixed Pulse-Per-Second output

The Ethernet module supports the pulse-per-second (PPS) output that is given to indicate 1 second interval (default). You can change the frequency of the PPS output by setting the PPSCTRL0 field in the MAC_PPS_Control register.

49.3.9.4.5 Flexible Pulse-Per-Second output

The Ethernet module also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. The Ethernet module provides the following features with the flexible PPS output:

- Supports programming the start or stop time in terms of system time.
- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Supports programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed.
- Supports programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programmed in the MAC_Sub_Second_Increment register. You can program the width of pulse from 1 to 2^{32}-1 units of sub-second increment value.
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^{32}-1 units of sub-second increment value.
- Provides the option to cancel the programmed PPS start or stop request.
- Indicates error if the start or stop time being programmed has already elapsed.

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of MAC_Timestamp_Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated (using incr_sub_sec_reg shown in Figure 961).

49.3.9.4.5.1 PPS Start or Stop time

You can initially program the start time in the Target Time register. If required, you can again program the start or stop time but you can do it only after the earlier programmed value is synchronized to the PTP clock domain. Bit 0 of MAC_PPS*n*_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

49.3.9.4.5.2 PPS width and interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

49.3.9.4.6 Auxiliary snapshots with external events

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the ptp_aux_ts_trig_i sideband signal.

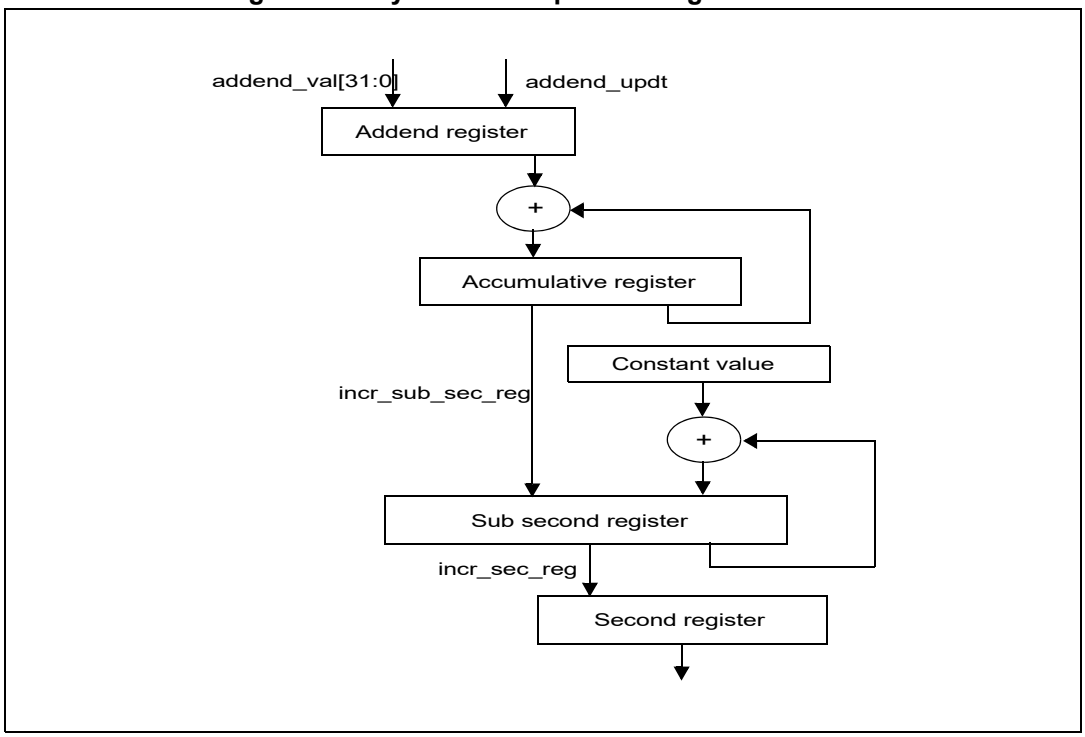
The Ethernet module has two auxiliary snapshot inputs and depth 4 of a single common auxiliary snapshot FIFO. The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Timestamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

The MAC stores these snapshots in a FIFO. Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from the MAC_System_Time_Higher_Word_Seconds register. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in Bits[4:6] of MAC_Timestamp_Status register.

49.3.9.4.7 System time register module

The 64-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the MII interface.



The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in *Figure 961*. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

This algorithm is shown in *Figure 961*.

Figure 961. System time update using fine method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is

calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programmed.

In 5-12, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32}$ / FreqDivisionRatio

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  $FreqCompensationValue_n = FreqScaleFactor_n \times FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

49.3.9.5 Transmit path functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can do this by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

49.3.9.6 Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Note: The Ethernet module also supports the PTP messages over VLAN packets.

49.3.9.7 Timestamp correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock ***clk_ptp_ref_i***) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

49.3.9.7.1 Ingress correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programmed in the Ingress Correction register. The value that needs to be programmed in the ingress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value as follows:

```
INGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp as follows:

```
Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY
```

Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

It is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programmed value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <ingress_correction_value> represented in binary.

49.3.9.7.2 Egress correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value) programmed in the Egress Correction register. The value that needs to be programmed in the egress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value as follows:

When Enable one step timestamp feature is selected,

```
EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)
```

Otherwise,

```
EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp as follows:

```
Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY
```

Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The value must not exceed 0x3B9A_C9FF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programmed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31

containing <egress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <egress_correction_value> represented in binary.

49.3.9.8 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains, that is, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

49.3.9.8.1 Maximum PTP clock frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

49.3.9.8.2 Minimum PTP clock frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the MII clock domain. This relationship is given in the following equation:

Equation 33

$$\mathbf{3 \times PTP\ clock\ period + 4 \times MII\ clock\ period <= Minimum\ gap\ between\ two\ SFDs}$$

The MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in *Table 1055*.

Note: It is recommended that you use a clock that has constant frequency, preferably a divided application clock.
When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Increment register limits the minimum PTP frequency that can be used to ~4 MHz.

Table 1055. Minimum PTP clock frequency example

Mode	Minimum gap between two SFDs	Minimum PTP frequency with internal timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
10 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
100 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz

49.3.9.9 PTP processing and control

Table 1056 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 1056. Message format defined in IEEE 1588-2008

Bits								Octets	Offset
0	1	2	3	4	5	6	7		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField(1)								1	32
logMessageInterval								1	33

1. ControlField is used in version 1. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets over IPv4Packets over IPv4
- PTP Frames over IPv6Frames over IPv6
- PTP Packets over EthernetPackets over Ethernet

49.3.9.9.1 PTP packets over IPv4

Table 1057 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1057*.

Table 1057. IPv4-UDP PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP Primary multicast address: 224.0.1.129 PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	0x013F: PTP event message(1) 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management

Table 1057. IPv4-UDP PTP packet fields required for control and status (continued)

Field matched	Octet position	Matched value	Description
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only).

49.3.9.9.2 PTP frames over IPv6

Table 1058 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1058*.

Table 1058. IPv6-UDP PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [0:3])	0x6	IP version is IPv6
Layer 4 Protocol	20(1)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57(1)	0x013F, 0x140	0x013F: PTP event message 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94(1)	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management (version1)

Table 1058. IPv6-UDP PTP packet fields required for control and status (continued)

Field matched	Octet position	Matched value	Description
PTP Message Type Field (IEEE 1588 version 2)	62[1] (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The Extension Header is not defined for PTP packets.

49.3.9.9.3 PTP packets over Ethernet

Table 1059 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in Table 5-12 Message Format Defined in IEEE 1588-2008n 5-12.

Table 1059. Ethernet PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Destination Multicast Address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: 01-1B-19-00-00-00 01-80-C2-00-00-0E[3]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management

Table 1059. Ethernet PTP packet fields required for control and status (continued)

Field matched	Octet position	Matched value	Description
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, *Annex F.*
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

49.3.9.10 One-step timestamp

The Ethernet module supports the one-step timestamp feature. When this feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application at that offset.

You can enable the one-step timestamp feature for a packet by setting Bit 11 (OSTC) in ATI Control Word. The inserted timestamp consists of 80-bits, the 64-bit TSSL and TSSH received from the application and the content of higher 16 bits of Higher Timestamp Word register.

Note: The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets because the timestamp insertion happens in the MAC and the IP payload checksum needs to be updated. However, the checksum computation happens in the MTL.

49.3.9.10.1 MAC transmit PTP mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- Correction Field in the PTP header of messages
- OriginTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 1060 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the *Section 49.2.2.148: Timestamp control register (MAC_TIMESTAMP_CONTROL)* and the fields that are updated for the incoming PTP

packets based on the message type in that mode, during the one-step timestamping operation.

Table 1060. MAC transmit PTP mode and one-step timestamping operation

Programming			Mode	Per packet control[1]			Messages processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE	OSTC	TTS	
X	X	X	N/A	1	X	X	Timestamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
2’b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)
2’b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

Table 1060. MAC transmit PTP mode and one-step timestamping operation (continued)

Programming			Mode	Per packet control[1]			Messages processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE	OSTC	TTS	
2'b01	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

1. The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.

Note: Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp. When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy. Clocks supporting peer delay mechanism does not use delay request or response, but it is included in OST for flexibility.

49.3.10 TCP/IP offloading features

49.3.10.1 IPv4 ARP offload

The Ethernet module supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. The Ethernet module generates the ARP reply packets for appropriate ARP request packets**.** The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programmed in the L3 register of the MAC.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   – DA field of the Ethernet packet header.
   – Target Hardware Address field of the ARP reply packet.
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   – SA field of the Ethernet packet header.
   – Sender Hardware Address field of the ARP reply packet.
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 21) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of an ARP request Packet. The ARP request Packet must always have a valid CRC. It can generate an ARP response packet if the other conditions are valid.

49.3.10.2 Checksum offload engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path.

Note: On the transmit path the Checksum Offload Engine is present in Queue0 only.

49.3.10.2.1 Transmit checksum offload engine

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[14:15]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the Ethernet module is configured for Threshold (cut-through) mode.
You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts

reading to avoid dead-lock. When reading starts, the COE fails and consequently all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the following number of bytes in size: TXFIFO_SIZE – ((PBL + N) × (DATAWIDTH/8)), Where N= 5

49.3.10.2.1.1 IP header checksum engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 31). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

49.3.10.2.1.2 TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 19). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the

store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 1061 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 1061. Transmit checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2 K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	No
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Authentication	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No

Table 1061. Transmit checksum offload engine functions for different packet types (continued)

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

49.3.10.2.2 Receive checksum offload engine

You can enable the Receive Checksum Offload Engine (Rx COE) by setting the IPC bit of MAC_Configuration register. When enabled, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is sent in the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 1062 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as “No” in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status, as described in *Table 1073*.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 1062. Receive checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	Yes
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

49.3.10.2.2.1 Splitting header on receive

Optionally, the incoming receive packet header can be split such that the header and the payload are stored in different buffers in the system memory.

Header splitting is also useful for non-IP packets such as AVB traffic which are generally multicast type. This enables the application to store the packet header of AVB streams and payload for AVTP (Audio Video Transport Protocol) packets and the DMA can process the header and payload of the received packets separately.

Table 1063 shows how DMA processes a packet depending upon its type and the value of the SPLM bit.

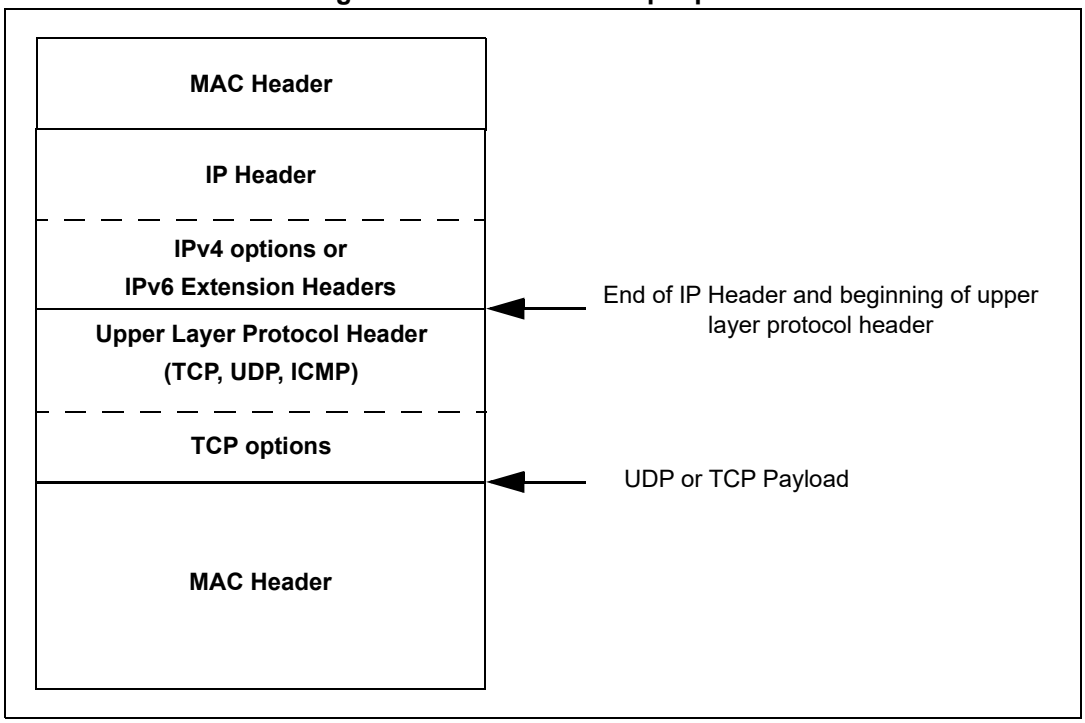
Table 1063. Split header support depending on the packet type

Packet type	SPLM	Description
TCP or UDP packet	00 (L3/L4 split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
IP packet and non IP packet	01 (L2 split)	The DMA writes the Ethernet header based on split offset (SPLOFST) into the header buffer.
IP packet	10 (combination of L2 or L3/L4 split)	L3/L4 split
Non-IP packet		L2 split
NA	11	Reserved

Note: L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped.

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames. The points at which the L3/L4 header is split are shown in the below figure.

Figure 962. L3/L4 header split points



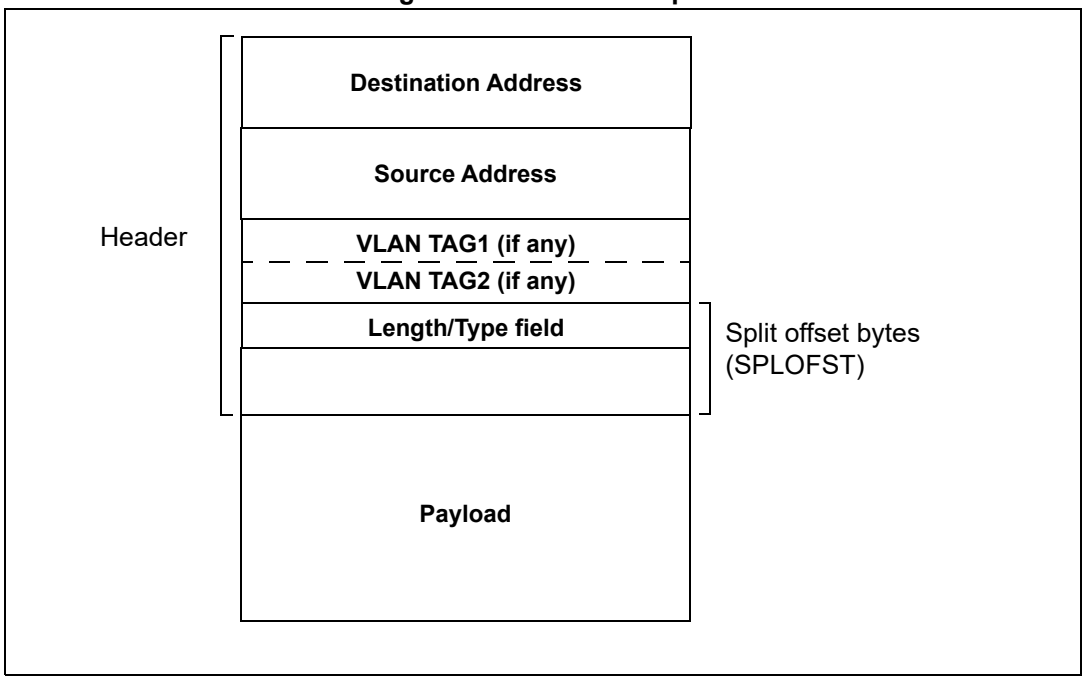


Figure 963 shows the IP header split for L2. The split is based on SPLM filed which is a programmable 2-bit field of MAC_Ext_Cfg1 register. The programmable offset field allows the frames to be split at a fixed length starting from the Length/Type field, which is indicated by the SPLOFST field of the MAC_Ext_Cfg1 register. For more details, refer to *Section 49.2: Memory map and registers description*.

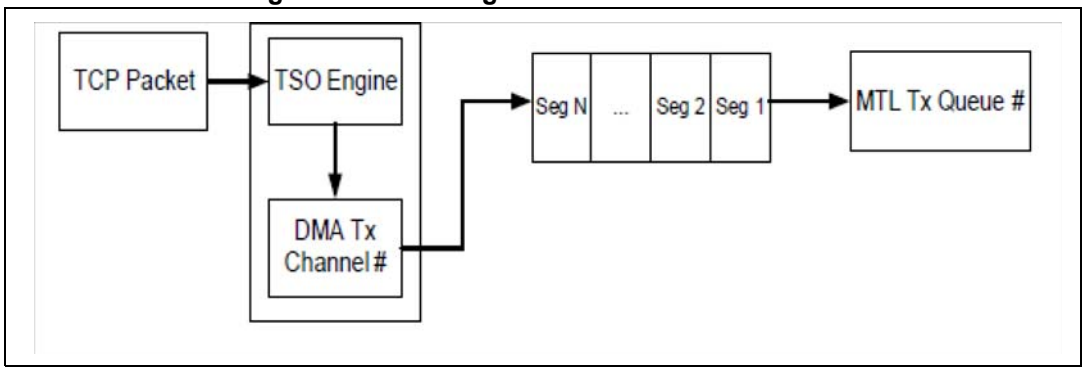
Figure 963. L2 header split

Refer to *Section 49.5.11: Programming guidelines for split header on Receive*.

49.3.10.3 Using the TCP/IP Segmentation Offload (TSO) engine

49.3.10.3.1 Introduction to the TSO engine



The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.

49.3.10.3.2 Description of TCP segmentation offload engine

In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in *Figure 964*.

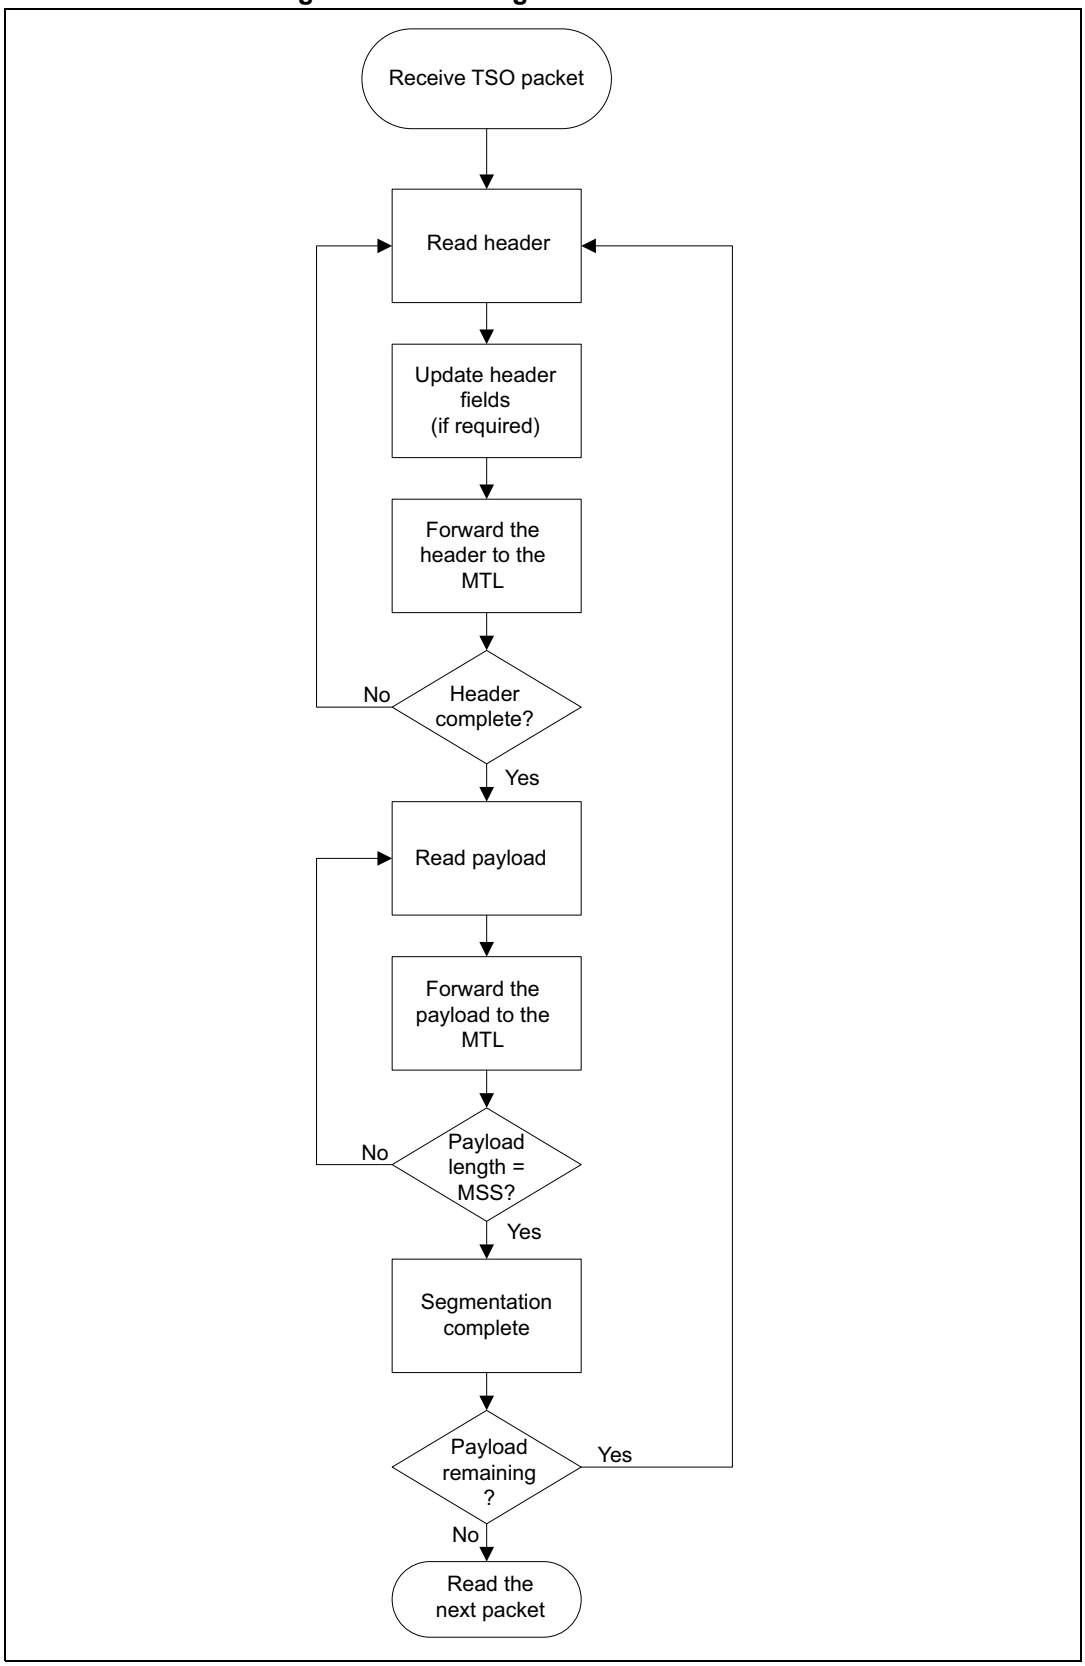


Figure 964. TCP segmentation offload overview

49.3.10.3.2.1 DMA operation with TSO feature

Figure 965 shows the TSO flow.

Figure 965. TCP segmentation offload flow

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application increases the offset value of the Descriptor Tail pointer of the DMA Tx channel.
3. While in the Run state, the DMA fetches the next available descriptor and does one of the following:
   a) If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
   b) If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.
   c) If the descriptor is a normal descriptor, the DMA checks for the TSE bit. If TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).
4. The DMA calculates the number of segments from the TCP payload length(TDES3[17:0]) and the MSS value.
5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.
6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size).
   If the current segmented packet is not the first segment, the DMA fetches the header from the local TSO memory if available. Otherwise, it will fetch the header buffer in system memory again, as done for the first segment. In such cases (header not available is TSO memory), the DMA will not close the first descriptor containing the header buffer until the header for last segment is fetched.
7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL TxQ.
8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory and directly pushes it into the MTL TxQ. In case the buffer(s) in the descriptor do not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.
9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the TxQ.
10. The DMA closes the last descriptor and also the first descriptor (containing the header buffer when it is not stored in TSO memory) and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

Note: The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

49.3.10.3.2.2 TCP/IP header fields

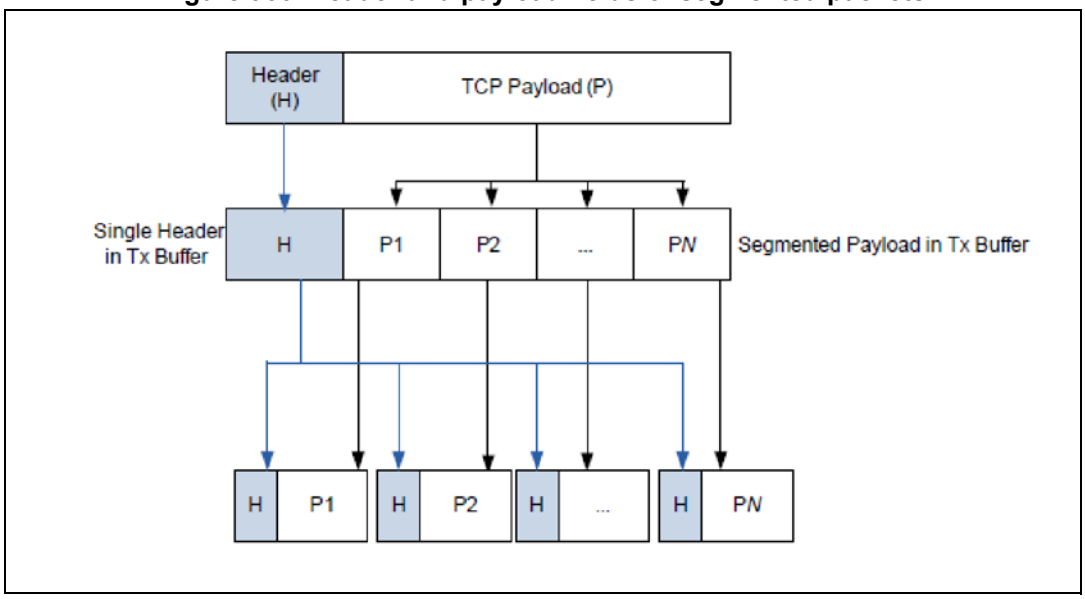
While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 1064* describes how the TCP and IP headers are updated.

Table 1064. TSO: TCP and IP header fields

Packet sequence	TCP header	IP header
First packet	– The sequence number is not updated. The value provided in the header is used. – The TCP checksum is calculated again. – If set, the FINand PSH flags are cleared.	– IPv4 Header – Total Length = MSS + TCP Header Length + IP Header Length – Identification field is not modified It is sent as per the header provided by the software – IPv4 Header Checksum is recalculated. – IPv6 Header Payload Length = MSS + TCP Header Length + IP Extension Header Length
Subsequent packets	– The sequence number is updated. The MSS value is added to the sequence number value of previous segment. – If set, the FINand PSH flags are cleared. – The TCP checksum is calculated again.	– IPv4 Header – Total Length = MSS + TCP Header Length + IP Header Length – Identification field = Previous Identification Field + 1 – IPv4 Header Checksum is recalculated – IPv6 Header Payload Length = MSS + TCP Header Length + IP Extension Header Length
Last packet	– The sequence number is updated. The MSS value is added to the sequence number value of previous segment. – If FINand PSH flags were set in original header, these flags are set. – The TCP checksum is calculated again.	– IPv4 Header – Total Length = Remaining payload + TCP Header – Identification field = Previous Identification Field + 1. – IPv4 Header Checksum is recalculated – IPv6 Header Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length

Note: In case of USO, the engine updates only the following fields in the IP-UDP headers:

- *Total Length, Identification Field, and Header Checksum field in IPv4 header*
- *Payload Length field in IPv6 header*
- *Length and Checksum field in UDP header*



49.3.10.3.2.3 Header and payload fields of segmented packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in *Table 1064*. *Figure 966* shows how the same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When

the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Figure 966. Header and payload fields of segmented packets

49.3.10.3.2.4 Context descriptor sequence

You can use the context descriptor to provide the MSS value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application wants to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset.

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this MSS value for all subsequent packets that have the TSO Enabled through the TSE bit of TDES3 normal descriptor.

49.3.10.3.3 Building the descriptor and the packet for the TSO feature

Set the TSE bit of TDES3 of first normal descriptor. If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 KB.

Note: The TDES3[22:19] field is used as slot number in case of AV configurations. If both TSO and AV are enabled for the same DMA Tx channel (TSE bit is set in DMA_Tx_Control_Register), then you must not enable slot checking for that DMA Tx Channel (do not set ESC bit in DMA_CH[n]_Slot_Function_Control_Status).

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in the DMA_CH#_Control register or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in DMA_CH#_Tx_Control register should be lesser than the Tx Queue size programmed in TQS field of MTL_TxQ#_Operation_mode register. Synopsys recommends a MSS+header equal to half the programmed Tx Queue size.

The DMA also supports segmentation of VLAN Tagged TCP/IP frames, so if the TCP packet has a VLAN Tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN Tag insert/replace control bits are used for all segments.

If the Double VLAN Feature is selected, then the DMA passes both the tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN Tag Insert/Replace control bits for both tags is applicable for all segments.

If Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 2'b00 (MAC does CRC and padding) and checksum insertion control bits are forced to 2'b11 (Hardware does the checksum calculation for both header and payload).

49.3.11 Memory access in Debug mode

The Ethernet module supports the debug access to the FIFO memory. When you enable this feature, you must program the entire selected Tx memory to Tx Queue 0 and Rx memory to Rx Queue 0. In addition, the offload features such as Checksum Offload Engine and IEEE timestamp should not be enabled with this feature.

When this feature is enabled, the MAC insert the pad (if required) and computed CRC in the Transmit packet. The FIFOs operate in the store-and-forward mode.

49.3.11.1 Slave mode access

You can use this mode to send or receive a packet through a slave interface. The following sections describe how to transmit or receive a packet through a slave interface.

49.3.11.1.1 Transmitting packets through a slave interface

To write a packet to the Tx memory through a slave interface, complete the steps given in *Table 1065*.

Table 1065. Steps to write a packet to Tx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the Packet control word.
MTL_DBG_CTL	Complete the following: a. Set the PKTSTATE field to Control field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Reset the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write the SOP, the first word of the packet data.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to SOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write subsequent data words.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to Packet Data. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL and MTL_DBG_STS	Repeat Write subsequent data words. and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). till the penultimate word of the packet data.
MTL_FIFO_DEBUG_DATA	Write the last data word in the FDBGDATA field.

Table 1065. Steps to write a packet to Tx memory through a slave interface (continued)

Register name	Step number and description
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to EOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Set the number of valid bytes in the field.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.

After Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations. in *Table 1065*, the core automatically initiates the packet transmission. The status of the packet transmission can be obtained as explained in *Table 1065*. To get the status of a Tx packet, complete the steps given in *Table 1066*.

Table 1066. Steps to get the status of a Tx packet

Register name	Step number and description
MTL_DBG_STS	Wait for the STSI interrupt bit to set.
MTL_DBG_CTL	Complete the following steps: a. Set the FIFOSEL field to Tx Status FIFO. b. Reset the FIFWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_CTL	Read the FIFOBUSY bit and wait till this bit is low.
MTL_FIFO_DEBUG_DATA	Read the FDBGDATA field.

49.3.11.1.2 Receiving packets through a slave interface

To read a packet from the Rx memory through a slave interface, complete the steps given in *Table 1067*.

Table 1067. Steps to read a packet from Rx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_DBG_STS	Wait for the PKTI interrupt.
MTL_DBG_CTL	Complete the following: a. Set the FIFOSEL field to Rx FIFO. b. Reset the FIFOWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low.

Table 1067. Steps to read a packet from Rx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Read the PKTSTATE and fields.
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field to know the number of available locations.
MTL_DBG_STS, MTL_DBG_CTL, MTL_FIFO_DEBUG_DATA	Repeat Read the FIFOBUSY bit and wait till this bit is low. through Read the LOCR field to know the number of available locations. till the complete packet, along with the Rx status, is received. **Note:** The format of the received packet is as follows First (One or multiple words) Last Status Word (One Word. Acts as delimiter between the status and data) Frame Data Word (multiple) Last Frame Data Word (One Word. Acts as a delimited among subsequent packets on the received Queue)

49.3.11.2 Debug mode access

Debug mode enables you to do both the following operations:

- Write and Read back the Tx Queue
- Read and Write to the Tx Queue

This mode is useful for Memory BIST applications.

49.3.11.2.1 Writing to FIFO memory in debug mode

To write to FIFO memory in the debug mode, complete the steps given in *Table 1068*.

Table 1068. Steps to write to FIFO memory in debug mode

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the data in the FDBGDATA field.
MTL_DBG_CTL	Complete the following: – Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. – Reset the FIFORDEN bit. – Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL - MTL_DBG_STS	Repeat Complete the following: and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). twice to write one complete data word in 64-bit mode.

49.3.11.2.2 Reading from FIFO memory in debug mode

To read from FIFO memory in the debug mode, complete the steps given in *Table 1069*.

Table 1069. Steps to read from FIFO memory in debug mode

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. b. Reset the FIFOWEN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field (if required).
MTL_DBG_CTL, MTL_DBG_STS, MTL_FIFO_DEBUG_DATA	Repeat Complete the following: and Read the LOCR field (if required). twice to read one complete data word in 64-bit mode.

49.3.12 Loopback

The MAC supports Loopback of transmitted packets to its receiver. By default, the MAC Loopback function is disabled. You can enable this feature by programming the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block. The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip, you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.
- The MAC does not process ARP or PMT packets that are looped back.

49.3.13 MAC flow control

This section describes the flow control for Transmit and Receive paths.

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

In the Receive path, the Flow Control is functional only in the full-duplex mode. The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

49.3.13.1 Transmit flow control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

The Transmit Flow Control is enabled independently for each Rx queue when TFE bit is set in MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

The software can request the MAC to send a Pause packet or initiate backpressure by setting the FCB_BPA bit in the corresponding MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

The hardware can automatically trigger TX flow control based on the Rx Queue Threshold**.** The hardware flow control operation of the MAC is enabled when the EHFC bit of the corresponding MTL_RxQ*n*_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in the RFA field of the MTL_RxQ*n*_Operation_Mode register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field.

Table 1070, describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE bit of the MAC_Q0_Tx_Flow_Ctrl register
- DM bit of the MAC_Configuration register
- RFA field of the MTL_RxQ0_Operation_Mode register
- RFD field of the MTL_RxQ0_Operation_Mode register
- FCB_BPA bit of the MAC_Q0_Tx_Flow_Ctrl

Flow control is similar for Queue1.

Table 1070. TX MAC flow control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX performs backpressure when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the pause packet when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	1	The MAC transmitter sends the pause packet when FCB_BPA of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX sends a pause packet when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.

49.3.13.1.1 Flow control in full-duplex mode

In full-duplex mode, the Ethernet module uses IEEE 802.3x Pause packets for flow control. *Table 1071*, describes the fields of a Pause packet. When the FCB_BPA bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Table 1071. Pause packet fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets
PT	Contains Pause time specified in the PT field of the MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register

49.3.13.1.2 Flow control in half-duplex mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

49.3.13.2 Receive flow control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet. You can enable the Pause flow control by setting the RFE bit in the MAC_Rx_Flow_Ctrl register. *Table 1072*, describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 1072. RX MAC flow control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

When the RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   – Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001).
   – Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set.
   If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.
2. The MAC decodes the following fields of the received packet:
   – Type field: This field is checked for 16'h8808.
   – Opcode field: This field is checked for 16'h0001 (Pause packet).
   – Pause Time: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).
3. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register.
4. If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

49.3.14 MAC management counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the CSR. Each register is 32-bit wide. The width of each MMC counter is 32-bit.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, you should set Bit 31 in the MAC_Packet_Filter register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

The following definitions define the terminology.

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - MII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1518
  - VLAN Frame maxsize = 1522
  - Jumbo Frame maxsize = 9018
  - JumboVLAN Frame maxsize = 9022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in *Table 1073*

Table 1073. Size of the maximum receive packet size

JE	S2KP	GPSLCE	EDVLP	Untagged frame maxsize in bytes	Single VLAN frame maxsize in bytes	Double VLAN frame maxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

49.3.15 Low power modes

This chapter describes the low power modes supported by the Ethernet module. It contains the following sections:

- Energy Efficient Ethernet
- Power Management

49.3.15.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities, negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Note: The EEE feature is not supported when the MAC is configured to use the RMII PHY interface. Even if the MAC supports multiple PHY interfaces, you should activate the EEE mode only when the MAC is operating with the MII interface.
According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

49.3.15.1.1 Transmit path functions

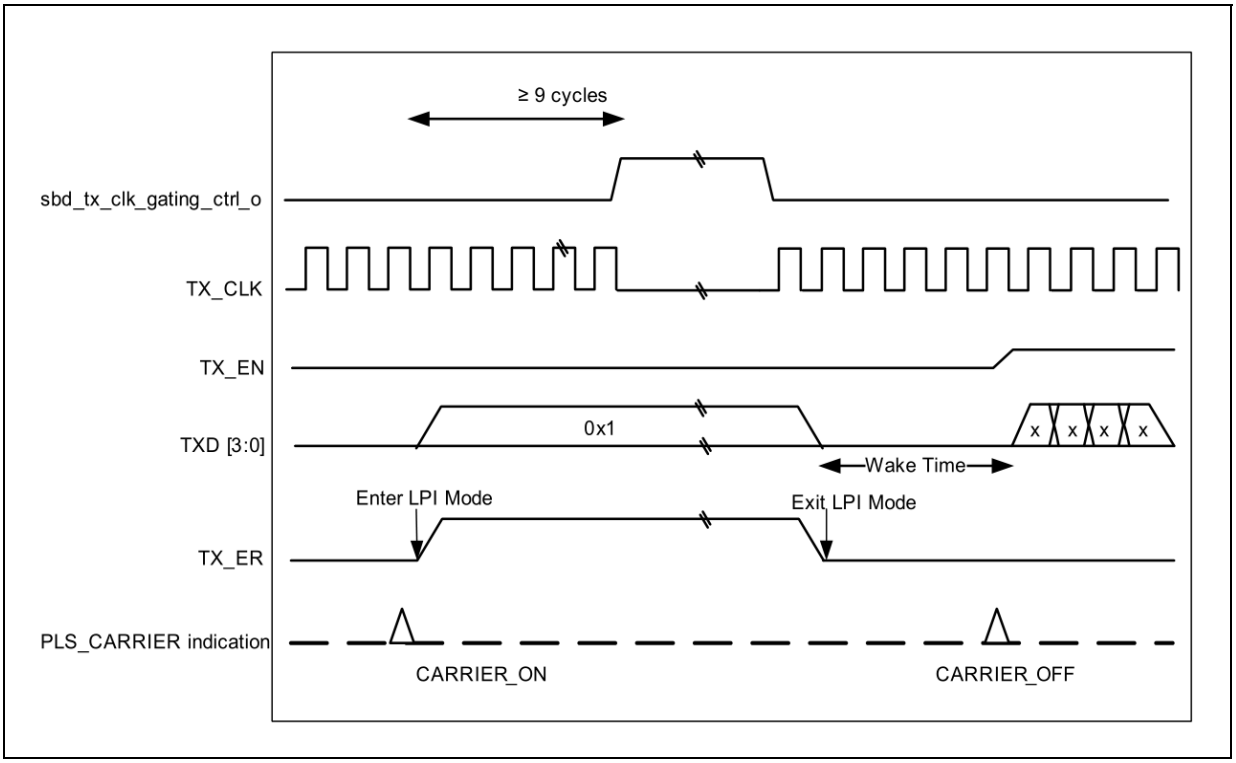
In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Timers_Control register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

Note: According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps).
4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt.

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:



1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC_LPI_Timers_Control register.
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt.

Figure 967 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

Note: The MAC maintains the same state as the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

The MAC does not stop the TX_CLK clock. You can stop this clock (as shown in Figure 967) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after 9 Tx Clock Cycles, one Pulse Synchronizer delay (BCM22), and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status Register.
If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

Figure 967. LPI transitions (transmit)

49.3.15.1.1.1 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[12]) and LPITXEN (Bit[15]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[11] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

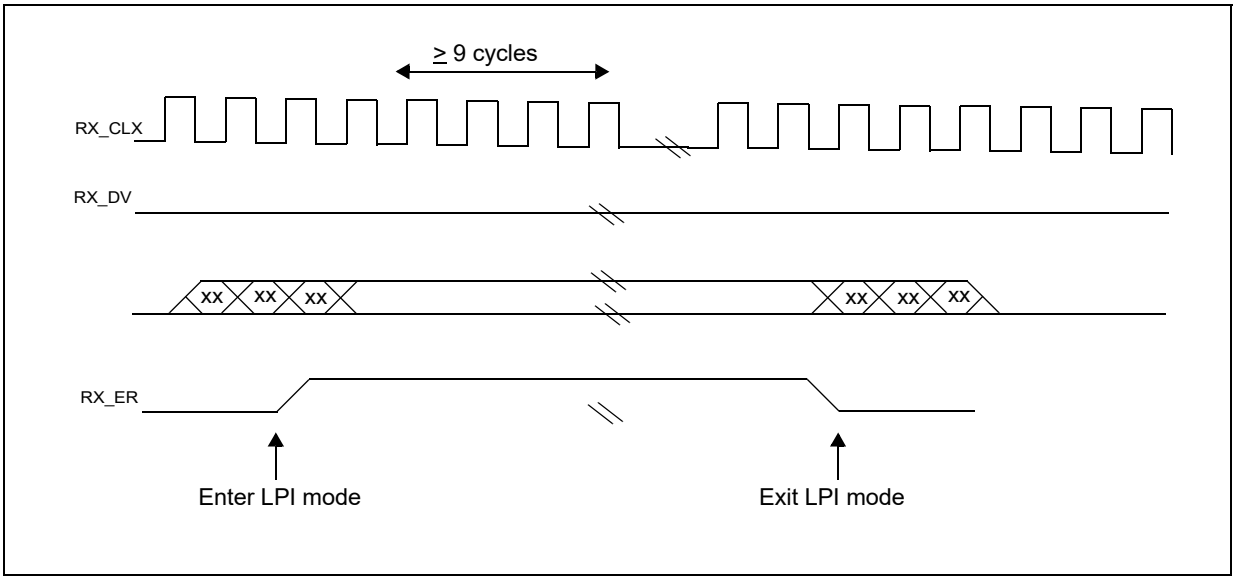
When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

49.3.15.1.2 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt.

Note: If the LPI pattern is detected for a very short duration (that is, less than 2 cycles of Rx clock), the MAC does not enter the Rx LPI mode.
If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than 2 cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.



The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 968 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 968. LPI transitions (receive)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in Figure 968.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.
When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

49.3.15.1.3 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER: The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.
  This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in Bits[6:15] of the MAC_LPI_Timers_Control register. The MII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.
- LPI TW TIMER: The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[16:31] of MAC_LPI_Timers_Control register. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal

operation after the TW timer reaches the terminal count.
The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µs.

- LPI AUTO ENTRY TIMER: This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

49.3.15.2 Power management

The power management (PMT) block supports the reception of network (remote) wake-up packets and magic packets. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up packets and magic packets that the MAC receives.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up packet is received and the corresponding detection is enabled.

The PMT block is available in the receive path of MAC. You can select both types of power management packet (remote wake-up packet and magic packet). You can use the RWKPKTEN and MGKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

Note: The magic packet feature is implemented based on the Magic Packet Technology white paper. The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

49.3.15.2.1 PMT block registers

The following are the PMT block registers:

- MAC_PMT_Control_Status
- MAC_RWK_Packet_Filter

49.3.15.2.2 Remote wake-up packet detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status, the normal operation is resumed after a remote wake-up packet is received. The application writes all eight wake-up filter registers, by performing a sequential Write to address (00C4H). The application enables remote wake-up by writing 1 to the RWKPKTEN bit of the MAC_PMT_Control_Status register.

The PMT block supports 4 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wake-up packet.

The Filter Offset determines the offset from which the packet is to be examined. The Filter Byte Mask determines which bytes of the packet must be examined. The bit 0 of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up packet is checked only for length error, FCS error, dribble bit

error, MII error, and collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wake-up packet detection is updated in the PMT Control and Status register for every remote wake-up packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wake-up packet.

Note: The watchdog timeout limit for a remote wake-up frame is 2048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a remote wake-up frame only when Enable IPv4 ARP Offload is selected in the configuration.

49.3.15.2.3 Magic packet detection

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wake-up packet data format of 6 bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wake-up by writing 1 to the MGKPKTEN bit of the MAC_PMT_Control_Status register. The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48’hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48’hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48’hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

Destination Address Source Address …….. FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

The Ethernet module checks the remote wake-up packet only for length error, FCS error, dribble bit error, MII error, collision. In addition, the remote wake-up packet is checked to

ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, the Ethernet module considers it a valid packet.

The magic packet detection is updated in the MAC_PMT_Control_Status register for the received magic packet. A PMT interrupt to the Application triggers a read to the MAC_PMT_Control_Status register to determine whether a magic packet has been received.

Note: The watchdog timeout limit for a magic packet is 2048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet only when Enable IPv4 ARP Offload is selected in the configuration.

49.3.15.2.4 System considerations during power down

The Ethernet module neither gates nor stops clocks when the power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during the power-down mode, because it is involved in the magic packet or remote wake-up packet detection. However, the application path clock can be gated during the power-down mode. The transmit Path clock must be gated during the power-down mode only if ARP Offload is not enabled.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt [Bit 31 of the register] is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC_Configuration register.
3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. You can do this by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter the Power-Down mode.
6. Gate the application and transmit clock (transmit clock must be gated only if ARP Offload is not enabled) inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid remote wake-up packet, the Ethernet module asserts the pmt_intr_o signal and exits the Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

49.3.16 Interrupts

Interrupt can be generated as a result of various events in the Ethernet IP core. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (interrupt) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the DMA_Interrupt_Status register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX and RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH*n*_STATUS register
- MTL_INTERRUPT_STATUS register
- MAC_INTERRUPT_STATUS register

The interrupt is a level signal and will get de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

49.3.16.1 DMA interrupts

The DMA_CHn_STATUS register captures all the interrupt events of that TxDMA and RxDMA channel pair. The DMA_CH*n*_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[16:17] of DMA_CHn_STATUS register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[25] of DMA_CHn_STATUS register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the register for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of the DMA_Interrupt_Status register are cleared.

49.3.16.1.1 Periodic scheduling of DMA Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet IP gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[0]) once for every “required” number of packets to be transmitted.
2. Similarly, set the IOC (RDES3[1]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.

In addition to above, an interrupt timer (DMA_CHn_RX_INTERRUPT_WATCHDOG_TIMER) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a

non-zero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[1]) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH*n*_Interrupt_Enable register. The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

49.3.16.1.2 Per DMA channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CHn_STATUS register. The TI bit is set whenever the Tx DMA channel closes the a descriptor in which the IOC (Interrupt On Completion - TDES2[0]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[1]) bit is set.

The common interrupt output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH*n*_Interrupt_Enable register.

49.3.16.2 MTL interrupts

In MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the Transmit and Receive paths respectively. The interrupt status are captured and organized in a hierarchical manner in order to identify the root cause quickly.

The MTL_INTERRUPT_STATUS register identifies the top level modules that can cause the interrupt to be asserted.

- Bits[30:31] identify 2 Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Q*n*_Interrupt_Status register to identify the exact cause and set the corresponding bits to 1 to clear the interrupt event. The assertion of interrupt due to these events is enabled by the corresponding enable bits in MTL_Q*n*_Interrupt_Enable register.
- Bit[15] is made high in case the event is present in the MAC core. The application should in turn read the MTL_INTERRUPT_STATUS register to identify the cause.
- Bit[14] is related to indirect access completion events to the TxFIFO and RxFIFO memory in Debug Mode.

49.3.16.3 MAC interrupts

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_INTERRUPT_STATUS register describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the MAC_INTERRUPT_ENABLE register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, Bit 26 of the MAC_INTERRUPT_STATUS register indicates that

the LPI interrupt status has changed. You must read the TLPIEN bit of MAC_LPI_Control_Status register to clear this interrupt event.

The interrupts from the MAC are combined (OR'ed) and given as the MACIS bit in the DMA_Interrupt_Status register.

49.3.16.4 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt mci_intr_o (interrupt in EQOS-DMA configurations) is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the mci_intr_o (interrupt in EQOS-DMA configurations), the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. You can use the lpi_intr_o signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state. If you do not want to gate-off the application clock during the Rx LPI state, you can leave the lpi_intr_o signal unconnected and use the mci_intr_o (interrupt in EQOS-DMA configurations) signal to detect Rx LPI exit.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

49.3.16.5 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. In addition to the interrupt, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode.

You can use the pmt_intr_o interrupt to trigger the external clock-gating circuitry to restore the application clock and Tx clock to the MAC. If you do not want to gate-off these clocks during the power-down mode, you can leave the pmt_intr_o signal unconnected and use the interrupt to detect the MAC wake-up operation.

The pmt_intr_o signal is generated in the Rx clock domain. It is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

When software resets the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

49.3.16.6 Overview of interrupt for MDIO transaction completion

This is to generate an interrupt on completion of MDIO read or write transactions. The application does not need to poll the GMII Busy bit of MAC_MDIO_Address register to know the completion of MDIO commands.

49.3.16.6.1 Related registers

The following are the registers are modified for the design changes:

- MAC_INTERRUPT_STATUS
- MAC_INTERRUPT_ENABLE

49.3.17 PHY interfaces

Refer to the Device Configuration chapter for PHY interfaces configuration.

49.3.17.1 Station management agent

49.3.17.1.1 Introduction to station management agent

The application can access the PHY registers through the Station Management Agent (SMA) module. SMA is a two-wire Station Management interface (MIM).

49.3.17.1.2 Functional description of station management agent

In the ethernet module core, the gmii_mdc_o clock is derived from the APB clock, using a divider-counter. The divide factor depends on the clock range setting (CR field) in the MAC_MDIO_Address register.

Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register, to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, there is a provision to select a different divider.

The MDIO frame structure is as follows:

Table 1074. MDIO clause 45 frame structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2’b00
OPCODE	– 2’b00 – 2’b01 – 2’b10 – 2’b11
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices

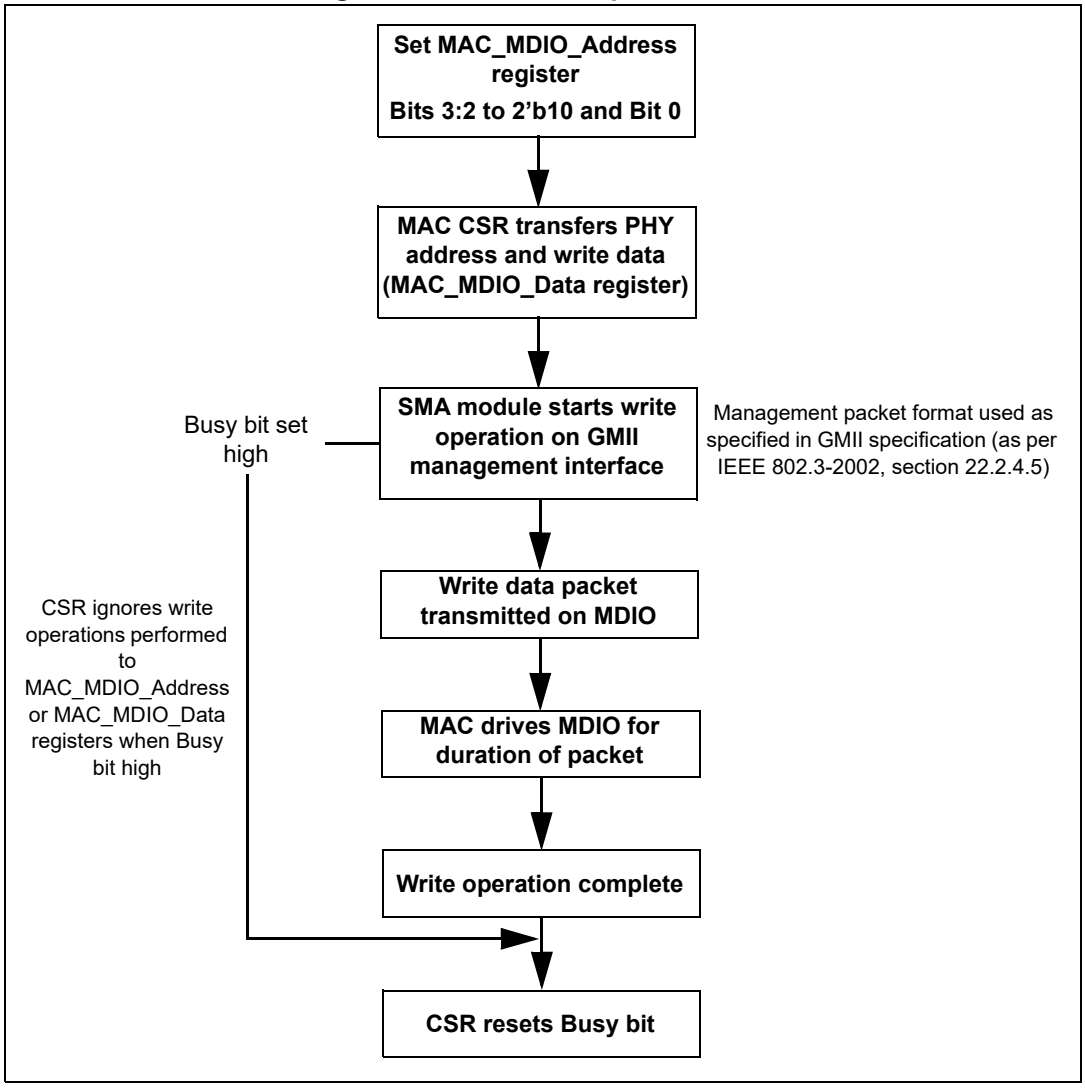
Table 1074. MDIO clause 45 frame structure (continued)

Field	Description
TA	Turnaround – 2'bZ0: Read and post-read increment address – 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value: For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. – In address and data write cycles, the ethernet module drives the MDIO line during the transfer of these 16 bits. – In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Address register can be programmed to enable Clause 22 or Clause 45 mode of operation. The table below shows the Clause 22 frame format.

Table 1075. MDIO clause 22 frame structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2'b01
OPCODE	– 2'b01 for Write – 2'b10 for Read
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address to select the register within each MMD
TA	Turnaround – 2'bZ0: Read and post-read increment address – 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	Any 16-bit value: – In a write operation, the ethernet module drives MDIO. – In read operation, the PHY drives MDIO.



In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

49.3.17.1.2.1 GMII/MII management write operation

After the Station Management Agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

The following figure illustrates the flow for a Write operation from the SMA module to the PHY registers.

Figure 969. SMA write operation flow

When you set Bit[3:2] to 2'b01 and Bit 0 in the MAC_MDIO_Address register, the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MAC_MDIO_Data register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MAC_MDIO_Address register or the MAC_MDIO_Data register during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit.

The packet format for the Write operation is shown in the following figure:

Figure 970. Packet format for the write operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD...DDD	Z

49.3.17.1.2.2 GMII/MII management read operation

After the Station Management Agent receives the PHY address and the register address in the PHY from the MAC CSR module, the SMA initiates a Read operation to the PHY registers.

The flow of a Management read operation is as follows:

1. Set Bit[3:2] to 2'b11 and Bit 0 in the MAC_MDIO_Address register.
2. The MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers.
3. The SMA module starts a Read operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).
4. When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MAC_MDIO_Address or MAC_MDIO_Data register during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface.
5. When the Read operation is complete, the SMA indicates this to the CSR.
6. The CSR resets the Busy bit and updates the MAC_MDIO_Data register with the data read from the PHY.

For more information about the communication from the application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

Figure 971. Packet format for the read operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD...DDD	Z

Note: The MAC drives the MDO on negedge of MDC so that it can be sampled on posedge with sufficient setup or hold time (half cycle of MDC). Similarly, the PHY can drive MDI on negedge so that the MAC samples it on posedge, thus providing half cycle setup or hold time.

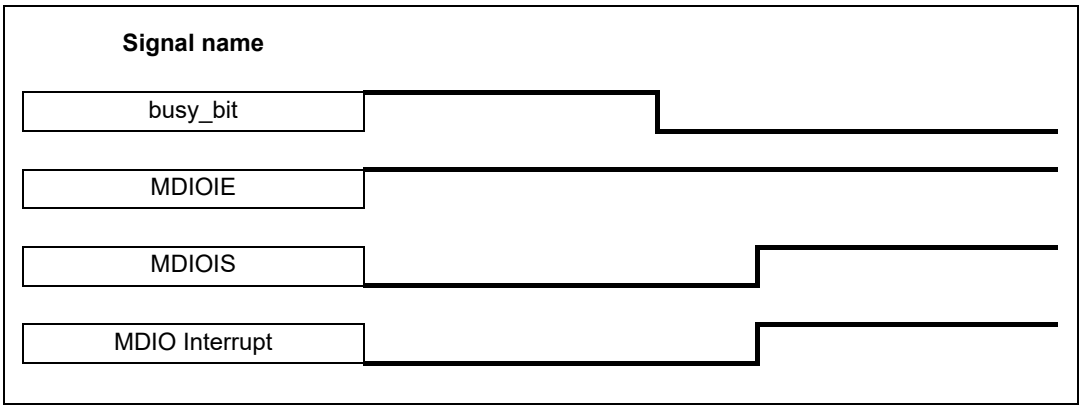
49.3.17.1.2.3 Preamble suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The ethernet module provides controls to support preamble suppression, it will transmit MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting PSE bit of MAC_MDIO_Address register.

49.3.17.1.2.4 Trailing clocks and back to back transactions

The ethernet module drives MDC clock on the gmii_mdc_o port for duration of the MDIO frame. There is no clock driven during the idle period. The trailing clocks feature can be used if the PHY needs the MDC clock to be active for some cycles after the MDIO frame. The NTC field in MAC_MDIO_Address register allows programming of trailing clocks from 0 to 7.

The ethernet module supports Back to Back transactions which allows start of next MDIO frame even before the trailing clocks are completed for previous MDIO frame. This feature can be enabled by setting BTB bit in MAC_MDIO_Address register when trailing clocks feature is also enabled. When Back to Back transactions is enabled, the GMII Busy will be cleared immediately after MDIO frame completion allowing the software to issue next command, which will be executed by ethernet module while trailing clocks are still on for previous MDIO frame. When Back to Back transactions is not enabled, the GMII Busy will be cleared after the trailing clocks are completed for MDIO frame.



49.3.17.1.3 Interrupt for MDIO transaction completion

The application does not need to poll the GMII Busy bit of MAC_MDIO_Address register to know the completion of MDIO commands.

GMII busy bit is set to instruct the SMA to initiate a Read or Write access to the MDIO slave. After the completion of the command, the busy signal is de-asserted to indicate the completion of MDIO transaction.

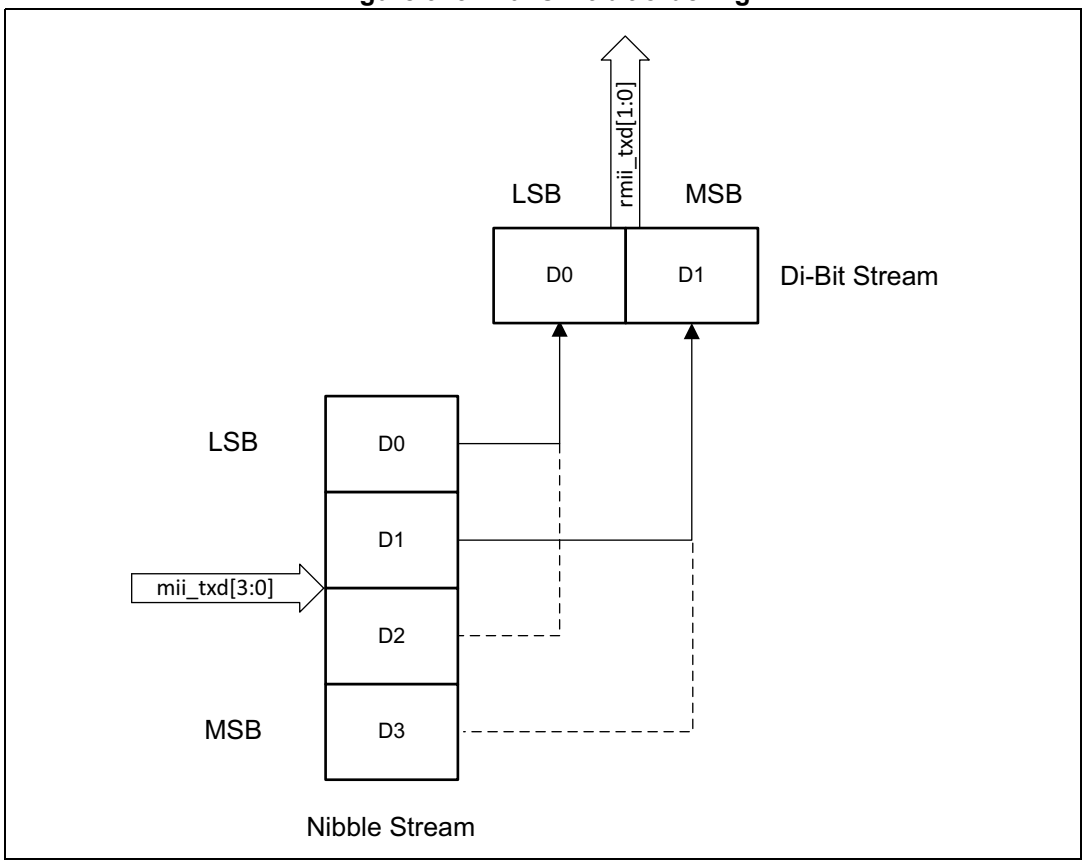
A pulse generated at the falling edge of the busy signal is used to set the MDIO interrupt status bit of MAC Interrupt Status register. The interrupt is generated only if the MDIO Interrupt Enable bit of MAC Interrupt Enable bit is set.

Figure 972. MDIO interrupt timing diagram

49.3.17.2 Reduced Media Independent Interface

49.3.17.2.1 Introduction to Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode).



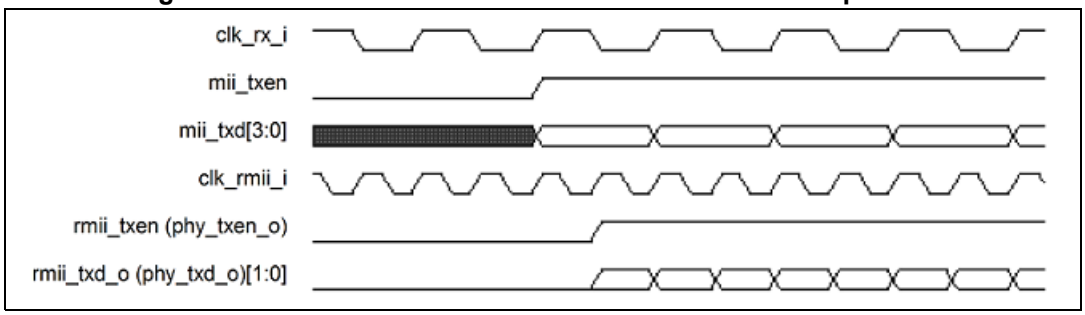
The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bit wide Transmit and Receive paths.

49.3.17.2.1.1 Transmit bit ordering

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in below figure. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

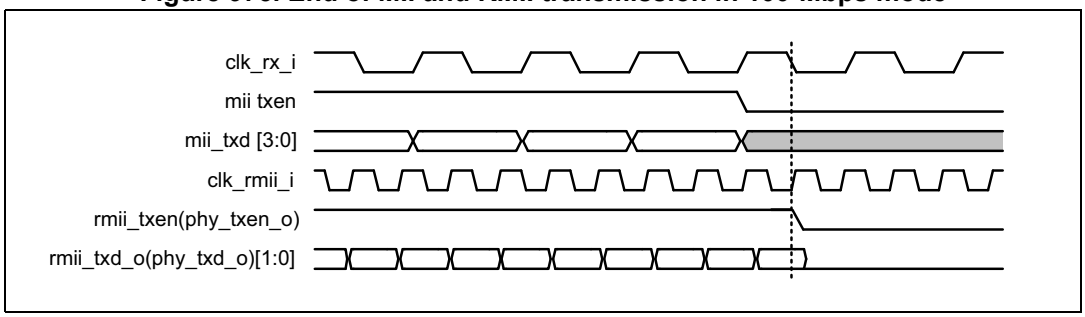
Figure 973. Transmit bit ordering



49.3.17.2.1.2 RMII transmit timing diagrams

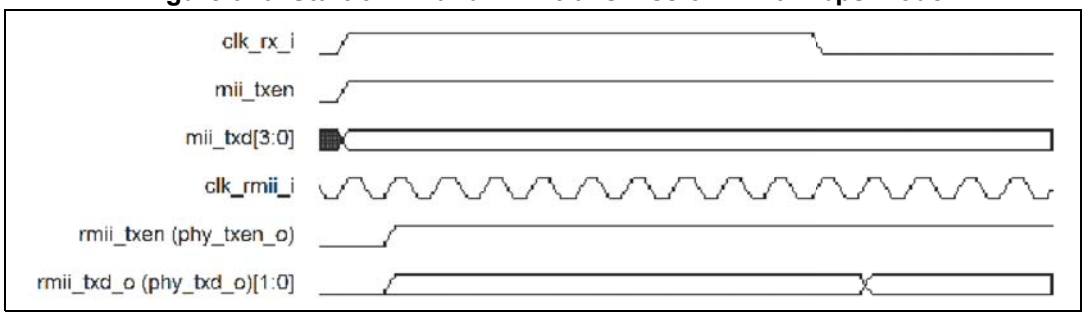
RMII transmit timing diagrams depict the various MII transmissions.

Figure 974 through *Figure 977* show MII-to-RMII transaction timing.



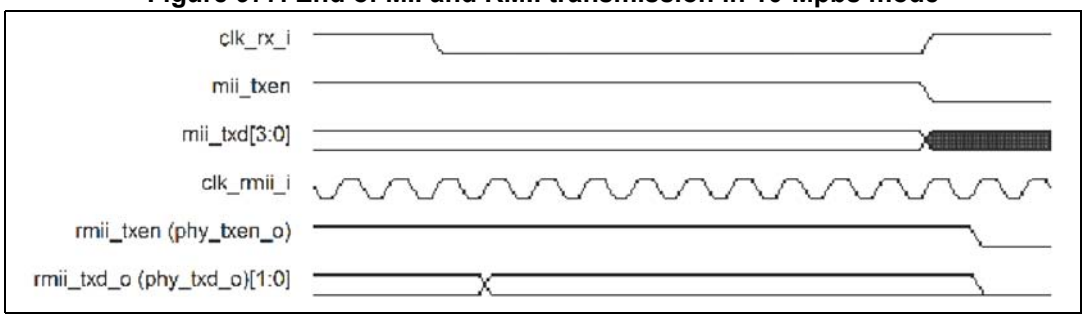
The figure below shows the start of MII transmission and the following RMII transmission in 100-Mbps mode.

Figure 974. Start of MII and RMII transmission in 100-Mbps mode



The figure below shows the end of packet transmission for MII and RMII in 100-Mbps mode.

Figure 975. End of MII and RMII transmission in 100-Mbps mode



The figure below shows the start of MII transmission and the following RMII transmission in 10-Mbps mode.

Figure 976. Start of MII and RMII transmission in 10-Mbps mode

The figure below shows the end of MII transmission and RMII transmission in 10-Mbps mode.

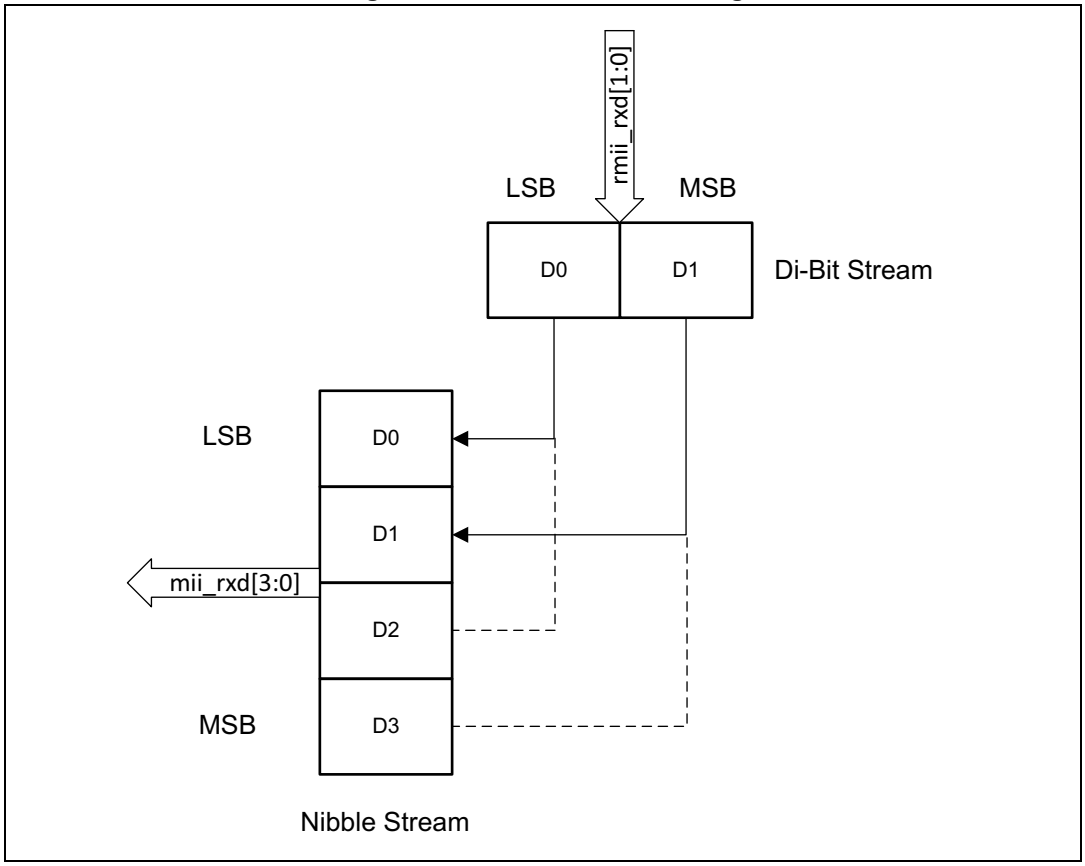


Figure 977. End of MII and RMII transmission in 10-Mpbs mode

49.3.17.2.1.3 Receive bit ordering

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in the below figure. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 978. Receive bit ordering

49.3.18 Safety

To make an IP better suited for applications in the automotive space, functional safety has been considered throughout the IP development process. ISO 26262 addresses functional safety and requires the hardware components to be analyzed with respect to their ability to detect and/or control the effects of random hardware faults. Random hardware faults can occur at any point in time during the life-cycle of the hardware component. They can take the form of permanent faults, or transient faults, and require safety mechanisms to be in place to ensure that severe consequences do not occur as a result of those faults.

The module includes the internal safety mechanisms which assist in detecting and handling random hardware faults. These complement the mechanisms already defined in the module protocol. The automotive safety features are targeted to improve the reliability and reduce

the time taken to detect faults in the controller. The module supports the following features for automotive safety:

- Error Correction Code (ECC) Protection for all Memories
- On-Chip Data Path Parity Protection
- FSM Parity and Timeout Protection
- AHB Master Interface Timeout Protection

49.3.18.1 Error Correction Code (ECC) Protection for Memories

49.3.18.1.1 Overview

Error Correction Code (ECC) protects all local memories of the module. ECC can correct single-bit error and detect double-bit error.

At the write interface, ECC check bits are computed on the contents of the data bus and respective write address. These ECC check bits are appended with the data that is written to the memory.

At the read interface, ECC check bits are recomputed on the content of the read data and the respective read address. This recomputed ECC is compared with the ECC check bits received from memory. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

49.3.18.1.2 Diagnostic Support for the Error Management

The following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_ECC_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first erred memory address is reported or the latest erred memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors.
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected and the corresponding interrupt enable bits are set.
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Interrupt_Status registers.
- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

49.3.18.1.3 Handling the Uncorrectable Errors

Recovery from an uncorrectable error is based on the memory block and the operating mode of Ethernet module.

49.3.18.1.3.1 MTL Tx memory

If an uncorrectable error is detected, the packet is terminated with a forcible EOF. A CRC error is introduced by MAC for the transmitted packet, and the remaining packets in the FIFO are flushed and flush status (Bit 13) is indicated to the application in the TDES3 write-back descriptor belonging to that queue.

When an uncorrectable error is detected and reported by asserting the safety uncorrectable interrupt, reset the module to ensure proper functionality.

49.3.18.1.3.2 MTL Rx memory

When an uncorrectable error is detected, reset the module to ensure proper functionality.

49.3.18.1.3.3 MTL EST memory

This section is applicable only if the module configuration supports EST feature.

When an uncorrectable error is detected in the MTL EST memory, the module follows this sequence of actions for recovery:

1. The module disables the EST feature by resetting the EEST bit of MTL_EST_Control register. It sets all the gates to open state, generates an interrupt, and sets the status in the MTL_ECC_Interrupt_status register. This allows the software to reprogram the correct value in the EST memory.
2. The location of the uncorrected error in the EST memory is available in the ESTUEA/ESTCEA field of the MTL_EST_ECC_Err_Addr_Status register.

49.3.18.1.3.4 MTL Rx Parser memory

This section is applicable only if the module configuration supports FRP feature.

When an uncorrectable error is detected in the MTL Rx Parser memory, an error indication is provided to the Rx Parser block. The parser halts the parsing of the corresponding packet and all subsequent packets are accepted and marked as 'Parsing Incomplete (RXPI)' in the packet status of descriptor.

49.3.18.1.4 ECC Error Injection Capabilities

The module supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection.
- Two bits to indicate the type of error to be injected:
  - 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for:

- Tx/Rx FIFO memory are specified in the MTL_DBG_CTL register.
- EST memory are specified in the MTL_EST_GCL_Control register. Applicable only if the module configuration has EST feature enabled.
- RX parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register.
- Applicable only if the module configuration has EST feature enabled.

While using debug mode for ECC error injection:

- There should be no traffic.
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write maintains the same value for the error injection control word.

49.3.18.2 On-Chip Data Path Parity Protection

49.3.18.2.1 Overview

This feature provides parity protection for Transmit and Receive data paths, where feasible. For every byte of data, one bit parity is generated.

At the transmit side, the data from the host memory is protected with parity until it is written into the MTL Tx FIFO.

At the receive side, data from the MTL Rx FIFO read side is protected with parity until it is sent to the host.

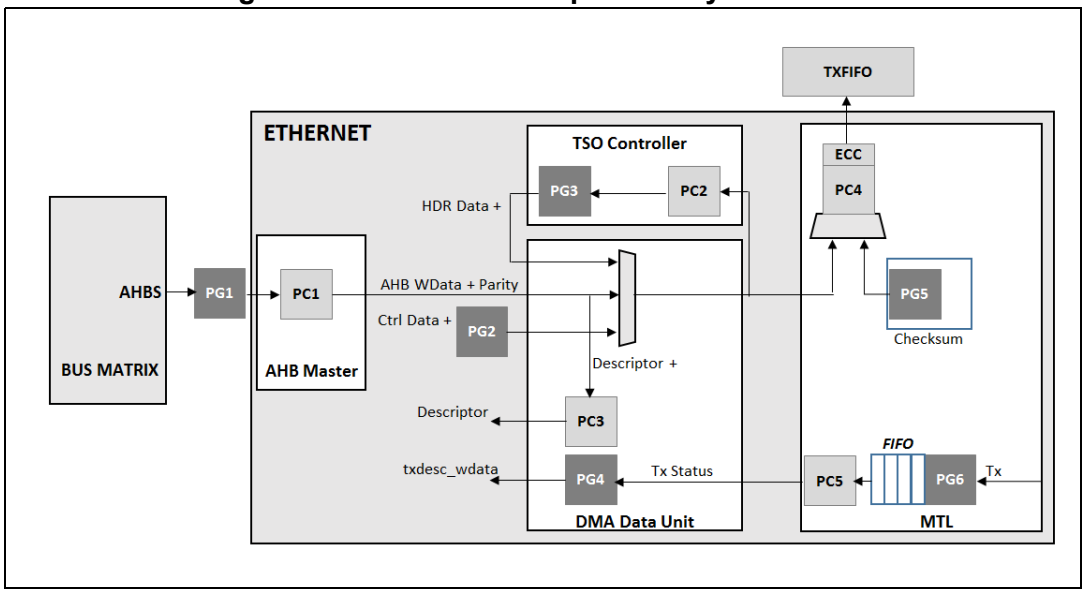
By default, even parity generation/detection is enabled. You can program to select odd parity generation/detection (OPE bit of MTL_DPP_Control register). It is recommended to keep the default value that is even parity.

Module does not support parity protection for data paths in MAC and MTI/MRI interface side in MTL. This is because data manipulation and offloading is performed on the data.

49.3.18.2.2 Transmit Datapath Parity Protection

The transmit DMA fetches the data packet and descriptors from the host memory through the AHB Master interface. The descriptors are consumed in the transmit DMA.

When the TSO feature is enabled, the transmit DMA modifies some of the header fields of the packet for segmentation. So the header data from TSO controller and the control data from the data transmit module are multiplexed with data from host memory and sent on the ATI interface, to MTL.



When the TSO feature is not enabled, the fetched packet is transferred by the transmit DMA to the MTL TXFIFO after aligning/concatenating the fetched data (when necessary) into different burst transfers. The transmit DMA also generates and pushes the “control words” for each packet in the same data path before the start of a packet.

In the MTL, when TX Checksum Offload Engine is enabled, the data packet is stored/written into the TXFIFO memory. The calculated checksums and the generated control signals are also written into the TXFIFO memory. Therefore, the input data from the ATI interface along with the internally generated checksum control word are multiplexed and then written into the MTL TX FIFO.

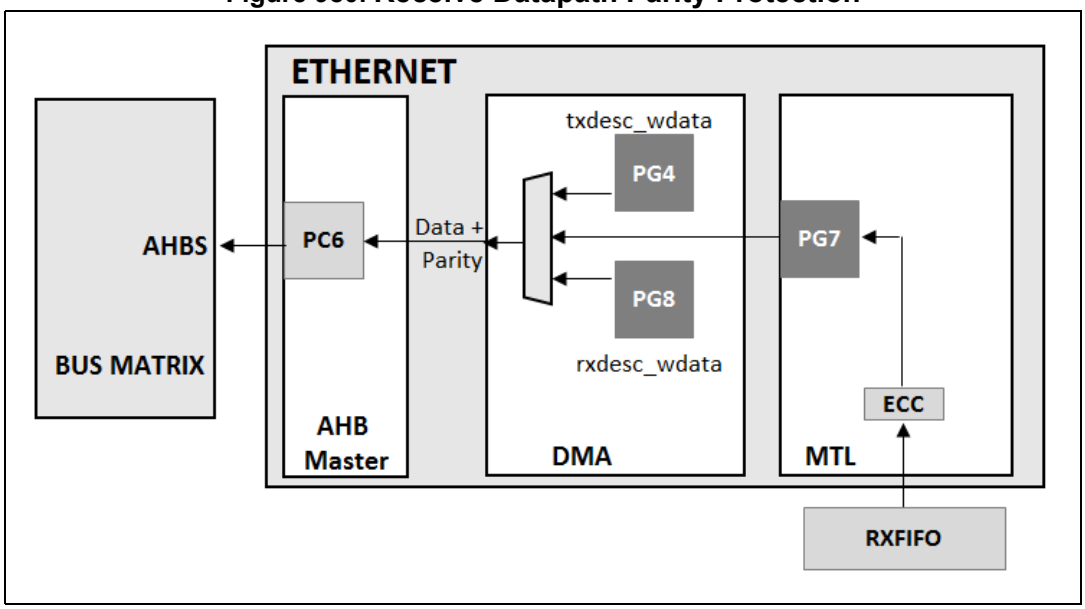
Transmit status received from MAC is written into a FIFO and sent to the DMA where it is updated along with the descriptor write-back status and then written to the host memory.

Figure below describes the locations of parity generators and checkers in the transmit data path:

Figure 979. Transmit Datapath Parity Protection

The following are the locations of the parity generators and checkers in the transmit data path:

- Parity is generated on the input data port, PG1.
- A parity check is performed on the input parity data received from the application interface, PC1, and the respective error status is specified in the ATPES field of MAC_DPP_FSM_Interrupt_status register. This check identifies if the fault is internal or external to Ethernet module.
- A parity is generated on the control data received from the data transmit module, PG2.
- When TCP segmentation is enabled, parity is generated on the modified header data provided by the DMA TSO controller, PG3.
- When TCP segmentation is enabled, parity check is performed on the feedback header data, PC2, which is originally generated from the DMA TSO controller. The respective parity error is reported in the TPES field of MAC_DPP_FSM_Interrupt_status register.
- As the read descriptor data is consumed in both data transmit and data receive modules, parity check is performed on this data, PC3. The respective parity error is reported in RDPES field of MAC_DPP_FSM_Interrupt_status register.
- Parity is generated on the modified Tx write-back status which is generated from DMA data unit, PG4.
- When the checksum offloading is enabled parity is generated on the checksum data generated in MTL, PG5.
- Parity check is performed at the transmit write controller in MTL, PC4 before writing the data to TX FIFO. The parity generation is terminated at this checker because the ECC protection for memories feature protects the external memory paths. The respective



parity error status is reported in MPES field of MAC_DPP_FSM_Interrupt_status register.

- If transmit Status drop disabled in MTL, parity is generated on the status received from MAC, PG6
- If transmit Status drop is disabled in MTL, parity check is performed on the Tx Status which is transferred on ATI interface, PC5. The respective parity error status is reported in MTSPES bit of MAC_DPP_FSM_Interrupt_Status register.

49.3.18.2.3 Receive Data Path Parity Protection

On the receive side, the data packet and status from the MTL Rx FIFO are sent to DMA where it is multiplexed with the descriptor write-back status from the data transmit/receive module, before transferring to the host.

Figure 980. Receive Datapath Parity Protection

The following are the locations of parity generators and checkers in the receive data path:

- Parity is generated on the MTL Rx FIFO read data, PG7 after ECC correction.
- Parity is generated on the DMA Rx write-back descriptor status after the update by the DMA data unit, PG8.
- Parity check is performed on the output data of AHB Master interface, PC6 and the respective parity error status is reported in the ARPES field of MAC_DPP_FSM_Interrupt_Status register.

49.3.18.2.4 Parity Error Injection

Each parity generator supports a control to inject parity error. When enabled, the parity of the first valid data at the generators are flipped. Application must set the appropriate bit in the MTL_DPP_Control register; after the respective parity bit is flipped the hardware clears the same. After the generator inserts error in the generated parity data, the subsequent parity checker should detect the mismatch and report the error status in the MAC_DPP_FSM_Interrupt_Status register.

For example, to insert an error in the input data at parity generator PG1, the sequence of operations are as follows:

1. Application sets the IPEID bit of MTL_DPP_Control register.
2. The parity generator PG1 inserts an error in the parity bits generated for the first valid data.
3. After the error is inserted, IPEID field of the MTL_DPP_Control register is reset.

As the data traverses through multiple paths, the subsequent checkers PC3 or PC4 in this example detects the parity mismatch and reports the error status in MAC_DPP_FSM_Interrupt_Status register and generates the sbd_sfty_ue_intr_o interrupt.

49.3.18.2.5 Interrupt for Parity Error

Ethernet module generates an interrupt, sbd_sfty_ue_intr_o to indicate to the application if any parity error is detected. Appropriate status is indicated in DMA/MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status registers. All the parity errors reported by the different checkers are logged in the MAC_DPP_FSM_Interrupt_Status register.

49.3.18.3 FSM Parity and Timeout Protection

The FSM protection feature supports FSM parity and FSM time out protection.

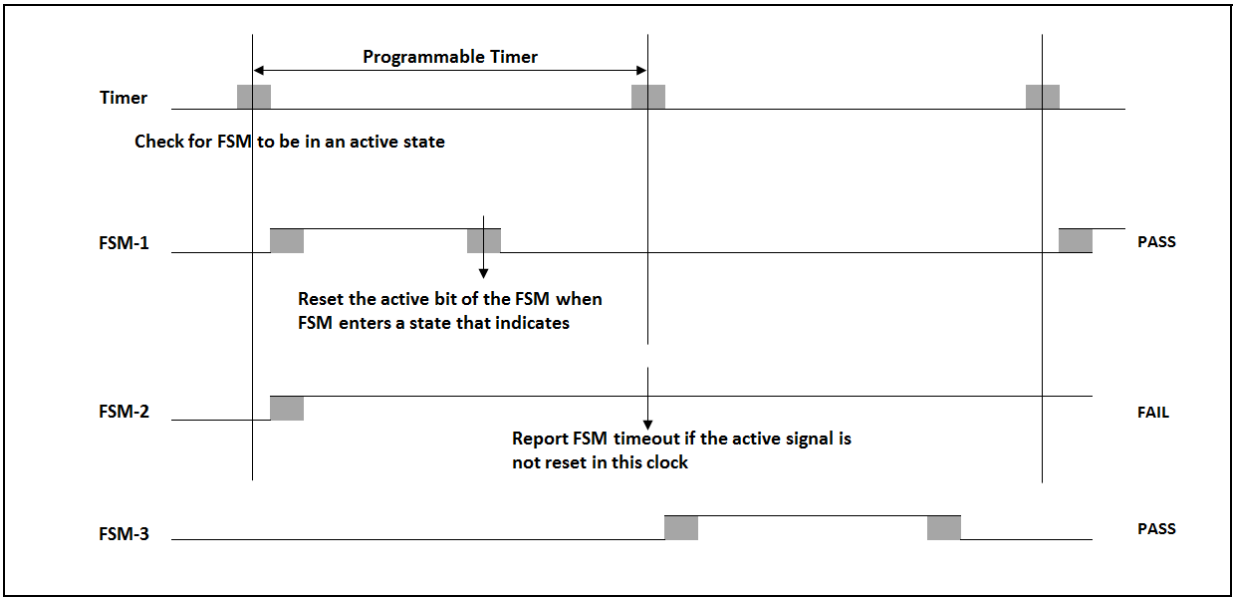
49.3.18.3.1 FSM State Parity Protection

The module implements one-hot encoding scheme for holding the state register. Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control register.

The FSM Parity error is classified as non-recoverable error and software intervention (IP reset) is required to recover from the error state.



49.3.18.3.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of APB cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1µs, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on

the programmable bits NTMRMD and LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

Figure 981. FSM Timeout Timing diagram

In *Figure 981*, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains.

The module does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting the module).

49.3.18.4 AHB Master Interface Timeout Protection

This feature provides timeout protection to the AHB Master Interface request. The timeout is triggered when AHB master interface initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register.

The hardware does not attempt to recover from AHB Master Interface hangs and relies on software to take appropriate corrective action.

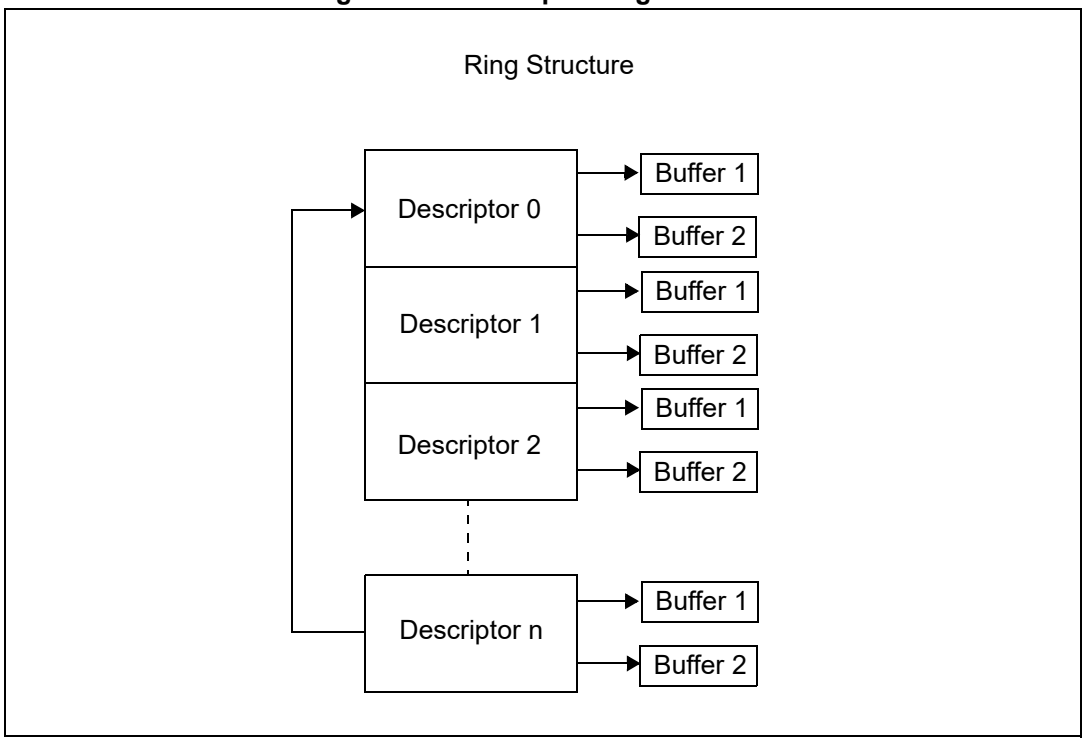
The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when AHB Master Interface timeout status is set.

49.4 Descriptors

49.4.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The Ethernet module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted



Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for number of descriptors that can be used for a single packet.

49.4.2 Descriptor structure

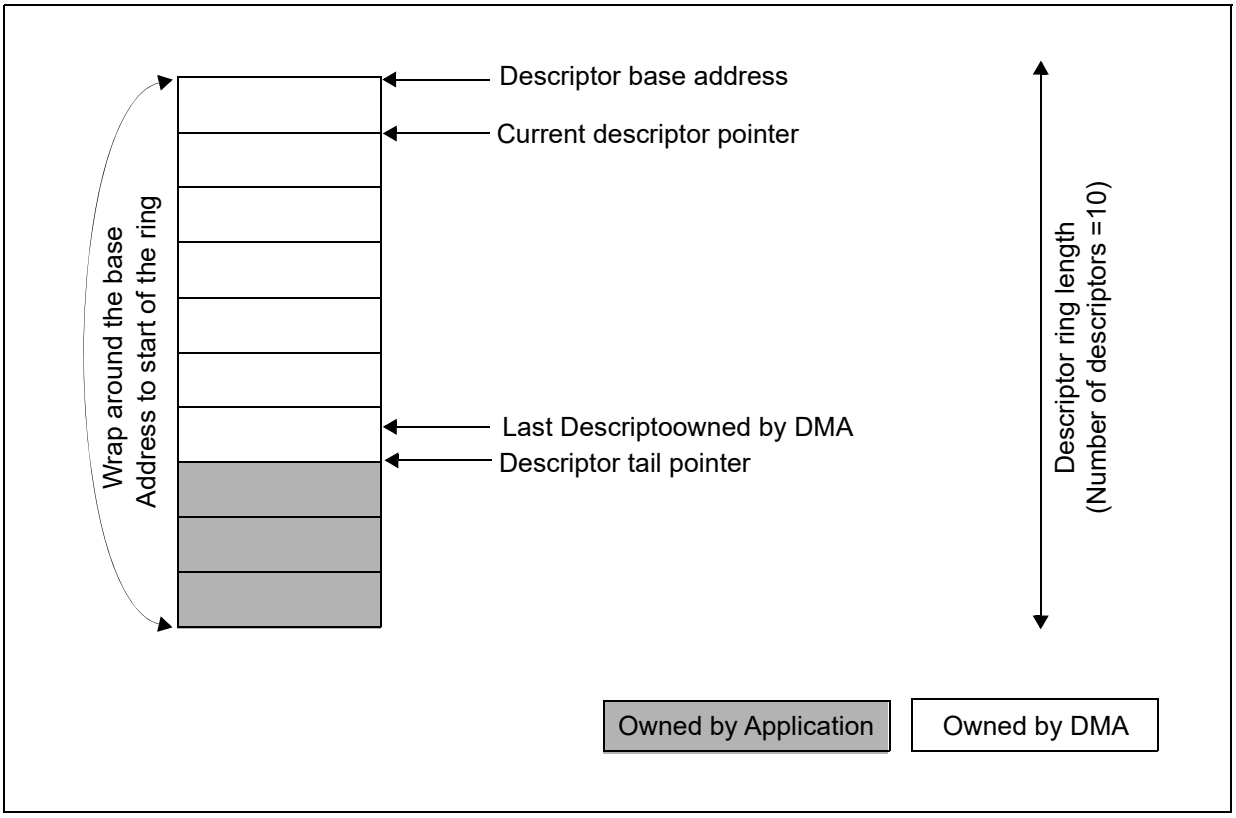
The Ethernet module supports the ring structure for DMA descriptor.

Figure 982. Descriptor ring structure

In Ring structure, descriptors are separated by the DWord number programmed in the DSL field of the DMA_CH*n*_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH*n*_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH*n*_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (*N*). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (*N* – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:



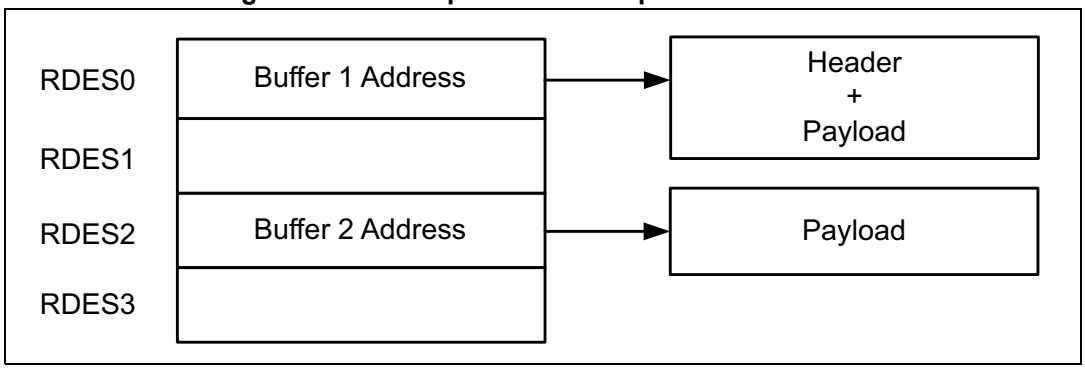
```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in *Figure 983*.

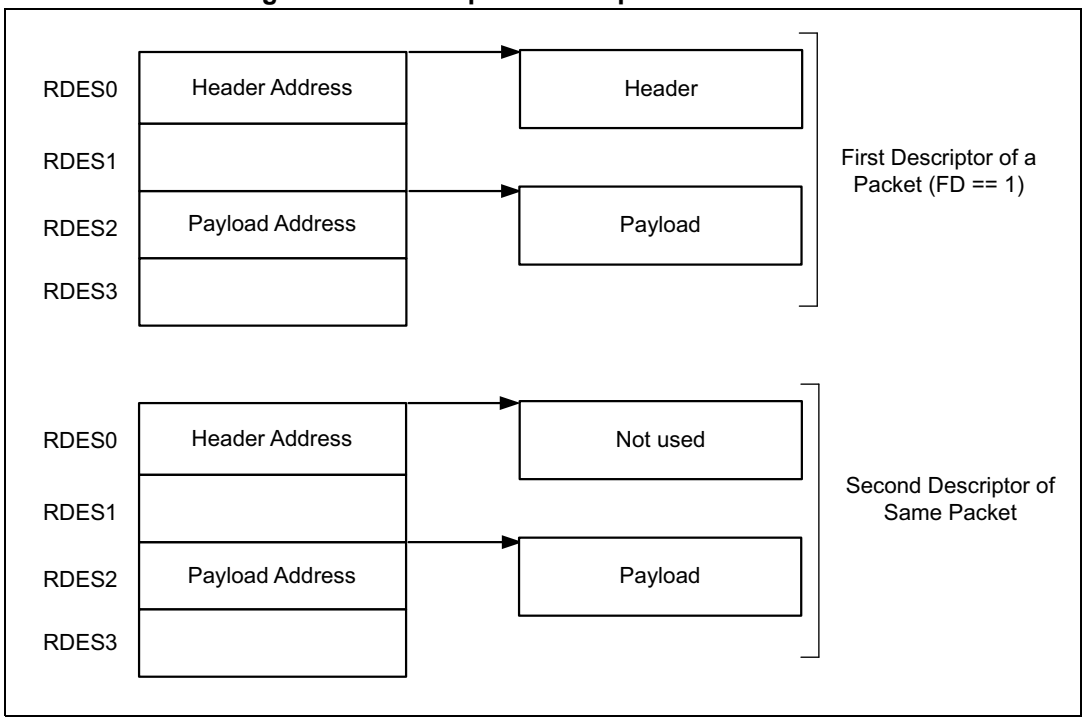
Figure 983. DMA descriptor ring



For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

49.4.2.1 Descriptor structure for split header support

Ethernet module supports splitting the incoming receive packet header such that the header and the payload are stored in different buffers in the system memory. For more details about splitting header on receive packets, refer to *Section 49.3.10.2.2.1: Splitting header on receive*.



The figure below shows the descriptor structure without the Split Header feature.

Figure 984. Descriptors without split header feature

The figure below shows the descriptor structure with the Split Header feature.

Figure 985. Descriptors with split header feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[2] (FD Bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[3] (LD Bit) set). The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA Channel Register 2 (Receive Control Register). The DMA fills receive buffers fully in all except the last descriptor.

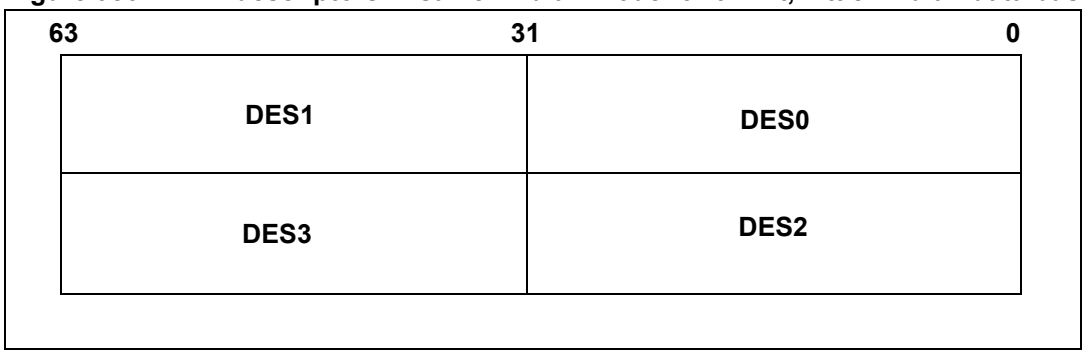
The header length is taken to be the value based on the bits programmed in the MAC Extended Configuration Register HDSMS field (Bits [9:11]).

49.4.2.2 Descriptor endianness

The descriptor addresses must be aligned to configured bus width (DWord for 64-bit bus). The data bus can be configured for either little-endian or big-endian format.

Figure 986 shows the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is little-endian or big-endian and the endian mode of descriptors is reverse-endian.

Figure 986. Rx/Tx descriptors in same-Endian mode for 64-Bit, Little-Endian data bus



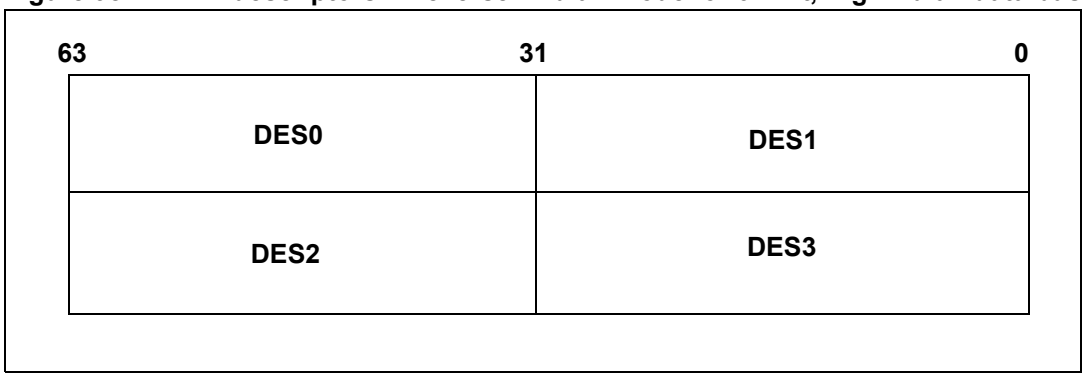


Figure 986 and *Figure 987* show the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is big-endian and the endian mode of descriptors is reverse-endian. In 64-bit big-endian data bus systems, when the descriptors are configured for reverse endianness, the order of the descriptor subset is reversed from the default (7-3 Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus). For example, Bits[63:32] are DES0 while Bits[31:0] are DES1.

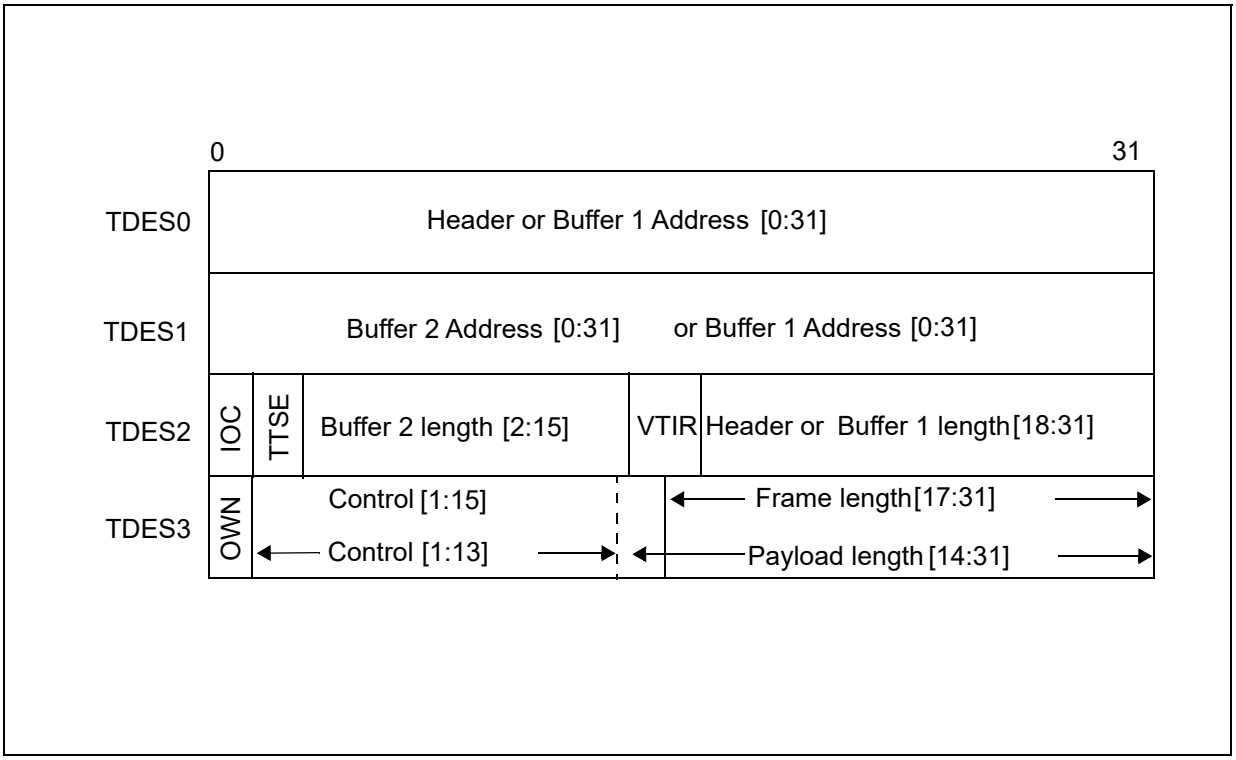
Figure 987. Rx/Tx descriptors in reverse-Endian mode for 64-Bit, Big-Endian data bus



49.4.3 Transmit descriptor

The DMA in the Ethernet module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has the following two formats: Read format and Write-Back format.

49.4.3.1 Transmit normal descriptor (Read format)

Figure 988 shows the Read format for a Transmit normal descriptor.

Figure 988. Transmit descriptor Read format

49.4.3.1.1 TDES0 normal descriptor (Read format)

Table 1076. TDES0 normal descriptor (Read format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: – TSE bit of TDES3 – FD bit of TDES3

49.4.3.1.2 TDES1 normal descriptor (Read format)

Table 1077. TDES1 normal descriptor (Read format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

49.4.3.1.3 TDES2 normal descriptor (Read format)

Figure 989. TDES2 normal descriptor (Read format)

0	1	2:15	16:17	18:31
IOC	TTSE	B2L	VTIR	HL or B1L

Table 1078. TDES2 normal descriptor (Read format)

Field	Description
0 IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CHn_STATUS register after the present packet has been transmitted.
1 TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor.
2:15 B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
16:17 VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: 00 Do not add a VLAN tag. 01 Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. 10 Insert a VLAN tag with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. 11 Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. This option should be used only with the VLAN packets.
18:31 HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

49.4.3.1.4 TDES3 normal descriptor (Read format)

Figure 990. TDES3 normal descriptor (Read format)

0	1	2	3	4:5	6:8	9:12	13	14:15	16	17:31
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM/THL	TSE	CIC/TPL	TPL	FL/TPL

Table 1079. TDES3 normal descriptor (Read format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
1 CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
2 FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
4:5 CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[2]) is set. The following list describes the values of Bits[4:5]: 00 CRC and Pad Insertion - The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. 01 CRC Insertion (Disable Pad Insertion) - The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. 10 Disable CRC Insertion - The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. 11 CRC Replacement - The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. *Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.*

Table 1079. TDES3 normal descriptor (Read format) (continued)

Field	Description
6:8 SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 6 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[7:8]: 00 Do not include the source address 01 Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 Reserved This field is valid only for the first descriptor and when the First Segment control bit (TDES3 [29]) is set.
9:12 SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH*n*_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
13 TSE	TCP Segmentation Enable When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the DMA_CH*n*_Tx_Control Register. This bit is valid only if the FD bit is set.
14:15 CIC or TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: 00 Checksum Insertion Disabled. 01 Only IP header checksum calculation and insertion are enabled. 10 IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload. This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.

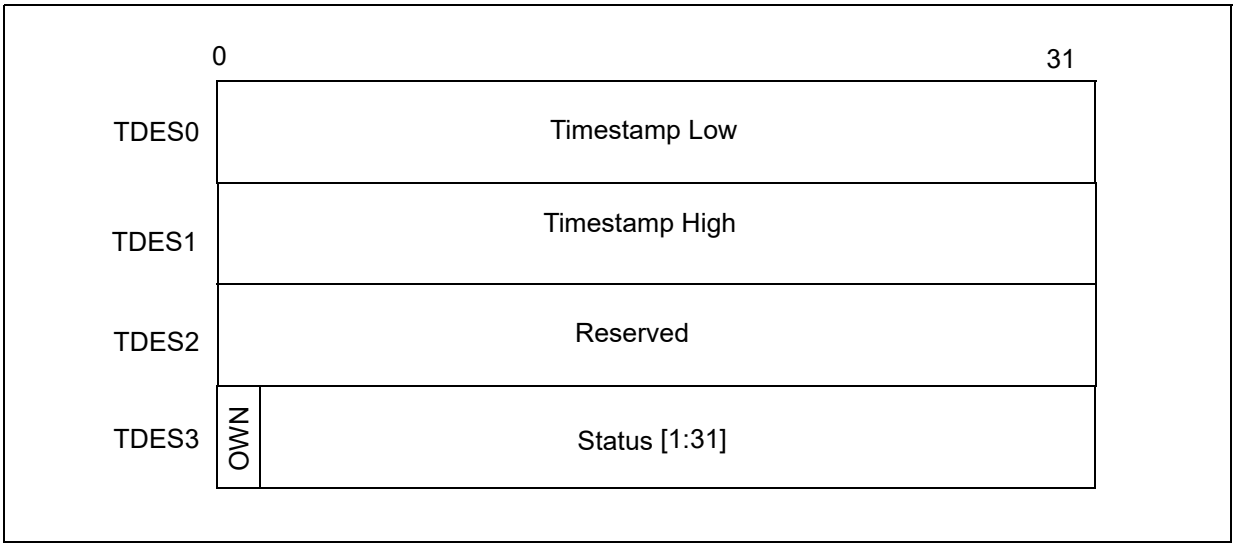


Table 1079. TDES3 normal descriptor (Read format) (continued)

Field	Description
16 TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0].
17:31 FL or TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length.

49.4.3.1.5 Transmit normal descriptor (Write-Back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[3]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 991. Transmit descriptor Write-Back format

49.4.3.1.6 TDES0 normal descriptor (Write-Back format)

This format is only applicable to the last descriptor of a packet.

Table 1080. TDES0 normal descriptor (Write-Back format)

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

49.4.3.1.7 TDES1 normal descriptor (Write-Back format)

This format is only applicable to the last descriptor of a packet.

Table 1081. TDES1 normal descriptor (Write-Back format)

Field	Description
0:31 TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding Receive packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

49.4.3.1.8 TDES2 normal descriptor (Write-Back format)

This format is applicable only to the last descriptor of a packet.

Table 1082. TDES2 normal descriptor (Write-Back format)

Field	Description
0:31	Reserved

49.4.3.1.9 TDES3 normal descriptor (Write-Back format)

This format is applicable only to the last descriptor of a packet.

Figure 992. TDES3 normal descriptor (Write-Back format)

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
OWN	CTXT	FD	LD	Reserved				DE	Reserved					TTSS	Reserved

ES	JT	FF	PCE	LoC	NC	LC	EC	CC				ED	UF	DB	IHE

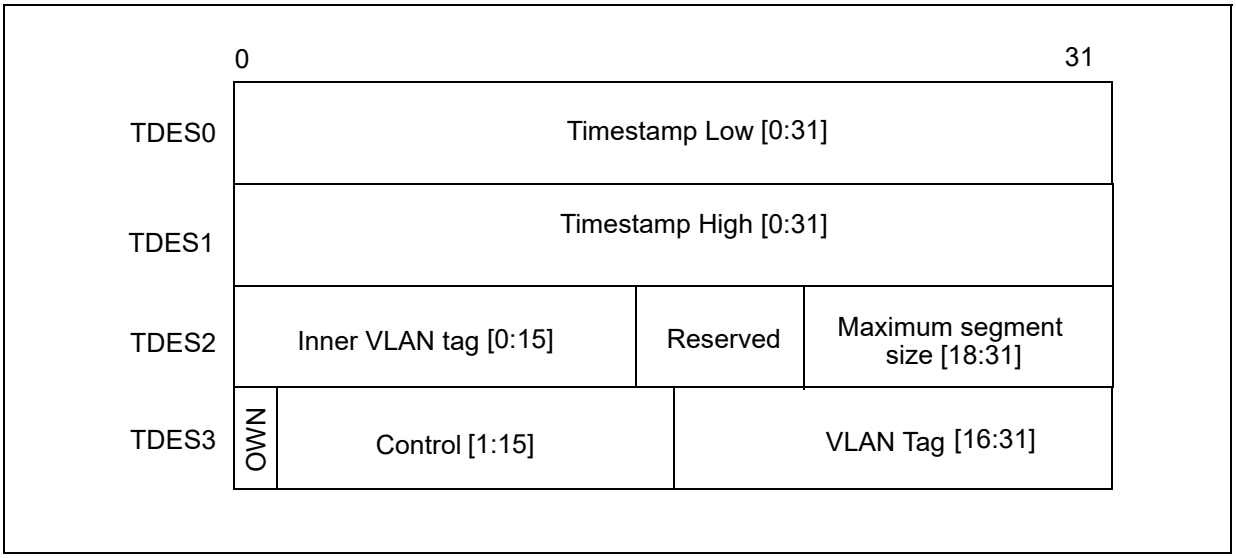
Table 1083. TDES3 normal descriptor (Write-Back format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
1 CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
2 FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
8 DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: – Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. – All 1s – CTXT, LD, and FD bits set to 1 **Note:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register **Note:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
14 TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [3]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16 ES	Error Summary This bit indicates the logical OR of the following bits: TDES3[31]: IP Header Error TDES3[17]: Jabber Timeout TDES3[18]: Packet Flush TDES3[19]: Payload Checksum Error TDES3[20]: Loss of Carrier TDES3[21]: No Carrier TDES3[22]: Late Collision TDES3[23]: Excessive Collision TDES3[28]: Excessive Deferral TDES3[29]: Underflow Error

Table 1083. TDES3 normal descriptor (Write-Back format) (continued)

Field	Description
17 JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
18 FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
19 PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
20 LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the MII_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
21 NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
22 LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
23 EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
24:27 CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
28 ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24288 bit times (155680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.

Table 1083. TDES3 normal descriptor (Write-Back format) (continued)



Field	Description
29 UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: The DMA encountered an empty Transmit Buffer while transmitting the packet The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_INTERRUPT_STATUS register.
30 DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
31 IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

49.4.3.1.10 Transmit context descriptor

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.
When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.
The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 993. Transmit context descriptor format

49.4.3.1.11 TDES0 context descriptor

Table 1084. TDES0 context descriptor

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

49.4.3.1.12 TDES1 context descriptor

Table 1085. TDES1 context descriptor

Field	Description
0:31 TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

49.4.3.1.13 TDES2 context descriptor

Table 1086. TDES2 context descriptor

Field	Description
0:15 IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[0:15] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
16:17	Reserved
18:31 MSS	Maximum Segment Size When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

49.4.3.1.14 TDES3 context descriptor

Figure 994. TDES3 context descriptor

0	1	2:3	4	5	6:7	8	9:13	14	15	16:31
OWN	CTXT	Reserved	OSTC	TCMSSV	Reserved	DE	Reserved	IVLTV	VLTV	VT

Table 1087. TDES3 context descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
2:3	Reserved
4 OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
5 TCMSSV	One-Step Timestamp Correction Input When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.

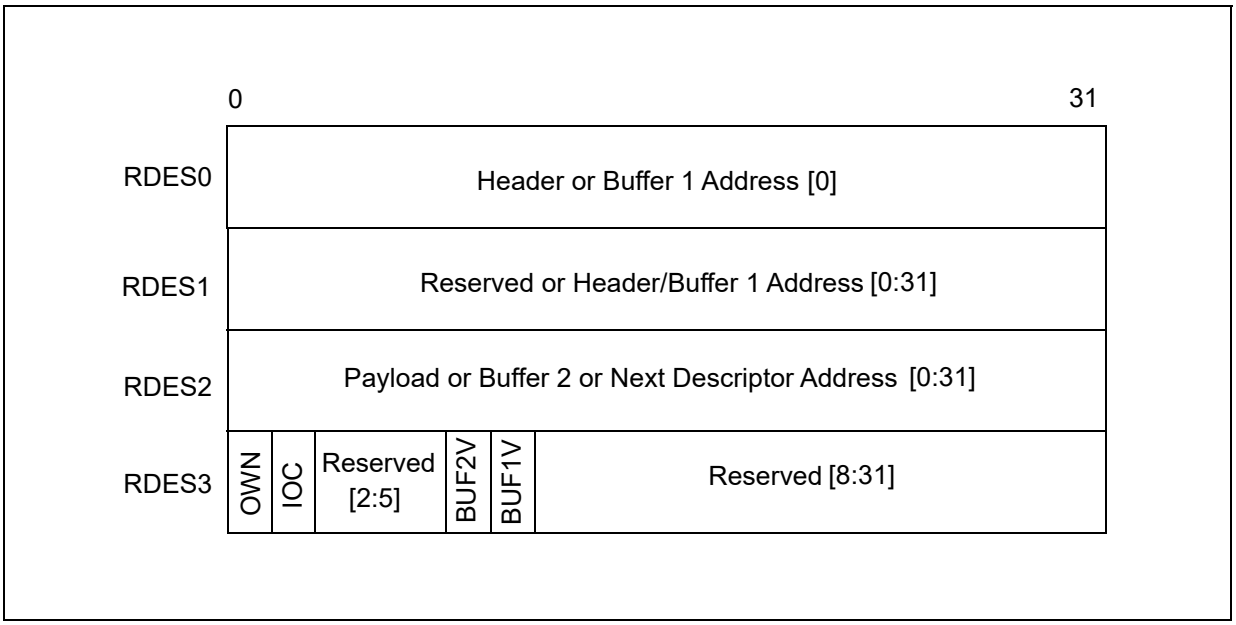
Table 1087. TDES3 context descriptor (continued)

Field	Description
6:7	Reserved
8 DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: – Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. – All 1s. – CD, LD, and FD bits set to 1. **Note:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CHn_STATUS register **Note:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
9:11	Reserved
12:13 IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: 00 Do not add the inner VLAN tag. 01 Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. 10 Insert an inner VLAN tag with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. 11 Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames.
14 IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
15 VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
16:13 VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_INCL register is reset.

49.4.4 Receive descriptor

The DMA in the Ethernet module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive descriptors are present:



- Normal
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in *Section 49.4.4.1: Receive normal descriptor (Read format)*. The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the *Section 49.4.4.2: Receive normal descriptor (Write-Back format)*.

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA will write the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in *Section 49.4.4.3: Receive context descriptor*.

49.4.4.1 Receive normal descriptor (Read format)

Figure 995. Receive normal descriptor (Read format)

Note: In the Receive Descriptor (Read format), if the Buffer Address field is all 0s, the Ethernet module does not transfer data to that buffer and skips to the next buffer or next descriptor.

49.4.4.1.1 RDES0 normal descriptor (Read format)

Table 1088. RDES0 normal descriptor (Read format)

Field	Description
0:31 BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[30:31] (or RDES0[29:31]/[28:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

49.4.4.1.2 RDES1 normal descriptor (Read format)

Table 1089. RDES1 normal descriptor (Read format)

Field	Description
0:31	This field is reserved.

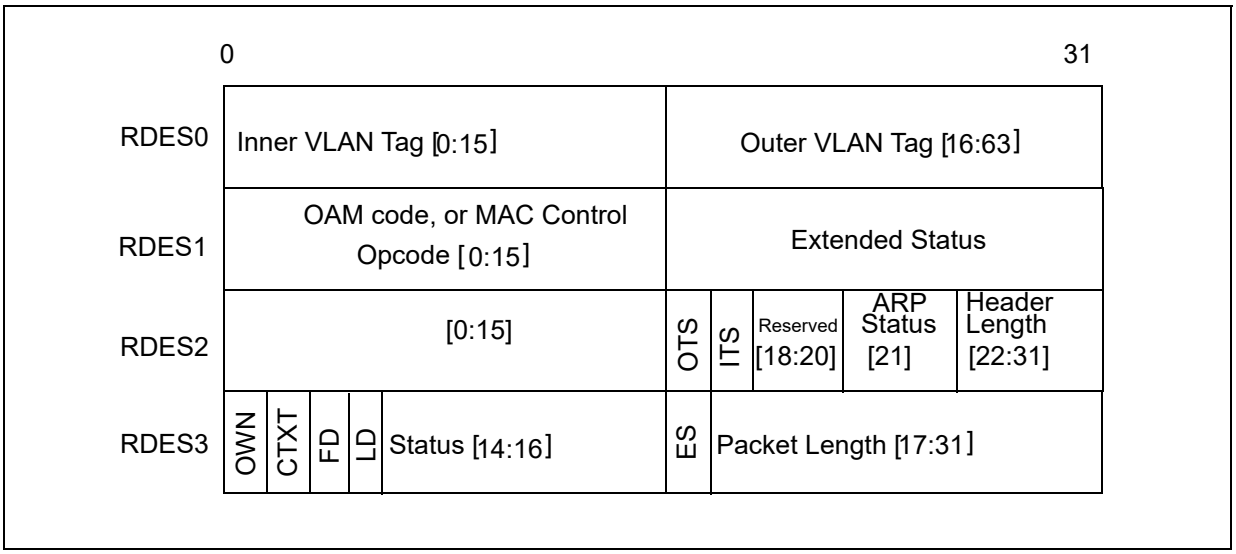
49.4.4.1.3 RDES2 normal descriptor (Read format)

Table 1090. RDES2 normal descriptor (Read format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[28:31, 29:31, or 30:31] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[28:31, 29:31, or 30:31] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

49.4.4.1.4 RDES3 normal descriptor (Read format)

Figure 996. RDES3 normal descriptor (Read format)



0	1	2:5	6	7	8:31
OWN	IOC	Reserved	BUF2V	BUF1V	Reserved

Table 1091. RDES3 normal descriptor (Read format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
2:5	Reserved
6 BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is Valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
7 BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
8:31	Reserved

49.4.4.2 Receive normal descriptor (Write-Back format)

Figure 997. Receive normal descriptor (Write-Back format)

49.4.4.2.1 RDES0 normal descriptor (Write-Back format)

Figure 998. RDES0 normal descriptor (Write-Back format)

0:15	16:31
IVT	OVT

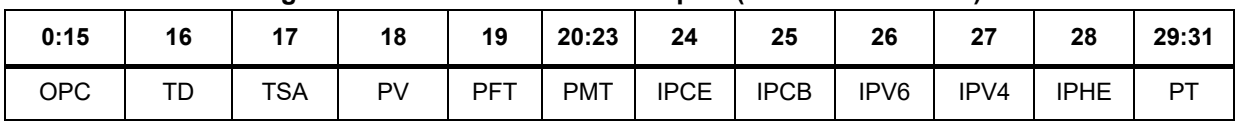


Table 1092. RDES0 normal descriptor (Write-Back format)

Field	Description
0:15 IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
16:31 OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

49.4.4.2.2 RDES1 normal descriptor (Write-Back format)

The status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

Figure 999. RDES1 normal descriptor (Write-Back format)

0:15	16	17	18	19	20:23	24	25	26	27	28	29:31
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 1093. RDES1 normal descriptor (Write-Back format)

Field	Description
0:15 OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If bits[13:15] of RDES3 are set to 111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If bits[13:15] of RDES3 are set to 110, this field contains the MAC Control packet opcode field.
16 TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table 1093. RDES1 normal descriptor (Write-Back format) (continued)

Field	Description
17 TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [3]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
18 PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
19 PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
20:23 PMT	PTP Message Type These bits are encoded to give the type of the message received: 0000 No PTP message received 0001 SYNC (all clock types) 0010 Follow_Up (all clock types) 0011 Delay_Req (all clock types) 0100 Delay_Resp (all clock types) 0101 Pdelay_Req (in peer-to-peer transparent clock) 0110 Pdelay_Resp (in peer-to-peer transparent clock) 0111 Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) 1000 Announce 1001 Management 1010 Signaling 1011–1110 Reserved 1111 PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
24 IPCE	IP Payload Error When this bit is set, it indicates either of the following: The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 16 (ES) of RDES3 is not set when this bit is set.
25 IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed.
26 IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected.
27 IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected.

Table 1093. RDES1 normal descriptor (Write-Back format) (continued)

Field	Description
28 IPHE	IP Header Error When this bit is set, it indicates either of the following: The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. The IP datagram version is not consistent with the Ethernet Type value. Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 26 or bit 27 is set.
29:31 PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): 000 Unknown type or IP/AV payload not processed 001 UDP 010 TCP 011 ICMP 110 AV Tagged Data Packet 111 AV Tagged Control Packet 101 AV Untagged Control Packet 100 IGMP if IPV4 Header Present bit is set else data center bridging (DCB) link layer discovery protocol (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000.

49.4.4.2.3 RDES2 normal descriptor (Write-Back format)

Figure 1000. RDES2 normal descriptor (Write-Back format)

Table 1094. RDES2 normal descriptor (Write-Back format)

Field	Description
0:2 L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: 000 Filter 0 This field is valid only when Bit 3 or Bit 4 is set high. When more than one filter matches, these bits give the number of lowest filter. **Note:** This status is not available when Flexible RX Parser is enabled.
3 L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: Layer 3 fields are not enabled and all enabled Layer 4 fields match All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[0:2]. **Note:** This status is not available when Flexible RX Parser is enabled.
4 L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. All enabled filter fields match. When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[0:2]. **Note:** This status is not available when Flexible RX Parser is enabled.
5:12 MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. **Note:** This status is not available when Flexible RX Parser is enabled.
13 HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[5:12] indicate the hash value. **Note:** This status is not available when Flexible RX Parser is enabled.
14 DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC.
15 SAF	SA Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC.
16 OTS	Outer VLAN Tag Filter Status (OTS) This bit is valid for both Single and Double VLAN Tagged frames.
17 ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames.

Table 1094. RDES2 normal descriptor (Write-Back format) (continued)

Field	Description
18:20	Reserved
21 ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).
22:31HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header.

49.4.4.2.4 RDES3 normal descriptor (Write-Back format)

Figure 1001. RDES3 normal descriptor (Write-Back format)

Table 1095. RDES3 normal descriptor (Write-Back format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} 00 Intermediate Descriptor 01 First Descriptor 10 Reserved 11 Descriptor Error (due to all 1s) **Note:** When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.

Table 1095. RDES3 normal descriptor (Write-Back format) (continued)

Field	Description
2 FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
4 RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
5 RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
6 RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
7 CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
8 GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). **Note:** Giant packet indicates only the packet length. It does not cause any packet truncation.
9 RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
10 OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. **Note:** This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
11 RE	Receive Error When this bit is set, it indicates that the MII_RXER signal is asserted while the MII_RX_DV signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
12 DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.

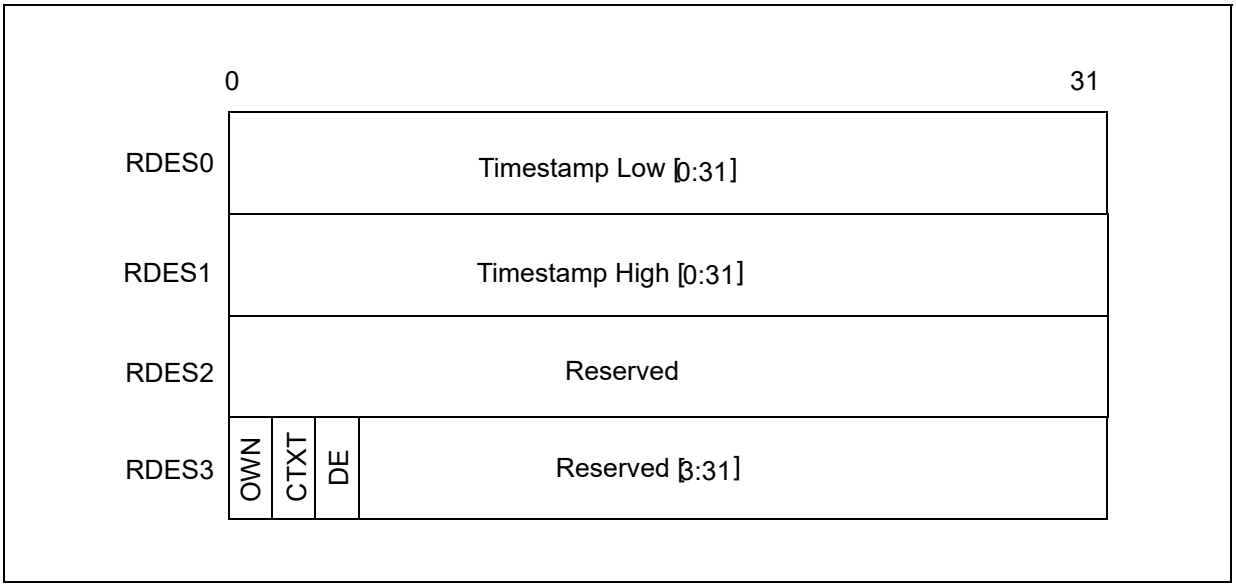

Table 1095. RDES3 normal descriptor (Write-Back format) (continued)

Field	Description
13:15 LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: 000 The packet is a length packet 001 The packet is a type packet. 011 The packet is a ARP Request packet type 100 The packet is a type packet with VLAN Tag 101 The packet is a type packet with Double VLAN Tag 110 The packet is a MAC Control packet type 111 The packet is a OAM packet type 010 Reserved
16 ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: RDES3[7]: CRC Error RDES3[12]: Dribble Error RDES3[11]: Receive Error RDES3[9]: Watchdog Timeout RDES3[10]: Overflow Error RDES3[8]: Giant Packet This field is valid only when the LD bit of RDES3 is set.
17:31 PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

49.4.4.3 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 1 of RDES3 indicates the context type descriptor.

Figure 1002. Receive context descriptor

49.4.4.3.1 RDES0 context descriptor

Table 1096. RDES0 context descriptor

Field	Description
0:31 RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

49.4.4.3.2 RDES1 context descriptor

Table 1097. RDES1 context descriptor

Field	Description
0:31 RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

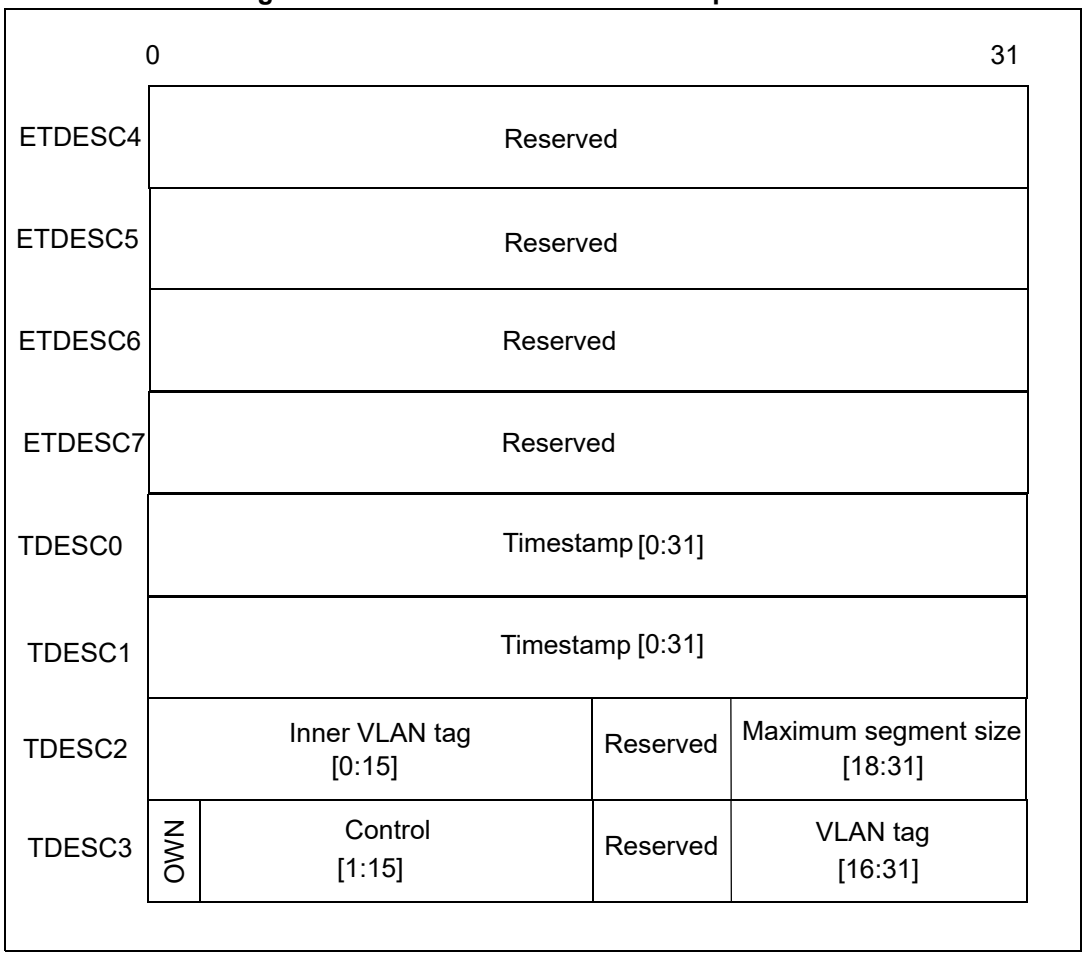
Table 1099. RDES3 context descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor. DMA writes 2fb11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} 00 Reserved 01 Reserved 10 Context Descriptor 11 Descriptor Error **Note:** When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
2 DE	Descriptor Error Refer to the CTXT bit description for details of using the DE bit along with CTXT bit.
3:31	Reserved

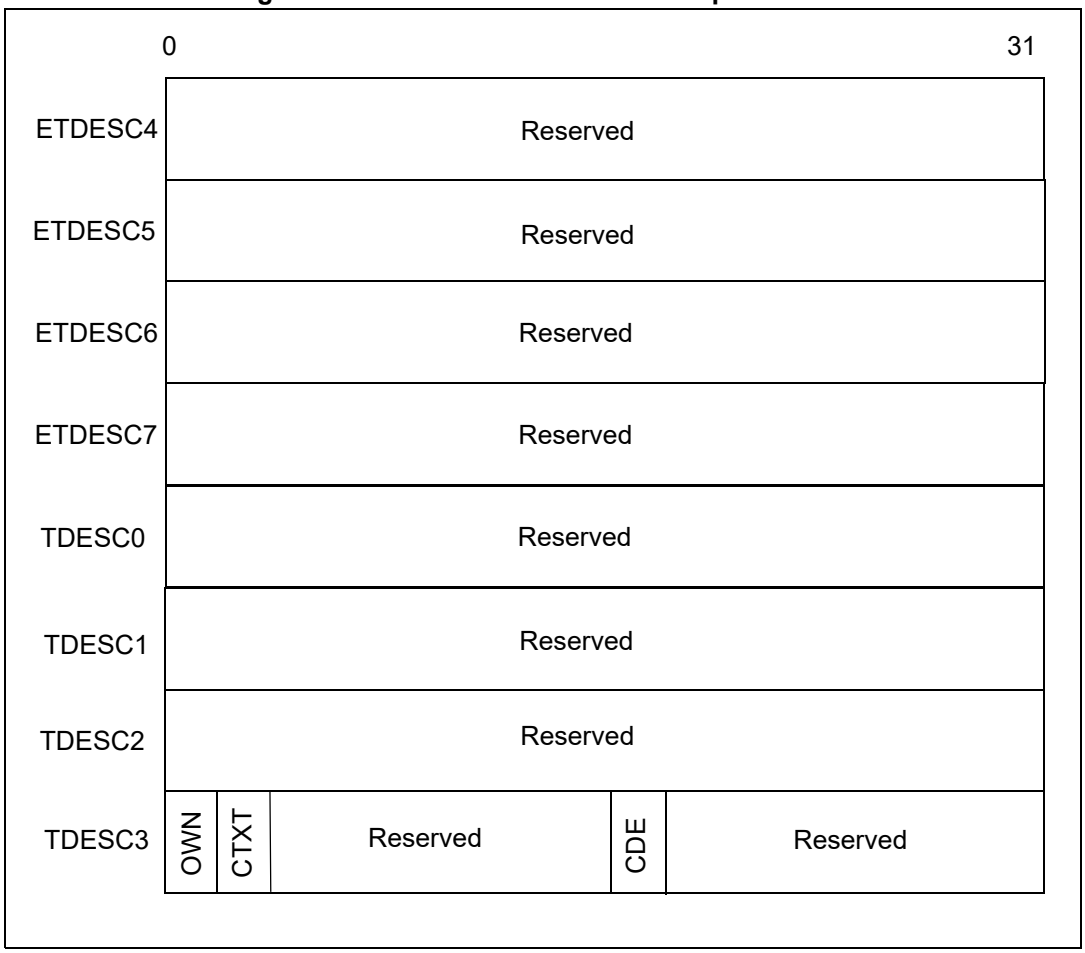
49.4.5 Enhanced descriptor for time-based scheduling



The time-based scheduling feature needs Enhanced Descriptors (that are 32 Bytes) to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH*n*_TX_Control register).

The structure of 32-byte descriptor for the context and the normal descriptor in Read and Write formats are described in the following sections.

49.4.5.1 Enhanced context descriptor (Read, 32-bit mode)



The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

Figure 1004. Enhanced context descriptor - Read

49.4.5.2 Enhanced context descriptor (Write, 32-bit mode)

Figure 1005. Enhanced context descriptor - Write

49.4.5.3 Enhanced Normal descriptor - Read (32-bit mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid.

  The LTV must be set only if the FD bit of the descriptor is not.
- GSN

  This field indicates the GCL slot number associated with the packet.
- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

Figure 1006. Enhanced normal descriptor - Read (32-bit mode)

49.4.5.4 Enhanced normal descriptor (Write, 32-bit mode)

Figure 1007. Enhanced normal descriptor Write (32-bit mode)

Note: All the enhanced descriptor examples, assumes a 32-bit data width configuration. However, the same definitions are valid in 64- and 128-bit configurations.

In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.

Fetch time when enabled overrides the AV slot function.

When TSO is enabled, the Launch and Fetch times are applicable to first segment that is transferred, all subsequent segments do not have any time restrictions.

When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed.

49.5 Programming guidelines

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

49.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit 31 of *DMA mode register (DMA_MODE)*).
2. Wait for the completion of the reset process (poll bit 31 of the *DMA mode register (DMA_MODE)*, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the *DMA system bus mode register (DMA_SYSBUS_MODE)*:
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values for AHB bus interface
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 0 of descriptor TDES3/RDES3).

Note: Descriptor address from start to end of the ring should not cross the 4 GB boundary.

5. Program the Transmit and Receive Ring length registers (DMA_CH*n*_TxDesc_Ring_Length and DMA_CH*n*_RxDesc_Ring_Length). The ring length programmed must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH*n*_TxDesc_List_Address, DMA_CH*n*_RxDesc_List_Address). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH*n*_TxDesc_Tail_Pointer and DMA_CH*n*_RxDesc_Tail_Pointer).
7. Program the settings of the following registers for the parameters such as maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   a) DMA_CH*n*_TX_Control
   b) DMA_CH*n*_TX_Control
   c) DMA_CH*n*_TX_Control
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register.
9. Start the Receive and Transmit DMAs by setting SR (bit 31) of the DMA_CH*n*_RX_Control and ST (bit 31) of the DMA_CH*n*_TX_Control register.
10. Repeat steps *4* to *9* for all the Tx DMA and Rx DMA channels selected in the hardware.

49.5.2 Initializing MTL registers

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation for multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in the MTL_RxQ_DMA_Map0 register.

3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode.
   b) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0.
   c) Transmit Queue Size (TQS).
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a) Receive Store and Forward (RSF) or RTC in case of Threshold mode.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d) Receive Queue Size (RQS).
5. Repeat previous two steps for the second MTL Tx and Rx queue.

49.5.3 Initializing MAC

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. For more than one MAC address program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   a) Receive All
   b) Promiscuous mode
   c) Hash or Perfect Filter
   d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a) Pause time and other Pause frame control bits
   b) Transmit Flow control bits
   c) Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required.
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 31 and 30 in MAC_Configuration registers to start the MAC transmitter and receiver.

49.5.3.1 For normal operation

Complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register.
   a) DMA_CH*n*_TxDesc_Tail_Pointer
   b) DMA_CH*n*_RxDesc_Tail_Pointer
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process.
   a) DMA_CH*n*_Current_App_TxDesc
   b) DMA_CH*n*_Current_App_RxDesc
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process.
   a) DMA_CH*n*_Current_App_TxBuffer
   b) DMA_CH*n*_Current_App_RxBuffer

49.5.3.2 For stopping and starting transmission

Complete the following steps to pause the transmission for some time.

Note: The steps are provided for Channel 0.

1. Disable the transmit DMA (if applicable) by clearing Bit 31 (ST) of the DMA_CH*n*_TX_Control register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of the MTL_TxQ0_Debug register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit 31 (RE) and Bit 30(TE) of the MAC_Configuration register.
4. Disable the receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of the MTL_RxQ0_Debug register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register).
6. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver.

Note: Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. The Software should change these parameters only when the MAC transmitter and receiver are not active.
Similarly the DMA related configuration should not be changed when Transmit and Receive DMA are in active.

49.5.3.3 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

49.5.4 Programming guidelines for multi-channel multi-queuing

Following are the steps for Transmit:

1. Program the Transmit queue size in the TQS field of MTL_TxQ*n*_Operation_Mode register. Based on the value programmed in TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel to Queue mapping is fixed.
2. Enable ST bit of DMA_CH*n*_TX_Control register and corresponding TXQEN in MTL_TxQ*n*_Operation_Mode register.
3. The scheduling method need to be programmed in SCHALG of the MTL_Operation_Mode register.
4. In case of CBS algorithm in AVB queues, the following registers also needs to be programmed as required:
   a) MTL_TxQ*n*_ETS_Control
   b) MTL_TxQ*n*_SendSlopeCredit
   c) MTL_TxQ*n*_HiCredit
   d) MTL_TxQ*n*_LoCredit

Following are the steps for Receive:

1. Program the Receive queue size in the RQS field of MTL_RxQ*n*_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 1 in the fields RXQ0EN to RXQ1EN in MAC_RxQ_Ctrl0 Register for AV. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH*n*_RX_Control Register and corresponding RXQ*n*_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a) AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
   b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 register.
   c) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ1-0 of the MAC_RxQ_Ctrl2 register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 1.
   d) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 register.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b) Program the MTL_RxQ*n*_Control to decide the weights and the packet arbitration for each RxQ.
   c) If static mapping is programmed in MTL_RxQ_DMA_Map0 register (RXQ*n*DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d) Set RXQ*n*DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue.
   e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

Note: The priorities set in PSRQ1-0 should be unique.

49.5.4.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

49.5.4.1.1 Recovering from the receive DMA channel failure

Follow these steps if you get bus error in the Receive DMA channel:

1. Set the RPF bit to 1. This flushes all the packets one after the other.
   This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.
2. Re-program the specific Registers of the DMA channel.
3. Start the DMA channel.

49.5.4.1.2 Recovering from the transmit DMA channel failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Re-program the specific Registers of the DMA channel.
4. Start the DMA channel.

49.5.5 Programming guidelines for MII link state transitions

The following steps are to be performed when the link is down but the Transmit and Receive clocks are running:

Note: The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 31 (ST) of DMA_CH*n*_TX_Control register.
2. Disable the MAC receiver by clearing Bit 29 (RE) of the MAC_Configuration register
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01).
   -or-
   Flush the Tx FIFO for faster empty operation.
4. Disable the MAC transmitter by clearing Bit 30 (TE) of the MAC_Configuration register.

5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register).
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers.
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver.

You do not need to disable the Rx DMA. As the Receiver is disabled, the FIFO does not get any data in the Rx FIFO.

Do the following steps when the link is down and the Transmit and Receive clocks are stopped:

Note: The steps are provided for Channel 0.

1. Disable the MAC Transmitter and Receiver by clearing bits RE and TE of MAC_Configuration register. This will not take effect immediately as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait for the completion of the transfer of any partial frame if any at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug Register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

49.5.6 Programming guidelines for IEEE 1588 timestamping

49.5.6.1 Initialization guideline for system time generation

The timestamp feature is enabled by setting Bit 31 of the MAC_Timestamp_Control register. However, it is essential that the timestamp counter should be initialized after this bit is set. Complete the following steps during for initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 15 of MAC_INTERRUPT_ENABLE register.
2. Set Bit 31 of MAC_Timestamp_Control register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 26 of MAC_Timestamp_Control register.
5. Poll the MAC_Timestamp_Control register until Bit 26 is cleared.
6. Program Bit 30 of MAC_Timestamp_Control register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value.
8. Set Bit 29 in MAC_Timestamp_Control register.
   The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers.

If one-step timestamping is enabled:

a) To enable one-step timestamping, program Bit 4 of the TDES Context Descriptor.

b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.

9. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing Bit 31 of MAC_Timestamp_Control Register, you need to repeat all these steps to restart the timestamp operation.

49.5.6.2 System time correction

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 28 (TSUPDT) of the MAC_Timestamp_Control Register.
   The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in System Time Register Module, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_Timestamp_Addend with the new value and set Bit 26 of the MAC_Timestamp_Control register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in the MAC_PPS0_Target_Time_Seconds register and the MAC_PPS0_Target_Time_Nanoseconds register.
5. Enable the Timestamp interrupt in bit 19 of MAC_INTERRUPT_ENABLE register.
6. Set bit 27 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS register.
8. Reprogram MAC_Timestamp_Addend register with the old value and set bit 26 again.

49.5.7 Programming guidelines for AV feature

Complete the following steps to initialize the DMA for AV feature:

1. Provide a software reset to reset all QOS internal registers and logic (bit 31 in DMA_Mode register).
2. Wait for the completion of the reset process. Poll bit 31 of the DMA_Mode register, which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers. The ring length programmed must be at least 4. Then initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor. Finally program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors:
   a) DMA_CH*n*_TxDesc_Ring_Length
   b) DMA_CH*n*_RxDesc_Ring_Length
   c) DMA_CH*n*_TxDesc_List_Address
   d) DMA_CH*n*_RxDesc_List_Address
   e) DMA_CH*n*_TxDesc_Tail_Pointer
   f) DMA_CHn_RxDesc_Tail_Pointer
7. Program the following fields to initialize the mode of operation in the MTL_TxQ1_Operation_Mode register:
   a) Transmit Store And Forward (TSF)
   b) Transmit Threshold Control (TTC)
   c) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d) Transmit Queue Size (TQS)
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register.
9. Repeat steps *4* through *9* for all additional channels of AV feature.
10. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
11. Start the Receive and Transmit DMA by setting bit 31 of the DMA_CH*n*_TX_Control register and bit 31 of the DMA_CH*n*_RX_Control register.

49.5.7.1 Enabling slot number checking

The slot number check feature is used to specify the intervals at which the DMA Channels mapped to AV Queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable time-stamping and program the MAC_Sub_Second_Increment register. Complete the following steps to enable the slot number checking:

Note: These steps should be completed after Step 10 and before Step 11 of Section 49.5.7: Programming guidelines for AV feature.

1. Enable time-stamping by following the steps described in *Section 49.5.6.1: Initialization guideline for system time generation*.
2. Make sure that the SLOTNUM field (bits 9:12) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH*n*_Slot_Function_Control_Status.
3. Set Bit 31 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

49.5.7.2 Enabling average bits per slot reporting

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this

register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. Enable time-stamping by following the steps described in *Section 49.5.6.1: Initialization guideline for system time generation*.
2. Program Bits [25:27], SLC, of the MTL_TxQ*n*_ETS_Control register of a channel with number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 22 (ABPSSIE) of the MTL_Q*n*_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.
4. Read Bits [15:31], ABS, from the MTL_TxQ*n*_ETS_Status register of a channel on each interrupt.

Note: The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 30 (ABPSIS) of the MTL_TxQn_ETS_Status register indicates that a new value is updated in the ABS field.

The frequency of this interrupt depends on the value programmed in the Step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
When not required, you can disable this interrupt to stop the interrupt flooding.

49.5.8 Programming guidelines for energy efficient ethernet

49.5.8.1 Entering and exiting the Tx LPI mode

For entering and exiting the Tx LPI Mode, complete the following steps:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode).
3. Program Bits[6:15] and Bits[16:31] in MAC_LPI_Timers_Control register.
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 14 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPIET and LPITXA (bit[11:12]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Set Bit 15 of MAC_LPI_Control_Status register to make the MAC Transmitter enter the LPI state.
   The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[31]) after entry to LPI state.
9. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits

LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
11. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set Bit 12 in MAC_LPI_Control_Status register.
To switch off the MII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.
To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

49.5.8.2 Gating off the CSR clock in the LPI mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

49.5.8.3 Gating off the CSR clock in the Rx LPI mode

The following operations are performed when the MAC receives the LPI pattern from the PHY.

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN] interrupt of MAC_LPI_Control_Status register is set.
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register.

After the interrupt is asserted and the MAC Tx is also in the LPI mode, you can gate-off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status register is read.

49.5.8.4 Gating off the CSR clock in the Tx LPI mode

The following operations are performed when Bit 15 (LPIEN) of MAC_LPI_Control_Status register is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of MAC_LPI_Control_Status register) is set.
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register.

After the interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR.

For restoring the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. After the CSR clock is resumed, reset Bit 15 (LPIEN) of MAC_LPI_Control_Status register to bring the MAC out of the LPI mode.

49.5.9 Programming guidelines for flexible Pulse-Per-Second (PPS) output

49.5.9.1 Generating single pulse on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the width of the PPS signal output in MAC_PPS0_Width Register.
4. Program Bits [28:31], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS0_Width.
3. Program Bits [28:3], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

49.5.9.2 Generating a pulse train on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of the PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS0_Interval Register.
4. Program the width of the PPS signal output in MAC_PPS0_Width Register.
5. Program Bits[28:3], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands

6. Program the stop value in the Target Time registers. Ensure that Bit 0 (TSTRBUSY) of MAC_PPS0_Target_Time_Nanoseconds Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit [28:31]) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step *6* elapses.

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

49.5.9.3 Generating an Interrupt without affecting the PPS

The Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) to do any one of the following:

- Generate only interrupts
- Generate interrupts and the PPS start and stop time
- Generate only PPS start and stop time

To program the Target Time registers to generate only interrupt event:

1. Program 00 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.
   If Bits [25:26], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programmed Target Time register value.

49.5.10 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.

Complete the following steps to program TSO:

1. Program the TSE bit of corresponding DMA_CH[n]_Tx_Control register to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a) Enable TSE in Bit 18 of TDES3.
   b) Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of TDES3 and the TCP header in bits [22:19] of TDES3.
   c) Program the maximum size of the segment in MSS of DMA_CH[n]_Control register or MSS in the context descriptor.

If MSS field is programmed in both DMA_CH[n]_Control register and in the context descriptor, the latest software programmed sequence is considered.

3. The header of the unsegmented TCP/IP packet should be in Buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

Note: If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.

49.5.11 Programming guidelines for split header on Receive

Split Header support is an optional feature that you can enable by selecting the Enable Split Header Feature option and by setting the SPH bit in the DMA_CH#_Control register. The DMA can process the header and payload of received packets separately.

When split header support is enabled, the buffer 1 (RDES0) of the descriptors is used only for the header. Therefore the DMA writes the header of the received packet in buffer 1 when FD bit of RDES3 is set. The payload of the received packet is directed to the buffer2 (RDES2).

For subsequent descriptors (FD is set to 0), buffer1 is not used and the payload is written only to buffer 2. When the host enables split header structure by setting the SPH Bit[24] of register DMA_CH[n]_Control_register, the host must ensure that Buffer1 is always valid in all descriptors by creating Buffer1 and indicating this by setting Bit[24] (BUF1V) of RDES3 for all descriptors.

49.5.12 Programming guidelines for VLAN filtering on Receive

1. Program MAC_VLAN_Tag Register for the following bit to select the filtering method:
   a) ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison. VTHM: VLAN Tag Hash Table Match Enable.
   b) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP).
   c) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL).
   d) DOVLTC: Ignores VLAN Type for Tag Match.
   e) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching.
2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table Register. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

49.5.13 Programming guidelines for extended VLAN filtering and routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps:

- Write
  - Write the required data into the MAC VLAN Tag Data register.
  - Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
  - Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  - Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  - Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

49.5.14 Programming sequence for queue/channel based VLAN inclusion register

To program the queue/channel-based VLAN inclusion register, complete the following steps:

Note: Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCLn register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCLn register.
3. The BUSY bit of MAC_VLAN_INCL register is set by ethernet module to indicate the progress of access to indirect access MAC_VLAN_INCLn register. On completion of the access, the BUSY bit is cleared.
   The application must not attempt subsequent access to MAC_VLAN_INCL *n* register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

49.5.15 Programming the launch time in time-based scheduling

The launch time is programmed in the Enhanced Normal Tx Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

49.5.16 Programming guidelines for ECC protection for memories

Programming guidelines for the ECC protection for memories:

- Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_Control register.
- A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_Interrupt_Status register.
- Debug mode is provided for each memory to specify errors.

Note: Enable the ECC feature before the traffic is online (or after the reset). Otherwise false interrupts might be triggered.

49.5.16.1 Programming guidelines for ECC hardware error injection (debug mode)

Follow these steps for ECC Hardware Error Injection:

- Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register. For more details about accessing memory in debug mode, refer to Accessing Memory In Slave/Debug Mode.
- Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_Control register.
- Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_ Indirect_Acc_Control_Status register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_Opeartion_Mode register to 0.
- Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

49.5.17 Programming guidelines for On-Chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Set the EDPP bit of MTL_DPP_Control register to enable the generation of parity and detection of parity Mismatch on datapath. An odd parity generation/detection can be enabled by setting the OPE bit of MTL_DPP_control register else by default even parity generation/detection will be active.
- An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated ti indicate to the application if any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_Safety_Interrupt_ status and MAC_DPP_FSM_Interrupt_Status register.
- Debug mode is supported for each parity generator, to insert error. For details of how to insert errors, refer to Parity Error Injection.

Note: To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

49.5.18 Programming guidelines for FSM parity and timeout

Follow these steps to program the FSM parity and timeout:

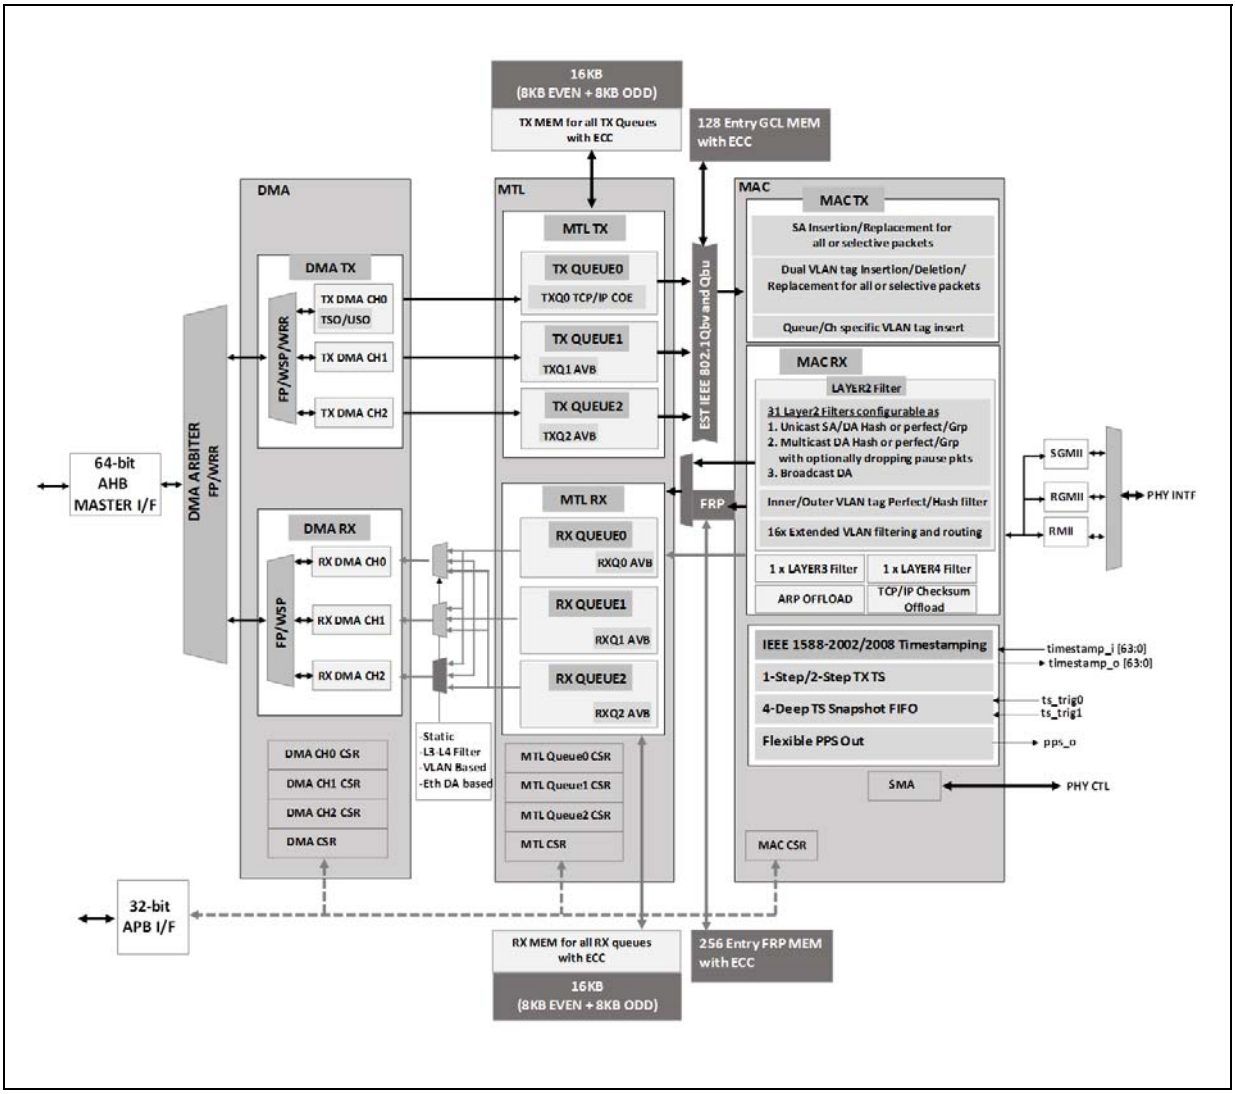
- Set the PRTYEN and TMOUTEN fields of MAC_FSM_Control register to enable the FSM parity and timeout feature respectively.
- For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_Interrupt_Status.
- For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_Control register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_Interrupt_Status.
- For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_Timer register.
- Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_Control Register.
- Set the TMR field of the MAC_ACT_Timer field with the appropriate number of CSR clock cycles used to generate 1us tic.
- Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_Interrupt_Status register.
- For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_Interrupt_Status.
- For application /CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_interrupt_ Status is set along with the safety interrupt.

50 Ethernet 10 Mbps/100 Mbps/1000M bps

50.1 Overview

The Ethernet module enables a host to transmit and receive data over the Ethernet in compliance with the IEEE 802.3-2015. *Figure 1008* shows a block diagram of the Ethernet module.

As shown in *Figure 1008*, the Ethernet module uses a 64-bit AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through AHB master interface. One AHB master interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all the paths (Transmit and Receive) in all channels.



As shown in *Figure 1008*, the Ethernet module uses a 32-bit APB interface to program the Control and Status registers (CSR). Each channel has a separate set of Control and Status registers (CSR) for managing the Transmit and Receive functions, descriptor handling, and interrupt handling.

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the Ethernet module. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are one-ported RAM of 68-bit width for 64 data bus widths. The extra bits are used for storing the byte-enable information.

For multiple queues, all Tx queue share the Tx FIFO memory and all Rx queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue. The Ethernet module provides a direct read or write access to the FIFO memories in Debug mode.

The Ethernet module can be programmed to use one of the multiple PHY interfaces.

Figure 1008. Module block diagram

50.1.1 Ethernet module features

For Ethernet features, refer to the Ethernet Configuration section of the Device Configuration chapter.

50.2 Memory map and registers description

This section provides a detailed description of all registers accessible in this module.

50.2.1 Memory map

Table 1100. Ethernet memory map

Address offset (hex)	Register	Location
0x0000	MAC Configuration register (MAC_CONFIGURATION)	*Section 50.2.2.1*
0x0004	MAC Extended Configuration register (MAC_EXT_CONFIGURATION)	*Section 50.2.2.2*
0x0008	MAC Packet Filter register (MAC_PACKET_FILTER)	*Section 50.2.2.3*
0x000C	MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)	*Section 50.2.2.4*
0x0010	MAC Hash Table register 0 (MAC_HASH_TABLE_REG0)	*Section 50.2.2.5*
0x0014	MAC Hash Table register 1 (MAC_HASH_TABLE_REG1)	*Section 50.2.2.6*
0x0018–0x004F	Reserved	
0x0050	MAC VLAN Tag Control register (MAC_VLAN_TAG_CTRL)	*Section 50.2.2.7*
0x0054	MAC VLAN Tag Data register (MAC_VLAN_TAG_DATA)	*Section 50.2.2.8*
0x0054	MAC VLAN Tag Filter n register (MAC_VLAN_TAG_FILTERn) for n = 0 to 15	*Section 50.2.2.9*
0x0058	MAC VLAN Hash Table register (MAC_VLAN_HASH_TABLE)	*Section 50.2.2.10*
0x0060	MAC VLAN Tag Inclusion register (MAC_VLAN_INCL)	*Section 50.2.2.11*
0x0060	MAC VLAN Tag Inclusion register n (MAC_VLAN_INCLn) for n = 0 to 2	*Section 50.2.2.12*
0x0064	MAC Inner VLAN Tag Inclusion register (MAC_INNER_VLAN_INCL)	*Section 50.2.2.13*

50.2.2 Registers definition

50.2.2.1 MAC configuration register (MAC_CONFIGURATION)

The MAC configuration register establishes the operating mode of the MAC.

Offset 0x0000 Access: User Read/Write

Figure 1009. MAC configuration register (MAC_CONFIGURATION)

Table 1101. MAC_CONFIGURATION field descriptions

Field	Description
0 ARPEN	ARP Offload Enable When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It forwards the ARP packet to the application and also indicate the events in the RxStatus. When this bit is reset, the receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.
1:3 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 1 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[2:3]: 0x If TDES3[SAIC] = 3'b000 then the application provides the correct SA field else insertion logic will work according to the setting of TDES3[SAIC]. 10 If Bit 1 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 11 If Bit 1 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets. If Bit 1 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. **Note:** Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
4 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. Always set this bit when Layer 3 and Layer 4 Packet Filter is enabled or Split Header is enabled.

Table 1101. MAC_CONFIGURATION field descriptions (continued)

Field	Description
5:7 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. Values: 0x0 (IPG96): 96 bit times IPG 0x1 (IPG88): 88 bit times IPG 0x2 (IPG80): 80 bit times IPG 0x3 (IPG72): 72 bit times IPG 0x4 (IPG64): 64 bit times IPG 0x5 (IPG56): 56 bit times IPG 0x6 (IPG48): 48 bit times IPG 0x7 (IPG40): 40 bit times IPG
8 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1518 bytes. Otherwise, the MAC considers 1518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9018 bytes (9022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.
9 S2KP	IEEE 802.3 as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1518 bytes (1522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, refer to Giant Packet Status based on S2KP and JE Bits. **Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.

Table 1101. MAC_CONFIGURATION field descriptions (continued)

Field	Description
10 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. This function is valid when Type 2 Checksum Offload Engine is enabled. **Note:** For information about how the settings of the ACS bit and this bit impact the packet length, refer to *Table 1102*.
11 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1536 bytes. All received packets with length field greater than or equal to 1536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. For more details refer to *Table 1102*. **Note:** For information about how the settings of CST bit and this bit impact the packet length, refer to *Table 1102*.
12 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16383 bytes. When this bit is reset, the MAC does not allow more than 2048 bytes (10240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2048 bytes.
14 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16383 bytes. When this bit is reset, if the application sends more than 2048 bytes of data (10240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.
15 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9018 bytes (9022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
16 PS	Port Select 0 For 1000 Mbps operations 1 For 10 or 100 Mbps operations
17 FES	Speed This bit selects the speed in the 10/100 Mbps mode: 0 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1 100 Mbps when PS bit is 1
18 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. The module supports full duplex only. Hence, this bit is always “1”.
19 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Table 1101. MAC_CONFIGURATION field descriptions (continued)

Field	Description
20 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal.
28:29 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 7 bytes of preamble 01 5 bytes of preamble 10 3 bytes of preamble 11 Reserved
30 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the selected interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.
31 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the selected interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the selected interface.

Table 1102. Packet length based on the CST and ACS bits

Receive checksum offload engine	Receive packet length	CST	ACS	FCS stripping done
IPCKSUM_EN = 0 and IPC_FULL_OFFLOAD = 0 or IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 1	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	0	x	No
		1	x	Yes (for Type packets)
IPCKSUM_EN = 1 and IPC_FULL_OFFLOAD = 0	< 1536	x	0	No
		x	1	Yes (for Ethernet packets)
	>= 1536	x	x	No

50.2.2.2 MAC extended configuration register (MAC_EXT_CONFIGURATION)

The MAC extended configuration register establishes the operating mode of the MAC.

Offset 0x0004 Access: User Read/Write

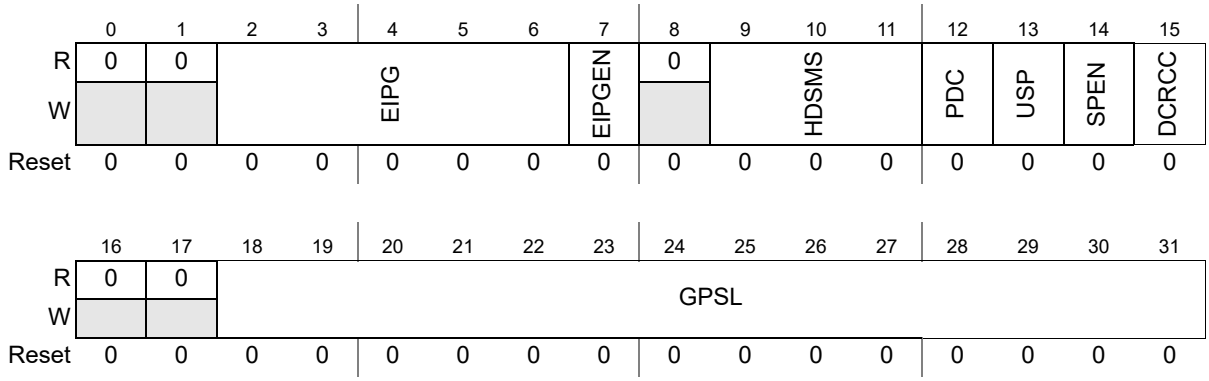

Figure 1010. MAC_ext_configuration register (MAC_EXT_CONFIGURATION)

Table 1103. MAC_EXT_CONFIGURATION field descriptions

Field	Description
2:6 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
7 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. **Note:** The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode.
9:11 HDSMS	Maximum Size for Splitting the Header Data These bits indicate the maximum header size allowed for splitting the header data in the received packet: The following values are valid only: 000 64 bytes 001 128 bytes 010 256 bytes 011 512 bytes 100 1024 bytes

Table 1103. MAC_EXT_CONFIGURATION field descriptions (continued)

Field	Description
12 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_Address *n*_High register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of MAC_Address *n*_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value.
13 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.
14 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.
15 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.
18:31 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1518 bytes. Any other programmed value is considered as 1518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register.

50.2.2.3 MAC packet filter register (MAC_PACKET_FILTER)

The MAC packet filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Figure 1011. MAC packet filter register (MAC_PACKET_FILTER)

Table 1104. MAC_PACKET_FILTER field descriptions

Field	Description
0 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.
10 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
11 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.
15 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.
21 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter.

Table 1104. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
22 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. **Note:** According to the IEEE specification, Bit 47 of the SA is reserved. However, in the Ethernet module, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.
23 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.
24:25 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 The MAC filters all control packets from reaching the application. 01 The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 10 The MAC forwards all control packets to the application even if they fail the Address filter. 11 The MAC forwards the control packets that pass the Address filter.
26 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets.
27 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.
28 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
29 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.

Table 1104. MAC_PACKET_FILTER field descriptions (continued)

Field	Description
30 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.
31 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.

50.2.2.4 MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

Offset 0x000C — Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1012. MAC Watchdog Timeout register (MAC_WATCHDOG_TIMEOUT)

Table 1105. MAC_WATCHDOG_TIMEOUT field descriptions

Field	Description
23 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_Configuration register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Configuration register.
28:31 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_Configuration register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Encoding is as follows: 0x0: 2 KB 0x1: 3 KB 0x2: 4 KB 0x3: 5 KB ... 0xC: 14 KB 0xD: 15 KB 0xE: 16383 Bytes 0xF: Reserved **Note:** When the PWE bit is set, the value in this field should be more than 1522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.

50.2.2.5 MAC Hash table register 0 (MAC_HASH_TABLE_REG0)

The Hash table register 0 contains the first 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

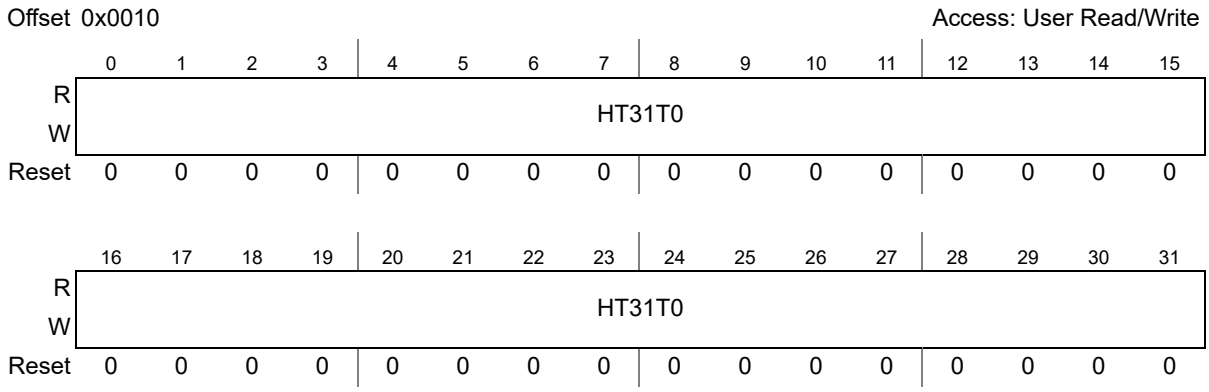

Figure 1013. MAC Hash Table Reg0 register (MAC_HASH_TABLE_REG0)

Table 1106. MAC_HASH_TABLE_REG0 field descriptions

Field	Description
0:31 HT31T0	This field contains the first 32 bits [0:31] of the MAC Hash table.

50.2.2.6 MAC Hash Table register 1 (MAC_HASH_TABLE_REG1)

The Hash table register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (refer to IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
- Perform bitwise reversal for the value obtained in Step 1.
- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

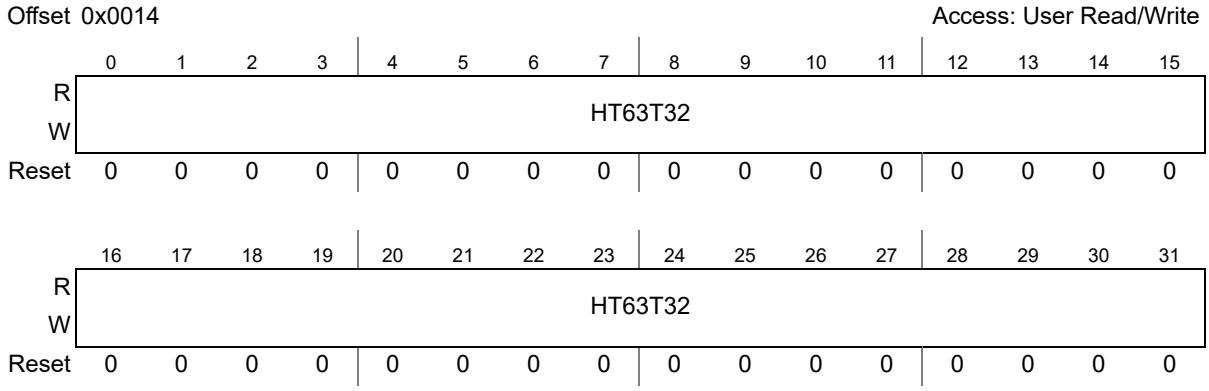

Figure 1014. MAC Hash table Reg1 register (MAC_HASH_TABLE_REG1)

Table 1107. MAC_HASH_TABLE_REG1 field descriptions

Field	Description
0:31 HT63T32	This field contains the second 32 bits [31:0] of the MAC Hash table.

50.2.2.7 MAC VLAN tag control register (MAC_VLAN_TAG_CTRL)

This register is the redefined format of the MAC VLAN Tag register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.

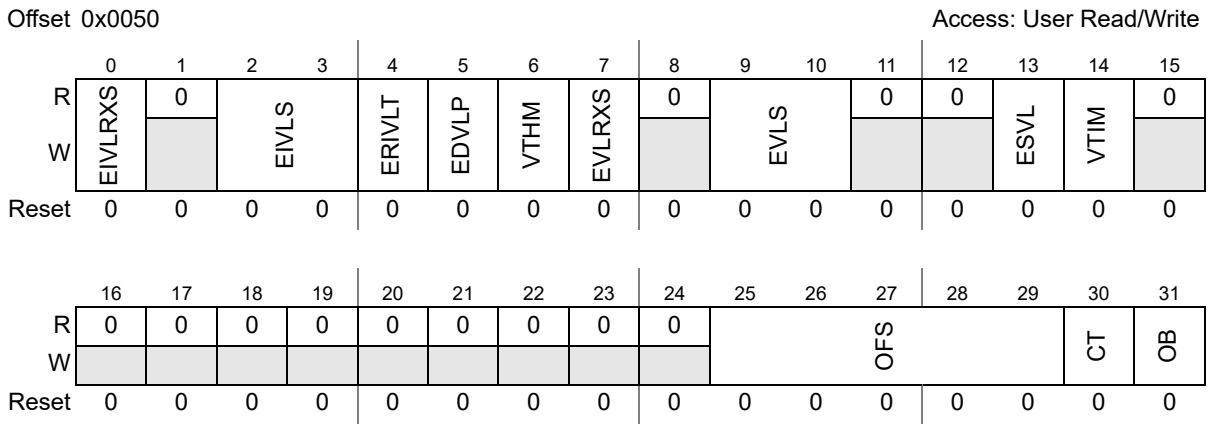

Figure 1015. MAC VLAN tag control register (MAC_VLAN_TAG_CTRL)

Table 1108. MAC_VLAN_TAG_CTRL field descriptions

Field	Description
0 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.
2:3 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
4 ERIVLT	Enable Inner VLAN Tag When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
5 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).
6 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed.
7 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.
9:10 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet: 00 Do not strip 01 Strip if VLAN filter passes 10 Strip if VLAN filter fails 11 Always strip
13 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.
14 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Table 1108. MAC_VLAN_TAG_CTRL field descriptions (continued)

Field	Description
25:29 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
30 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicates a read operation. When reset, it indicates a write operation.
31 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the MAC_VLAN_Tag_Data register only after this bit is reset.

50.2.2.8 MAC VLAN tag data register (MAC_VLAN_TAG_DATA)

This register holds the read/write data for Indirect Access of the Per VLAN tag registers.

During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_TAG_CTRL register.

Figure 1016. MAC VLAN tag data register (MAC_VLAN_TAG_DATA)

Table 1109. MAC_VLAN_TAG_DATA field descriptions

Field	Description
5:6 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
7 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing.
11 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present).
12 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
13 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit.
14 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet.
15 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields.
16:31 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

50.2.2.9 MAC VLAN tag filter register *n* (MAC_VLAN_TAG_FILTER*n*)

Figure 1017. MAC VLAN tag filter register *n* (MAC_VLAN_TAG_FILTER*n*)

Table 1110. MAC_VLAN_TAG_FILTERn field descriptions

Field	Description
5:6 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field needs not be programmed.
7 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing.
11 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present).
12 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.
13 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit.

Table 1110. MAC_VLAN_TAG_FILTERn field descriptions (continued)

Field	Description
14 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet.
15 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields.
16:31 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

50.2.2.10 MAC VLAN hash table register (MAC_VLAN_HASH_TABLE)

When the VTHM bit of MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4’b1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, refer to Section 3.2.8 of IEEE 802.3 - 2008).
- Perform bitwise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Figure 1019. MAC VLAN tag inclusion register (MAC_VLAN_INCL)

Table 1112. MAC_VLAN_INCL field descriptions

Field	Description
0 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register.
1 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset.
6:7 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
10 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register.
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet to be taken from the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
13 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored.

Table 1112. MAC_VLAN_INCL field descriptions (continued)

Field	Description
14:15 VLC	VLAN Tag Control in Transmit Packets – 2'b00: No VLAN tag deletion, insertion, or replacement – 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. – 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. – 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

50.2.2.12 MAC VLAN tag inclusion register *n* (MAC_VLAN_INCL*n*)

The Tx Queue VLAN tag inclusion register contains the VLAN tag for insertion in the transmit packets from Tx Queue *n*. It also contains the VLAN tag insertion controls.

Figure 1021. MAC Inner VLAN tag inclusion register (MAC_INNER_VLAN_INCL)

Table 1114. MAC_INNER_VLAN_INCL field descriptions

Field	Description
11 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.
12 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

Table 1114. MAC_INNER_VLAN_INCL field descriptions (continued)

Field	Description
13 VLP	VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.
14:15 VLC	VLAN Tag Control in Transmit Packets 00 No VLAN tag deletion, insertion, or replacement 01 VLAN tag deletion. The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. 10 VLAN tag insertion. The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11 VLAN tag replacement. The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). **Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
16:31 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[16:18] are the User Priority field, Bit 19 is the CFI/DEI field, and Bits[20:31] are the VID field in the VLAN tag. The following list describes the bits of this field: – Bits[16:18] User Priority – Bit 19 Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) – Bits[20:31] VLAN Identifier (VID) field of VLAN tag

50.2.2.14 MAC Q0 TX flow control register (MAC_Q0_TX_FLOW_CTRL)

The Flow control register controls the generation and reception of the control (Pause command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

Figure 1022. MAC Q0 TX flow control register (MAC_Q0_TX_FLOW_CTRL)

Table 1115. MAC_Q0_TX_FLOW_CTRL field descriptions

Field	Description
0:15 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
24 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
25:27 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[0:15]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 000 Pause Time minus 4 Slot Times (PT -4 slot times) 001 Pause Time minus 28 Slot Times (PT -28 slot times) 010 Pause Time minus 36 Slot Times (PT -36 slot times) 011 Pause Time minus 144 Slot Times (PT -144 slot times) 100 Pause Time minus 256 Slot Times (PT -256 slot times) 101 Pause Time minus 512 Slot Times (PT -512 slot times) 110 Reserved 111 Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Table 1115. MAC_Q0_TX_FLOW_CTRL field descriptions (continued)

Field	Description
30 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.
31 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.15 MAC receive flow control register (MAC_RX_FLOW_CTRL)

The Receive flow control register controls the pausing of MAC Transmit based on the received Pause packet.

Offset 0x0090 Access: User Read/Write

Figure 1023. MAC receive flow control register (MAC_RX_FLOW_CTRL)

Table 1116. MAC_RX_FLOW_CTRL field descriptions

Field	Description
30 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. **Note:** The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.
31 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

50.2.2.16 MAC Receive queue control 4 register (MAC_RXQ_CTRL4)

The Receive queue control 4 register controls the routing of unicast and multicast packets that fail the destination or source address filter to the Rx queues.

Figure 1026. MAC Receive queue control 1 register (MAC_RXQ_CTRL1)

Table 1119. MAC_RXQ_CTRL1 field descriptions

Field	Description
5:7 FPRQ	Frame Preemption Residue Queue This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.
8:9 TPQC	Tagged PTP over Ethernet Packets Queuing Control This field controls the routing of the VLAN Tagged PTPoE packets. 00 VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx Queues). 01 VLAN Tagged PTPoE packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic). 10 VLAN Tagged PTPoE packets are routed to only AV enabled Rx Queues based on PSRQ. 11 Reserved
10 TACPQE	Tagged AV Control Packets Queuing Enable When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.
11 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field.
13:15 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/AV traffic can be used to route the Multicast or Broadcast Packets. 000 Rx Queue 0 001 Rx Queue 1 010 Rx Queue 2 others: Reserved
17:19 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/AV traffic can be used to route the Untagged Packets. 000 Rx Queue 0 001 Rx Queue 1 010 Rx Queue 2 others: Reserved

Table 1119. MAC_RXQ_CTRL1 field descriptions (continued)

Field	Description
25:27 PTPQ	AV PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. 000 Rx Queue 0 001 Rx Queue 1 010 Rx Queue 2 others: Reserved When the AV8021ASMEN bit of MAC_Timestamp_Control register is set, only untagged PTP over Ethernet packets are routed on an Rx queue.
29:31 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed: 000 Rx Queue 0 001 Rx Queue 1 010 Rx Queue 2 others: Reserved The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field.

50.2.2.19 MAC Receive queue control 2 register (MAC_RXQ_CTRL2)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 1.

Offset 0x00A8 Access: User Read/Write

Figure 1027. MAC Receive queue control 2 register (MAC_RXQ_CTRL2)

Table 1120. MAC_RXQ_CTRL2 field descriptions

Field	Description
8:15 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. When the DCB feature is selected, this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.
16:23 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
24:31 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. Value After Reset: 0x0

50.2.2.20 MAC Interrupt status register (MAC_INTERRUPT_STATUS)

The Interrupt status register contains the status of interrupts.

Offset 0x00B0 Access: User Read-only

Figure 1028. MAC Interrupt status register (MAC_INTERRUPT_STATUS)

Table 1121. MAC_INTERRUPT_STATUS field descriptions

Field	Description
11 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support.
12 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support.
13 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of MAC_CSR_SW_Ctrl register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
14 FPEIS	Frame Preemption Interrupt Status This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt.
17 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.
18 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: – Excessive Collision (EXCOL) – Late Collision (LCOL) – Excessive Deferral (EXDEF) – Loss of Carrier (LCARR) – No Carrier (NCARR) – Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.

Table 1121. MAC_INTERRUPT_STATUS field descriptions (continued)

Field	Description
19 TSIS	Timestamp Interrupt Status This bit is set when any of the following conditions is true: – The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. – There is an overflow in the Seconds register. – The Target Time Error occurred, that is, programmed target time already elapsed. – When the auxiliary snapshot trigger is asserted. – When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register.
20 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
21 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
22 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared.
23 MMCIS	MMC Interrupt Status This bit is set high when Bit 20, Bit 21, or Bit 22 is set high. This bit is cleared only when all these bits are low.
26 LPIIS	LPI Interrupt Status This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RWCERCWE bit of MAC_CSR_SW_Ctrl register is set).
27 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when Bits [25:26] are cleared because of a Read operation to the MAC_PMT_Control_Status register (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).

Table 1121. MAC_INTERRUPT_STATUS field descriptions (continued)

Field	Description
28 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
31 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_Control_Status register). This bit is cleared when the MAC_PHYIF_Control_Status register is read (or LNKSTS bit of MAC_PHYIF_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface.

50.2.2.21 MAC Interrupt enable register (MAC_INTERRUPT_ENABLE)

The Interrupt enable register contains the masks for generating the interrupts.

Offset 0x00B4 Access: User Read/Write

Figure 1029. MAC Interrupt enable register (MAC_INTERRUPT_ENABLE)

Table 1122. MAC_INTERRUPT_ENABLE field descriptions

Field	Description
13 MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_INTERRUPT_STATUS register.
14 FPEIE	Frame Preemption Interrupt Enable When this bit is set, it enables the assertion of the interrupt when FPEIS field is set in the MAC_INTERRUPT_STATUS register.
17 RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the MAC_INTERRUPT_STATUS register.
18 TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the MAC_INTERRUPT_STATUS register.

Table 1122. MAC_INTERRUPT_ENABLE field descriptions (continued)

Field	Description
19 TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in MAC_INTERRUPT_STATUS register.
26 LPIIE	LPI Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in MAC_INTERRUPT_STATUS register.
27 PMTIE	PMT Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in MAC_INTERRUPT_STATUS register.
28 PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in MAC_INTERRUPT_STATUS register.
31 RGSMIIIE	RGMII or SMII Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RGSMIIIS bit in MAC_INTERRUPT_STATUS register.

50.2.2.22 MAC Receive transmit status register (MAC_RX_TX_STATUS)

The Receive transmit status register contains the Receive and Transmit Error status.

Offset 0x00B8 Access: User Read-only

Figure 1030. MAC Receive transmit status register (MAC_RX_TX_STATUS)

Table 1123. MAC_RX_TX_STATUS field descriptions

Field	Description
23 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2048 bytes is received (10240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
31 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2048 bytes (10240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

50.2.2.23 MAC PMT control and status register (MAC_PMT_CONTROL_STATUS)

This register captures the remote wakeup control and status.

Offset 0x00C0 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1031. MAC PMT control and status register (MAC_PMT_CONTROL_STATUS)

Table 1124. MAC_PMT_CONTROL_STATUS field descriptions

Field	Description
0 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
3:7 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 31) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to 31, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
21 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. **Note:** If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
22 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet.
25 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
26 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
29 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.

Table 1124. MAC_PMT_CONTROL_STATUS field descriptions (continued)

Field	Description
30 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet.
31 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.24 Wake-up packet filter registers

The wkuppktfilter_reg register at address 0x00C4 loads the Wake-up packet filter register.

To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight register values in address (0x00C4) for wkuppktfilter_reg0, wkuppktfilter_reg1, …, wkuppktfilter_reg7, respectively. The wkuppktfilter_reg register is read in a similar way.

The Ethernet module updates the wkuppktfilter_reg register current pointer value in Bits[5:7] of MAC_PMT_Control_Status register.

- Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3) to determine whether or not a packet is a wake-up packet.
  - The MSB (bit 0) must be zero.
  - Bit j[1:31] is the byte mask.
  - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.
- Filter i Command: The 4-bit filter i command controls the filter i operation.
  - Bit 28 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.
  - Bit 29 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.
  - Bit 29, along with Bit 30, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2".
  - Bit 30 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three,

or four filters. This depends on the number of filters that have the And_Previous bit set.

– Bit 31 is the enable for filter i. If Bit 31 is not set, filter i is disabled.

- Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.
  – This 8-bit pattern-offset is the offset for the filter i first byte to be examined.
  – The minimum allowed offset is 12, which refers to the 13th byte of the packet.
  – The offset value 0 refers to the first byte of the packet.
- Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.
  – The 16-bit CRC calculation uses the following polynomial:
  $G(x) = x^{16} + x^{15} + x^2 + 1$
  Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:
  – 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.
  – 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.

The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.

Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).

When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Therefore, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).

50.2.2.24.1 Notes on And_Previous bit setting

The And_Previous bit setting is applicable within a set of 4 filters.

- Setting of And_Previous bit of filter that is not enabled has no effect. In other words, setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.
- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example:

  If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set) but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered.

  If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 2 is not enabled (bit 0 of in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. If filters chained by And_Previous bit setting have complementary programming, then a frame may never

pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 of Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 of Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Figure 1038. Wakeup filter 0123 command register (RWK_FILTER0123_COMMAND)

Table 1130. RWK_FILTER0123_COMMAND field descriptions

Field	Description
4:7 Filter3_Command	Filter${l} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2". – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
12:15 Filter2_Command	Filter${k} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2". – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.

Table 1130. RWK_FILTER0123_COMMAND field descriptions (continued)

Field	Description
20:23 Filter1_Command	Filter${j} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2". – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
28:31 Filter0_Command	Filter${i} Command The 4-bit filter command controls the filter operation. – Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. – Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. – Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2". – Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. – Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.

50.2.2.24.8 Wakeup filter 0123 offset register (RWK_FILTER0123_OFFSET)

Corresponds to registers wkuppktfilter_reg5 described in *Figure 1032*.

Offset 0x00C4 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1042. MAC LPI control and status register (MAC_LPI_CONTROL_STATUS)

Table 1134. MAC_LPI_CONTROL_STATUS field descriptions

Field	Description
10 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0 LPI Tx Clock Stop is disabled 1 LPI Tx Clock Stop is enabled
11 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPITE, LPITXA and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions. 0 LPI Timer is disabled 1 LPI Timer is enabled
12 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of the MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0 LPI Tx Automate is disabled 1 LPI Tx Automate is enabled
13 PLSEN	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_Control_Status register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_Control_Status register and takes only the PLS bit. 0 PHY Link Status is disabled 1 PHY Link Status is enabled

Table 1134. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
14 PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. 0 Link is down 1 Link is okay
15 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0 LPI state is disabled 1 LPI state is enabled
22 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface. 0 Receive LPI state not detected 1 Receive LPI state detected
23 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface. 0 Transmit LPI state not detected 1 Transmit LPI state detected
28 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 Receive LPI exit not detected 1 Receive LPI exit detected
29 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note:** This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 Receive LPI entry not detected 1 Receive LPI entry detected

Table 1134. MAC_LPI_CONTROL_STATUS field descriptions (continued)

Field	Description
30 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0 Transmit LPI exit not detected 1 Transmit LPI exit detected
31 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0 Transmit LPI entry not detected 1 Transmit LPI entry detected

50.2.2.26 MAC LPI timers control register (MAC_LPI_TIMERS_CONTROL)

The LPI timers control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Offset 0x00D4 Access: User Read/Write

Figure 1043. MAC LPI timers control register (MAC_LPI_TIMERS_CONTROL)

Table 1135. MAC_LPI_TIMERS_CONTROL field descriptions

Field	Description
6:15 LST	LPI LS TIMER This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
16:31 TWT	LPI TW TIMER This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

50.2.2.27 MAC LPI entry timer register (MAC_LPI_ENTRY_TIMER)

This register controls the Tx LPI entry timer. This counter is enabled only when bit[11](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Offset 0x00D8 Access: User Read/Write

Figure 1044. MAC LPI entry timer register (MAC_LPI_ENTRY_TIMER)

Table 1136. MAC_LPI_ENTRY_TIMER field descriptions

Field	Description
12:28 LPIET	LPI Entry Timer This field specifies the time in microseconds the MAC will wait to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [29:31] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

50.2.2.28 MAC 1US Tic counter register (MAC_1US_TIC_COUNTER)

This register controls the generation of the reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

Offset 0x00DC Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1045. MAC 1US Tic counter register (MAC_1US_TIC_COUNTER)

Table 1137. MAC_1US_TIC_COUNTER field descriptions

Field	Description
20:31 TIC_1US_CNTR	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100 MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

50.2.2.29 MAC PHYIF Control Status register (MAC_PHYIF_CONTROL_STATUS)

The PHY Interface Control and Status register indicates the status signals received by the SGMII, RGMII, or SMII interface (selected at reset) from the PHY. This register is optional.

Figure 1048. MAC Debug register (MAC_DEBUG)

Table 1140. MAC_DEBUG field descriptions

Field	Description
13:14 TFCSTS	MAC Transmit Packet Controller Status This field indicates the state of the MAC Transmit Packet Controller module: 00 Idle state 01 Waiting for one of the following: Status of the previous packet OR IPG or backoff period to be over 10 Generating and transmitting a Pause control packet (in full-duplex mode) 11 Transferring input packet for transmission
15 TPESTS	MAC MII Transmit Protocol Engine Status When this bit is set, it indicates that the MAC MII transmit protocol engine is actively transmitting data, and it is not in the Idle state.
29:30 RFCFCSTS	MAC Receive Packet Controller FIFO Status When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.
31 RPESTS	MAC MII Receive Protocol Engine Status When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving data, and it is not in the Idle state.

50.2.2.32 MAC Hardware feature 0 register (MAC_HW_FEATURE0)

This register indicates the presence of the optional features or functions of the Ethernet module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Offset 0x011C Access: User Read-only

Field	Description
1:3 ACTPHYSEL	Active PHY Selected When you have multiple PHY interfaces in your configuration, this field indicates the sampled value of phy_intf_sel_i during reset de-assertion: 000 MII 001 RGMII 100 RMII All Others Reserved
4 SAVLANINS	Source Address or VLAN Insertion Enable
5:6 TSSTSSEL	Timestamp System Time Source This bit indicates the source of the Timestamp system time: 11 Both internal and external source of Timestamp
9:13 ADDMACADRSEL	MAC Addresses 1-31 Selected This bit is set to 1 when the Additional 1-31 MAC Address Registers are present.
15 RXCOESEL	Receive Checksum Offload present This bit is set to 1 when the Receive TCP/IP Checksum Check is present.
17 TXCOESEL	Transmit Checksum Offload present
18 EEESEL	Energy Efficient Ethernet present
19 TSSEL	IEEE 1588-2008 Timestamp present

Table 1141. MAC_HW_FEATURE0 field descriptions (continued)

Field	Description
22 ARPOFFSEL	ARP Offload present
23 MMCSEL	RMON Module Present
24 MGKSEL	PMT Magic Packet present
25 RWKSEL	PMT Remote Wake-up Packet Enable
26 SMASEL	SMA (MDIO) Interface present
27 VLHASH	VLAN Hash Filter selection
29 HDSEL	Half-duplex support selection 0 Not selected 1 Selected
30 GMIISEL	1000 Mbps Support This bit is set to 1 when 1000 Mbps is selected as the mode of operation.
31 MIISEL	10 or 100 Mbps Support

50.2.2.33 MAC Hardware feature 1 register (MAC_HW_FEATURE1)

This register indicates the presence of the optional features or functions of the Ethernet module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Offset 0x0120 Access: User Read-only

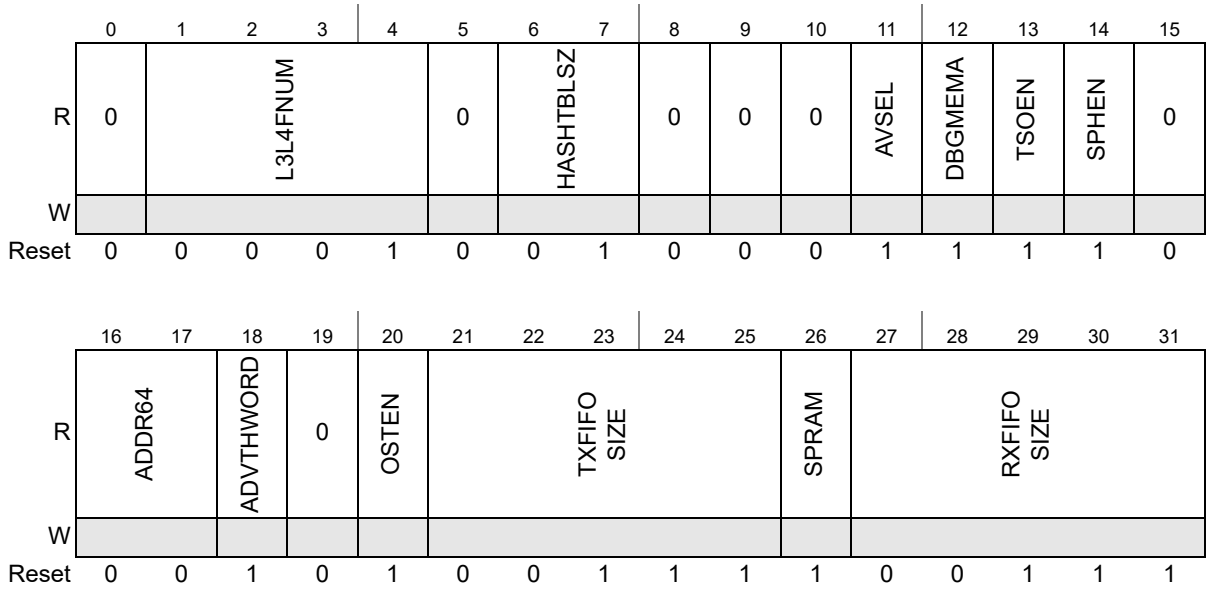

Figure 1050. MAC Hardware feature 1 register (MAC_HW_FEATURE1)

Table 1142. MAC_HW_FEATURE1 field descriptions

Field	Description
1:4 L3L4FNUM	Total number of L3 or L4 Filters This field indicates the total number of L3 or L4 filters: 0001 1 L3 or L4 Filter
6:7 HASHTBLSZ	Hash Table Size This field indicates the size of the hash table: 01 64-bit hash table
11 AVSEL	AV Feature Enabled This bit is set to 1 when the Enable Audio Video Bridging is present.
12 DBGMEMA	DMA Debug Registers Enabled This bit is set to 1 when the Debug Mode is present.
13 TSOEN	TCP Segmentation Offload Enable This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP. Packets option is selected.
14 SPHEN	Split Header Feature Enable This bit is set to 1 when the Enable Split Header Structure option is selected.
16:17 ADDR64	Address Width This field indicates the configured address width: 00 32-bit address width
18 ADVTHWORD	IEEE 1588 High Word Register Enable This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected.

Table 1142. MAC_HW_FEATURE1 field descriptions (continued)

Field	Description
20 OSTEN	One-Step Timestamping Enable This bit is set to 1 when the Enable One-Step Timestamp feature is selected.
21:25 TXFIFOSIZE	MTL Transmit FIFO Size This field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(TXFIFO_SIZE) -7: 00111 16384 bytes
26 SPRAM	Single Port RAM Enable This bit is set to 1 when the Use single port RAM feature is selected.
27:31 RXFIFOSIZE	MTL Receive FIFO Size This field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, Log2(RXFIFO_SIZE) -7: 00111 16384 bytes

50.2.2.34 MAC Hardware feature 2 register (MAC_HW_FEATURE2)

This register indicates the presence of the optional features or functions of the Ethernet module. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Table 1145. MAC_DPP_FSM_INTERRUPT_STATUS field descriptions

Field	Description
7 FSMPES	FSM State Parity Error Status This field when set indicates one of the FSMs State registers has a parity error detected. 0 FSM State Parity Error Status not detected 1 FSM State Parity Error Status detected
15 MSTTES	Master Read/Write Timeout Error Status This field when set indicates that an Application/CSR Timeout has occurred on the master (AXI/AHB/ARI/ATI) interface. 0 Master Read/Write Timeout Error Status not detected 1 Master Read/Write Timeout Error Status detected
19 PTES	PTP FSM Timeout Error Status This field when set indicates that one of the PTP FSM Timeout has occurred. 0 PTP FSM Timeout Error Status not detected 1 PTP FSM Timeout Error Status detected
20 ATES	APP FSM Timeout Error Status This field when set indicates that one of the APP FSM Timeout has occurred. 0 APP FSM Timeout Error Status not detected 1 APP FSM Timeout Error Status detected
21 CTES	CSR FSM Timeout Error Status This field when set indicates that one of the CSR FSM Timeout has occurred. 0 CSR FSM Timeout Error Status not detected 1 CSR FSM Timeout Error Status detected
22 RTES	Rx FSM Timeout Error Status This field when set indicates that one of the Rx FSM Timeout has occurred. 0 Rx FSM Timeout Error Status not detected 1 Rx FSM Timeout Error Status detected
23 TTES	Tx FSM Timeout Error Status This field when set indicates that one of the Tx FSM Timeout has occurred. 0 Tx FSM Timeout Error Status not detected 1 Tx FSM Timeout Error Status detected
26 ARPES	Application Receive interface data path Parity Error Status This bit when set indicates that a parity error is detected at following checkers based on the system configuration as described below: AHB parity checker (PC6 as shown in *Figure 1319: Receive Datapath Parity Protection*) at AHB master interface. 0 Application Receive interface data path Parity Error Status not detected 1 Application Receive interface data path Parity Error Status detected
27 MTSPES	MTL TX Status data path Parity checker Error Status This field when set indicates that, parity error is detected on the MTL TX Status data on ati interface (or at PC5 as shown in *Figure 1318: Transmit Datapath Parity Protection*). 0 MTL TX Status data path Parity checker Error Status not detected 1 MTL TX Status data path Parity checker Error Status detected

Table 1145. MAC_DPP_FSM_INTERRUPT_STATUS field descriptions (continued)

Field	Description
28 MPES	MTL data path Parity checker Error Status This bit when set indicates that a parity error is detected at the MTL transmit write controller parity checker (or at PC4 as shown in *Figure 1318: Transmit Datapath Parity Protection*). 0 MTL data path Parity checker Error Status not detected 1 MTL data path Parity checker Error Status detected
29 RDPES	Read Descriptor Parity checker Error Status This bit when set indicates that a parity error is detected at the DMA Read descriptor parity checker (or at PC3 as shown in *Figure 1318: Transmit Datapath Parity Protection*). 0 Read Descriptor Parity checker Error Status not detected 1 Read Descriptor Parity checker Error Status detected
30 TPES	TSO data path Parity checker Error Status This bit when set indicates that a parity error is detected at the DMA TSO parity checker (or at PC2 as shown in *Figure 1318: Transmit Datapath Parity Protection*). 0 TSO data path Parity checker Error Status not detected 1 TSO data path Parity checker Error Status detected
31 ATPES	Application Transmit Interface Parity checker Error Status This bit when set indicates that a parity error is detected on the AHB Master read data parity checker. This bit when set indicates that a parity error is detected on the interface port parity checker. Following are the checkers located based on the system configuration: AHB parity checker (PC1 as shown in *Figure 1318: Transmit Datapath Parity Protection*) at AHB master interface. 0 Application Transmit Interface Parity checker Error Status not detected 1 Application Transmit Interface Parity checker Error Status detected

50.2.2.37 MAC FSM control register (MAC_FSM_CONTROL)

This register is used to control the FSM State parity and timeout error injection in Debug mode.

Offset 0x0148 Access: User Read/Write

Figure 1056. MAC MDIO address register (MAC_MDIO_ADDRESS)

Table 1148. MAC_MDIO_ADDRESS field description

Field	Description
4 PSE	Preamble Suppression Enable When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.
5 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0.
6:10 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
11:15 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
17:19 NTC	Number of Training Clocks This field controls the number of trailing clock cycles generated on sma_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.

Table 1148. MAC_MDIO_ADDRESS field description (continued)

Field	Description
20:23 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0000 CSR clock = 60-100 MHz; MDC clock = CSR clock/42 0001 CSR clock = 100-150 MHz; MDC clock = CSR clock/62 0010 CSR clock = 20-35 MHz; MDC clock = CSR clock/16 0011 CSR clock = 35-60 MHz; MDC clock = CSR clock/26 0100 CSR clock = 150-250 MHz; MDC clock = CSR clock/102 0101 CSR clock = 250-300 MHz; MDC clock = CSR clock/124 0110 CSR clock = 300-500 MHz; MDC clock = CSR clock/204 0111 CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 20 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 20 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000 CSR clock/4 1001 CSR clock/6 1010 CSR clock/8 1011 CSR clock/10 1100 CSR clock/12 1101 CSR clock/14 1110 CSR clock/16 1111 CSR clock/18
27 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
28:29 GOC	PHY SMA interface Operation Command This field indicates the operation command to the PHY: 00 Reserved 01 Write 10 Post Read Increment Address for Clause 45 PHY 11 Read When Clause 22 PHY is enabled, only Write (01) and Read (11) commands are valid.

Table 1148. MAC_MDIO_ADDRESS field description (continued)

Field	Description
30 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO.
31 GB	PHY SMA interface Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.40 MAC MDIO data register (MAC_MDIO_DATA)

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

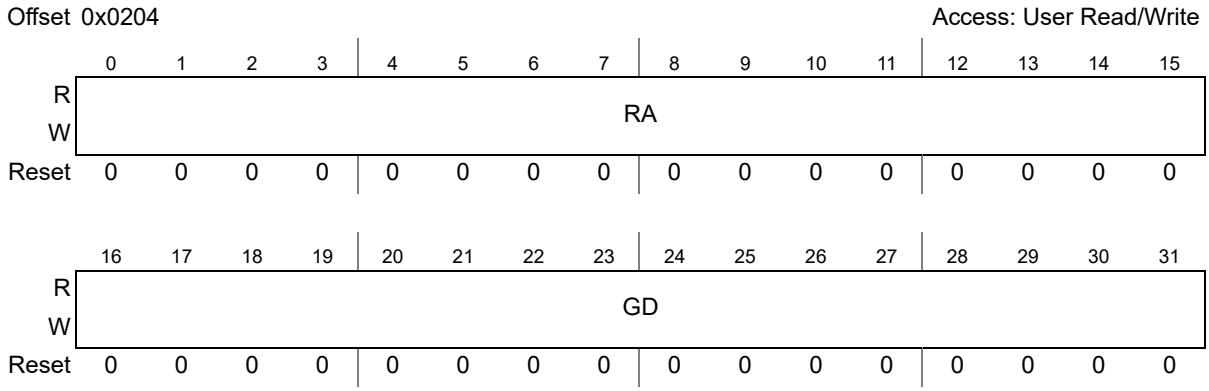

Figure 1057. MAC MDIO data register (MAC_MDIO_DATA)

Table 1149. MAC_MDIO_DATA field descriptions

Field	Description
0:15 RA	Register Address This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.
16:31 GD	PHY management Data This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY.

50.2.2.41 MAC GPIO control register (MAC_GPIO_CONTROL)

The GPIO control register controls the GPIO.

Offset 0x0208 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1058. MAC GPIO control register (MAC_GPIO_CONTROL)

Table 1150. MAC_GPIO_CONTROL field descriptions

Field	Description
0:15 GPIT	GPI Type When this bit is set, it indicates that the corresponding GPIS bit in MAC_GPIO_Status register is of latched-low (LL) type. When this bit is reset, it indicates that the corresponding GPIS is of latched-high (LH) type. The number of bits available in this field depends on the GP Input Signal Width option. Other bits are not used (reserved and always reset).
28:31 GPIE	GPI Interrupt Enable When this bit is set and the programmed event (LL or LH) occurs on the corresponding GPIS bit of MAC_GPIO_Status register, the GPIIS bit of DMA_Interrupt_Status register is set and an interrupt is generated on the mci_intr_o or sbd_intr_o signal. The GPIIS bit is cleared when the application reads the Bits[7:0] of MAC_GPIO_Status register. When this bit is reset, the GPIIS bit is not set when any event occurs on the corresponding GPIS bits.

50.2.2.42 MAC GPIO status register (MAC_GPIO_STATUS)

The General Purpose IO register provides the control to drive the following: up to 16 bits of output ports (GPO) and status of up to 16 input ports (GPIS).

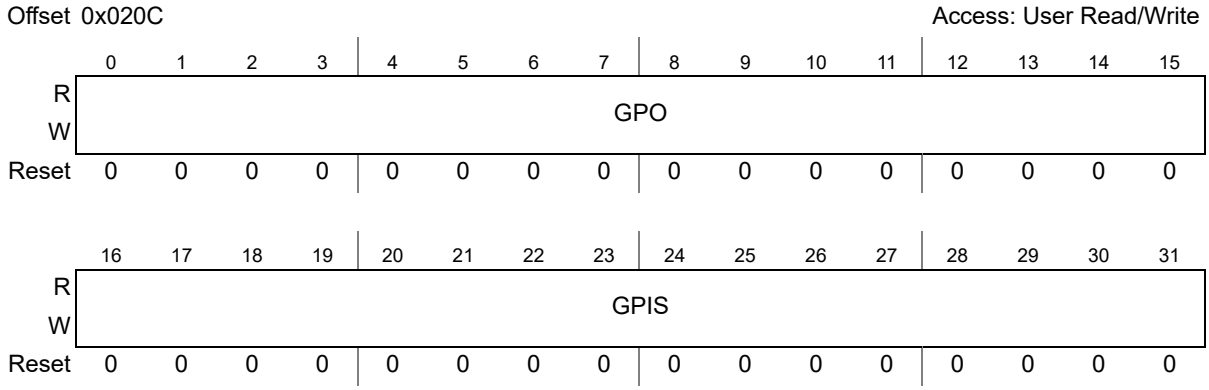

Figure 1059. MAC GPIO status register (MAC_GPIO_STATUS)

Table 1151. MAC_GPIO_STATUS field descriptions

Field	Description
0:15 GPO	General Purpose Output When this bit is set, it directly drives the gpo_o output ports. When this bit is reset, it does not directly drive the gpo_o output ports.
16:31 GPIS	General Purpose Input Status This field gives the status of the signals connected to the gpi_i port. This field is of the following types based on the setting of the corresponding GPIT field of MAC_GPIO_Control register: Latched-low (LL): this field is cleared when the corresponding gpi_i input becomes low. This field remains low until the application reads this field after which this field reflects the current value of gpi_i input. Latched-high (LH): this field is set when the corresponding gpi_i input becomes high. This field remains high until the application reads this field after which this field reflects the current value of gpi_i input.

50.2.2.43 MAC ARP address register (MAC_ARP_ADDRESS)

The ARP address register contains the IPv4 Destination Address of the MAC.

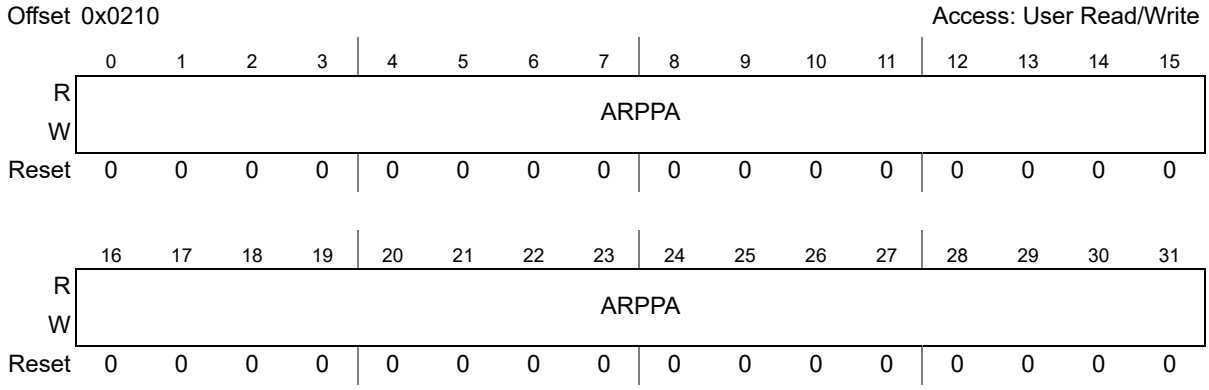

Figure 1060. MAC ARP address register (MAC_ARP_ADDRESS)

Table 1152. MAC_ARP_ADDRESS field descriptions

Field	Description
0:31 ARPPA	ARP Protocol Address This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.

50.2.2.44 MAC CSR SW control register (MAC_CSR_SW_CTRL)

This register contains software programmable controls for changing the CSR access response and status bits clearing.

Offset 0x0230 Access: User Read/Write

Figure 1062. MAC FPE control STS register (MAC_FPE_CTRL_STS)

Table 1154. MAC_FPE_CTRL_STS field descriptions

Field	Description
12 TRSP	Transmitted Respond Frame Set when a Respond mPacket is transmitted (triggered by setting SRSP field). An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
13 TVER	Transmitted Verify Frame Set when a Verify mPacket is transmitted (triggered by setting SVER field). An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
14 RRSP	Received Respond Frame Set when a Respond mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
15 RVER	Received Verify Frame Set when a Verify mPacket is received. An interrupt can be generated for this event if FPEIE bit of MAC_INTERRUPT_ENABLE is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
28 S1_SET_0	Synopsys Reserved, Must be set to “0”. This field is reserved for Synopsys Internal use, and must always be set to “0” unless instructed by Synopsys. Setting to “1” might cause unexpected behavior in the IP.
29 SRSP	Send Respond mPacket When set indicates hardware to send a Respond mPacket. Reset by hardware after sending the Respond mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table 1154. MAC_FPE_CTRL_STS field descriptions (continued)

Field	Description
30 SVER	Send Verify mPacket When set indicates hardware to send a verify mPacket. Reset by hardware after sending the Verify mPacket. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
31 EFPE	Enable Tx Frame Preemption When set Frame Preemption Tx functionality is enabled.

50.2.2.46 MAC_Ext_Cfg1 register (MAC_EXT_CFG1)

This register contains Split mode control field and offset field for Split Header feature.

Offset 0x0238 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1063. MAC_Ext_Cfg1 register (MAC_EXT_CFG1)

Table 1155. MAC_EXT_CFG1 field descriptions

Field	Description
22:23 SPLM	Split Mode These bits indicate the mode of splitting the incoming Rx packets. They are: 00 Split at L3/L4 header 01 Split at L2 header with an offset. Always Split at SPLOFST bytes from the beginning of Length/Type field of the Frame 10 Combination mode: split similar to SPLM=00 for IP packets that are untagged or tagged and VLAN stripped 11 Reserved
25:31 SPLOFST	Split Offset These bits indicate the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.

50.2.2.47 MAC Presentation Time in Nanoseconds register (MAC_PRESN_TIME_NS)

This register contains the 32-bit binary rollover equivalent time of the PTP System Time in ns.

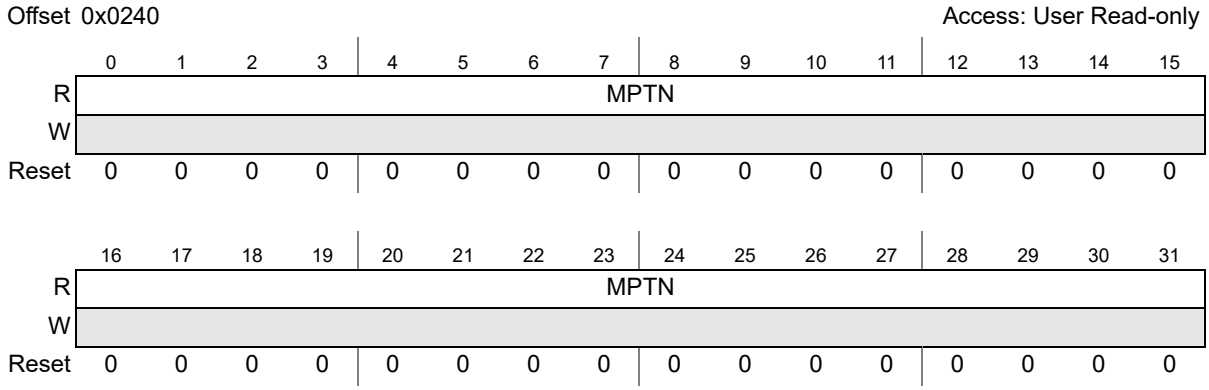

Figure 1064. MAC Presentation time in nanoseconds register (MAC_PRESN_TIME_NS)

Table 1156. MAC_PRESN_TIME_NS field descriptions

Field	Description
0:31 MPTN	MAC 1722 Presentation Time in ns These bits indicate the value of the 32-bit binary rollover equivalent time of the PTP System Time in ns.

50.2.2.48 MAC Presentation Time Update register (MAC_PRESN_TIME_UPDT)

This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSUPDT are defined in *Section 50.2.2.153: Timestamp control register (MAC_TIMESTAMP_CONTROL)*).

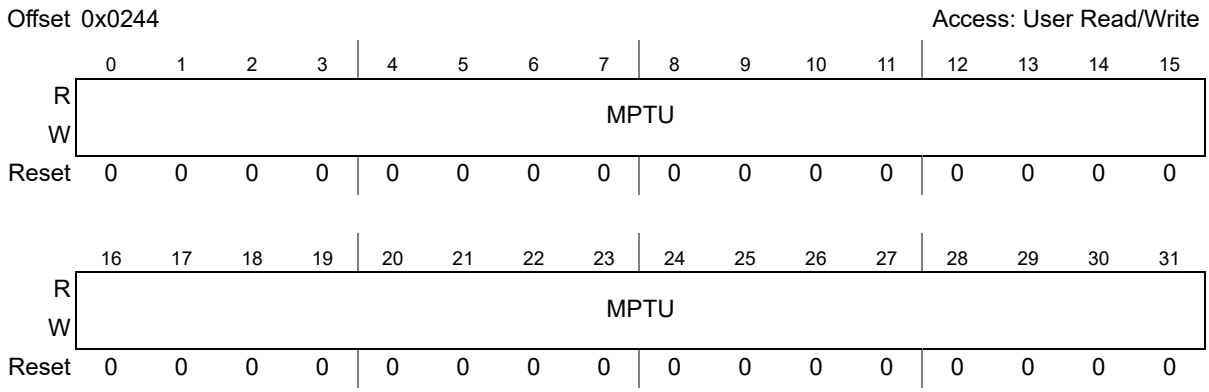

Figure 1065. MAC Presentation time update register (MAC_PRESN_TIME_UPDT)

Table 1157. MAC_PRESN_TIME_UPDT field descriptions

Field	Description
0:31 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSUPDT defined in *Section 50.2.2.153: Timestamp control register (MAC_TIMESTAMP_CONTROL)*). When ADDSUB field of MAC_System_Time_Nanoseconds_Update is set, this value is directly used for subtraction.

50.2.2.49 MAC address 0 high register (MAC_ADDRESS0_HIGH)

The MAC Address 0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [24:31]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MAC Address 0 Register [0:47] is compared with 0x665544332211.

Clock domain synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Offset 0x0300 Access: User Read/Write

Figure 1066. MAC address 0 high register (MAC_ADDRESS0_HIGH)

Table 1158. MAC_ADDRESS0_HIGH field descriptions

Field	Description
0 AE	Address Enable This bit is always set to 1.
13:15 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: this field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. If the PDC bit of MAC_Ext_Configuration register is set: this field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address0 content is routed.
16:31 ADDRHI	MAC Address0[0:15] This field contains the upper 16 bits [0:15] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

50.2.2.50 MAC address 0 low register (MAC_ADDRESS0_LOW)

The MAC address 0 low register holds the lower 32 bits of the 6-byte first MAC address of the station.

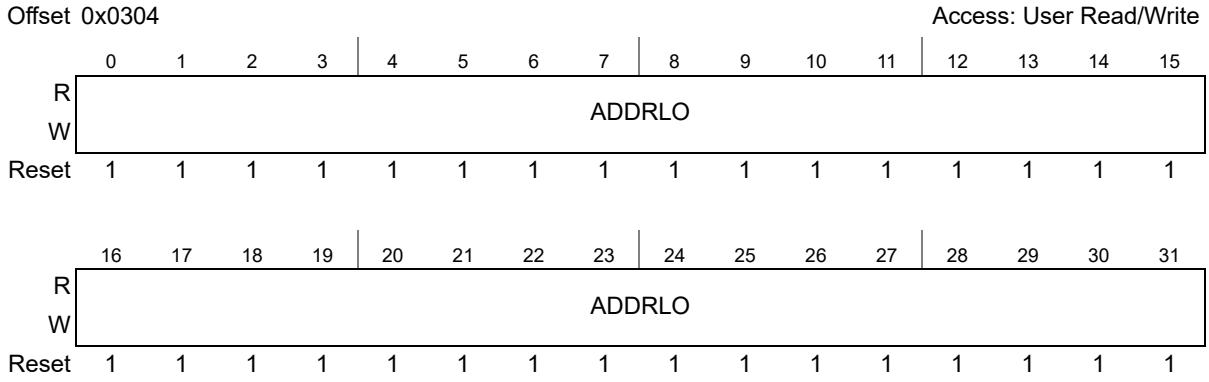

Figure 1067. MAC address 0 low register (MAC_ADDRESS0_LOW)

Table 1159. MAC_ADDRESS0_LOW field descriptions

Field	Description
0:31 ADDRLO	MAC address 0 [16:47] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

50.2.2.51 MAC address *n* High register (MAC_ADDRESS*n*_HIGH)

The MAC address *n* high register holds the upper 16 bits of the second 6-byte MAC address of the station.

Clock domain synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper

synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Figure 1068. MAC address *n* high register (MAC_ADDRESS*n*_HIGH)

Table 1160. MAC_ADDRESS*n*_HIGH field descriptions

Field	Description
0 AE	Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.
1 SA	Source Address When this bit is set, the MAC Address1[0:47] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[0:47] is used to compare with the DA fields of the received packet.
2:7 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: Bit 2: Register 194 [16:23] Bit 3: Register 194 [24:31] Bit 4: Register 195 [0:7] … Bit 7: Register 195 [24:31] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
13:15 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: this field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address *n* content is routed. If the PDC bit of MAC_Ext_Configuration register is set: this field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address *n* content is routed.
16:31 ADDRHI	MAC Address *n* [0:15] This field contains the upper 16 bits [0:15] of the second 6-byte MAC address.

50.2.2.52 MAC address *n* low register (MAC_ADDRESS*n*_LOW)

The MAC address *n* low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Offset 0x0304 + *n**0x8 (*n*=1 to 31) Access: User Read/Write

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1070. MMC control register (MMC_CONTROL)

Table 1162. MMC_CONTROL field descriptions

Field	Description
23 UCDBC	Update MMC Counters for Dropped Broadcast Packets When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets.
26 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16).
27 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.
28 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.
29 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[0:7]) is read.
30 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value.
31 CNTRST	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set.

50.2.2.54 MMC receive interrupt register (MMC_RX_INTERRUPT)

The MMC receive interrupt register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values, that is 0x8000_0000.
- Receive statistic counters cross their maximum values, that is 0xFFFF_FFFF.
- When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Field	Description
4 RXLPITRCIS	MMC Receive LPI Transition Counter Interrupt Status This bit is set when the RX_LPI_TRAN_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5 RXLPIUSCIS	MMC Receive LPI Microsecond Counter Interrupt Status This bit is set when the RX_LPI_USEC_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
6 RXCTRLPIS	MMC Receive Control Packet Counter Interrupt Status This bit is set when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
7 RXRCVERRPIS	MMC Receive Error Packet Counter Interrupt Status This bit is set when the rxrcverror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
8 RXWDOGPIS	MMC Receive Watchdog Error Packet Counter Interrupt Status This bit is set when the rxwatchdog error counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
9 RXVLANGBPIS	MMC Receive VLAN Good Bad Packet Counter Interrupt Status This bit is set when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
10 RXFOVPIS	MMC Receive FIFO Overflow Packet Counter Interrupt Status This bit is set when the rxfifooverflow counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
11 RXPAUSPIS	MMC Receive Pause Packet Counter Interrupt Status This bit is set when the rxpausepackets counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
12 RXORANGEPIS	MMC Receive Out Of Range Error Packet Counter Interrupt Status This bit is set when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1163. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
13 RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
14 RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15 RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
16 RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
17 RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
18 RX128T255OCTGBPIS	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
19 RX65T127OCTGBPIS	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 RX64OCTGBPIS	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1163. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
21 RXOSIZEGPIS	MMC Receive Oversize Good Packet Counter Interrupt Status This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
22 RXUSIZEGPIS	MMC Receive Undersize Good Packet Counter Interrupt Status This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
23 RXJABERPIS	MMC Receive Jabber Error Packet Counter Interrupt Status This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
24 RXRUNTPIS	MMC Receive Runt Packet Counter Interrupt Status This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
25 RXALGNERPIS	MMC Receive Alignment Error Packet Counter Interrupt Status This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 RXCRCERPIS	MMC Receive CRC Error Packet Counter Interrupt Status This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
27 RXMCGPIS	MMC Receive Multicast Good Packet Counter Interrupt Status This bit is set when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
28 RXBCGPIS	MMC Receive Broadcast Good Packet Counter Interrupt Status This bit is set when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 RXGOCTIS	MMC Receive Good Octet Counter Interrupt Status This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1163. MMC_RX_INTERRUPT field descriptions (continued)

Field	Description
30 RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.55 MMC Tx interrupt register (MMC_TX_INTERRUPT)

The MMC transmit interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values, that is 0x8000_0000, and when they cross their maximum values, that is 0xFFFF_FFFF. When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC transmit interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[0:7]) of the respective counter must be read in order to clear the interrupt bit.

Table 1164. MMC_TX_INTERRUPT field descriptions

Field	Description
4 TXLPITRCIS	MMC Transmit LPI Transition Counter Interrupt Status This bit is set when the TX_LPI_TRAN_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5 TXLPIUSCIS	MMC Transmit LPI Microsecond Counter Interrupt Status This bit is set when the TX_LPI_USEC_CNTR counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
6 TXOSIZEGPIS	MMC Transmit Oversize Good Packet Counter Interrupt Status This bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
7 TXVLANGPIS	MMC Transmit VLAN Good Packet Counter Interrupt Status This bit is set when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
8 TXPAUSPIS	MMC Transmit Pause Packet Counter Interrupt Status This bit is set when the txpausepacketserror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
10 TXGPKTIS	MMC Transmit Good Packet Counter Interrupt Status This bit is set when the txpacketcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
11 TXGOCTIS	MMC Transmit Good Octet Counter Interrupt Status This bit is set when the txoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
18 TXUFLOWERPIS	MMC Transmit Underflow Error Packet Counter Interrupt Status This bit is set when the txunderflowerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
19 TXBCGBPIS	MMC Transmit Broadcast Good Bad Packet Counter Interrupt Status This bit is set when the txbroadcastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1164. MMC_TX_INTERRUPT field descriptions (continued)

Field	Description
20 TXMCGBPIS	MMC Transmit Multicast Good Bad Packet Counter Interrupt Status The bit is set when the txmulticastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21 TXUCGBPIS	MMC Transmit Unicast Good Bad Packet Counter Interrupt Status This bit is set when the txunicastpackets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
22 TX1024TMAXOCTGBPIS	MMC Transmit 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
23 TX512T1023OCTGBPIS	MMC Transmit 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
24 TX256T511OCTGBPIS	MMC Transmit 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
25 TX128T255OCTGBPIS	MMC Transmit 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
26 TX65T127OCTGBPIS	MMC Transmit 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
27 TX64OCTGBPIS	MMC Transmit 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the tx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

Table 1164. MMC_TX_INTERRUPT field descriptions (continued)

Field	Description
28 TXMCGPIS	MMC Transmit Multicast Good Packet Counter Interrupt Status This bit is set when the txmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
29 TXBCGPIS	MMC Transmit Broadcast Good Packet Counter Interrupt Status This bit is set when the txbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
30 TXGBPKTIS	MMC Transmit Good Bad Packet Counter Interrupt Status This bit is set when the txpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.
31 TXGBOCTIS	MMC Transmit Good Bad Octet Counter Interrupt Status This bit is set when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.56 MMC Rx interrupt mask register (MMC_RX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Receive statistics counters.

Table 1165. MMC_RX_INTERRUPT_MASK field descriptions

Field	Description
4 RXLPITRCIM	MMC Receive LPI Transition Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_TRAN_CNTR reaches half the maximum value or the maximum value.
5 RXLPIUSCIM	MMC Receive LPI Microsecond Counter Interrupt Mask Setting this bit masks the interrupt when RX_LPI_USEC_CNTR reaches half the maximum value or the maximum value.
6 RXCTRLPIM	MMC Receive Control Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxctrlpackets_g counter reaches half of the maximum value or the maximum value.
7 RXRCVERRPIM	MMC Receive Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrcverror counter reaches half of the maximum value or the maximum value.
8 RXWDOGPIM	MMC Receive Watchdog Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value.
9 RXVLANGBPIM	MMC Receive VLAN Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxvlanpackets_gb counter reaches half of the maximum value or the maximum value.

Table 1165. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
10 RXFOVPIM	MMC Receive FIFO Overflow Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxfifooverflow counter reaches half of the maximum value or the maximum value.
11 RXPAUSPIM	MMC Receive Pause Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpausepackets counter reaches half of the maximum value or the maximum value.
12 RXORANGEPIM	MMC Receive Out Of Range Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value.
13 RXLENERPIM	MMC Receive Length Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value.
14 RXUCGPIM	MMC Receive Unicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.
15 RX1024TMAXOCTGBPIM	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.
16 RX512T1023OCTGBPIM	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value.
17 RX256T511OCTGBPIM	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value.
18 RX128T255OCTGBPIM	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value.
19 RX65T127OCTGBPIM	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value.
20 RX64OCTGBPIM	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value.
21 RXOSIZEGPIM	MMC Receive Oversize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value.
22 RXUSIZEGPIM	MMC Receive Undersize Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value.

Table 1165. MMC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
23 RXJABERPIM	MMC Receive Jabber Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value.
24 RXRUNTPIM	MMC Receive Runt Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value.
25 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value.
26 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value.
27 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value.
28 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value.
29 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value.
30 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value.
31 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value.

Table 1170. TX_MULTICAST_PACKETS_GOOD field descriptions

Field	Description
0:31 TXMCASTG	This field indicates the number of good multicast packets transmitted.

50.2.2.62 Transmit 64 octets packets good bad register (TX_64OCTETS_PACKETS_GOOD_BAD)

This register provides the number of good and bad packets transmitted by the Ethernet module with length 64 bytes, exclusive of preamble and retried packets.

Offset 0x0724 Access: User Read-only

Table 1195. RX_UNDERSIZE_PACKETS_GOOD field descriptions

Field	Description
0:31 RXUNDERSZG	Rx Undersize Packets Good This field indicates the number of packets received with length less than 64 bytes, without any errors.

50.2.2.87 Receive oversize packets good register (RX_OVERSIZE_PACKETS_GOOD)

This register provides the number of packets received by the Ethernet module without errors, with length greater than the maxsize (1518 bytes or 1522 bytes for VLAN tagged packets; 2000 bytes if enabled in the S2KP bit of the MAC_Configuration register).

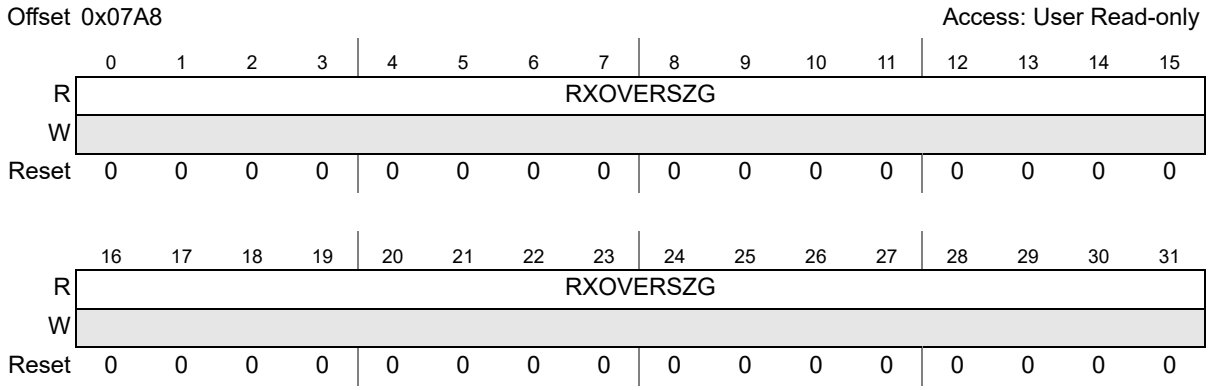

Figure 1104. Receive oversize packets good register (RX_OVERSIZE_PACKETS_GOOD)

50.2.2.107 MMC IPC receive interrupt mask register (MMC_IPC_RX_INTERRUPT_MASK)

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Offload Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Offload) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32-bit wide.

18 RXICMPERPIM	MMC Receive ICMP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_err_pkts counter reaches half of the maximum value or the maximum value.
19 RXICMPGPIM	MMC Receive ICMP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxicmp_gd_pkts counter reaches half of the maximum value or the maximum value.
20 RXTCPERPIM	MMC Receive TCP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_err_pkts counter reaches half of the maximum value or the maximum value.
21 RXTCPGPIM	MMC Receive TCP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxtcp_gd_pkts counter reaches half of the maximum value or the maximum value.
22 RXUDPERPIM	MMC Receive UDP Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_err_pkts counter reaches half of the maximum value or the maximum value.
23 RXUDPGPIM	MMC Receive UDP Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxudp_gd_pkts counter reaches half of the maximum value or the maximum value.
24 RXIPV6NOPAYPIM	MMC Receive IPV6 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_nopay_pkts counter reaches half of the maximum value or the maximum value.

Table 1216. MMC_IPC_RX_INTERRUPT_MASK field descriptions (continued)

Field	Description
25 RXIPV6HERPIM	MMC Receive IPV6 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
26 RXIPV6GPIM	MMC Receive IPV6 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv6_gd_pkts counter reaches half of the maximum value or the maximum value.
27 RXIPV4UDSBLPIM	MMC Receive IPV4 UDP Checksum Disabled Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_udsbl_pkts counter reaches half of the maximum value or the maximum value.
28 RXIPV4FRAGPIM	MMC Receive IPV4 Fragmented Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_frag_pkts counter reaches half of the maximum value or the maximum value.
29 RXIPV4NOPAYPIM	MMC Receive IPV4 No Payload Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_nopay_pkts counter reaches half of the maximum value or the maximum value.
30 RXIPV4HERPIM	MMC Receive IPV4 Header Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_hdrerr_pkts counter reaches half of the maximum value or the maximum value.
31 RXIPV4GPIM	MMC Receive IPV4 Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxipv4_gd_pkts counter reaches half of the maximum value or the maximum value.

50.2.2.108 MMC IPC receive interrupt register (MMC_IPC_RX_INTERRUPT)

This register maintains the interrupt that the receive IPC statistic counters generate.

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

Table 1233. RXIPV4_HEADER_ERROR_OCTETS field descriptions

Field	Description
0:31 RXIPV4HDRERROCT	This field indicates the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.125 Receive IPv4 no payload octets register (RXIPV4_NO_PAYLOAD_OCTETS)

This register provides the number of bytes received by the Ethernet module in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

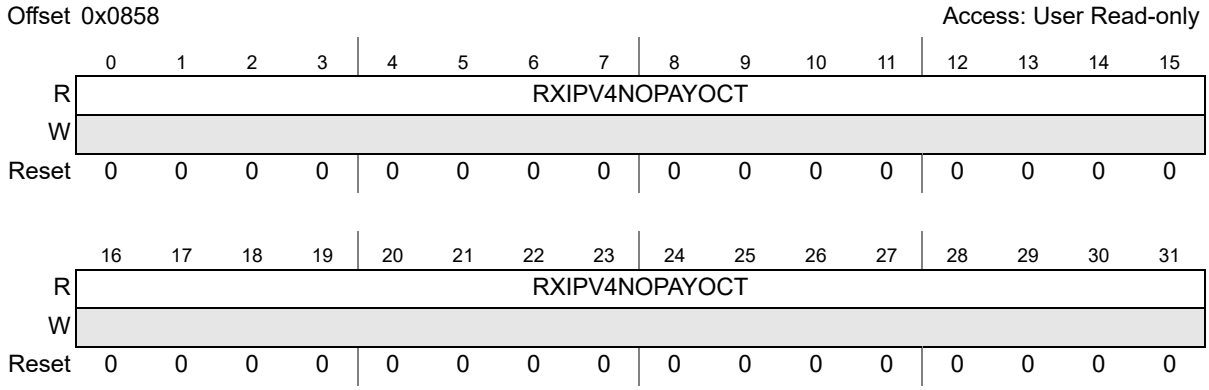

Figure 1142. Receive IPv4 no payload octets register (RXIPV4_NO_PAYLOAD_OCTETS)

Table 1234. RXIPV4_NO_PAYLOAD_OCTETS field descriptions

Field	Description
0:31 RXIPV4NOPAYOCT	This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.126 Receive IPv4 fragmented octets register (RXIPV4_FRAGMENTED_OCTETS)

This register provides the number of bytes received by the Ethernet module in fragmented IPv4 datagrams. The value in the length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

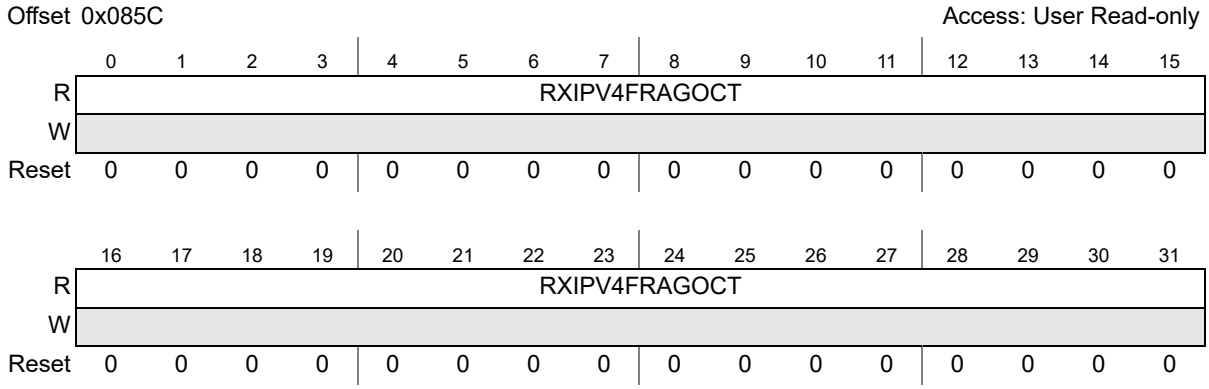

Figure 1143. Receive IPv4 fragmented octets register (RXIPV4_FRAGMENTED_OCTETS)

Table 1235. RXIPV4_FRAGMENTED_OCTETS field descriptions

Field	Description
0:31 RXIPV4FRAGOCT	This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.127 Receive IPv4 UDP checksum disable octets register (RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS)

This register provides the number of bytes received by the Ethernet module in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

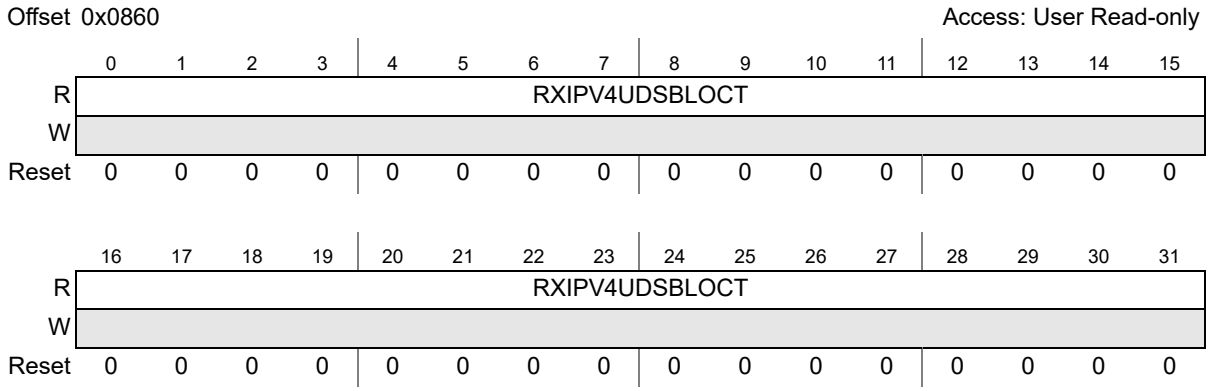

Figure 1144. Receive IPv4 UDP checksum disable octets register (RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS)

Table 1236. RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS field descriptions

Field	Description
0:31 RXIPV4UDSBLOCT	This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.128 Receive IPv6 good octets register (RXIPV6_GOOD_OCTETS)

This register provides the number of bytes received by the Ethernet module in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

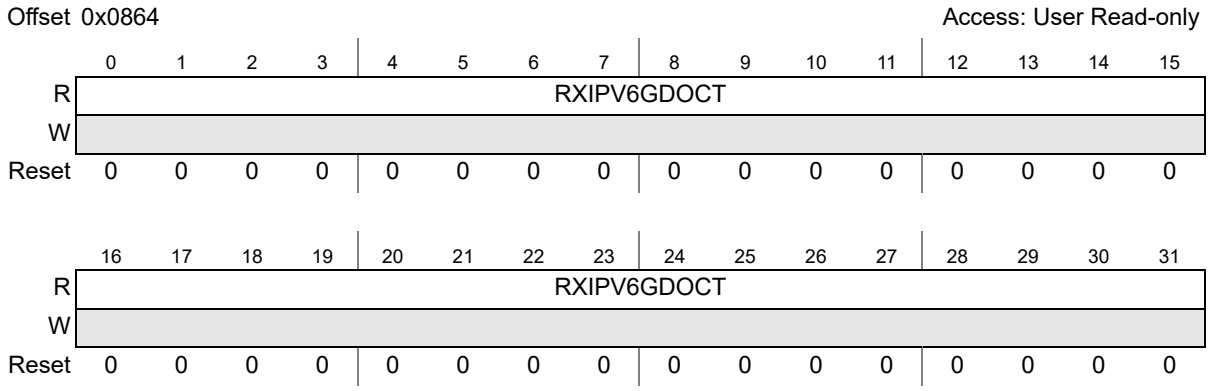

Figure 1145. Receive IPv6 good octets register (RXIPV6_GOOD_OCTETS)

Table 1237. RXIPV6_GOOD_OCTETS field descriptions

Field	Description
0:31 RXIPV6GDOCT	This field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.129 Receive header error octets register (RXIPV6_HEADER_ERROR_OCTETS)

This register provides the number of bytes received by the Ethernet module in IPv6 datagrams with header errors (length, version mismatch). The value in the Length field of IPv6 header is used to update this counter. Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

50.2.2.137 MMC FPE Tx interrupt register (MMC_FPE_TX_INTERRUPT)

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Offset 0x08A0 Access: User Read-only

Figure 1164. Layer 3 and Layer 4 control 0 register (MAC_L3_L4_CONTROL0)

Table 1256. MAC_L3_L4_CONTROL0 field descriptions

Field	Description
3 DMCHEN0	DMA Channel Select Enable When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When this bit is reset, the DMA channel is not decided by this filter.
6:7 DMCHN0	DMA Channel Number When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. 0 Packet is passed by this filter to DMA CH 0 1 Packet is passed by this filter to DMA CH 1 2 Packet is passed by this filter to DMA CH 2
10 L4DPIM0	Layer 4 Destination Port Inverse Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high.
11 L4DPM0	Layer 4 Destination Port Match Enable When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
12 L4SPIM0	Layer 4 Source Port Inverse Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high.

Table 1256. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
13 L4SPM0	Layer 4 Source Port Match Enable When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
15 L4PEN0	Layer 4 Protocol Enable When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.
16:20 L3HDBM0	Layer 3 IP DA Higher Bits Match **IPv4 Packets:** This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: 0x00: No bits are masked. 0x01: 1 LSb is masked 0x02: Two LSbs are masked ... 0x1F: All bits except MSb are masked. **IPv6 Packets:** Bits[29:30] of this field correspond to Bits[25:26] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[30:31] and L3HSBM0 bits: - 0x00: No bits are masked. - 0x01: 1 LSb is masked. - 0x02:Two LSbs are masked - ... - 0x7F: All bits except MSb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
21:25 L3HSBM0	Layer 3 IP SA Higher Bits Match **IPv4 Packets:** This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: 0x00: No bits are masked. 0x01: 1 LSb is masked 0x02: Two LSbs are masked ... 0x1F: All bits except MSb are masked. **IPv6 Packets:** This field contains Bits[27:31] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
26 L3DAIM0	Layer 3 IP DA Inverse Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.

Table 1256. MAC_L3_L4_CONTROL0 field descriptions (continued)

Field	Description
27 L3DAM0	Layer 3 IP DA Match Enable When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.
28 L3SAIM0	Layer 3 IP SA Inverse Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
29 L3SAM0	Layer 3 IP SA Match Enable When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. **Note:** When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
31 L3PEN0	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

50.2.2.148 Layer 4 address 0 register (MAC_LAYER4_ADDRESS0)

This register holds the TCP source and destination port numbers against which a match is performed.

Clock domain crossing synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Figure 1165. Layer4 address 0 register (MAC_LAYER4_ADDRESS0)

Table 1257. MAC_LAYER4_ADDRESS0 field descriptions

Field	Description
0:15 L4DP0	Layer 4 Destination Port Number Field When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
16:31 L4SP0	Layer 4 Source Port Number Field When the L4PEN0 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4SPM0 bits are set in MAC_L3_L4_Control0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

50.2.2.149 Layer 3 address 0 register 0 register (MAC_LAYER3_ADDR0_REG0)

For IPv4 packets, the Layer 3 address 0 register 0 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[96:127] of the 128-bit IP Source Address or Destination Address field.

Offset 0x0910 Access: User Read/Write

Table 1258. MAC_LAYER3_ADDR0_REG0 field descriptions

Field	Description
0:31 L3A00	Layer 3 Address 0 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[96:127] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Source Address field in the IPv4 packets.

50.2.2.150 Layer3 address1 register 0 register (MAC_LAYER3_ADDR1_REG0)

For IPv4 packets, the Layer 3 address 1 register 0 register contains the 32-bit IP Destination Address field. For IPv6 packets, it contains Bits[64:95] of the 128-bit IP Source Address or Destination Address field.

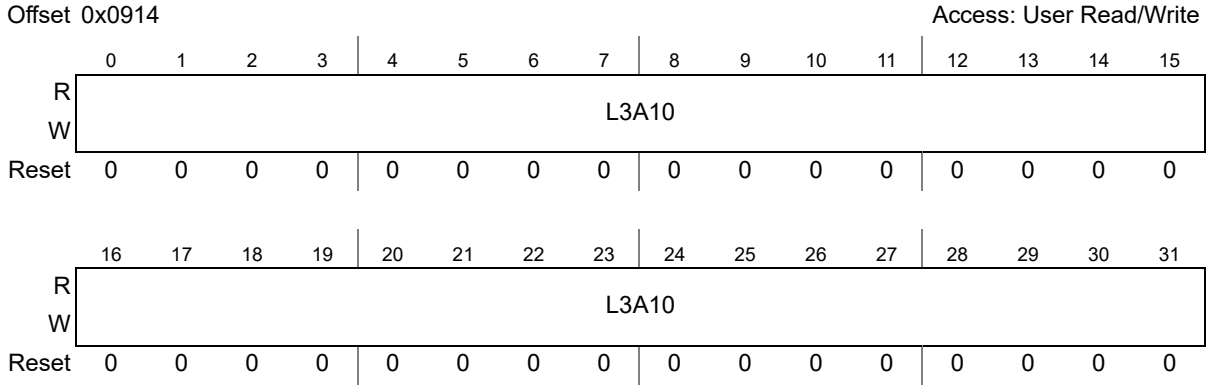

Figure 1167. Layer3 address1 register 0 register (MAC_LAYER3_ADDR1_REG0)

Table 1259. MAC_LAYER3_ADDR1_REG0 field descriptions

Field	Description
0:31 L3A10	Layer 3 Address 1 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[64:95] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[64:95] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset and the L3SAM0 bit is set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with the IP Destination Address field in the IPv4 packets.

50.2.2.151 Layer3 address2 register 0 register (MAC_LAYER3_ADDR2_REG0)

The Layer 3 address 2 register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[32:63] of 128-bit IP Source Address or Destination Address field.

Offset 0x0918 Access: User Read/Write

Figure 1168. Layer3 address2 register 0 register (MAC_LAYER3_ADDR2_REG0)

Table 1260. MAC_LAYER3_ADDR2_REG0 field descriptions

Field	Description
0:31 L3A20	Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[32:63] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

50.2.2.152 Layer3 address3 register 0 register (MAC_LAYER3_ADDR3_REG0)

The Layer 3 address 3 register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[0:31] of 128-bit IP Source Address or Destination Address field.

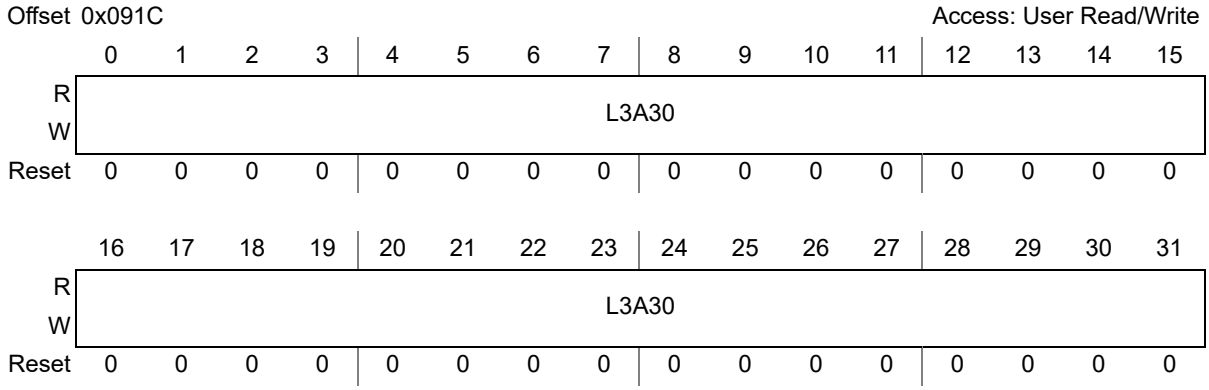

Figure 1169. Layer3 Address3 Register 0 register (MAC_LAYER3_ADDR3_REG0)

Table 1261. MAC_LAYER3_ADDR3_REG0 field descriptions

Field	Description
0:31 L3A30	Layer 3 Address 3 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_Control0 register, this field contains the value to be matched with Bits[0:31] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_Control0 register, this field is not used.

50.2.2.153 Timestamp control register (MAC_TIMESTAMP_CONTROL)

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Offset 0x0B00 Access: User Read/Write

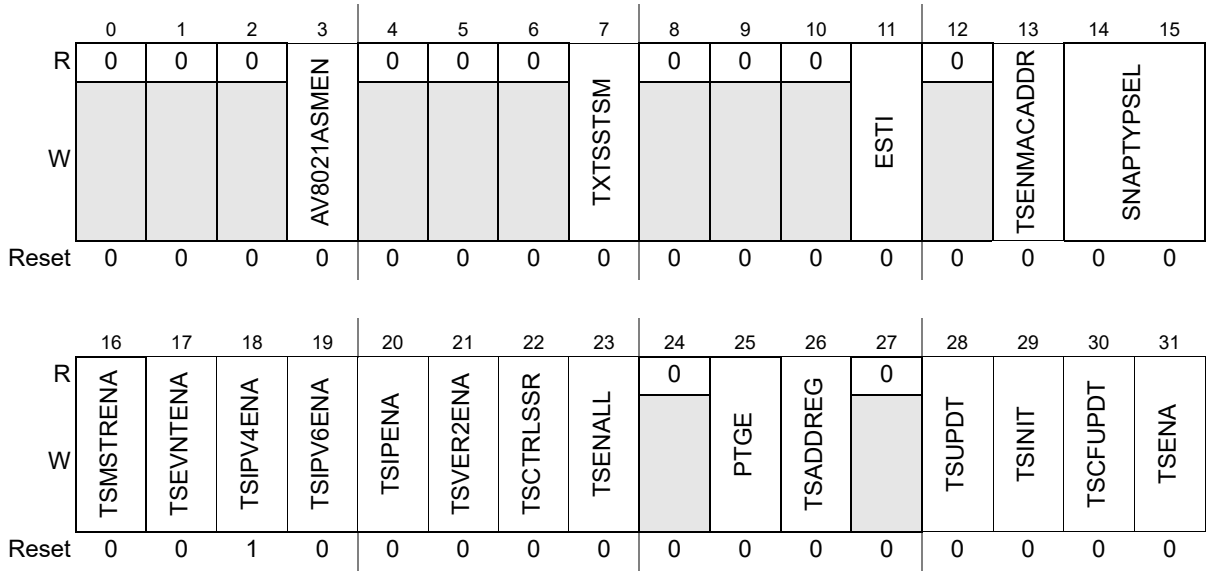

Figure 1170. Timestamp control register (MAC_TIMESTAMP_CONTROL)

Table 1262. MAC_TIMESTAMP_CONTROL field descriptions

Field	Description
3 AV8021ASMEN	AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation.
7 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the MAC_TxTimestamp_Status_Seconds register.
11 ESTI	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: – to take the timestamp provided as status – to insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled When this bit is reset, the MAC uses the internal reference System Time.

Table 1262. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
13 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. MAC address registers 0 to 31 is considered for unicast destination address matching.
14:15 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 16 and 17, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
16 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.
17 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, refer to Timestamp Snapshot Dependency on Register Bits Table.
18 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.
19 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.
20 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
21 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'.
22 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Table 1262. MAC_TIMESTAMP_CONTROL field descriptions (continued)

Field	Description
23 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.
25 PTGE	Presentation Time Generation Enable When this bit is set the Presentation Time generation will be enabled.
26 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
28 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
29 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
30 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.
31 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set.

50.2.2.154 Sub second increment register (MAC_SUB_SECOND_INCREMENT)

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref clock.

Offset 0x0B04 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1171. Sub second increment register (MAC_SUB_SECOND_INCREMENT)

Table 1263. MAC_SUB_SECOND_INCREMENT field descriptions

Field	Description
8:15 SSINC	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 22 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

50.2.2.155 System time seconds register (MAC_SYSTEM_TIME_SECONDS)

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Figure 1173. System time nanoseconds register (MAC_SYSTEM_TIME_NANOSECONDS)

Table 1265. MAC_SYSTEM_TIME_NANOSECONDS field descriptions

Field	Description
1:31 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 22 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

50.2.2.157 System time seconds update register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in MAC_Timestamp_Control.

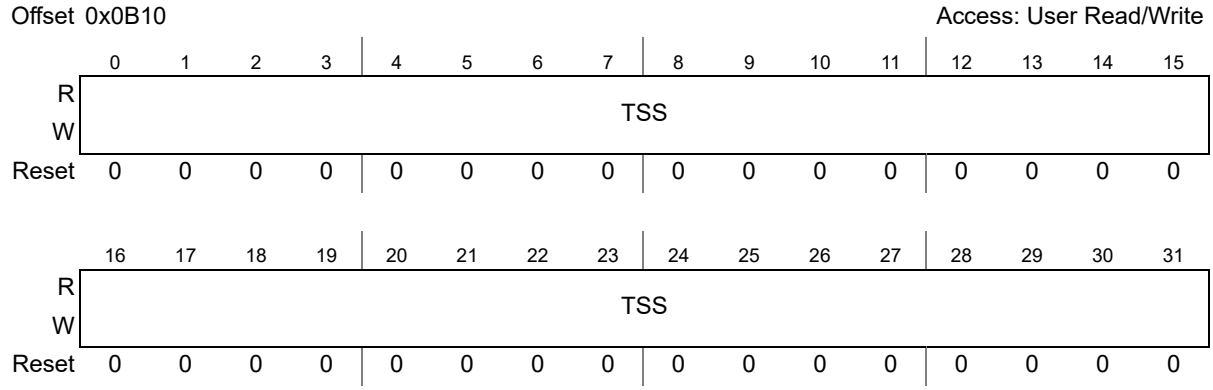

Figure 1174. System time seconds update register (MAC_SYSTEM_TIME_SECONDS_UPDATE)

Table 1266. MAC_SYSTEM_TIME_SECONDS_UPDATE field descriptions

Field	Description
0:31 TSS	Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, then this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSS field in the MAC_Timestamp Seconds update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

50.2.2.158 System time nanoseconds update register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

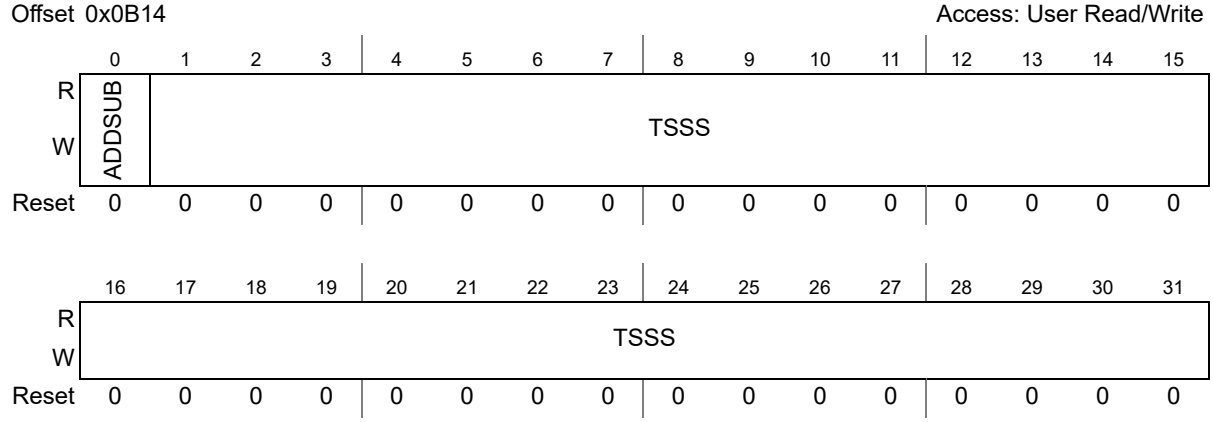

Figure 1175. System time nanoseconds update register (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

Table 1267. MAC_SYSTEM_TIME_NANOSECONDS_UPDATE field descriptions

Field	Description
0 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.
1:31 TSSS	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_Timestamp_Control is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_Timestamp_Control is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

50.2.2.159 Timestamp addend register (MAC_TIMESTAMP_ADDEND)

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Figure 1178. Timestamp status register (MAC_TIMESTAMP_STATUS)

Table 1270. MAC_TIMESTAMP_STATUS field descriptions

Field	Description
2:6 ATSNS	Number of Auxiliary Timestamp Snapshots This field indicates the number of Snapshots available in the FIFO. value equal to 4 indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.
7 ATSSTM	Auxiliary Timestamp Snapshot Trigger Missed This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO.
14:15 ATSSTN	Auxiliary Timestamp Snapshot Trigger Identifier These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. Bit 15: Auxiliary trigger 0 Bit 14: Auxiliary trigger 1 The software can read this register to find the triggers that are set when the timestamp is taken. Access restriction applies. Clears on read. Self-set to 1 on internal event.
16 TXTSSIS	Tx Timestamp Status Interrupt Status When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set).

Table 1270. MAC_TIMESTAMP_STATUS field descriptions (continued)

Field	Description
28 TSTRGTERR0	Timestamp Target Time Error This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
29 AUXTSTRIG	Auxiliary Timestamp Trigger Snapshot This bit is set high when the auxiliary snapshot is written to the FIFO. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
30 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
31 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

50.2.2.162 Transmit timestamp status nanoseconds register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

This register contains the nanosecond part of timestamp captured for Transmit when Tx status is disabled.

The MAC_TxTimestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TxTimestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits [31:24] are read; in big-endian mode, bits [7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [16] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

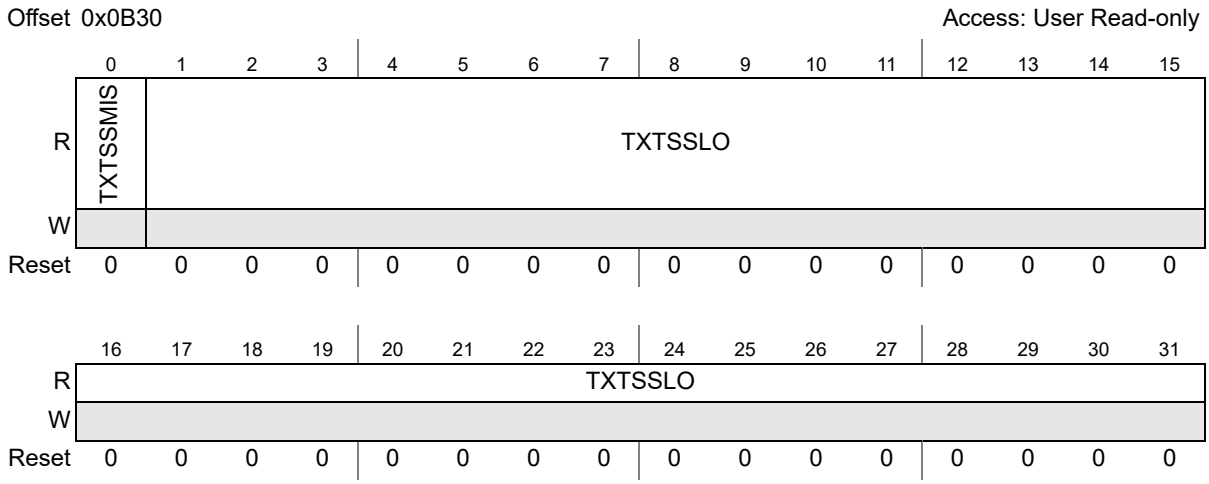

Figure 1179. Transmit timestamp status nanoseconds register (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

Table 1271. MAC_TX_TIMESTAMP_STATUS_NANOSECONDS field descriptions

Field	Description
0 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event.
1:31 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

50.2.2.163 Transmit timestamp status seconds register (MAC_TX_TIMESTAMP_STATUS_SECONDS)

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Figure 1181. Auxiliary control register (MAC_AUXILIARY_CONTROL)

Table 1273. MAC_AUXILIARY_CONTROL field descriptions

Field	Description
26 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored.
27 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored.
31 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.165 Auxiliary timestamp nanoseconds register (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4.

You can store multiple snapshots in this FIFO. Bits[2:6] in MAC_Timestamp_Status indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

Figure 1184. Timestamp ingress asymmetry correction register (MAC_TIMESTAMP_INGRESS_ASYM_CORR)

Table 1276. MAC_TIMESTAMP_INGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTIAC	One-Step Timestamp Ingress Asymmetry Correction This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 0 representing the sign bit.

50.2.2.168 Timestamp egress asymmetry correction register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

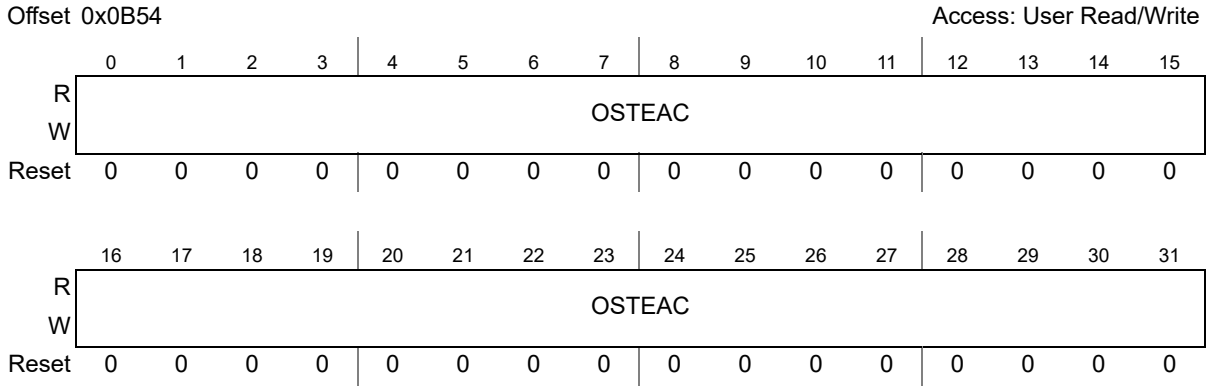

Figure 1185. Timestamp egress asymmetry correction register (MAC_TIMESTAMP_EGRESS_ASYM_CORR)

Table 1277. MAC_TIMESTAMP_EGRESS_ASYM_CORR field descriptions

Field	Description
0:31 OSTEAC	One-Step Timestamp Egress Asymmetry Correction This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000 (2.5 × 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 × 216).

50.2.2.169 Timestamp ingress correction nanosecond register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

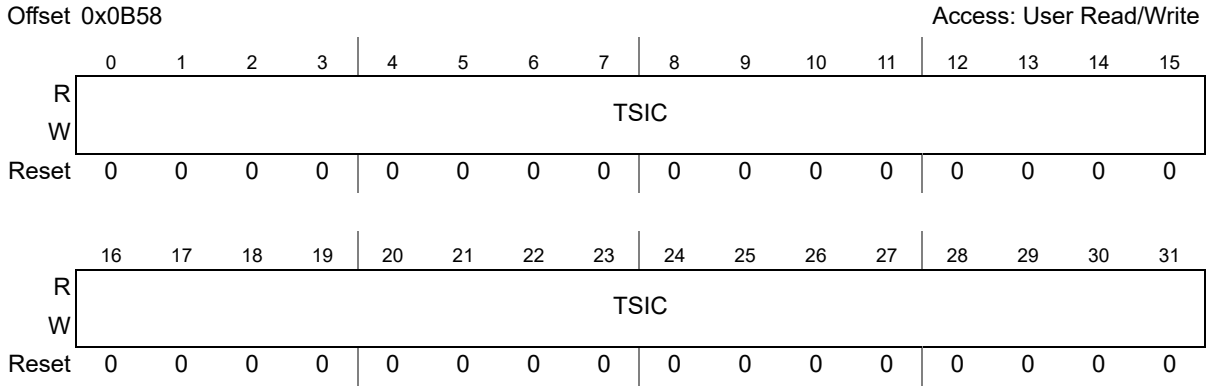

Figure 1186. Timestamp ingress correction nanosecond register (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

Table 1278. MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND field descriptions

Field	Description
0:31 TSIC	Timestamp Ingress Correction This field contains the ingress path correction value as defined by the Ingress Correction expression.

50.2.2.170 Timestamp egress correction nanosecond register (MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND)

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

Figure 1190. MAC PPS control register (MAC_PPS_CONTROL)

Table 1282. MAC_PPS_CONTROL field descriptions

Field	Description
24 MCGREN0	MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0 0^{th} PPS instance is enabled to operate in PPS mode 1 0^{th} PPS instance is enabled to operate in MCGR mode
25:26 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS0 output signal: 00 Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01 Reserved 10 Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11 Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.

Table 1282. MAC_PPS_CONTROL field descriptions (continued)

Field	Description
27 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[28:31] function as PPSCMD. When this bit is reset, Bits[28:31] function as PPSCTRL (Fixed PPS mode).
28:31 PPSCTRL_ PPSCMD	**PPS Output Frequency Control** This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 0001 The binary rollover is 2 Hz, and the digital rollover is 1 Hz 0010 The binary rollover is 4 Hz, and the digital rollover is 2 Hz 0011 The binary rollover is 8 Hz, and the digital rollover is 4 Hz 0100 The binary rollover is 16 Hz, and the digital rollover is 8 Hz ... 1111 The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz **Note:** In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second.(1) or **Flexible PPS Output (ptp_pps_o[0]) Control** Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: 0000 No Command 0001 START Single Pulse. This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. 0010 START Pulse Train. This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. 0011 Cancel START. This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. 0100 STOP Pulse train at time. This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. 0101 STOP Pulse Train immediately. This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). 0110 Cancel STOP Pulse train. This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. 0111–1111 Reserved Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

1. For example:
   When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
   When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and 537 ms period. Second clock of 463 ms period (268 ms low and 195 ms high)
   When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and 268 ms period. Fourth clock of 195 ms period (134 ms low and 61 ms high)
   This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

50.2.2.174 MAC PPS0 target time seconds register (MAC_PPS0_TARGET_TIME_SECONDS)

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 30 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Figure 1192. MAC PPS0 target time nanoseconds register (MAC_PPS0_TARGET_TIME_NANOSECONDS)

Table 1284. MAC_PPS0_TARGET_TIME_NANOSECONDS field descriptions

Field	Description
0 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.
1:31 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [25:26]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.176 MAC PPS0 interval register (MAC_PPS0_INTERVAL)

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B88 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	PPSINT0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	PPSINT0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1193. MAC PPS0 interval register (MAC_PPS0_INTERVAL)

Table 1285. MAC_PPS0_INTERVAL field descriptions

Field	Description
0:31 PPSINT0	PPS Output Signal Interval These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

50.2.2.177 MAC PPS0 width register (MAC_PPS0_WIDTH)

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Offset 0x0B8C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	PPSWIDTH0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1194. MAC PPS0 width register (MAC_PPS0_WIDTH)

Table 1286. MAC_PPS0_WIDTH field descriptions

Field	Description
0:31 PPSWIDTH0	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. **Note:** The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

50.2.2.178 MTL operation mode register (MTL_OPERATION_MODE)

The Operation mode register establishes the Transmit and Receive operating modes and commands.

Offset 0x0C00 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1195. MTL operation mode register (MTL_OPERATION_MODE)

Table 1287. MTL_OPERATION_MODE field descriptions

Field	Description
16 FRPE	Flexible Rx parser Enable When this bit is set to 1, the Programmable Rx Parser functionality is enabled. When the Rx parser is disabled and if the Rx parser is in the middle of the parsing then it gets disabled only after completing the current packet parsing. When the Rx parser is enabled from disabled state then the Rx parser gets activated for the next immediate packet. 0 Flexible Rx parser is disabled 1 Flexible Rx parser is enabled
22 CNTCLR	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 Counters are not reset 1 All counters are reset
23 CNTPRST	Counters Preset When this bit is set: – MTL_TxQ[0-7]_Underflow register is initialized/preset to 12'h7F0. – Missed Packet and Overflow Packet counters in MTL_RxQ[0-7]_Missed_Packet_Overflow_Cnt register is initialized/preset to 12'h7F0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 Counters Preset is disabled 1 Counters Preset is enabled
25:26 SCHALG	Tx Scheduling Algorithm This field indicates the algorithm for Tx scheduling: 00 WRR algorithm 01 WFQ algorithm when DCB feature is selected 10 DWRR algorithm when DCB feature is selected 11 Strict priority algorithm
29 RAA	Receive Arbitration Algorithm This field is used to select the arbitration algorithm for the Rx side. 0 Strict priority (SP) Queue 0 has the lowest priority and the last queue has the highest priority. 1 Weighted Strict Priority (WSP)
30 DTXSTS	Drop Transmit Status When this bit is set, the Tx packet status received from the MAC is dropped in the MTL. When this bit is reset, the Tx packet status received from the MAC is forwarded to the application. 0 Drop Transmit Status is disabled 1 Drop Transmit Status is enabled

50.2.2.179 MTL debug access control register (MTL_DBG_CTL)

The FIFO Debug Access Control and Status register controls the operation mode of FIFO debug access.

Offset 0x0C08 Access: User Read/Write

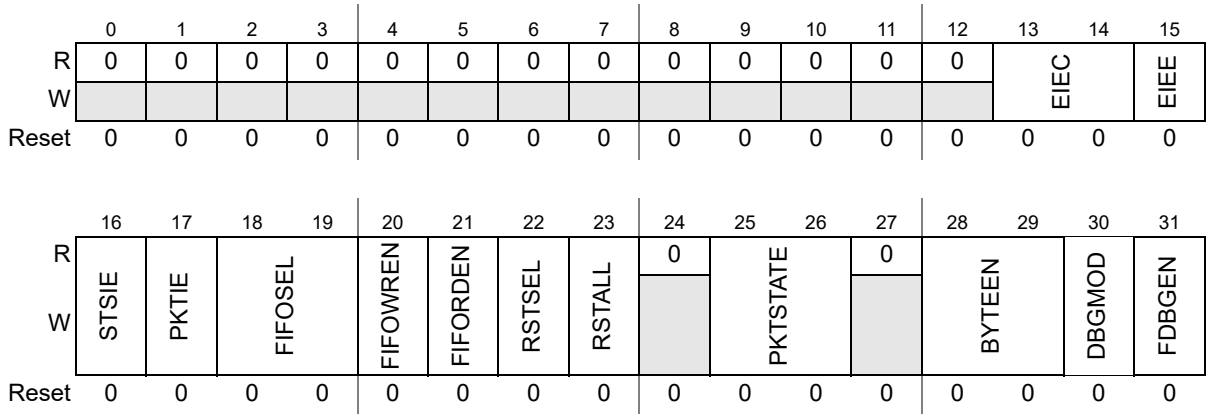

Figure 1196. MTL debug access control register (MTL_DBG_CTL)

Table 1288. MTL_DBG_CTL field descriptions

Field	Description
13:14 EIEC	ECC Inject Error Control for Tx, Rx and TSO memories When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. 00 Insert 1 bit error 01 Insert 2 bit errors 10 Insert 3 bit errors 11 Insert 1 bit error in address field
15 EIEE	ECC Inject Error Enable for Tx, Rx and TSO memories When set, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0 ECC Inject Error for Tx, Rx and TSO memories is disabled 1 ECC Inject Error for Tx, Rx and TSO memories is enabled
16 STSIE	Transmit Status Available Interrupt Status Enable When this bit is set, an interrupt is generated when Transmit status is available in slave mode. 0 Transmit Packet Available Interrupt Status is disabled 1 Packet Available Interrupt Status is enabled
17 PKTIE	Receive Packet Available Interrupt Status Enable When this bit is set, an interrupt is generated when EOP of received packet is written to the Rx FIFO. 0 Receive Packet Available Interrupt Status is disabled 1 Receive Packet Available Interrupt Status is enabled
18:19 FIFOSEL	FIFO Selected for Access This field indicates the FIFO selected for debug access: 00 Tx FIFO 01 Tx Status FIFO (only read access when SLVMOD is set) 10 TSO FIFO (cannot be accessed when SLVMOD is set) 11 Rx FIFO

Table 1288. MTL_DBG_CTL field descriptions (continued)

Field	Description
20 FIFOWREN	FIFO Write Enable When this bit is set, it enables the Write operation on selected FIFO, when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 FIFO Write is disabled 1 FIFO Write is enabled
21 FIFORDEN	FIFO Read Enable When this bit is set, it enables the Read operation on selected FIFO, when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 FIFO Read is disabled 1 FIFO Read is enabled
22 RSTSEL	Reset Pointers of Selected FIFO When this bit is set, the pointers of the currently-selected FIFO are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 Reset Pointers of Selected FIFO is disabled 1 Reset Pointers of Selected FIFO is enabled
23 RSTALL	Reset All Pointers When this bit is set, the pointers of all FIFOs are reset when FIFO Debug Access is enabled. This bit must not be written to 1 when FIFO Debug Access is not enabled, that is FDBGEN bit is 0. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 Reset All Pointers is disabled 1 Reset All Pointers is enabled
25:26 PKTSTATE	Encoded Packet State This field is used to write the control information to the Tx FIFO or Rx FIFO. Tx FIFO / Rx FIFO: 00 Tx Packet Data / Rx Packet Data 01 Tx Control Word / Rx Normal Status 10 Tx SOP Data / Rx Last Status 11 Tx EOP Data / Rx EOP
28:29 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Write operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid

Table 1288. MTL_DBG_CTL field descriptions (continued)

Field	Description
30 DBGMOD	Debug Mode Access to FIFO When this bit is set, it indicates that the current access to the FIFO is read, write, and debug access. In this mode, the following access types are allowed: – Read and Write access to Tx FIFO, TSO FIFO, and Rx FIFO – Read access is allowed to Tx Status FIFO. When this bit is reset, it indicates that the current access to the FIFO is slave access bypassing the DMA. In this mode, the following access are allowed: – Write access to the Tx FIFO – Read access to the Rx FIFO and Tx Status FIFO 0 Debug Mode Access to FIFO is disabled 1 Debug Mode Access to FIFO is enabled
31 FDBGEN	FIFO Debug Access Enable When this bit is set, it indicates that the debug mode access to the FIFO is enabled. When this bit is reset, it indicates that the FIFO can be accessed only through a master interface. 0 FIFO Debug Access is disabled 1 FIFO Debug Access is enabled

50.2.2.180 MTL debug status register (MTL_DBG_STS)

The FIFO Debug status register contains the status of FIFO debug access.

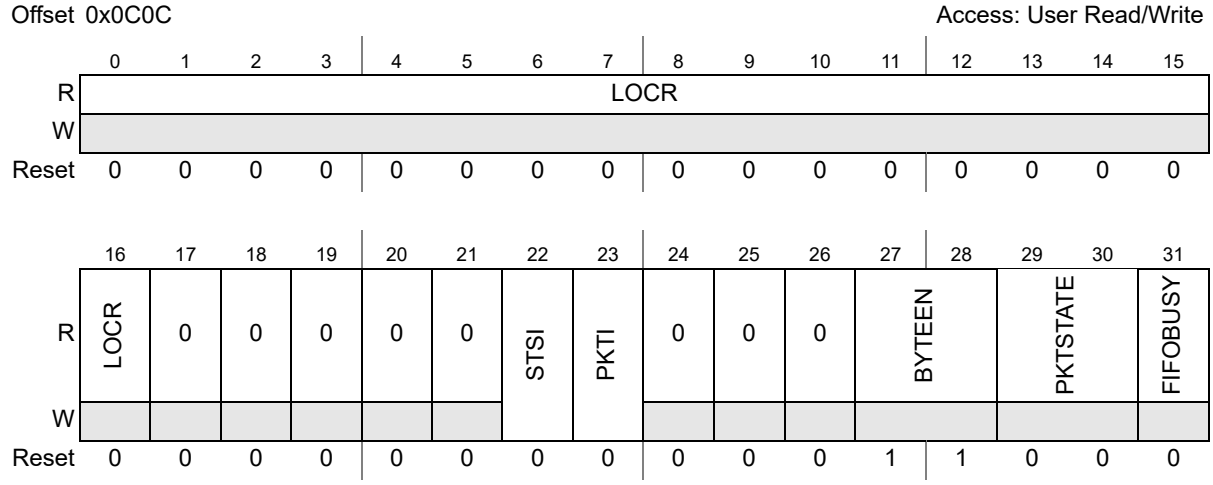

Figure 1197. MTL debug status register (MTL_DBG_STS)

Table 1289. MTL_DBG_STS field descriptions

Field	Description
0:16 LOCR	Remaining Locations in the FIFO Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively.
22 STSI	Transmit Status Available Interrupt Status When set, this bit indicates that the Slave mode Tx packet is transmitted, and the status is available in Tx Status FIFO. This bit is reset when 1 is written to this bit.
23 PKTI	Receive Packet Available Interrupt Status When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit.
27:28 BYTEEN	Byte Enables This field indicates the number of data bytes valid in the data register during Read operation. This is valid only when PKTSTATE is 2'b10 (EOP) and Tx FIFO or Rx FIFO is selected. 00 Byte 0 valid 01 Byte 0 and Byte 1 are valid 10 Byte 0, Byte 1, and Byte 2 are valid 11 All four bytes are valid
29:30 PKTSTATE	Encoded Packet State This field is used to get the control or status information of the selected FIFO. This field is applicable only for Tx FIFO and Rx FIFO during Read operation. Tx FIFO / Rx FIFO: 00 Tx Packet Data / Rx Packet Data 01 Tx Control Word / Rx Normal Status 10 Tx SOP Data / Rx Last Status 11 Tx EOP Data / Rx EOP
31 FIFOBUSY	FIFO Busy When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: All other fields of this register All fields of the MTL_FIFO_Debug_Data register

50.2.2.181 MTL FIFO debug data register (MTL_FIFO_DEBUG_DATA)

The FIFO debug data register contains the data to be written to or read from the FIFOs.

Offset 0x0C10 Access: User Read/Write

Figure 1199. MTL interrupt status register (MTL_INTERRUPT_STATUS)

Table 1291. MTL_INTERRUPT_STATUS field descriptions

Field	Description
8 MTLPIS	MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. To reset this bit, the application must read the MTL_ Rxp_Interrupt_Status register to get the exact cause of the interrupt and clear its source. 0 MTL Rx Parser Interrupt status not detected 1 MTL Rx Parser Interrupt status detected
13 ESTIS	EST (TAS- 802.1Qbv) Interrupt Status This bit indicates an interrupt event during the operation of 802.1Qbv. To reset this bit, the application must clear the error/event that has caused the Interrupt. 0 Interrupt status not detected 1 Interrupt status detected
14 DBGIS	Debug Interrupt status This bit indicates an interrupt event during the slave access. To reset this bit, the application must read the FIFO Debug Access Status register to get the exact cause of the interrupt and clear its source. 0 Debug Interrupt status not detected 1 Debug Interrupt status detected
29 Q2IS	Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. To reset this bit, the application must read the MTL_Q2_Interrupt_Control_Status register to get the exact cause of the interrupt and clear its source. 0 Queue 2 Interrupt status not detected 1 Queue 2 Interrupt status detected
30 Q1IS	Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. To reset this bit, the application must read the MTL_Q1_Interrupt_Control_Status register to get the exact cause of the interrupt and clear its source. 0 Queue 1 Interrupt status not detected 1 Queue 1 Interrupt status detected
31 Q0IS	Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. 0 Queue 0 Interrupt status not detected 1 Queue 0 Interrupt status detected

50.2.2.183 MTL receive queue and DMA channel mapping 0 register (MTL_RXQ_DMA_MAP0)

The Receive queue and DMA channel mapping 0 register.

Figure 1200. MTL receive queue and DMA channel mapping 0 register (MTL_RXQ_DMA_MAP0)

Table 1292. MTL_RXQ_DMA_MAP0 field descriptions

Field	Description
11 Q2DDMACH	Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field (Bits[18:16]).
14:15 Q2MDMACH	Queue 2 Mapped to DMA Channel This field controls the routing of the received packet in Queue 2 to the DMA channel. This field is valid when the Q2DDMACH field is reset. Following bit combinations are valid: 00 DMA Channel 0 01 DMA Channel 1 10 DMA Channel 2
19 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field.
22:23 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel. This field is valid when the Q1DDMACH field is reset. Following bit combinations are valid: 00 DMA Channel 0 01 DMA Channel 1 10 DMA Channel 2

Table 1292. MTL_RXQ_DMA_MAP0 field descriptions (continued)

Field	Description
27 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field.
30:31 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel. This field is valid when the Q0DDMACH field is reset. Following bit combinations are valid: 00 DMA Channel 0 01 DMA Channel 1 10 DMA Channel 2

50.2.2.184 MTL time based scheduling control register (MTL_TBS_CTRL)

This register controls the operation of Time Based Scheduling.

Offset 0x0C40 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1201. MTL time based scheduling control register (MTL_TBS_CTRL)

Table 1293. MTL_TBS_CTRL field descriptions

Field	Description
0:23 LEOS	Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is set since this value is a modulo CTR value.
25:27 LEGOS	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.

Table 1293. MTL_TBS_CTRL field descriptions (continued)

Field	Description
30 LEOV	Launch Expiry Offset Valid When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time.
31 ESTM	EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling will be interpreted as an EST offset value and will be added to the Base Time Register (BTR) of the current list. When reset, the Launch Time value will be used as an absolute value that should be compared with the System time [39:8].

50.2.2.185 MTL enhancements to scheduled transmission control register (MTL_EST_CONTROL)

This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Offset 0x0C50 Access: User Read/Write

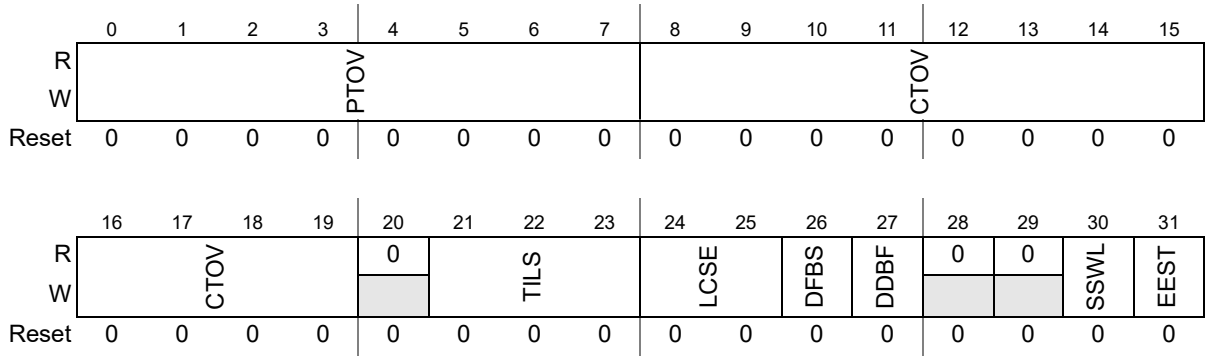

Figure 1202. MTL enhancements to scheduled transmission control register (MTL_EST_CONTROL)

Table 1294. MTL_EST_CONTROL field descriptions

Field	Description
0:7 PTOV	PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
8:19 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays etc. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).

Table 1294. MTL_EST_CONTROL field descriptions (continued)

Field	Description
21:23 TILS	Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. 000 No left shift needed (equal to x1 ns) 001 Left shift TI by 1 bit (equal to x2 ns) 010 Left shift TI by 2 bits (equal to x4 ns) 011 Left shift TI by 3 bits (equal to x8 ns) 100 Left shift TI by 4 bits (equal to x16 ns) 101 Left shift TI by 5 bits (equal to x32 ns) 110 Left shift TI by 6 bits (equal to x64 ns) 111 Left shift TI by 7 bits (equal to x128 ns)
24:25 LCSE	Loop Count to report Scheduling Error Programmable number of GCL list iterations before reporting an HLBS error defined in EST_Status register. 00 4 iterations 01 8 iterations 10 16 iterations 11 32 iterations
26 DFBS	Drop Frames causing Scheduling Error When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_Status register) after 4, 8, 16, 32 (based on LCSE field of this register) GCL iterations are dropped.
27 DDBF	Do not Drop frames during Frame Size Error When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of EST_Status register).
30 SSWL	Switch to S/W owned list When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
31 EEST	Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set.

50.2.2.186 MTL enhancements to scheduled transmission status register (MTL_EST_STATUS)

This register provides status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Offset 0x0C58 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	CGSN

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1203. MTL enhancements to scheduled transmission status register (MTL_EST_STATUS)

Table 1295. MTL_EST_STATUS field descriptions

Field	Description
12:15 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
20:23 BTRL	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time <= New BTR + (N × New Cycle Time) becomes true. N = “1111” indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
24 SWOL	S/W owned list When '0' indicates Gate control list number “0” is owned by software and when “1” indicates the Gate Control list “1” is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default.
27 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is less than or equal to the Cycle Time (CTR). The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1295. MTL_EST_STATUS field descriptions (continued)

Field	Description
28 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros.
29 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros.
30 BTRE	BTR Error When “1” indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = “1111”, SWOL is not updated and Software should reprogram the BTR to a value greater than current time and then set SSWL to re-initiate the switch to SWOL. Else if the value of BTRL < “1111”, SWOL is updated and this field indicates the number of iterations (of + Cycle Time) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 SWLC	Switch to S/W owned list Complete When “1” indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of EST_Control register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

50.2.2.187 MTL enhancements to scheduled transmission schedule error register (MTL_EST_SCH_ERROR)

This register provides the One Hot encoded queue numbers that are having the scheduling related error (timeout).

Offset 0x0C60 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1206. MTL enhancements to scheduled transmission frame size capture register (MTL_EST_FRM_SIZE_CAPTURE)

Table 1298. MTL_EST_FRM_SIZE_CAPTURE field descriptions

Field	Description
14:15 HBFQ	Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. Width is based on the number of Tx Queues configured; remaining bits are Read-Only. Cleared when MTL_EST_Frm_Size_Error register is all zeros.
17:31 HBFS	Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Contents of this register should be considered invalid, if this field is zero. Cleared when MTL_EST_Frm_Size_Error register is all zeros.

50.2.2.190 MTL enhancements to scheduled transmission interrupt enable register (MTL_EST_INTR_ENABLE)

This register implements the interrupt enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

Offset 0x0C70 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1207. MTL enhancements to scheduled transmission interrupt enable register (MTL_EST_INTR_ENABLE)

Table 1299. MTL_EST_INTR_ENABLE field descriptions

Field	Description
27 CGCE	Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset this event does not generate an interrupt.
28 IEHS	Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. When reset this event does not generate an interrupt.
29 IEHF	Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. When reset this event does not generate an interrupt.
30 IEBE	Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. When reset this event does not generate an interrupt.
31 IECC	Interrupt Enable for Switch List When set, generates interrupt when the configuration change is successful and the hardware has switched to the new list. When reset this event does not generate an interrupt.

50.2.2.191 MTL enhancements to scheduled transmission GCL control register (MTL_EST_GCL_CONTROL)

This register provides the control information for reading/writing to the gate control lists.

Offset 0x0C80 Access: User Read/Write

Figure 1208. MTL enhancements to scheduled transmission GCL control register (MTL_EST_GCL_CONTROL)

Table 1300. MTL_EST_GCL_CONTROL field descriptions

Field	Description
8:9 ESTEIEC	ECC Inject Error Control for EST Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. 00 Insert 1 bit error 01 Insert 2 bit errors 10 Insert 3 bit errors 11 Insert 1 bit error in address field
10 ESTEIEE	EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_Control register, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0 EST ECC Inject Error is disabled 1 EST ECC Inject Error is enabled
11 ERR0	When set indicates the last write operation was aborted as software writes to GCL and GCL registers is prohibited when SSWL bit of MTL_EST_Control Register is set. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1300. MTL_EST_GCL_CONTROL field descriptions (continued)

Field	Description
17:23 ADDR	Gate Control List Address: (GCLA when GCRR is “0”). Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. The width of this field is dependent on depth of EST memory (which is 128); unused bits should be treated as read only. Gate Control list Related Registers Address: (GCRA when GCRR is “1”). By default the GCL related register set pointed by SWOL of MTL_EST_Status is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as Do not Care. Following are the valid bit combinations: 000 BTR Low (31:0) 001 BTR High (63:31) 010 CTR Low (31:0) 011 CTR High (39:32) 100 TER (31:0) 101 LLR (n:0) (where n is (log{depth of EST memory} / log2))
26 DBGB	Debug Mode Bank Select When set to “0” indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to “1” indicates R/W in debug mode should be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides by value of SWOL which is normally used.
27 DBGM	Debug Mode When set to “1” indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value, when set to “0” SWOL bit is used to determine which bank to use.
29 GCRR	Gate Control Related Registers When set to “1” indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When “0” indicates R/W should be directed to GCL from the address provided by GCLA.
30 R1W0	Read '1', Write '0': When set to '1': read operation When set to '0': write operation.
31 SRWO	Start Read/Write Op When set indicates a Read/Write Op has started and is in progress. When reset by hardware indicates the R/W Op has completed or an error has occurred (when bit 20 is set) Reads: data can be read from MTL_EST_GCL_Data register after this bit is reset Writes: MTL_EST_GCL_Data should be programmed with write data before setting SRWO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.192 MTL enhancements to scheduled transmission gate control data register (MTL_EST_GCL_DATA)

This register holds the read data or write data in case of reads and writes respectively.

Figure 1210. MTL FPE Control STS register (MTL_FPE_CTRL_STS)

Table 1302. MTL_FPE_CTRL_STS field descriptions

Field	Description
3 HRS	Hold/Release Status 1 Indicates a Set-and-Hold-MAC operation was last executed and the pMAC is in Hold State. 0 Indicates a Set-and-Release-MAC operation was last executed and the pMAC is in Release State.
21:23 PEC	Preemption Classification When set indicates the corresponding Queue must be classified as pre-emptive, when '0' Queue is classified as express. When both EST (Qbv) and Pre-emption are enabled, Queue-0 is always assumed to be pre-emptive. When EST (Qbv) is enabled Queues categorized as pre-emptive here are always assumed to be in “Open” state in the Gate Control List.
30:31 AFSZ	Additional Fragment Size Used to indicate, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of pre-empted frames. The minimum non-final fragment size is (AFSZ +1) × 64 bytes.

50.2.2.194 MTL FPE advance register (MTL_FPE_ADVANCE)

This register holds the Hold and Release Advance time.

Offset 0x0C94 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1211. MTL FPE advance register (MTL_FPE_ADVANCE)

Table 1303. MTL_FPE_ADVANCE field descriptions

Field	Description
0:15 RADV	Release Advance The maximum time in nanoseconds that can elapse between issuing a Release to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.
16:31 HADV	Hold Advance The maximum time in nanoseconds that can elapse between issuing a Hold to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.

50.2.2.195 MTL RXP control status register (MTL_RXP_CONTROL_STATUS)

This register establishes the operating mode of Rx Parser and provides some status.

Offset 0x0CA0 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1212. MTL RXP control status register (MTL_RXP_Control_Status)

Table 1304. MTL_RXP_Control_Status field descriptions

Field	Description
0 RXPI	RX Parser in Idle state This status bit is set to 1 when the Rx parser is in Idle State and waiting for a new packet for processing. This bit is used as a handshake with software when parser gets disabled. After disabling, when bit is set then software can update the Rx parser instruction table. 0 RX Parser not in Idle state 1 RX Parser in Idle state
8:15 NPE	Number of parsable entries in the Instruction table This control indicates the number of parsable entries in the Instruction Memory. This is used in Rx parser logic to detect programming Error. In case number of parsed entries for a packet is more than this entry then NPEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set.
24:31 NVE	Number of valid entries in the Instruction table This control indicates the number of valid entries in the Instruction Memory. This is used in Rx parser logic to detect any programming Error. In case while parsing Table address (memory address) found to be more than this entry then NVEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set. **Note:** The minimum value of this should be 2.

50.2.2.196 MTL RXP interrupt control status register (MTL_RXP_INTERRUPT_CONTROL_STATUS)

This register provides enable control for the interrupts and provides interrupt status.

Offset 0x0CA4 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1213. MTL RXP interrupt control status register (MTL_RXP_Interrupt_Control_Status)

Table 1305. MTL_RXP_Interrupt_Control_Status field descriptions

Field	Description
12 PDRFIE	Packet Drop due to RF Interrupt Enable When this bit is set, the PDRFIS interrupt is enabled. When this bit is reset, the PDRFIS interrupt is disabled. 0 Packet Drop due to RF Interrupt is disabled 1 Packet Drop due to RF Interrupt is enabled
13 FOOVIE	Frame Offset Overflow Interrupt Enable When this bit is set, the FOOVIS interrupt is enabled. When this bit is reset, the FOOVIS interrupt is disabled. 0 Frame Offset Overflow Interrupt is disabled 1 Frame Offset Overflow Interrupt is enabled
14 NPEOVIE	Number of Parsable Entries Overflow Interrupt Enable When this bit is set, the NPEOVIS interrupt is enabled. When this bit is reset, the NPEOVIS interrupt is disabled. 0 Number of Parsable Entries Overflow Interrupt is disabled 1 Number of Parsable Entries Overflow Interrupt is enabled
15 NVEOVIE	Number of Valid Entries Overflow Interrupt Enable When this bit is set, the NVEOVIS interrupt is enabled. When this bit is reset, the NVEOVIS interrupt is disabled. 0 Number of Valid Entries Overflow Interrupt is disabled 1 Number of Valid Entries Overflow Interrupt is enabled
28 PDRFIS	Packet Dropped due to RF Interrupt Status If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 Packet Dropped due to RF Interrupt Status not detected 1 Packet Dropped due to RF Interrupt Status detected

Table 1305. MTL_RXP_Interrupt_Control_Status field descriptions (continued)

Field	Description
29 FOOVIS	Frame Offset Overflow Interrupt Status While parsing if the Instruction table entry's 'Frame Offset' found to be more than EOF offset, then this bit is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 Frame Offset Overflow Interrupt Status not detected 1 Frame Offset Overflow Interrupt Status detected
30 NPEOVIS	Number of Parsable Entries Overflow Interrupt Status While parsing a packet if the number of parsed entries found to be more than NPE[] (Number of Parseable Entries in MTL_RXP_Control register), then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 Number of Parsable Entries Overflow Interrupt Status not detected 1 Number of Parsable Entries Overflow Interrupt Status detected
31 NVEOVIS	Number of Valid Entries Overflow Interrupt Status While parsing if the Instruction address found to be more than NVE (Number of Valid Entries in MTL_RXP_Control register), then this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 Number of Valid Entries Overflow Interrupt Status not detected 1 Number of Valid Entries Overflow Interrupt Status detected

50.2.2.197 MTL RXP drop count register (MTL_RXP_DROP_CNT)

This register provides the drop count of Rx Parser initiated drops.

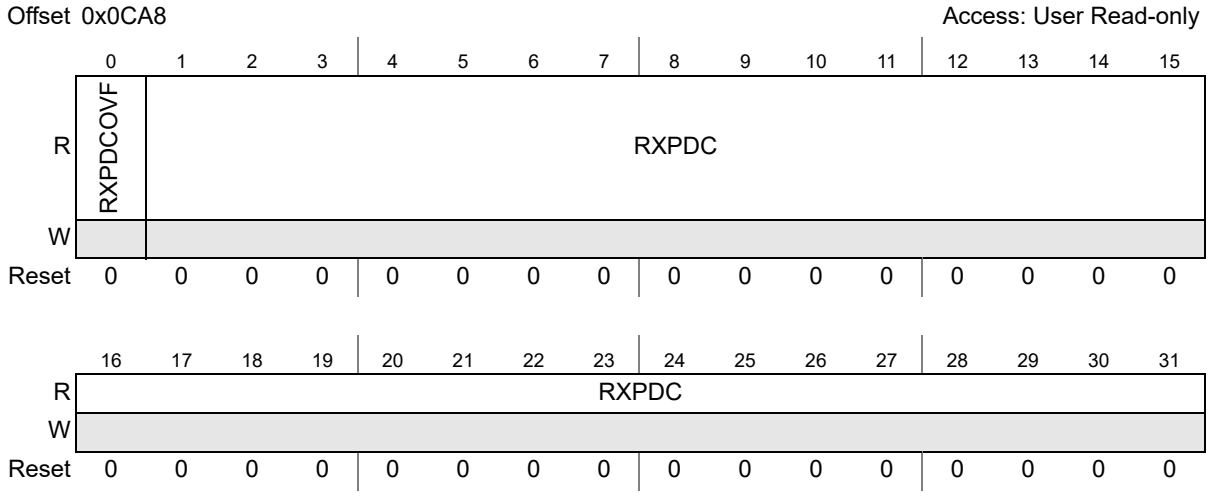

Figure 1214. MTL RXP drop count register (MTL_RXP_Drop_Cnt)

Table 1306. MTL_RXP_Drop_Cnt field descriptions

Field	Description
0 RXPDCOVF	Rx Parser Drop Counter Overflow Bit When set, this bit indicates that the MTL_RXP_Drop_cnt (RXPDC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 Rx Parser Drop count overflow not occurred 1 Rx Parser Drop count overflow occurred
1:31 RXPDC	Rx Parser Drop count This 31-bit counter is implemented whenever a Rx Parser drops a packet due to RF =1. The counter is cleared when the register is read.

50.2.2.198 MTL RXP error count register (MTL_RXP_ERROR_CNT)

This register provides the Rx Parser related error occurrence count.

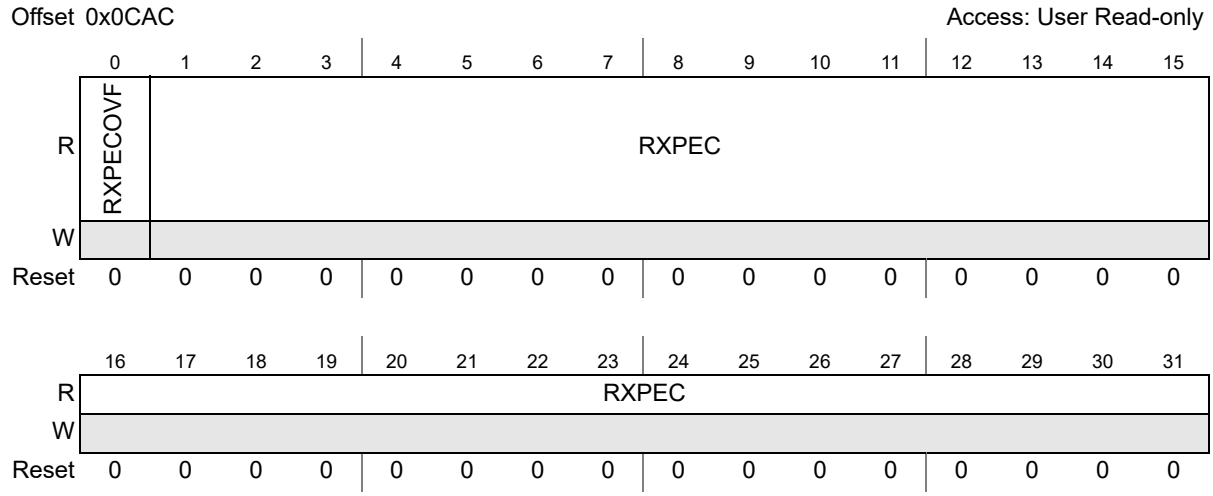

Figure 1215. MTL RXP error count register (MTL_RXP_Error_Cnt)

Table 1307. MTL_RXP_Error_Cnt field description

Field	Description
0 RXPECOVF	Rx Parser Error Counter Overflow Bit When set, this bit indicates that the MTL_RXP_Error_cnt (RXPEC) Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 Rx Parser Error count overflow not occurred 1 Rx Parser Error count overflow occurred
1:31 RXPEC	Rx Parser Error count This 31-bit counter is implemented whenever a Rx Parser encounters following Error scenarios: – Entry address ≥ NVE[] – Number Parsed Entries ≥ NPE[] – Entry address > EOF data entry address The counter is cleared when the register is read.

50.2.2.199 MTL RXP indirect access control status register (MTL_RXP_INDIRECT_ACC_CONTROL_STATUS)

This register provides the Indirect Access control and status for Rx Parser memory.

Offset 0x0CB0 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1216. MTL RXP indirect access control status register (MTL_RXP_Indirect_Acc_Control_Status)

Table 1308. MTL_RXP_Indirect_Acc_Control_Status field descriptions

Field	Description
0 STARTBUSY	FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions. This bit when set to 1 indicates that hardware is busy until it gets cleared by hardware and software should not issue any read or write operation. 0 Hardware not busy 1 Hardware is busy (Read/Write operation from/to the Rx Parser Memory)
9:10 RXPEIEC	ECC Inject Error Control for Rx Parser Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field: 00 Insert 1 bit error 01 Insert 2 bit errors 10 Insert 3 bit errors 11 Insert 1 bit error in address field
11 RXPEIEE	ECC Inject Error Enable for Rx Parser Memory When set, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0 ECC Inject Error for Rx Parser Memory is disabled 1 ECC Inject Error for Rx Parser Memory is enabled
15 WRRDN	Read Write Control When this bit is set to 1 indicates the write operation to the Rx Parser Memory. When this bit is set to 0 indicates the read operation to the Rx Parser Memory. 0 Read operation to the Rx Parser Memory 1 Write operation to the Rx Parser Memory
22:31 ADDR	FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. Each entry has 128-bit (4x32-bit words). The X depends on the configurable DWC_EQOS_FRP_ENTRIES. If DWC_EQOS_FRP_ENTRIES == 256, then X = 9. If DWC_EQOS_FRP_ENTRIES = 128, then X = 8. IF DWC_EQOS_FRP_ENTRIES = 64, then X = 7. This is can be written by the software before issuing any Read/Write command. The hardware auto-increments this field after the read-write operation gets completed.

50.2.2.200 MTL RXP indirect access data register (MTL_RXP_INDIRECT_ACC_DATA)

This register holds the data associated to Indirect Access to Rx Parser memory.

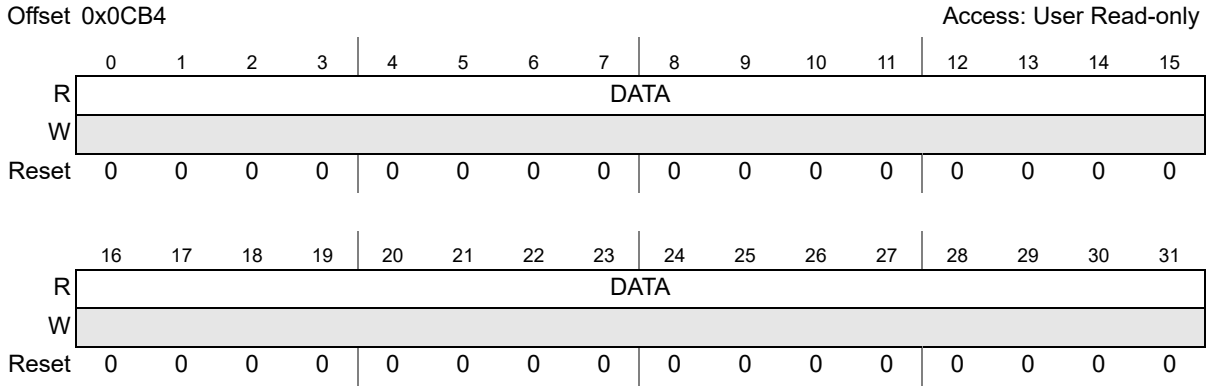

Figure 1217. MTL RXP indirect access data register (MTL_RXP_Indirect_Acc_Data)

Table 1309. MTL_RXP_Indirect_Acc_Data field description

Field	Description
0:31 DATA	FRP Instruction Table Write/Read Data Software should write this register before issuing any write command. The hardware provides the read data from the Rx Parser Memory for read operation when STARTBUSY = 0 after read command.

50.2.2.201 MTL ECC Control register (MTL_ECC_CONTROL)

This register establishes the operating mode of ECC related to MTL memories.

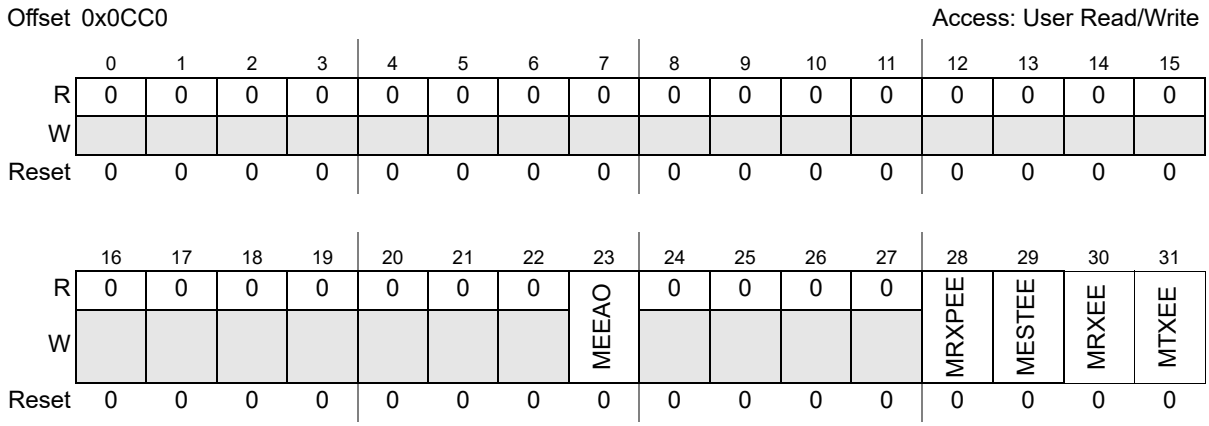

Figure 1218. MTL ECC control register (MTL_ECC_CONTROL)

Table 1310. MTL_ECC_CONTROL field descriptions

Field	Description
23 MEEAO	MTL ECC Error Address Status Over-ride When set, the following error address fields will hold the last valid address where the error is detected. When reset, the following error address fields will hold the first address where the error is detected. EUEAS/ECEAS of MTL_ECC_Err_Addr_Status register. 0 MTL ECC Error Address Status Over-ride is disabled 1 MTL ECC Error Address Status Over-ride is enabled
28 MRXPEE	MTL Rx Parser ECC Enable When set to 1, enables the ECC feature for Rx Parser memory. When set to zero, disables the ECC feature for Rx Parser memory. 0 MTL Rx Parser ECC is disabled 1 MTL Rx Parser ECC is enabled
29 MESTEE	MTL EST ECC Enable When set to 1, enables the ECC feature for EST memory. When set to zero, disables the ECC feature for EST memory. 0 MTL EST ECC is disabled 1 MTL EST ECC is enabled
30 MRXEE	MTL Rx FIFO ECC Enable When set to 1, enables the ECC feature for MTL Rx FIFO memory. When set to zero, disables the ECC feature for MTL Rx FIFO memory. 0 MTL Rx FIFO ECC is disabled 1 MTL Rx FIFO ECC is enabled
31 MTXEE	MTL Tx FIFO ECC Enable When set to 1, enables the ECC feature for MTL Tx FIFO memory. When set to zero, disables the ECC feature for MTL Tx FIFO memory. 0 MTL Tx FIFO ECC is disabled 1 MTL Tx FIFO ECC is enabled

50.2.2.202 MTL Safety Interrupt Status register (MTL_SAFETY_INTERRUPT_STATUS)

This register provides Safety interrupt status.

Offset 0x0CC4 Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1219. MTL safety interrupt status register (MTL_Safety_Interrupt_Status)

Table 1311. MTL_Safety_Interrupt_Status field descriptions

Field	Description
0 MCSIS	MAC Safety Uncorrectable Interrupt Status Indicates an uncorrectable Safety-related Interrupt is set in the MAC module. MAC_DPP_FSM_Interrupt_Status register should be read when this bit is set, to get the cause of the Safety Interrupt in MAC. 0 MAC Safety Uncorrectable Interrupt Status not detected 1 MAC Safety Uncorrectable Interrupt Status detected
30 MEUIS	MTL ECC Uncorrectable error Interrupt Status This bit indicates an uncorrectable error interrupt event in the MTL ECC safety feature. To get the exact cause of the interrupt the application should read the MTL_ECC_Interrupt_Status register. 0 MTL ECC Uncorrectable error Interrupt Status not detected 1 MTL ECC Uncorrectable error Interrupt Status detected
31 MECIS	MTL ECC Correctable error Interrupt Status This bit indicates a correctable error interrupt event in the MTL ECC safety feature. To get the exact cause of the interrupt the application should read the MTL_ECC_Interrupt_Status register. 0 MTL ECC Correctable error Interrupt Status not detected 1 MTL ECC Correctable error Interrupt Status detected

50.2.2.203 MTL ECC interrupt enable register (MTL_ECC_INTERRUPT_ENABLE)

This register provides enable bits for the ECC interrupts.

Offset 0x0CC8 Access: User Read/Write

Figure 1220. MTL ECC interrupt enable register (MTL_ECC_INTERRUPT_ENABLE)

Table 1312. MTL_ECC_INTERRUPT_ENABLE field descriptions

Field	Description
19 RPCEIE	Rx Parser memory Correctable Error Interrupt Enable When set, generates an interrupt when an uncorrectable error is detected at the Rx Parser memory interface. It is indicated in RPCES status bit of MTL_ECC_Interrupt_Status register. When reset this event does not generate an interrupt. 0 Rx Parser memory Correctable Error Interrupt is disabled 1 Rx Parser memory Correctable Error Interrupt is enabled
23 ECEIE	EST memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL EST memory interface. It is indicated in the ECES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generate an interrupt. 0 EST memory Correctable Error Interrupt is disabled 1 EST memory Correctable Error Interrupt is enabled
27 RXCEIE	Rx memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL Rx memory interface. It is indicated in the RXCES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generate an interrupt. 0 Rx memory Correctable Error Interrupt is disabled 1 Rx memory Correctable Error Interrupt is enabled
31 TXCEIE	Tx memory Correctable Error Interrupt Enable When set, generates an interrupt when a correctable error is detected at the MTL Tx memory interface. It is indicated in the TXCES bit of MTL_ECC_Interrupt_Status register. When reset this event does not generate an interrupt. 0 Tx memory Correctable Error Interrupt is disabled 1 Tx memory Correctable Error Interrupt is enabled

50.2.2.204 MTL ECC interrupt status register (MTL_ECC_INTERRUPT_STATUS)

This register provides MTL ECC Interrupt Status.

Figure 1225. MTL Data Parity Protection Control register (MTL_DPP_CONTROL)

Table 1317. MTL_DPP_Control field descriptions

Field	Description
20 IPERD	Insert Parity error in Rx write-back Descriptor parity generator When set to 1, parity bit of first valid data generated by the DMA Rx write-back descriptor parity generator (or at PG8 as shown in *Figure 1319: Receive Datapath Parity Protection*) is flipped. 0 Insert Parity error in Rx write-back Descriptor parity generator is disabled 1 Insert Parity error in Rx write-back Descriptor parity generator is enabled
21 IPETD	Insert Parity error in Tx write-back Descriptor parity generator When set to 1, parity bit of first valid data generated by the DMA Tx write-back descriptor parity generator (or at PG4 as shown in *Figure 1318: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. Values: 0 Insert Parity error in Tx write-back Descriptor parity generator is disabled 1 Insert Parity error in Tx write-back Descriptor parity generator is enabled
22 IPETSO	Insert Parity Error in DMA TSO parity generator When set to 1, parity bit of first valid data generated by the DMA TSO parity generator is (or at PG3 as shown in *Figure 1318: Transmit Datapath Parity Protection*) flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in DMA TSO parity generator is disabled 1 Insert Parity Error in DMA TSO parity generator is enabled

Table 1317. MTL_DPP_Control field descriptions (continued)

Field	Description
23 IPEDDC	Insert Parity Error in DMA DTX Control word parity generator When set to 1, parity bit of first valid data generated by the DMA DTX Control word parity generator (or at PG2 as shown in *Figure 1318: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in DMA DTX Control word parity generator is disabled 1 Insert Parity Error in DMA DTX Control word parity generator is enabled
24 IPEMRF	Insert Parity Error in MTL Rx FIFO read control parity generator When set to 1, parity bit of first valid data generated by the MTL Rx FIFO read control parity generator (or at PG7 as shown in *Figure 1319: Receive Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in MTL Rx FIFO read control parity generator is disabled 1 Insert Parity Error in MTL Rx FIFO read control parity generator is enabled
25 IPEMTS	Insert Parity Error in MTL Tx Status parity generator When set to 1, parity bit of first valid data generated by the MTL Tx Status parity generator (or at PG6 as shown in *Figure 1318: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once respective parity bit is flipped. 0 Insert Parity Error in MTL Tx Status parity generator is disabled 1 Insert Parity Error in MTL Tx Status parity generator is enabled
26 IPEMC	Insert Parity Error in MTL checksum parity generator When set to 1, parity bit of first valid data generated by the MTL checksum parity generator (or at PG5 as shown in *Figure 1318: Transmit Datapath Parity Protection*) is flipped. Hardware will clear this bit once the respective parity bit is flipped. 0 Insert Parity Error in MTL checksum parity generator is disabled 1 Insert Parity Error in MTL checksum parity generator is enabled
27 IPEID	Insert Parity Error in Interface Data parity generator When set to 1, parity bit of first valid input data generated by the Interface data parity generator (or at PG1 as shown in *Figure 1318: Transmit Datapath Parity Protection*) is flipped. Following are the input data bus on which parity bits are generated based on configuration selected: AHB hrdata_i Hardware will clear this bit once the respective parity bit is flipped. 0 Insert Parity Error in Interface Data parity generator is disabled 1 Insert Parity Error in Interface Data parity generator is enabled
29 EPSI	Enable Parity on Slave Interface port When set to 1, enables the parity check for the slave interface ports and disables the internal generation of parity for the input slave data port. When set to 0, disables the parity check for the slave interface ports and enables the internal parity generation for the input slave data port. 0 Parity on Slave Interface port is disabled 1 Parity on Slave Interface port is enabled

Table 1317. MTL_DPP_Control field descriptions (continued)

Field	Description
30 OPE	Odd Parity Enable When set to 1, enables odd parity protection on all the external interfaces and when set to 0, enables even parity protection on all the external interfaces. 0 Odd Parity is disabled 1 Odd Parity is enabled
31 EDPP	Enable Data path Parity Protection When set to 1, enables the parity protection for EQOS datapath by generating and checking the parity on EQOS datapath. When set to 0, disables the parity protection for EQOS datapath. 0 Data path Parity Protection is disabled 1 Data path Parity Protection is enabled

50.2.2.209 MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)

The Queue 0 transmit operation mode register establishes the Transmit queue operating modes and commands.

Offset 0x0D00 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1226. Queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)

Table 1318. MTL_TXQ0_OPERATION_MODE field descriptions

Field	Description
10:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. A value of 0 indicates 256 bytes.
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 00 Not enabled 01 Reserved 10 Enabled 11 Reserved
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.210 MTL queue 0 underflow counter register (MTL_TXQ0_UNDERFLOW)

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1227. Queue 0 underflow counter register (MTL_TXQ0_UNDERFLOW)

Table 1319. MTL_TXQ0_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.211 MTL queue 0 transmit debug register (MTL_TXQ0_DEBUG)

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 Access: User Read-only

Figure 1228. Queue 0 transmit debug register (MTL_TXQ0_DEBUG)

Table 1320. MTL_TXQ0_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.

Table 1320. MTL_TXQ0_DEBUG field descriptions (continued)

Field	Description
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled. Reception of 802.3x Pause packet when PFC is disabled.

50.2.2.212 MTL queue 0 ETS status register (MTL_TXQ0_ETS_STATUS)

The Queue 0 ETS status register provides the average traffic transmitted in Queue 0.

Offset 0x0D14 Access: User Read-only

Figure 1231. MTL interrupt control status register (MTL_Q0_INTERRUPT_CONTROL_STATUS)

Table 1323. MTL_Q0_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[10]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

50.2.2.215 MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)

The Queue 0 receive operation mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 Access: User Read/Write

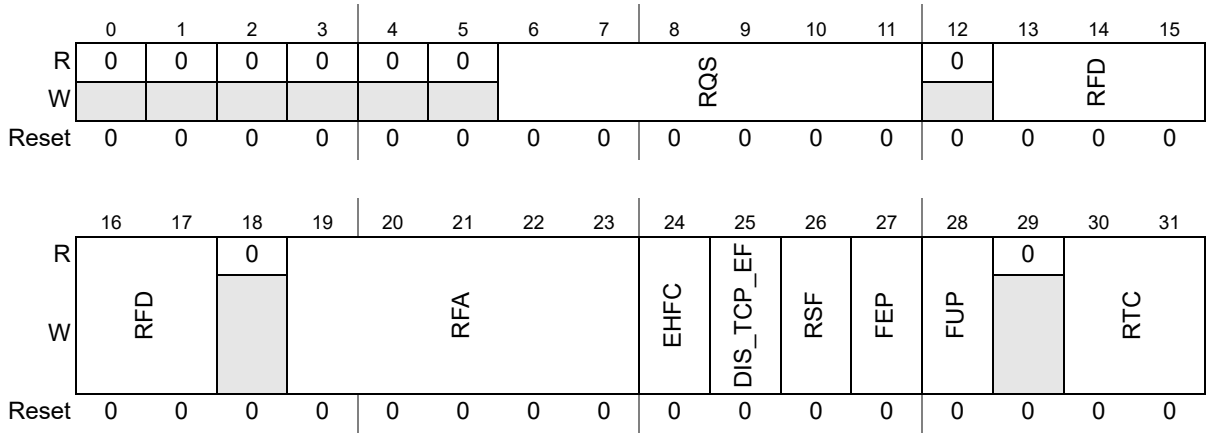

Figure 1232. MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)

Table 1324. MTL_RXQ0_OPERATION_MODE field descriptions

Field	Description
6:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes.
13:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
19:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.

Table 1324. MTL_RXQ0_OPERATION_MODE field descriptions (continued)

Field	Description
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

50.2.2.216 MTL RX Queue 0 missed packet and overflow counter register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

The Queue 0 missed packet and overflow counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 Access: User Read-only

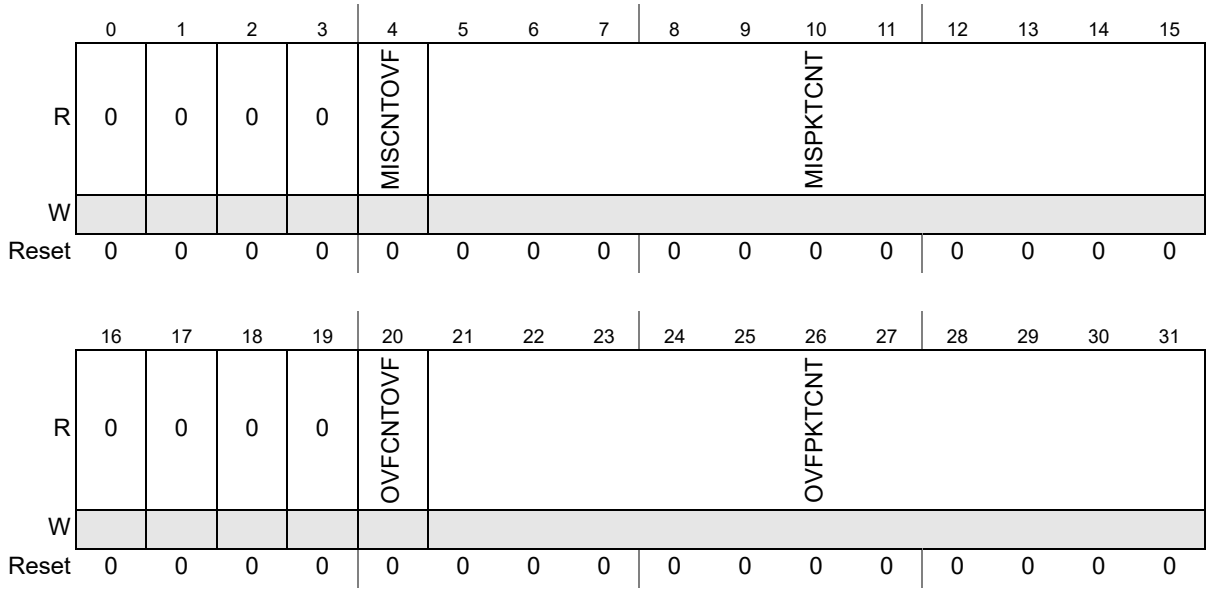

Figure 1233. MTL RX Queue 0 missed packet and overflow counter register (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

Table 1325. MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.217 MTL RX Queue 0 receive debug register (MTL_RXQ0_DEBUG)

The Queue 0 receive debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 Access: User Read-only

Figure 1234. MTL RX Queue 0 receive debug register (MTL_RXQ0_DEBUG)

Table 1326. MTL_RXQ0_DEBUG field descriptions

Field	Description
2:15 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
26:27 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00 Rx Queue empty 01 Rx Queue fill-level below flow-control deactivate threshold 10 Rx Queue fill-level above flow-control activate threshold 11 Rx Queue full
29:30 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00 Idle state 01 Reading packet data 10 Reading packet status (or timestamp) 11 Flushing the packet data and status
31 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.

50.2.2.218 MTL RX Queue receive control register (MTL_RXQ0_CONTROL)

The Queue receive control register controls the receive arbitration and passing of received packets to the application.

Offset 0x0D3C Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1235. MTL RX Queue receive control register (MTL_RXQ0_CONTROL)

Table 1327. MTL_RXQ0_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL packet requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

50.2.2.219 MTL Transmit Q*n* operation mode register (MTL_TXQ*n*_OPERATION_MODE)

The Queue transmit operation mode register establishes the Transmit queue operating modes and commands.

Offset 0x0D00 + *n**0x40 (n = 1 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
10:15 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes.
25:27 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 32 001 64 010 96 011 128 100 192 101 256 110 384 111 512
28:29 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue n. 00 Not enabled 01 Enable in AV mode 10 Enabled 11 Reserved

Table 1328. MTL_TXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
30 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[25:27] of this register are ignored. This bit should be changed only when the transmission is stopped.
31 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note:** The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.220 MTL Transmit Q*n* underflow register (MTL_TXQ*n*_UNDERFLOW)

The Queue underflow counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

Offset 0x0D04 + *n**0x40 (n = 1 to 2) Access: User Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1237. MTL Transmit Q*n* underflow register (MTL_TXQ*n*_UNDERFLOW)

Table 1329. MTL_TXQ*n*_UNDERFLOW field descriptions

Field	Description
20 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.221 MTL Transmit Q*n* debug register (MTL_TXQ*n*_DEBUG)

The Queue Transmit debug register gives the debug status of various blocks related to the Transmit queue.

Offset 0x0D08 + *n**0x40 (n = 1 to 2) Access: User Read-only

Table 1330. MTL_TXQ*n*_DEBUG field descriptions

Field	Description
9:11 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
13:15 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
26 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
27 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
28 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
29:30 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 Idle state 01 Read state (transferring data to the MAC transmitter) 10 Waiting for pending Tx Status from the MAC transmitter 11 Flushing the Tx queue because of the Packet Abort request from the MAC
31 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled

50.2.2.222 MTL Transmit Q*n* ETS control register (MTL_TXQ*n*_ETS_CONTROL)

The Queue ETS control register controls the enhanced transmission selection operation.

Offset 0x0D10 + *n**0x40 (n = 1 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1239. MTL Transmit Q*n* ETS control register (MTL_TXQ*n*_ETS_CONTROL)

Table 1331. MTL_TXQ*n*_ETS_CONTROL field descriptions

Field	Description
25:27 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CHn_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQn_ETS_Status register, need to be computed for Queue. The encoding is as follows: 000 1 Slot 001 2 Slots 010 4 Slots 011 8 Slots 100 16 Slots 101 Reserved 110 Reserved 111 Reserved
28 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel n. The credit accumulates even when there is no packet waiting in Channel n and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel. When there is no packet waiting in Channel n and other channel is transmitting, no credit is accumulated.
29 AVALG	AV Algorithm When Queue *n* is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue *n* traffic. When reset, strict priority is selected.

50.2.2.223 MTL Transmit Q*n* ETS status register (MTL_TXQ*n*_ETS_STATUS)

The Queue 1 ETS status register provides the average traffic transmitted in Queue 1.

Offset 0x0D14 + *n**0x40 (n = 1 to 2) Access: User Read-only

Figure 1240. MTL Transmit Q*n* ETS status register (MTL_TXQ*n*_ETS_STATUS)

Table 1332. MTL_TXQ*n*_ETS_STATUS field descriptions

Field	Description
8:31 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. For AV operation for Queue 1, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ*n*_ETS_CONTROL register. When Enable Slot Interval feature is selected, the maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps. The maximum value is 0x30D4 for 100 Mbps and 0x1E848 for 1000 Mbps. Bits [8:14] are always read as zero.

50.2.2.224 MTL Transmit Q*n* quantum weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

The Queue idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Offset 0x0D18 + *n**0x40 (n = 1 to 2) Access: User Read/Write

Figure 1241. MTL Transmit Q*n* quantum weight register (MTL_TXQ*n*_QUANTUM_WEIGHT)

Table 1333. MTL_TXQ*n*_QUANTUM_WEIGHT field descriptions

Field	Description
11:31 ISCQW	idleSlopeCredit, Quantum or Weights **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. **Weights** When enabled with WRR algorithm for Queue traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [11:24] must be written to zero.

50.2.2.225 MTL Transmit Q*n* send slope credit register (MTL_TXQ*n*_SENDSLOPECREDIT)

The SendSlopeCredit register contains the SendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D1C + *n**0x40 (n = 1 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1242. MTL Transmit Q*n* send slope credit register (MTL_TXQ*n*_SENDSLOPECREDIT)

Table 1334. MTL_TXQ*n*_SENDSPLOPECREDIT field descriptions

Field	Description
18:31 SSC	SendSlopeCredit With AV operation enabled, this field contains the SendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps and 8 ns for 1000 Mbps) when the credit is decreasing. The software should program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is 0x1000 in 100 Mbps mode and 0x2000 in 1000 Mbps. This field should be programmed with absolute SendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel n is selected for transmission.

50.2.2.226 MTL Transmit Q*n* high credit register (MTL_TXQ*n*_HICREDIT)

The HiCredit register contains the HiCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D20 + *n**0x40 (n = 1 to 2) Access: User Read/Write

Figure 1243. MTL Transmit Q*n* high credit register (MTL_TXQ*n*_HICREDIT)

Table 1335. MTL_TXQ*n*_HICREDIT field descriptions

Field	Description
3:31 HC	HiCredit When the AV feature is enabled, this field contains the HiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16384 bytes or 131072 bits). The value to be specified is 131072 × 1024 = 134217728 or 0x0800_0000.

50.2.2.227 MTL Transmit Q*n* low credit register (MTL_TXQ*n*_LOCREDIT)

The LoCredit register contains the LoCredit value required for the credit-based shaper algorithm for the Queue.

Offset 0x0D24 + *n**0x40 (n = 1 to 2) Access: User Read/Write

Figure 1244. MTL Transmit Q*n* low credit register (MTL_TXQ*n*_LOCREDIT)

Table 1336. MTL_TXQ*n*_LOCREDIT field descriptions

Field	Description
3:31 LC	loCredit When AV operation is enabled, this field contains the LoCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value to be programmed corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192 × 2) × 8 × 1024 = 134217728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

50.2.2.228 MTL Q*n* interrupt control status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue interrupts.

Offset 0x0D2C + *n**0x40 (n = 1 to 2) Access: User Read/Write

Figure 1245. MTL Q*n* interrupt control status register (MTL_Q*n*_INTERRUPT_CONTROL_STATUS)

Table 1337. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions

Field	Description
7 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.
15 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event.

Table 1337. MTL_Q*n*_INTERRUPT_CONTROL_STATUS field descriptions (continued)

Field	Description
23 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.
30 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

50.2.2.229 MTL Receive Q*n* operation mode register (MTL_RXQ*n*_OPERATION_MODE)

The Queue receive operation mode register establishes the Receive queue operating modes and command.

Offset 0x0D30 + *n**0x40 (n = 1 to 2) Access: User Read/Write

Figure 1246. MTL Receive Q*n* operation mode register (MTL_RXQ*n*_OPERATION_MODE)

Table 1338. MTL_RXQ*n*_OPERATION_MODE field descriptions

Field	Description
6:11 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes.
13:17 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: 0 Full minus 1 KB, that is, FULL 1 KB 1 Full minus 1.5 KB, that is, FULL 1.5 KB 2 Full minus 2 KB, that is, FULL 2 KB 3 Full minus 2.5 KB, that is, FULL 2.5 KB ... 62 Full minus 32 KB, that is, FULL 32 KB 63 Full minus 32.5 KB, that is, FULL 32.5 KB The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.
19:23 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
24 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
25 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.
26 RSF	Receive Queue Store and Forward When this bit is set, the Ethernet module reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Table 1338. MTL_RXQ*n*_OPERATION_MODE field descriptions (continued)

Field	Description
27 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, MII_RX_ERR, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.
28 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.
30:31 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): 00 64 01 32 10 96 11 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

50.2.2.230 MTL Receive Q*n* missed packet and overflow counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

The Queue Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset 0x0D34 + *n**0x40 (n = 1 to 2) Access: User Read-only

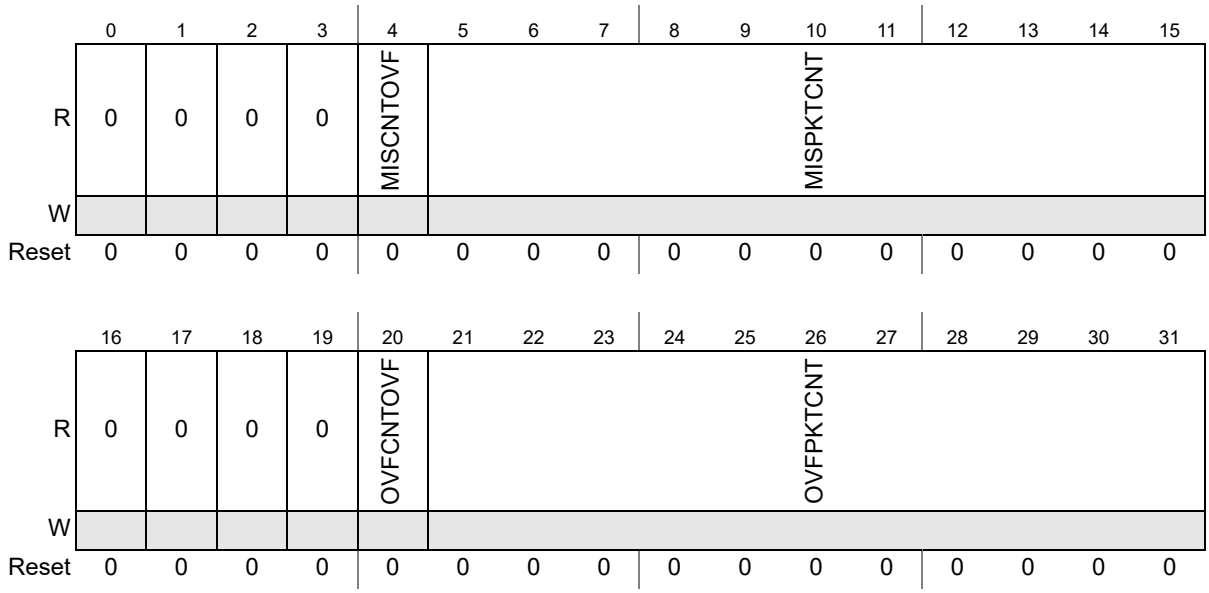

Figure 1247. MTL Receive Q*n* missed packet and overflow counter register (MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT)

Table 1339. MTL_RXQ*n*_MISSED_PACKET_OVERFLOW_CNT field descriptions

Field	Description
4 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
5:15 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the Ethernet module because the application asserted ari_pkt_flush_i[] for this queue. This counter is incremented each time the application issues ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
20 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event.
21:31 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the Ethernet module because of Receive queue overflow. This counter is incremented each time the Ethernet module discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

50.2.2.231 MTL Receive Q*n* debug register (MTL_RXQ*n*_DEBUG)

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset 0x0D38 + *n**0x40 (n = 1 to 2) Access: User Read-only

Figure 1249. MTL Receive Q*n* control register (MTL_RXQ*n*_CONTROL)

Table 1341. MTL_RXQ*n*_CONTROL field descriptions

Field	Description
28 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the Ethernet module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the Ethernet module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the Ethernet module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).
29:31 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL packet requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

50.2.2.233 DMA mode register (DMA_MODE)

The Bus mode register establishes the bus operating modes for the DMA.

Figure 1250. DMA mode register (DMA_MODE)

Table 1342. DMA_MODE field descriptions

Field	Description
14:15 INTM	Interrupt Mode This field defines the interrupt mode of the Ethernet module. The behavior of the following outputs changes depending on the following settings: – sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) – sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) – sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status. 00 sbd_perch_* are pulse signals for each completion events. sbd_intr_o is also asserted and cleared only when software clears the corresponding RI/TI status bits 01 sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these packet transfer completion events. 10 sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these packet transfer completion events. 11 Reserved
17:19 PR	Priority Ratio These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. 000 The priority ratio is 1:1 001 The priority ratio is 2:1 010 The priority ratio is 3:1 011 The priority ratio is 4:1 100 The priority ratio is 5:1 101 The priority ratio is 6:1 110 The priority ratio is 7:1 111 The priority ratio is 8:1
20 TXPR	Transmit Priority When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.

Table 1342. DMA_MODE field descriptions (continued)

Field	Description
27:29 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000 Fixed priority In fixed priority, Channel 0 has the lowest priority and the last channel has the highest priority. 001 Weighted Strict Priority (WSP) 010 Weighted Round-Robin (WRR) 011 Reserved ... 111 Reserved
30 DA	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: 0 Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[17:19] and the priority weight is specified in the TXPR bit. 1 Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.
31 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all Ethernet module clock domains. Before reprogramming any Ethernet module register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. **Note:** The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

50.2.2.234 DMA system bus mode register (DMA_SYSBUS_MODE)

The System Bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

Offset 0x1004 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1251. DMA system bus mode register (DMA_SYSBUS_MODE)

Table 1343. DMA_SYSBUS_MODE field descriptions

Field	Description
16 RB	Rebuild INCRx Burst When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.
17 MB	Mixed Burst When this bit is set high and the FB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).
19 AAL	Address-Aligned Beats When this bit is set to 1, AHB master performs address-aligned burst transfers on Read and Write channels.
31 FB	Fixed Burst Length When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE). When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.

50.2.2.235 DMA interrupt status register (DMA_INTERRUPT_STATUS)

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

Offset 0x1008 Access: User Read-only

Figure 1252. DMA interrupt status register (DMA_INTERRUPT_STATUS)

Table 1344. DMA_INTERRUPT_STATUS field descriptions

Field	Description
14 MACIS	MAC Interrupt Status This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.
15 MTLIS	MTL Interrupt Status This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.
29 DC2IS	DMA Channel 2 Interrupt Status This bit indicates an interrupt event in DMA Channel 2. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 2 to get the exact cause of the interrupt and clear its source.
30 DC1IS	DMA Channel 1 Interrupt Status This bit indicates an interrupt event in DMA Channel 1. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 1 to get the exact cause of the interrupt and clear its source.
31 DC0IS	DMA Channel 0 Interrupt Status This bit indicates an interrupt event in DMA Channel 0. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 0 to get the exact cause of the interrupt and clear its source.

50.2.2.236 DMA debug status 0 register (DMA_DEBUG_STATUS0)

The Debug Status 0 register gives the Receive and Transmit process status for DMA Channel 0-Channel 1 for debugging purpose.

Figure 1256. DMA channel 0 control register (DMA_CH0_CONTROL)

Table 1348. DMA_CH0_CONTROL field descriptions

Field	Description
7 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload.
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[10:15] in DMA_CH0_Tx_Control and Bits[10:15] in DMA_CH0_Rx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.
18:31 MSS	Maximum Segment Size This field specifies the maximum segment size that should be used while segmenting the packet. This field is valid only if the TSE bit of DMA_CH0_Tx_Control register is set. The value programmed in this field must be greater than the configured data width in bytes. It is recommended to use a MSS value of 64 bytes or more.

50.2.2.240 DMA channel *n* control register (DMA_CH*n*_CONTROL)

The DMA Channel *n* Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Offset 0x1100 + *n**0x80 (n = 1 to 2) Access: User Read/Write

Figure 1257. DMA channel *n* control register (DMA_CH*n*_CONTROL)

Table 1349. DMA_CH*n*_CONTROL field descriptions

Field	Description
7 SPH	Split Headers When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1 of RDES0. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload.
11:13 DSL	Descriptor Skip Length This bit specifies the Dword number (64-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
15 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[10:15] in DMA_CH0_Tx_Control and Bits[10:15] in DMA_CH0_Rx_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.

50.2.2.241 DMA channel *n* transmit control register (DMA_CH*n*_TX_CONTROL)

The DMA Channel Transmit Control register controls the Tx features such as PBL, and Tx Channel weights.

Offset 0x1104 + *n**0x80 (n = 0 to 2) Access: User Read/Write

Figure 1258. DMA channel *n* transmit control register (DMA_CH*n*_TX_CONTROL)

Table 1350. DMA_CH*n*_TX_CONTROL field descriptions

Field	Description
3 EDSE	Enhanced Descriptor Enable When this bit is set, the corresponding channel will use Enhanced Descriptors that are 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors that are 16 Bytes.
10:15 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: – Set the PBLx8 mode in DMA_CH0_Control register. – Set the TxPBL. **Note:** The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, the total locations in Tx Queue of size 512 bytes is 64, TxPBL and PBLx8 needs to be programmed to less than or equal to 32.
19 TSE	TCP Segmentation Enabled When this bit is set, the DMA performs the TCP segmentation or UDP Segmentation/Fragmentation for packets in this channel. The TCP segmentation or UDP packet's segmentation/Fragmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than 4.
27 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Table 1350. DMA_CH*n*_TX_CONTROL field descriptions (continued)

Field	Description
28:30 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
31 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: – The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. – The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.

50.2.2.242 DMA channel *n* receive control register (DMA_CH*n*_RX_CONTROL)

The DMA Channel *n* Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset 0x1108 + *n**0x80 (n = 0 to 2) Access: User Read/Write

Figure 1259. DMA channel *n* receive control register (DMA_CH*n*_RX_CONTROL)

Table 1351. DMA_CH*n*_RX_CONTROL field descriptions

Field	Description
0 RPF	Rx Packet Flush When this bit is set to 1, then Ethernet module automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the Ethernet module will not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue.
10:15 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the PBLx8 mode in the DMA_CH0_Control register. 2. Set the RxPBL. **Note:** The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
17:27 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 K bytes. The buffer size is applicable to payload buffers when split headers are enabled. **Note:** The buffer size must be a multiple of 8 (64-bit AHB bus). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).

Table 1351. DMA_CH*n*_RX_CONTROL field descriptions (continued)

Field	Description
28:30 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration.
31 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.

50.2.2.243 DMA channel *n* transmit descriptor list address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

The Channel *n* Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Figure 1260. DMA channel *n* transmit descriptor list address register (DMA_CH*n*_TXDESC_LIST_ADDRESS)

Table 1352. DMA_CH*n*_TXDESC_LIST_ADDRESS field descriptions

Field	Description
0:28 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the 3 LSB bits for 64-bit data bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

50.2.2.244 DMA channel *n* receive descriptor list address register (DMA_CH*n*_RXDESC_LIST_ADDRESS)

The Channel*n* Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Dword aligned (for 64-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Figure 1262. DMA channel *n* transmit descriptor tail pointer register (DMA_CH*n*_TXDESC_TAIL_POINTER)

Table 1354. DMA_CH*n*_TXDESC_TAIL_POINTER field descriptions

Field	Description
0:28 TDTP	Transmit Descriptor Tail Pointer This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.

50.2.2.246 DMA channel *n* receive descriptor tail pointer (DMA_CH*n*_RXDESC_TAIL_POINTER)

The Channel*n* Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Offset 0x1128 + *n**0x80 (n = 0 to 2) Access: User Read/Write

Figure 1264. DMA channel *n* transmit descriptor ring length register (DMA_CH*n*_TXDESC_RING_LENGTH)

Table 1356. DMA_CH*n*_TXDESC_RING_LENGTH field descriptions

Field	Description
22:31 TDRL	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. A minimum ring descriptor length of 4 is recommended. For example, it can be programmed to any value up to 0x3FF. This field is 10-bit wide, if programmed to 0x3FF, it can have 1024 descriptors. If 10 descriptors are required then program it to a value of 0x9.

50.2.2.248 DMA channel *n* receive descriptor ring length register (DMA_CH*n*_RXDESC_RING_LENGTH)

The Channel*n* Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Offset 0x1130 + *n**0x80 (n = 0 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1266. DMA channel *n* interrupt enable register (DMA_CH*n*_INTERRUPT_ENABLE)

Table 1358. DMA_CH*n*_INTERRUPT_ENABLE field descriptions

Field	Description
16 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 31: Transmit Interrupt – Bit 29: Transmit Buffer Unavailable – Bit 25: Receive Interrupt – Bit 20: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled.
17 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: – Bit 30: Transmit Process Stopped – Bit 24: Rx Buffer Unavailable – Bit 23: Receive Process Stopped – Bit 22: Receive Watchdog Timeout – Bit 21: Early Transmit Interrupt – Bit 19: Fatal Bus Error – Bit 18: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled.
18 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled.
19 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.
20 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.
21 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.
22 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.
23 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.
24 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.
25 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Table 1358. DMA_CH*n*_INTERRUPT_ENABLE field descriptions (continued)

Field	Description
29 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.
30 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.
31 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.

50.2.2.250 DMA channel *n* receive interrupt watchdog timer register (DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER)

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHn_STATUS register.

Offset 0x1138 + *n**0x80 (n = 0 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1267. DMA channel *n* receive interrupt watchdog timer register (DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER)

Table 1359. DMA_CH*n*_RX_INTERRUPT_WATCHDOG_TIMER field descriptions

Field	Description
14:15 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. 00 256 01 512 10 1024 11 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2x512=1024 system clock cycles.
24:31 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[1]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[1] of any received packet.

50.2.2.251 DMA channel *n* slot function control status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset 0x113C + *n**0x80 (n = 0 to 2) Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1268. DMA channel *n* slot function control status register (DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS)

Table 1360. DMA_CH*n*_SLOT_FUNCTION_CONTROL_STATUS field descriptions

Field	Description
12:15 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
16:27 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default/reset value is 0x07C which corresponds to slot interval of 125 us.
30 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is – equal to the reference slot number given in the RSN field or – ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set.
31 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is – equal to the reference slot number or – ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. **Note:** The TSO should not be enabled along with TBS/AVB Slot number check. The TSO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for the software to specify a slot number for subsequent packets.

50.2.2.252 DMA channel *n* current application transmit descriptor register (DMA_CH*n*_CURRENT_APP_TXDESC)

The Channel*n* Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

Offset 0x1144 + *n**0x80 (n = 0 to 2) Access: User Read-only

Figure 1273. DMA channel *n* status register (DMA_CHn_STATUS)

Table 1365. DMA_CHn_STATUS field descriptions

Field	Description
10:12 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 10 1'b1: Error during data transfer by Rx DMA 1'b0: No Error during data transfer by Rx DMA Bit 11 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 12 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
13:15 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface. Bit 13 1'b1: Error during data transfer by Tx DMA 1'b0: No Error during data transfer by Tx DMA Bit 14 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 15 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
16 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 31: Transmit Interrupt Bit 29: Transmit Buffer Unavailable Bit 25: Receive Interrupt Bit 20: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1365. DMA_CHn_STATUS field descriptions (continued)

Field	Description
17 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 30: Transmit Process Stopped Bit 24: Receive Buffer Unavailable Bit 23: Receive Process Stopped Bit 21: Early Transmit Interrupt Bit 19: Fatal Bus Error Bit 18: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
18 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
19 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
20 ERI	Early Receive Interrupt This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
21 ETI	Early Transmit Interrupt This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
22 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2048 bytes (10240 bytes when Jumbo Packet mode is enabled) is received.
23 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table 1365. DMA_CHn_STATUS field descriptions (continued)

Field	Description
24 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
25 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 0 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
29 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 0 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
30 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.
31 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 0 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

50.2.2.257 DMA channel *n* miss frame counter register (DMA_CH*n*_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in DMA_CH*n*_Rx_Control register.

Offset 0x1164 + *n**0x80 (n = 0 to 2) Access: User Read-only

Table 1368. DMA_CHn_RX_ERI_CNT field descriptions

Field	Description
20:31 ECNT	ERI Counter When ERIC bit of DMA_CH(#i)_RX_Control register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter will get reset at the start of new packet.

50.3 Functional description

50.3.1 AHB master interface

The DMA controller interfaces with the application through the AMBA AHB interface. The AHB master interface converts the internal DMA request cycles into AHB cycles. The AHB master interface has the following features:

- The AHB master interface is AMBA 2.0-compliant AHB master with no restrictions.
- The AHB master interface supports the following burst length modes: fixed, unspecified, and mixed. These modes are explained in *Section 50.3.1.1: AHB burst length modes*.
- The AHB master interface can handle the AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response halts all further transactions for that DMA and indicates the error as fatal through CSR and interrupt. The application can choose to give a hard or soft reset to the module to restart the operation.
- The AHB master interface can handle the AHB 1 K boundary breaking.
- The AHB master interface can handle all 64-bit data transfers except for Descriptor Status Write accesses (which may be 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.
- The AHB master interface can align all AHB burst transfers to an address value. For more information, refer to *Section 50.3.1.2: Aligning AHB burst transfers to an address value*.
- The DMA requests an AHB Burst Read transfer only when it can completely accept the received burst data. The data read from the AHB is always pushed into the DMA without any delay or Busy cycles. However, when multiple channels are selected, there may be some delay and busy cycles may be inserted because of the shared-memory architecture for the channels.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to completely transfer the burst. The AHB interface always assumes that it has the data available to push into the AHB bus. However, the DMA can prematurely indicate end-of-valid data (because of the transfer of EOP of an Ethernet packet) during the burst.
- In Fixed Burst Length mode, the AHB master interface continues the burst with dummy data until the specified length is completed. In INCR mode, it ends the burst transfer prematurely.

50.3.1.1 AHB burst length modes

The AHB master interface supports the following burst length modes:

- Fixed Burst Length: In fixed burst length mode, the AHB master always initiates a burst with SINGLE, INCR4, INCR8, or INCR16 type. However, when such a burst is responded with SPLIT, RETRY, or Early Burst Termination (EBT), by default, the AHB master again initiates the pending transfers of the burst with INCR or SINGLE burst length type. When only one beat is remaining, the AHB master performs a SINGLE transfer. If more than one beat is remaining, the AHB master performs an INCR transfer. The AHB master terminates such INCR bursts when remaining beats of the original requested fixed burst are transferred.
  To ensure that the AHB master always performs the INCRx and SINGLE transfers even when a part of the burst is initiated again after a SPLIT, RETRY, or EBT response, use the RIB bit of the register. However, when you enable this mode, the pending burst may further get split into multiple transfers as per the following rules before any new transfer is initiated:
  - If the DMA requests a burst transfer that is not equal to INCR4, INCR8, or INCR16, the AHB application interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4, and three SINGLE transactions.
  - If the burst length is more than 16, the AHB master interface splits it into multiple burst transfers. For example, if the burst length is 32 and the DMA starts a 32-beat transfer, the AHB master splits the burst into two INCR16.
- Unspecified Burst Length: In unspecified burst mode, the AHB master always initiates a transfer with INCR and completes the DMA requested burst in one transfer.
- Mixed Burst Mode: In mixed burst mode, the AHB master always initiates the bursts with fixed-size (INCRx) when the DMA requests transfers of size less than or equal to 16 beats. When the DMA requests bursts of length more than 16, the AHB master initiates such transfers with INCR and completes the request in one transfer.

To ensure that the pending burst of a transfer is rebuilt only with INCRx transfers when an INCRx transfer is interrupted by RETRY, SPLIT, or EBT response, use the RB bit of the DMA_SysBus_Mode register. However, if an INCR burst initiated in this mode is interrupted, the AHB master rebuilds the burst only with INCR transfers.

You can choose the burst modes by programming the FB bit in the DMA_SysBus_Mode register.

Note: The AHB master does not generate the WRAP bursts.

The AHB master does not generate the locked or protected transfers. Therefore, the Ethernet IP does not have the HLOCK or HPROT output signals.

50.3.1.2 Aligning AHB burst transfers to an address value

The AHB master interface can align all AHB burst transfers to an address value. You can enable this by using the AAL bit in the DMA_SysBus_Mode register. If Bit 31 and Bit 19 of DMA_SysBus_Mode register are set to 1, the AHB interface and the DMA ensure that all initiated beats are aligned to the address, completing the packet transfer in the minimum number of required beats.

The AHB interface and the DMA split unaligned address beats for a 64-bit data bus and initiate INCR16 beats only when the seven least-significant bits of the address have a zero value.

50.3.2 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The DMA supports up to 2 Tx and 2 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. You can control the offset by the DSL field of DMA_CH*n*_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The Ethernet IP supports the ring structure for the DMA descriptor. For more information on the descriptor, refer to *Section 50.3: Functional description* describes the descriptor structure and how the DMA accesses the descriptors.

50.3.2.1 Application bus burst access

When configured through Bit 31 of the DMA_SysBus_Mode register, the DMA attempts to execute the fixed-length burst transfers on the AHB master interface. The PBL field of Transmit Control and Receive Control registers of respective DMA channel indicates and limits the maximum burst length. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 $\times$ 8/bus width) burst length for 16 bytes to be read.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL × bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burs.
- EOP (when it is less than the configured burst length) is detected in the Rx Queue.

The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB Interface is configured for fixed-length burst, it transfers the data by using the best combination of INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed-burst ends on the AHB interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise [Bit 31 of DMA_SysBus_Mode register is reset], the DMA transfers the data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AHB is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16) for AHB interface because it does not support more than INCR16.

50.3.2.1.1 Application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 1369. Application data buffer alignment examples

Data buffer	Examples
Buffer Read	If the Tx buffer address is 32’h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32’h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32’h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32’h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

50.3.2.1.2 Buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FS bit of TDES2 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LS bit of TDES2), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FS bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits[17:30] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (FL bits of RDES3[17:31]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

Note: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to have a 0x1002 offset. The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programmed as 1024 bytes, because of the start address offset.

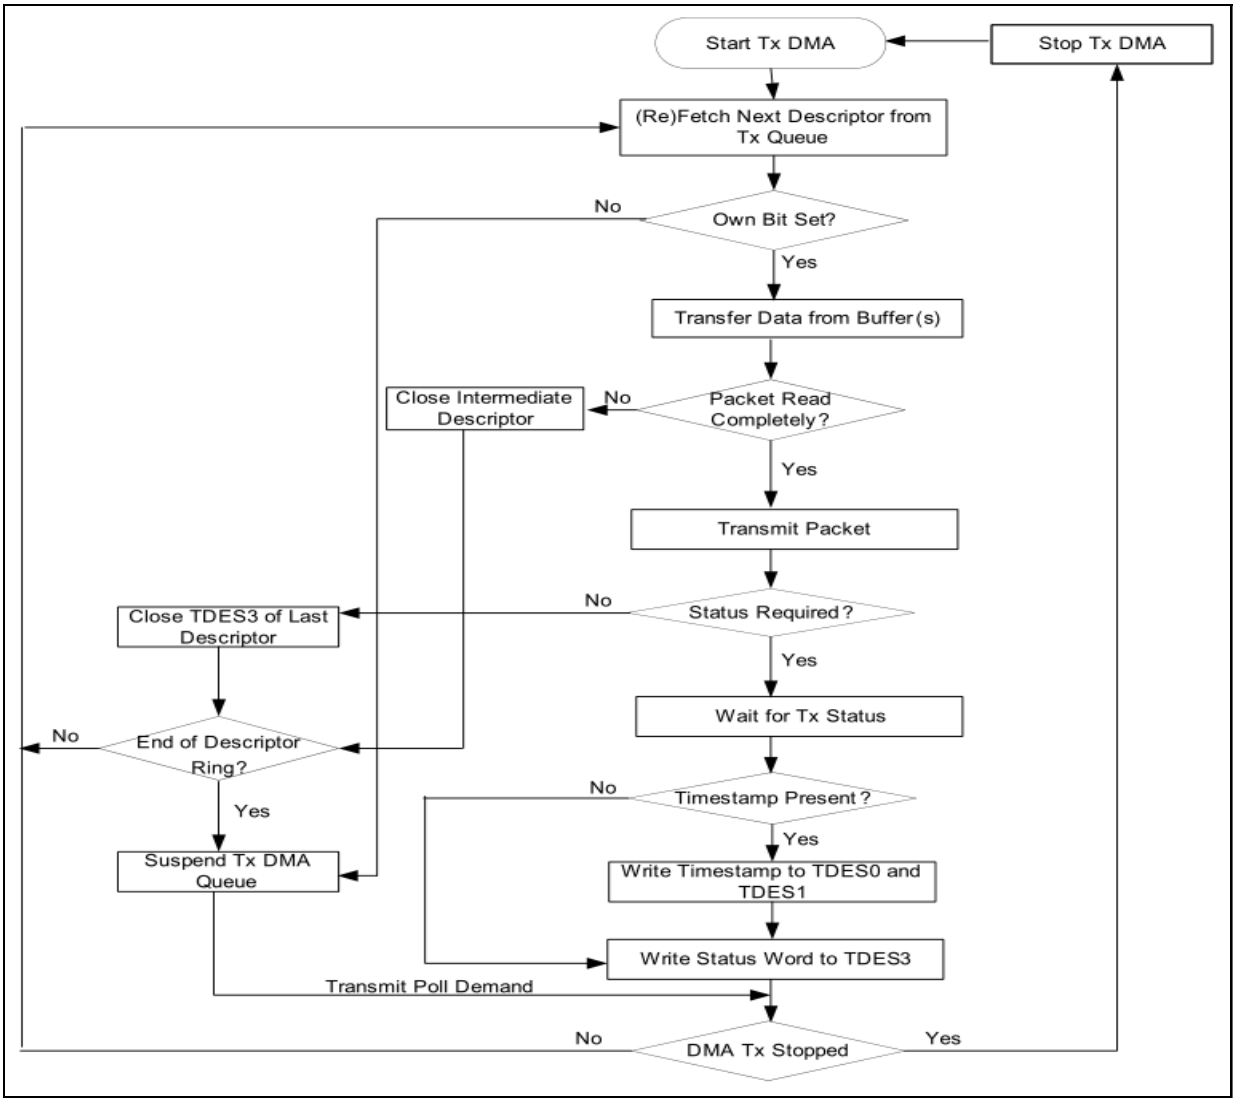
50.3.2.1.3 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface. The following two types of arbitrations are supported:

- Round-Robin Arbitration: When Bit 30 of the DMA_Mode register is reset and both Tx and Rx DMAs are simultaneously requesting for access, the arbiter allocates the data bus in ratio set by Bits[17:19] of DMA_Mode register
- Fixed-Priority Arbitration: When Bit 30 of the DMA_Mode register is set, the Rx DMA always gets priority over the Tx DMA for data access by default. When Bit 20 of DMA_Mode register is also set, the Tx DMA gets priority over the Rx DMA

50.3.2.2 DMA transmission

50.3.2.2.1 TX DMA operation: default (non-OSP) mode



The TX DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[0]) after setting up the corresponding data buffer(s) with Ethernet Packet data
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed

4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and Bit 29 and Bit 15 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to Step *11*:
   a) The descriptor is flagged as owned by the application (TDES3 [0] = 1'b0)
   b) The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   c) An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[0] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Step *3* through Step *7* are repeated until the end-of-Ethernet-packet data is transferred to the MTL
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.
   If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1
10. Bit 31 of Status Register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[0]) set in its Last Descriptor. The DMA engine returns to Step *3*
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to Step *3*). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state

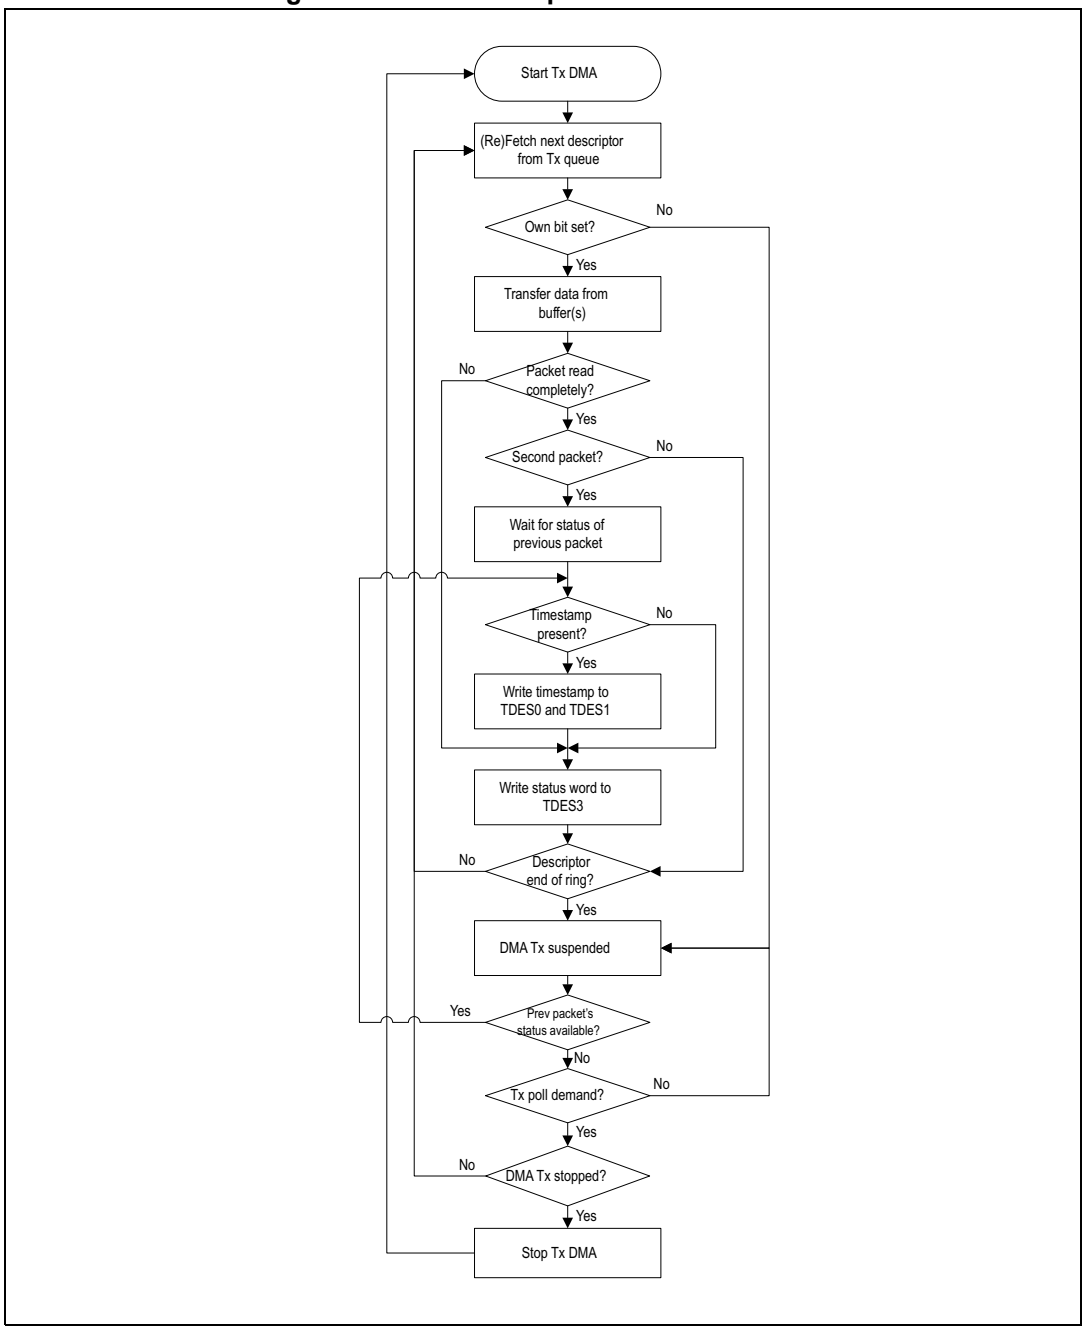
The Tx DMA transmission flow in default mode is shown in *Figure 1277*.

Figure 1277. TX DMA operation in default mode

50.3.2.2.2 TX DMA operation: OSP mode

In the Run state, if Bit 27 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:



1. The DMA operates as described in Step *1* – Step *7* of the Tx DMA (default mode).
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step *7*.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES0 and TDES1.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to Step *3* (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step *7*).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:
   a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1.
   b) Writes the status to the corresponding TDES3.
   c) Sets relevant interrupts and returns to Suspend mode.

   If no status is pending and the application stopped the DMA by clearing Bit 31 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (goes to Step *1* or Step *2* depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

Note: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. It is recommended to have a minimum descriptor length of four.

The basic flow is described in *Figure 1278*.

Figure 1278. Tx DMA operation in OSP mode

50.3.2.2.3 Transmit packet processing

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[2]) and the Last Descriptor (TDES3[3]). As transmission starts, the First Descriptor must have TDES3[2] set. When this occurs, the packet data is

transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[3]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[2] clear. If TDES3[3] is clear, it indicates an intermediary buffer. If TDES3[3] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor Bit set in Transmit Descriptor 3 (TDES3[3]). At this time, if Interrupt on Completion (TDES2[0]) is set, Bit 31 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (Bits[25:27] of Transmit Operation Mode register of corresponding MTL Transmit Queue).
- A full packet is contained in the FIFO.

You can also use the store-and-forward mode (Bit 30 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[0] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[3]) set.

50.3.2.2.4 Transmit polling suspended

Transmit polling can be suspended by any of the following conditions:

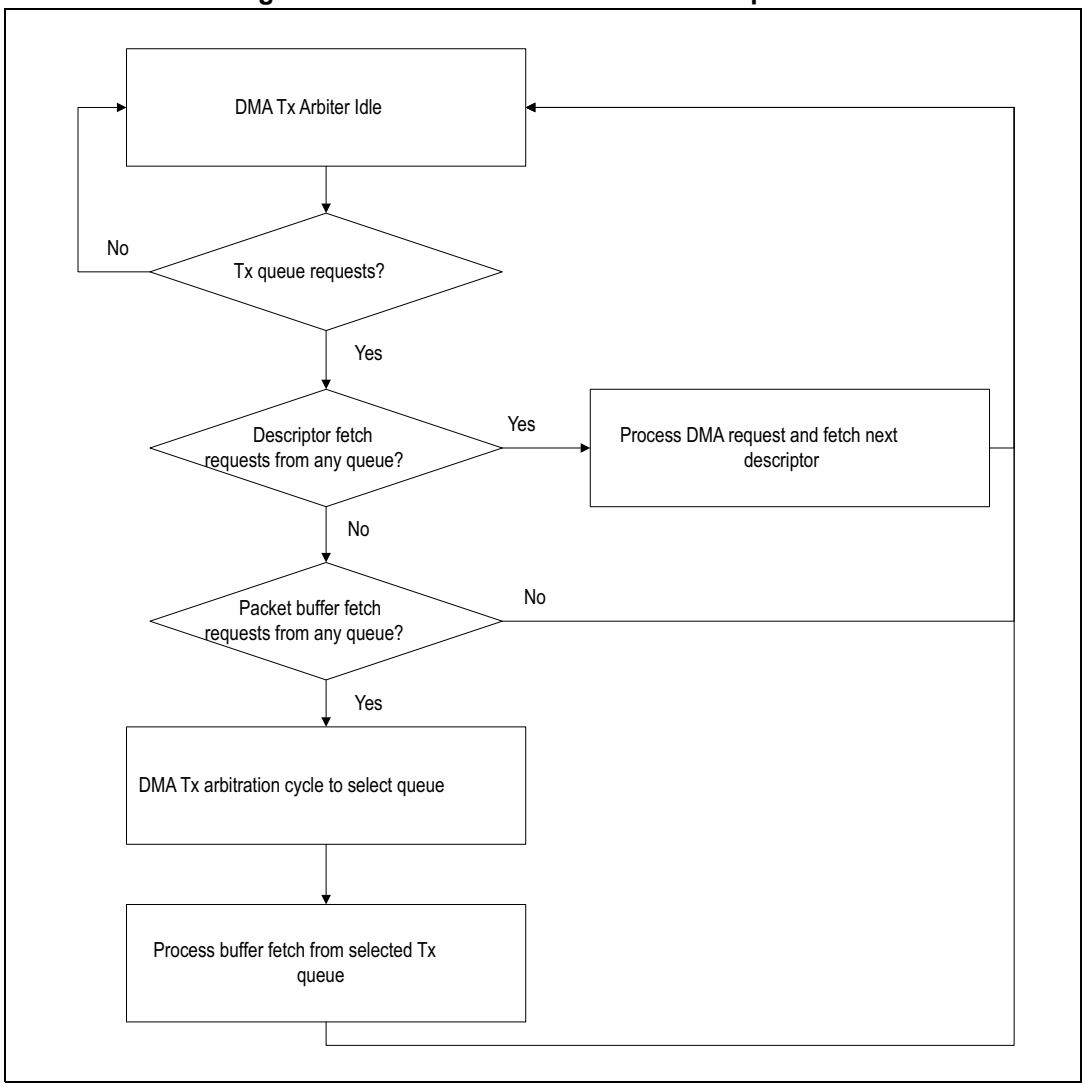
- The DMA detects a descriptor owned by the application (TDES3[0]=0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, Bit 16 and Bit 29 of Status Register of corresponding DMA channel are set.
- A packet transmission is aborted when a Transmit error is detected because of underflow.
  The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 17 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_INTERRUPT_STATUS
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by it.
  To resume, the software driver must modify the Tail Pointer register.

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

50.3.2.2.5 Transmit channel arbitration

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). *Figure 1279* shows the DMA Tx channel arbitration process.

When there is any request in the Tx queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the



DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 1 (or the last enabled channel) and then Channel 0. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to Channel1 (or last enabled channel). If Channel 1 has no frames to transmit, the remaining weight is assigned to Channel 0.
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit.
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the Transmit Control register of a channel is ignored.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

Figure 1279. DMA Tx channel arbitration process

50.3.2.3 DMA reception

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 1280 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[0]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel.
2. When Bit 31 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state.
   The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor

Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to Step *11*.

3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the RDES3[CTXT] field.
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to Step *10*.
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set.
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step *3*; otherwise, go to the Suspend state (Step *11*).
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel.

The engine proceeds to Step *2* and re-fetches the next descriptor.

Figure 1280. RX DMA operation

50.3.2.3.1 Receive descriptor acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 31 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state.
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA.
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed.
- A Receive poll demand is issued (update of the Tail Pointer register).

50.3.2.3.2 Receive packet processing

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless Bit 0 of MAC_Packet_Filter register is set).
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue.
3. When the DMA application Interface (AHB) becomes ready, it transfers the data and sets the following:
   a) If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[3]) and First Descriptor (RDES3[2]).
   b) If the packet fits into more than one descriptor, the DMA sets the First Descriptor (RDES3[2]) to delimit the packet.
4. The DMA releases the descriptors by resetting the Own (RDES3[0]) bit to 0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor.
5. If Interrupt Enabled on Completion (RDES3[1]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and Bit 25 of Interrupt Enable Register of corresponding DMA channel is set, the DMA sets Bit 25 of Status register of corresponding DMA channel.
   The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if Bit 24 of Interrupt Enable Register of corresponding DMA channel is set, the Receive Process sets Bit 24 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained.

50.3.2.4 DMA error response

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to Ethernet IP or re-initialize the DMA descriptor list and start again. The rest of the DMA

channels are not affected by such errors. In AHB the DMA receives the error response through hresp_i signal.

50.3.3 MAC Transaction Layer (MTL)

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The data path for both directions is 64-bit wide.

50.3.3.1 MTL transmit path

The DMA pushes the Ethernet packets read from the application or system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application. The fill level of the queue is indicated to the internal DMA (using PBL and watermark) so that it can initiate a data fetch in required bursts from the application or system memory. The following two modes of operation trigger reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode: In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the Queue.
  - The Tx FIFO becomes almost full.
  - The ATI watermark becomes low.

The watermark becomes low when the requested Queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx Queue size.

The application can flush complete content of the Tx Queue by setting Bit 31 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

50.3.3.1.1 Initialization flow

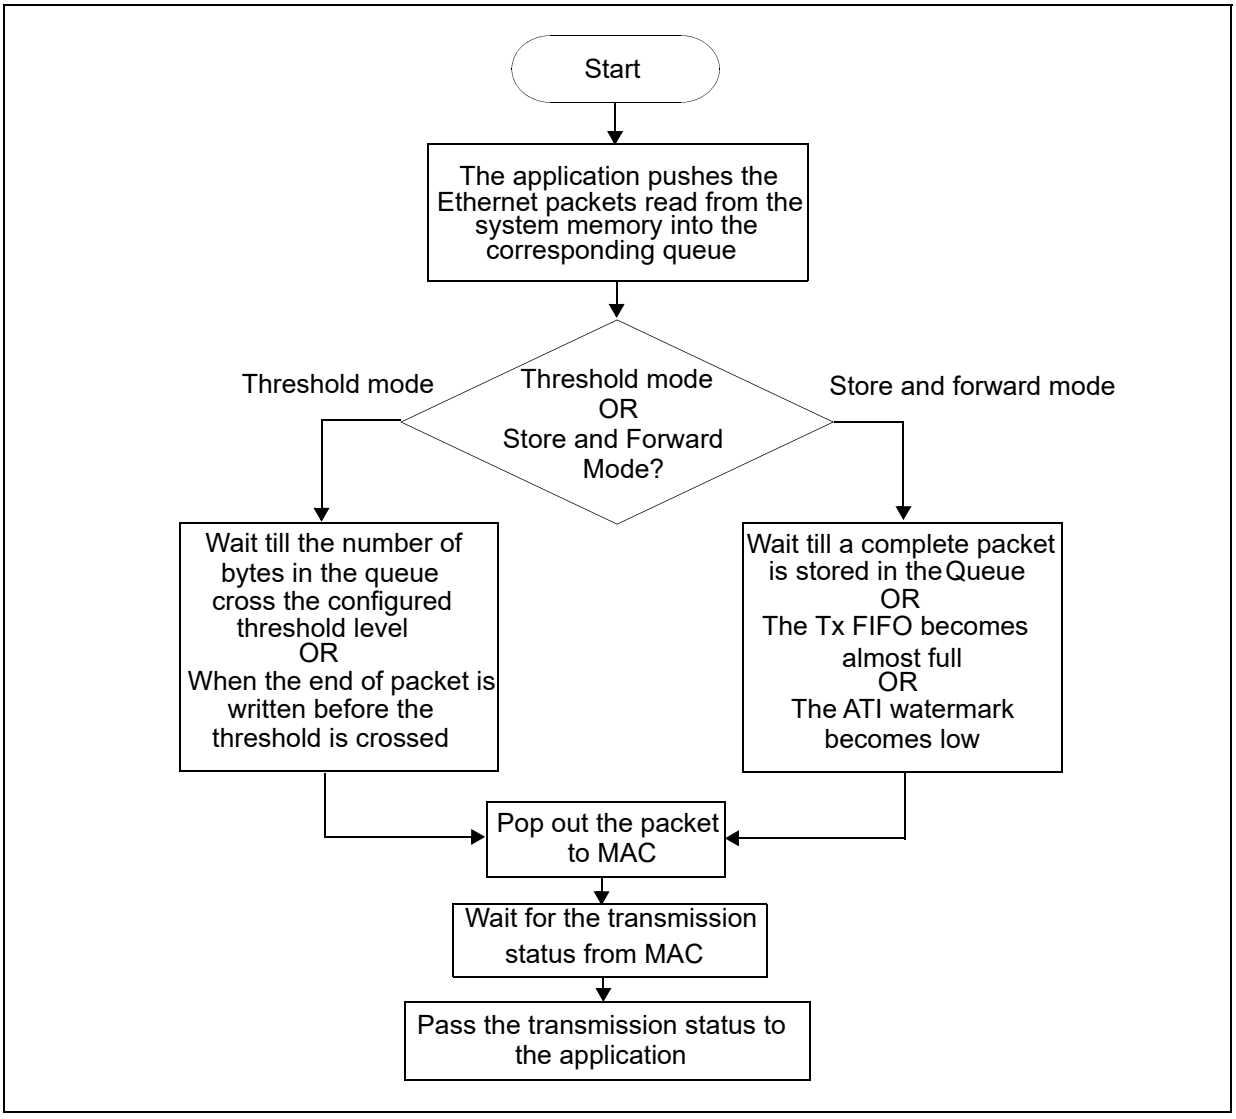
Upon reset, the MTL is ready to manage the flow of data to and from the application or DMA, and MAC.

First you need to initialize the Queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. You also need to initialize the MAC block. The internal DMA controllers must be individually enabled through their respective Cars.

50.3.3.1.2 Data flow between the DMA and the MTL

This section describes the interaction process between the MTL and the DMA.

50.3.3.1.2.1 Single-packet transmit operation



The following flow is valid when the core is operating in non-OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 0.

During a Transmit operation, the MTL block is a slave for the DMA controller. The general sequence of events for a Transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller (if enabled) fetches the data from the application through the AHB master interface and starts forwarding it to the MTL. The DMA descriptor memory contains the information related to packet control which is used to drive the MTL Control Word. The DMA data buffer memory contains the packet data.
2. The MTL pushes the data received from the DMA into the corresponding queue. This process continues until the EOP is transferred.
3. When the threshold level is crossed or a full packet of data is received into the queue, the MTL reads the packet data and drives it to the MAC.
4. The queue controller continues to transfer data from the queue until a complete packet is transferred to the MAC.
5. When the packet transfer is complete, the MTL receives the status from the MAC and notifies the DMA controller.

Figure 1281 illustrates the MTL single-packet transmit operation.

Figure 1281. MTL single packet transmit flow

Note: When Bit 30 (DTXSTS) of Section 50.2.2.178 register is set, the MTL does not provide any status to the DMA.

50.3.3.1.2.2 Transmit operation: two packets in the buffer

The following flow is valid when the core is operating in OSP mode, that is, when bit 27 (OSP) of the DMA_CH*n*_TX_Control register of the DMA channel is set to 1.

The flow is similar to the flow described in Single-Packet Transmit Operation. However after fetching a packet, the DMA instead of waiting for the status, it continues to fetch another packet if available in the system memory. So, MTL can receive the second packet while it is processing the first packet. This flow improves the performance because the DMA can process two packets back to back before waiting for the status of the first packet.

50.3.3.1.2.3 Relationship between the number of TX DMA channels and Tx queues

The number of Tx DMA channels is always equal to the Tx queues. This is because the DMA is designed to arbitrate among multiple channels (to fetch the descriptor and packet data from the system memory) in terms of PBLs (Programmable Bursts Lengths). However, the Tx queues are packet-based storage memory. Therefore, one to one mapping is required between the DMA channels and Tx queues to maintain the packet-level coherency.

50.3.3.1.2.4 Retransmission during collision

While a packet is being transferred from the MTL to the MAC, a collision event can occur on the MAC line interface in half-duplex mode. The MAC indicates a Retry attempt to the MTL by giving the status even before the EOP is transferred from the MTL. The MTL then enables the retransmission by popping out the packet again from the queue.

After more than 96 bytes are read out towards the MAC, the Queue Controller frees up that space and makes it available to the application or the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC indicates a late-collision event.

When a packet transmission is aborted because of underflow and a collision event immediately follows (initiating a retry), retry has higher priority than abort.

Note: Before issuing the Transmit Queue Flush command, make sure that the Tx Queue is not empty, that is, Bit 27 (TXQSTS) of Transmit Debug Register of corresponding queue is reset.

50.3.3.1.2.5 Transmit status word

At the end of transfer of the Ethernet packet to the MAC and after the MAC completes the transmission of the packet, the MTL provides the Transmit status on respective queues. The detailed description of the Transmit Status is the same as for Bits[17:31] of TDES3 normal descriptor in write-back format. If IEEE 1588 Timestamp feature is enabled, the MTL returns 64-bit timestamp of the packet, along with the Transmit status.

If Bit 30 (DTXSTS) of MTL_Operation_Mode register is set then it disables the dependency of the DMA to read the status words from the Status FIFO thus the DMA can push as many packets as possible into the Tx queues because the application or DMA is not required to read the status words from the Status FIFO.

50.3.3.2 MTL Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to the DMA when it crosses the configured Receive threshold (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

50.3.3.2.1 Receive operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. For the 64-bit bus, one additional location is taken.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the below two modes.
7. Threshold mode: In the (default) Threshold mode, the MTL reads the data and indicates its availability to DMA when one of the following happens:
   a) Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue).
   b) A full packet of data is received into the queue.
8. Store-and-forward mode: In the store-and-forward mode (when Bit 26 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 27 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

Note: In Threshold (cut-through) mode, the status words are stored after the packet EOP. In store-and-forward mode, the location for the maximum status words are reserved before writing the SOP and the status is written to reserved locations after writing the EOP.

50.3.3.2.2 Receive operation multi-packet handling

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

50.3.3.2.3 Error handling

If the MTL Rx queue is full before it receives the EOP data from the MAC, the following happens:

1. An overflow is declared.
2. The whole packet (including the status word) is dropped.
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 27 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such

packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[30:31] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. The MTL then starts the transfer of next packet (if available).

50.3.3.2.4 Receive status word format

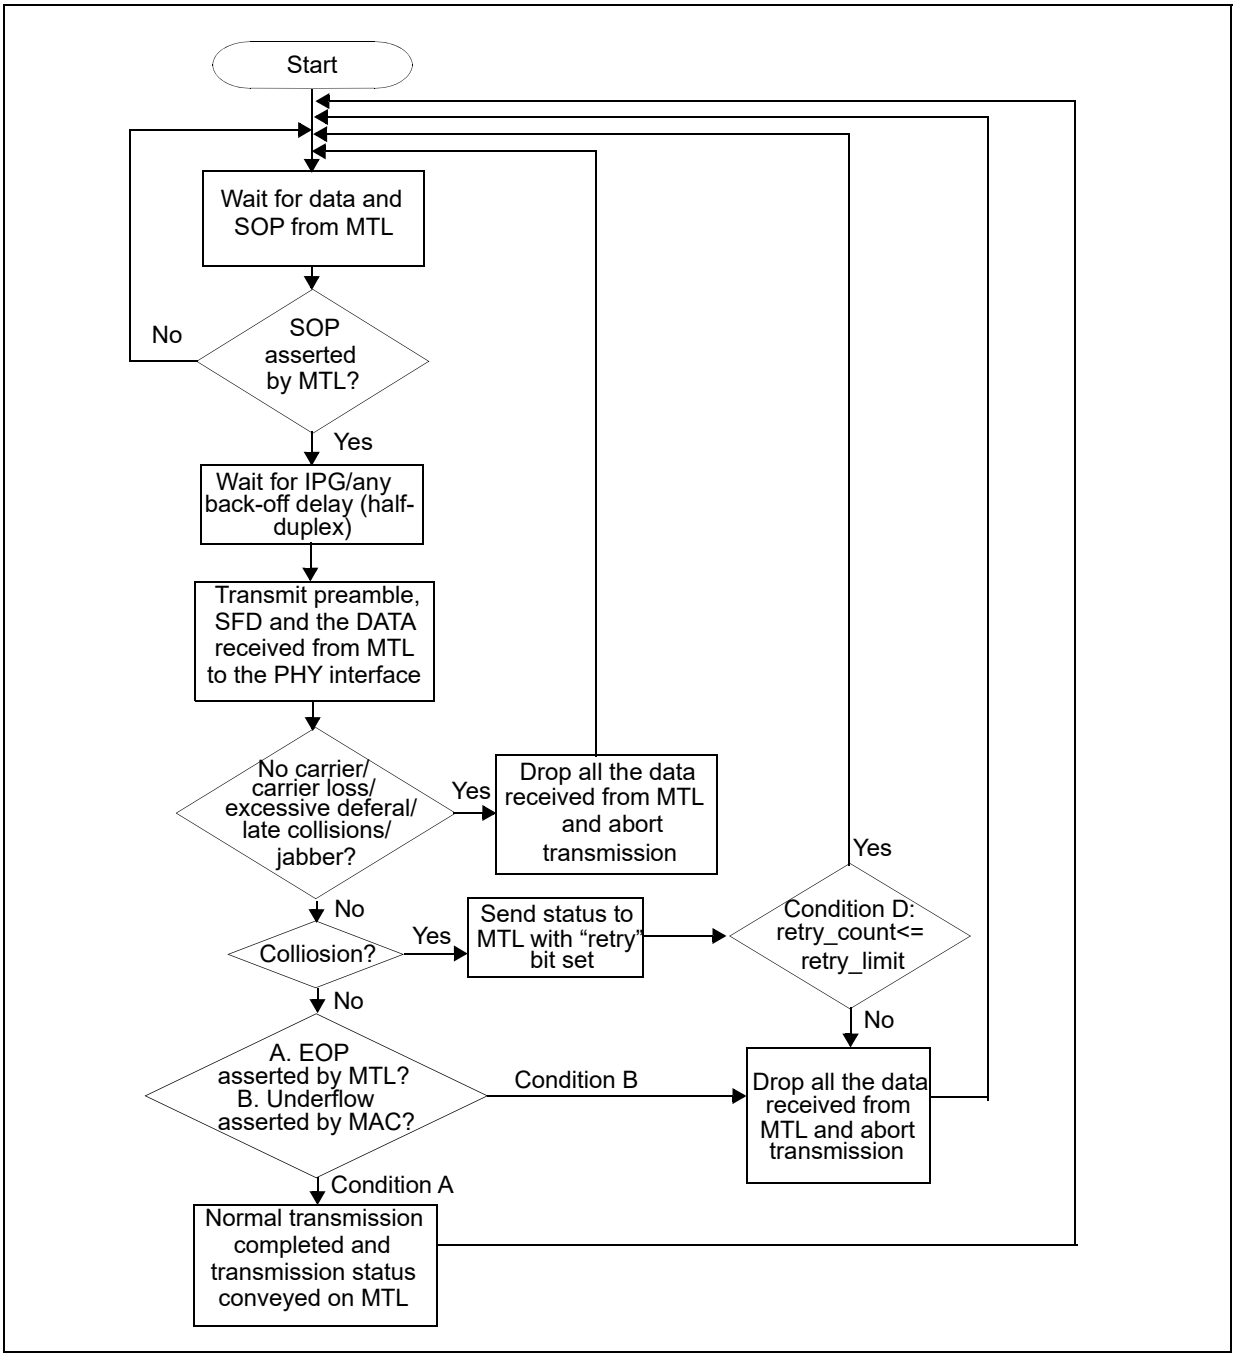
The Rx packet status words are sent to the application after the packet data in Threshold mode and before the packet data in the Store and Forward Mode.

50.3.4 MAC

The MAC supports MII and RMII interfaces towards the PHY chip. The PHY interface can be selected only once after reset.

50.3.4.1 MAC transmission

The transmission process is as follows:



1. Transmission is initiated when the MTL pushes in data with the SOP.
2. When the SOP is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the packet data to the MII after the application initiates the transmission depends on delay factors such as IPG delay, time to transmit preamble or SFD, and any back-off delays for half-duplex mode. While the packets data is being transmitted, the MAC can throttle the MTL.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   a) The MAC completes the normal transmission and gives the transmission status to the MTL.
   b) If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till either the packet is successfully transmitted or maximum retry requests expire.
4. When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.

5. The MAC aborts the packet transmission under the following conditions:
   a) No carrier (half-duplex mode)
   b) Loss of carrier (half-duplex mode)
   c) Excessive deferral (half-duplex mode)
   d) Late collisions (half-duplex mode)
   e) Jabber

   The MAC accepts and drops all further data until the next SOP is received.
6. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
7. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

Figure 1282 illustrates the MAC transmission process flow.

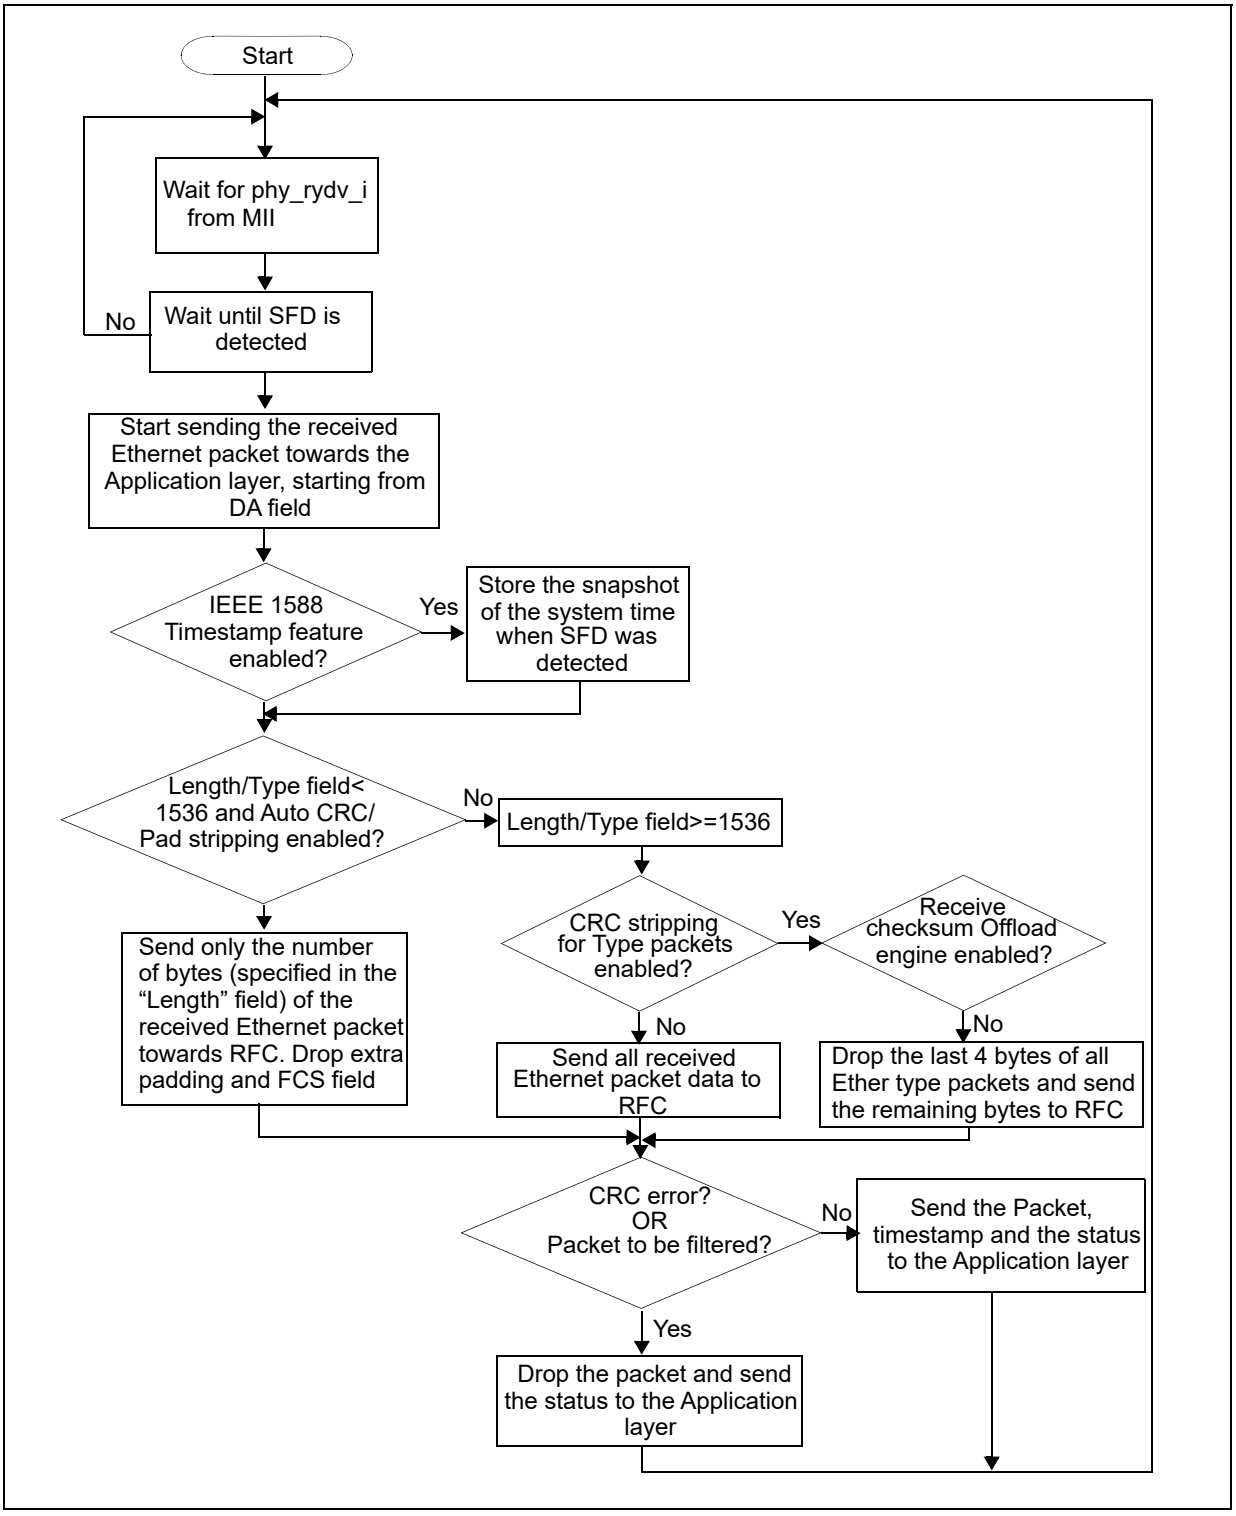


Figure 1282. Overview of MAC transmission process flow

50.3.4.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

Figure 1283. Overview of MAC RX operation

50.3.5 Multiple channels and queues support

The Ethernet module supports multiple queues and channels on Tx and Rx paths. *Figure 1008* shows the architecture of the Ethernet module with multiple queues and channels. This section describes how the Ethernet module supports multiple queues and channels. It contains the following sub-sections:

- DMA with Multiple Channels
- MTL with Multiple Queues

50.3.5.1 DMA with multiple channels

This section describes how multiple queues are supported in the Transmit and Receive DMA paths.

50.3.5.1.1 Multi-channel DMA transmit path

The Ethernet module supports multiple Tx channels with the following priority schemes:

- Fixed Priority Scheme
- Weighted Strict Priority
- Weighted Round Robin

50.3.5.1.1.1 Fixed priority scheme

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. In Fixed Priority Scheme, CH0 has the lowest priority and highest numbered channel has the highest priority.

50.3.5.1.1.2 Weighted strict priority

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. CH0 has lowest priority and the highest numbered channel has highest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

50.3.5.1.1.3 Weighted round robin

In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the DMA_CHn_Tx_Control register provides the weight for each Transmit channel as shown in Weights for DMA Channels.

Table 1370. Weights for DMA channels

TCW field	Transmit channel weight
000	1
001	2

Table 1370. Weights for DMA channels (continued)

TCW field	Transmit channel weight
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

50.3.5.1.2 Multi-channel DMA receive path

The Ethernet module supports multiple Rx channels. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

50.3.5.1.3 Priority scheme for Tx DMA and Rx DMA

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the register. For round-robin arbitration, you can use the PR field of the register to specify the weighted priority between the Tx DMA and Rx DMA. The table below provides information about the priority scheme between Tx DMA and Rx DMA.

Table 1371. Priority scheme for Tx DMA and Rx DMA

Bit 17(1)	Bit 18(1)	Bit 19(1)	Bit 20(1)	Bit 30(1)	Priority scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table 1371. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 17(1)	Bit 18(1)	Bit 19(1)	Bit 20(1)	Bit 30(1)	Priority scheme
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

1. Bits 17, 18, 19, 20 and 30 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

50.3.5.1.4 Rx queue to DMA RX channel mapping

The packets in the MTL Rx Queues can be routed to any one of the 2-RX DMA channels by programming the MTL_RxQ_DMA_Map0 Register. The following types of Rx Queue to DMA mapping is possible through programming:

- Static mapping
- Dynamic (per packet) mapping
- Broadcast/multicast packet duplication

50.3.5.1.4.1 Static mapping

In this mode, all the packets of an Rx Queue is connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[28:31]) and Q0DDMACH (bit[24] = 0) of the MTL_RxQ_DMA_Map0 register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

50.3.5.1.4.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet being read from an Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx

Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: When the Layer 3 and Layer 4 Packet Filter is enabled, the TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If the L3-L4 Registers do not give a comparison match, then the Ethernet module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set.
   The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to 0. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.
   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

Broadcast/multicast packet duplication

Broadcast/multicast packet duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

In a virtual system that supports multiple guest OS's (for instance, each OS owning a DMA), where each DMA could act as an independent Ethernet Node, there can be requirement to route the received multicast/broadcast packets to all/multiple DMA channels. This is implemented by having the MTL_RX_FIFO_read_controller to read the packet from the same queue multiple times and route the same packet to the specified multiple DMA channels.

The DCS field of the of MAC_ADDRESS0_HIGH and other optional MAC_ADDRESSn_HIGH (n = 1 to 31) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register)

must be routed.
The DCS field allows more than one DMA channel number to be selected. The DCS field can hold any one of the following values:

- Binary value of the channel number when the PDC bit of the MAC_Ext_Configuration register is set to 0.

- One-hot value of the channel number when PDC bit of the MAC_Ext_Configuration register is set to 1.

To enable the Multicast/Broadcast packets to be routed to multiple DMA channels, use the DA based routing. Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing. In other words, if the destination DMA channel is decided by the VLAN or L3-L4 filter result, it is routed only to the specific channel even if the DA of the packet matches the multicast address in the MAC_Address register.
The Packet Duplication feature is supported only on the highest MTL Queue. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present.

In a packet duplication, the MTL Read Controller sequentially transfers the same packet to all the required RxDMA. This packet is removed from the MTL FIFO only after the packet is transferred to all the selected DMA channels. Therefore this feature is suitable for smaller packet sizes or very low bandwidth traffic; to ensure that the MTL RxQ does not overflow due to the long period for which the packet remains in the queue during the packet duplication.

Note: When more than one bit is set for the DMA channel number, a packet that is not routed to the highest receive queue is routed to only one DMA channel as indicated by the lowest bit set in the dmach_sel.

50.3.5.1.5 Selection of tag priorities assigned Rx queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The setting in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

50.3.5.1.6 Rx side routing from MAC to queues

The MAC routes the Rx packets to the Rx Queues based on following packet types:

- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged IEEE1588 PTP over Ethernet packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for generic through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the AVPTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled for AV through RXQ*n*EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RXQ_CTRL1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RXQ_CTRL0 register. If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

50.3.5.1.7 Rx side arbitration between DMA and MTL

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

50.3.5.1.8 Tx side arbitration between DMA and MTL

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its

respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX Checksum Engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DM A starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

50.3.5.2 MTL with multiple queues

The Ethernet module supports 2xTx and 2xRx queues. The number of Tx queues is equal to the number of DMA channels. You can control a Tx queue through *Section 50.2.2.209: MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)*. You can control an Rx queue through *Section 50.2.2.215: MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)*.

50.3.5.2.1 Queue memory

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of *Section 50.2.2.209: MTL queue 0 transmit operation mode register (MTL_TXQ0_OPERATION_MODE)* and the Rx queue size in the RQS field of the *Section 50.2.2.215: MTL RX queue 0 receive operation mode register (MTL_RXQ0_OPERATION_MODE)*.

50.3.5.2.2 Queue modes

You can enable a Tx queue for generic, AV, or all types of traffic. Generic Tx queues use WRR or WSP queuing algorithms. AV Tx queue uses CBS or SP queuing algorithms.

You can enable an Rx queue for generic, AV, or all types of traffic. A particular queue enabled for generic or AV based routing is determined by the RXQ*n*EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Generic Rx queues

  All queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. Untagged packets are routed through Queue 0. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.
- Multiple Rx queues with AV feature

  When you select the *Enable Audio Video Bridging* option, AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register.

50.3.5.2.3 AV feature

The Ethernet module supports the AV data transfer in 100 Mbps mode. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

50.3.5.2.3.1 Transmit path functions

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue, as shown in *Figure 1008*. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit.
- If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Fixed Priority Scheme for DMA Channels.

50.3.5.2.3.2 Receive path functions

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in *Section 50.4.4: Receive descriptor*. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets

  The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program Bits[16:23] in the Transmit Flow Control Register of the corresponding queue.

- AV control packets

  The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these packets on any other queue, you can program Bits[29:31] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[25:27] of the MAC_RxQ_Ctrl1 register.

50.3.5.2.3.3 Credit-based shaper algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

Credit value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in Credit Value Per Transmit Cycle Example.

Table 1372. Credit value per transmit cycle example

Mode	Values	Description
100 Mbps	– portTransmitRate = 100 Mbps – idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) – sendSlope = 30 Mbps	– credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. – credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The Ethernet module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 30 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, $2.8 \times 1024 = 2867$ and $1.2 \times 1024 = 1229$. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12000 bits and 3036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000×1024 bits and two's complement of 3036×1024, respectively.

Bandwidth status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[25:27] of the CBS control register of the respective queue. For example, if you have

programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

50.3.5.2.3.4 Slot number function

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals. You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels.

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated every 125 µs of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the second's field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program Bit 31 of the Slot Function Control and Status register of the corresponding DMA channel.

You can enable the check for slot number by setting Bit 31 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, Bits [12:15] indicate the value of the reference slot number in DMA.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

50.3.5.3 Overview of time-based scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. This is an optional feature. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and

avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.

- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

50.3.5.3.1 Description of time-based scheduling

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode.
- Link speed is 100 Mbps or higher.
- Configurations in which time-stamping is enabled.
- EST enabled configurations. In these configurations, the ESTM mode bit setting impacts the time-based scheduling feature only when the DUT processes the GCL list.

Note: Time-based scheduling should not be enabled for the channel for which TSO feature is enabled.

Following are the definitions specific to the time-based scheduling feature:

- Launch Time
- Fetch Time
- Expiry Time

50.3.5.3.1.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time is specified in the Enhanced Normal Descriptor in the DMA configurations. For more details, refer to *Section 50.5.16: Programming the launch time in time-based scheduling*.

The launch time can also be specified as a Control Word for each packet in the MTL configurations.

When the launch time is specified in the DMA configuration, it is valid only for the specific frame that is scheduled for transmission. The launch time is reset after the transmission of one frame.

Following are the two formats of the launch time:

- Normal/Absolute Format
- EST/Offset Format

Normal/absolute format

In this format, the Launch time is an absolute time value at which the packet is launched for transmission. This format is supported in all configurations in which Time-Based Scheduling feature (DWC_EQOS_TBS) is enabled.

When both Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec.
- Launch Time is less than current System Time when its value is between “System Time[39:8] + 128sec” and “System Time[39:8] + 256 sec”, because this is a modulo 256 computation.

EST/Offset format

(BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

This format is enabled only when both Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled. For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled).

If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as,
Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

50.3.5.3.1.2 GCL Slot Number (GSN)

When Time-Based scheduling (DWC_EQOS_TBS) and Enhancements to Scheduled Traffic, EST (DWC_EQOS_AV_EST) features are enabled, a modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

50.3.5.3.1.3 Launch expiry time

In the EST mode of operation, if the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:
Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) where,

CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

Note: Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.

50.3.5.3.1.4 Fetch time

In configurations with DMA, the Fetch Time can also be indicated for each packet by the software. This is done by setting FTOV field of DMA_TBS_CTRL register.

If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

Normal mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as “greater” than System Time if the Fetch Time is in the range of “System Time[39:8]” and “System Time[39:8] + 128 sec”. The frame is considered as not-eligible for fetch.
- The Fetch time is defined as “smaller” than the System Time if the Fetch time is in the range of “System Time[39:8] + 128 sec” and “System Time[39:8] + 256 sec”. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

```
If (Launch Time Offset >= FTOS):
Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)
CBFS(CTR Borrow for Fetch Subtraction) = 0
```

```
If (Launch Time Offset < FTOS)
Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)
CBFS (CTR Borrow for Fetch Subtraction) = 1
```

The Fetch GSN is computed as follows:

```
Fetch GSN = Launch GSN - FGOS - CBFS
Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset
```

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

Note: Max value of FGOS is 7. This implies that when FTOV is set, the frame can be fetched at a maximum of <8 GCL loop iterations before it becomes eligible for Launch.

DMA operations sequence

Following is the sequence of operations when FTOV = 1.

1. Fetch the first Enhanced Normal Descriptor. (FD is set).
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time. Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

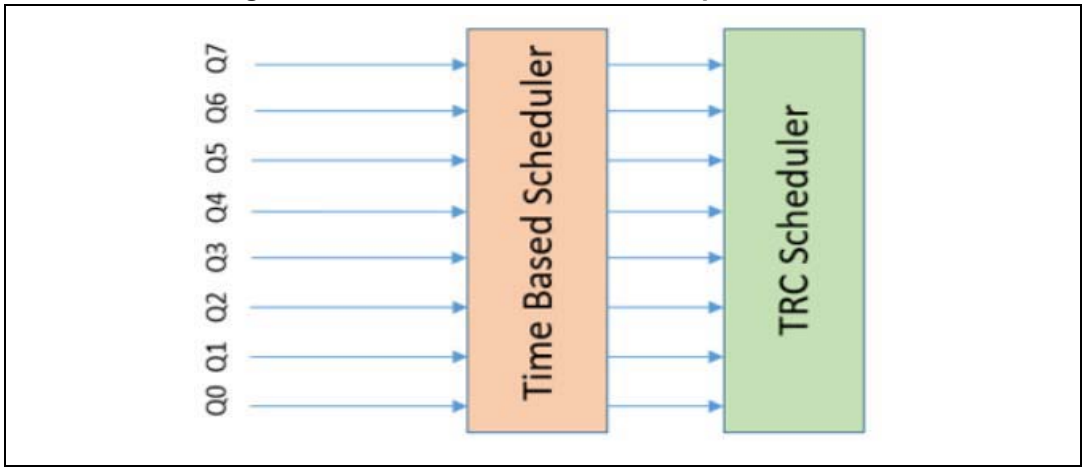
50.3.5.3.2 Control word (MTL configurations)

Time-based scheduling ensures that a Ethernet Frame is allowed to arbitrate for transmission only if the System Time is greater than the Launch Time.

In MTL configuration,

- Launch Time and GSN, use the same field that is used to hold the 64-bit timestamp value for OSTC (One Step Timestamping Correction). If the LTV bit is set and OSTC bit is not set (bit 19 of first control word), the Time Stamp field is interpreted as Launch Time. Launch Time uses the fields meant for OSTC TimeStamp[39:8] and GSN uses OSTC TimeStamp[43:40] field.
- Bit-31 of Control-Word0 is the equivalent of the LTV field, and the last two Control D-Words is used for providing the Launch Time and GST.
- The last two Control D-words is considered to the Time Stamp for OSTC, when bit-19 of Control-Word0 (OSTC) is set.

When the MTL TXFIFO Read Controller reads the first control word, it checks bit-31 to determine if the frame has a valid Launch Time. If bit-31 is set, it reads the subsequent control words to get the Launch Time.



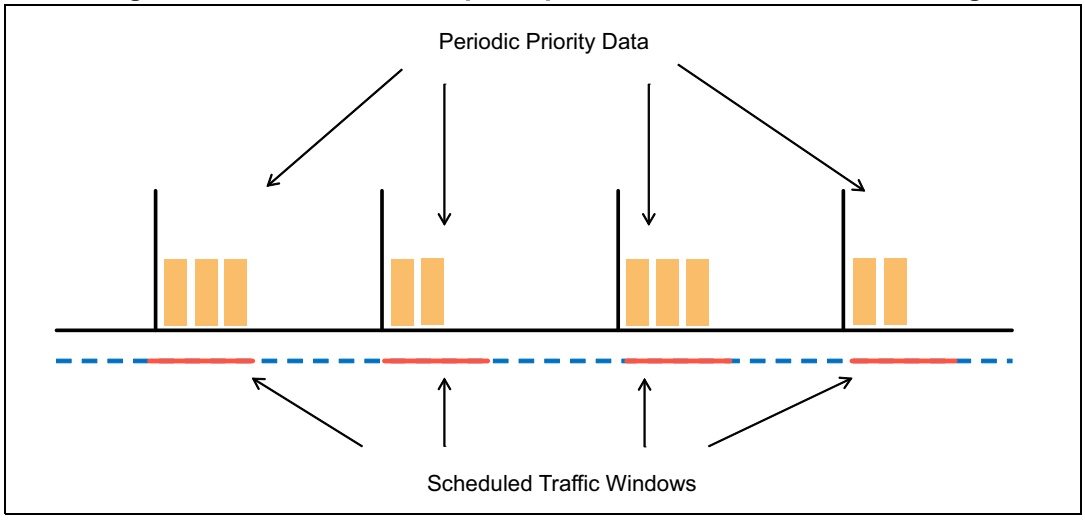
50.3.5.3.3 Impact on transmission selection algorithm

Time-Based Scheduler does not directly influence the Transmission Selection Algorithm but has an indirect influence as it determines if a queue is eligible to participate in the scheduling.

If a frame of a specific queue has a valid Launch Time, the Time Based Scheduler ensures that the frame participates in Transmit Scheduling (TRC Scheduler) only after the Launch time has elapsed.

The gating done by Time-Base scheduler is only for the Scheduling (picking frame for Transmission). It might not alter any other characteristics and behavior of the frame. For example, the Frame waiting for the Launch time to lapse will continue to gain credits in CBS, and the CBS credits will not be lost as the frame is marked as available but not ready. Strict Priority or CBS are recommended Transmit Scheduling algorithms for the TBS implementation because, scheduling for TBS enabled queues are more predictable.

Figure 1284. Time based scheduler implementation



50.3.5.4 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This

ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

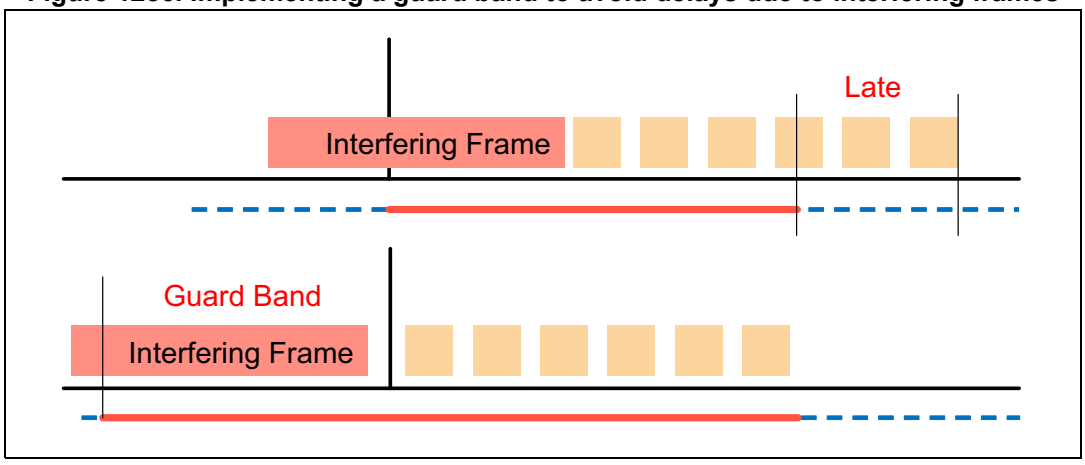


Figure 1285. Time aware shaper implementation for traffic scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in the figure below, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

Figure 1286. Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

50.3.5.4.1 Frequently used terms in EST

Following are some of the frequently used terms in the EST support and their definitions.

- Gate control list

  The list in the hardware memory that holds the gate controls and the associated time intervals.

- Gate controls

  For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the Gate Controls.

  Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.

- Time interval

  Time interval (in nano seconds) is a 16, 20, or 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid.

- Base time register

  Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

50.3.5.4.2 Updates to the Transmit Scheduling to Support EST

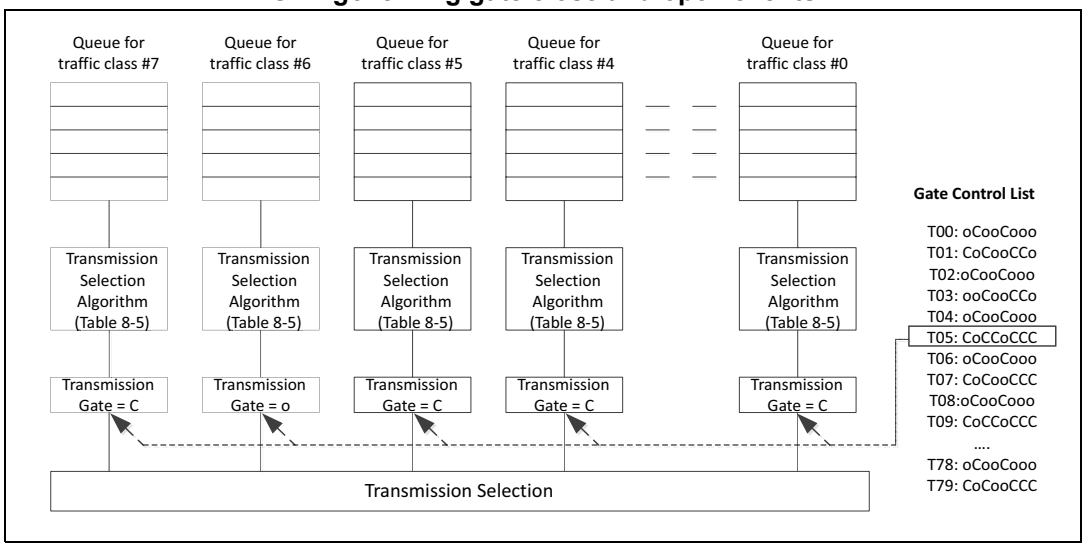
To support EST, the following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

50.3.5.4.2.1 Implementation of Gate Control List (GCL)

The figure below shows the block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event.

GCL has the following two parts:



- Time interval

  Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 16, 20 or 24 to represent a maximum of 64 us, 1 ms, or 16 ms schedule interval respectively. Supports left shift of the time interval up to 7 bits to be able to apply a multiplication factor from 1 to 128 ns (in steps of 2^n). The maximum value (post shifting) of this field must be 999999999 ns.

- Gate control

  Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

Figure 1287. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL
  Hardware Owned List which is a list for hardware access.
- SWOL
  Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. The following table provides the implementation details of GCL.

Table 1373. External memory used for holding the two gate-control lists

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
...	...	
OCOCOCOO		
OOOOCCCC	T last	

Table 1373. External memory used for holding the two gate-control lists (continued)

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
...	...	
OCOCCCCC		
OOCCCCCC	T last	

50.3.5.4.2.2 Registers related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)
2. 40-bit Cycle Time (CTR)
3. m-bit Time Extension (TER)
4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds).

Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register).

For a given Gate Control List the start time is “Base Time” + N $\times$ “Cycle Time” where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This will be useful in avoiding small fragments of the current list being executed before switching to a new list.

List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

50.3.5.4.2.3 Transmission gating implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. Open

   Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.

2. Closed

   Queued frames are not selected for transmission.

   A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

   The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals.

   This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

   The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

   The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

Note: A 20 Byte overhead is added to the packet size to account for the IFG and Preamble overheads on the line. Therefore for a 128 Byte frame to be transmitted, the Gate Open window should at least be able to accommodate148 Bytes.

In 100 Mbps mode of operation, the rounding down error is about 0.4%. For example, the Gate open duration must be at least 1024 Bytes for transmitting 1000 Byte Frames at a speed of 100 Mbps (20 Bytes for line overheads, and 4 Bytes for rounding down error).

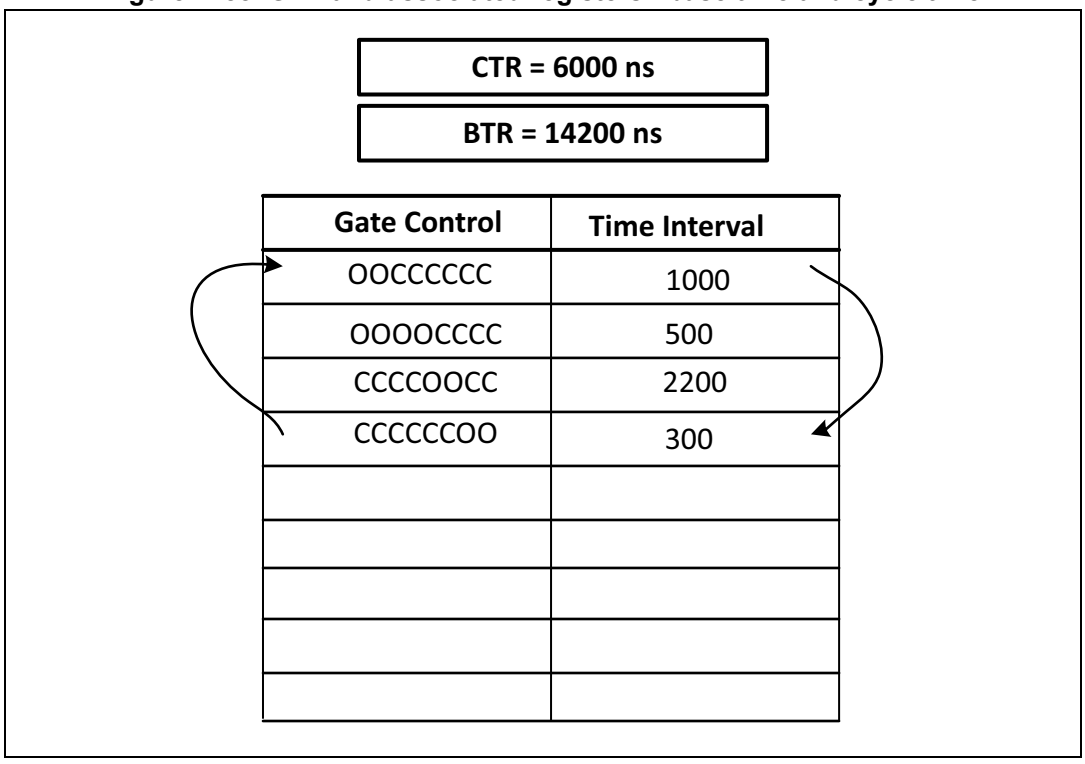
50.3.5.4.3 Idle slope computation updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the

following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

```
idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)
```



50.3.5.4.3.1 Operational details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed “Time Interval” value.

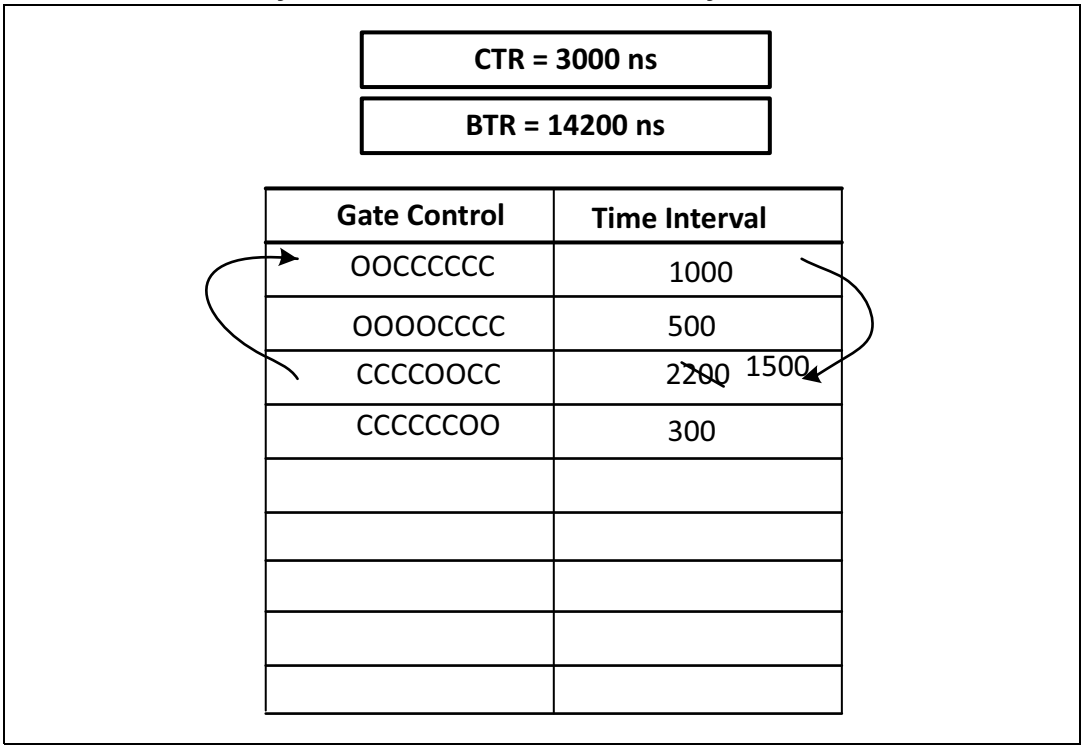
To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

Figure 1288. GCL and associated registers - base time and cycle time

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time.

At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.



In cases where the execution time of the list is greater than the Cycle Time, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 1374. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

In the example in *Table 1374*, the execution starts at 14200 and the first set of Gate Controls “OOCCCCCC” are applied immediately. As the time interval is 1000 ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns as shown in *Table 1373*. As there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in *Table 1374*.

Figure 1289. GCL and associated registers - Base Time and Cycle Time List Execution Time > Cycle Time

As the list execution takes longer than the allocated Cycle Time, the list is truncated and the list is started from the BTR+CTR as shown in the table below.

Table 1375. GCL and associated registers - BTR and CTR, execution Time > Cycle Time

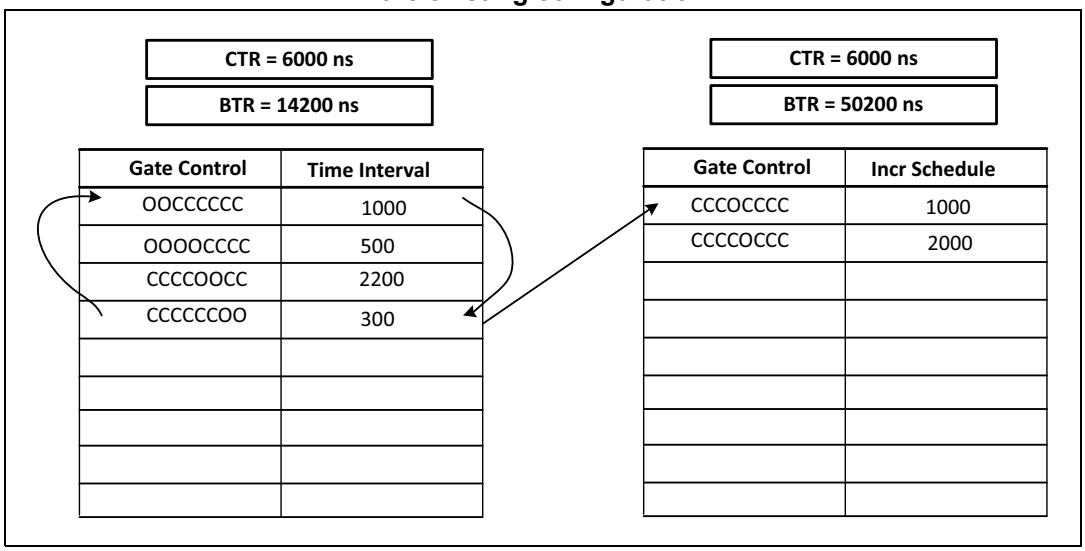
Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

While applying the third set of gate controls, the BTR + Cycle Time (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

50.3.5.4.3.2 Installing a new GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New base time aligned with current schedule
- New base time unaligned with current schedule



New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the Base Time listed in the new list.

```
If (New BaseTime > = Current Time)
  ConfigChangeTime = New BaseTime
Else If (New BaseTime < Current Time)
  1. Set the BTRError
  2. ConfigChangeTime = (New BaseTime + N * New CycleTime)
     Where N is the smallest integer for which the relation
     ConfigChangeTime >= CurrentTime and (N =< 8) is TRUE.
     When N > 8 the hardware cannot auto recover and the loop count
     value in BTRError reporting is set to 1111 requiring the software
     to reprogram the New Base Time.
```

The figure below illustrates the installation of the new GCL along with the timelines.

Figure 1290. Switching to a new configuration that is aligned with the existing configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

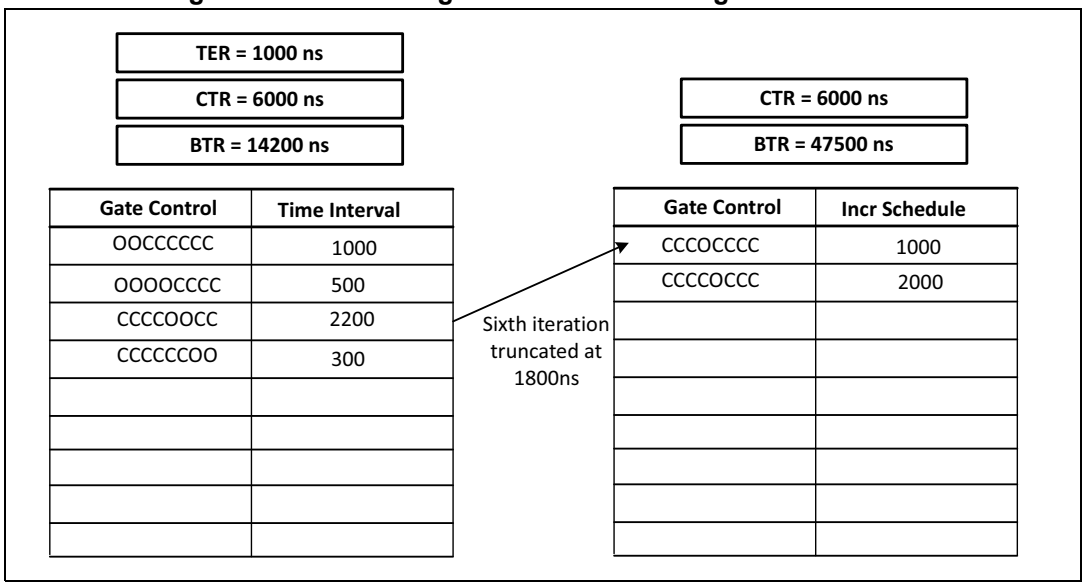


Table 1376. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

New base time unaligned with current schedule

If new Cycle Time differs from current Cycle Time or New Base Time is in the future and is not an integer multiple of current Cycle Time, then the old and new cycles do not line up; when new Base Time is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current configuration list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new Base Time is reached is extended so that it ends at new Base Time.

Figure 1291. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 1377. Extending to new list by truncating the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Below is an example where the current configuration list is extended instead of starting a new iteration as the extension time of 800ns is less than the allowed cycle extension time (TER) of 1000ns.

Figure 1292. Switching to new list by extending the current list

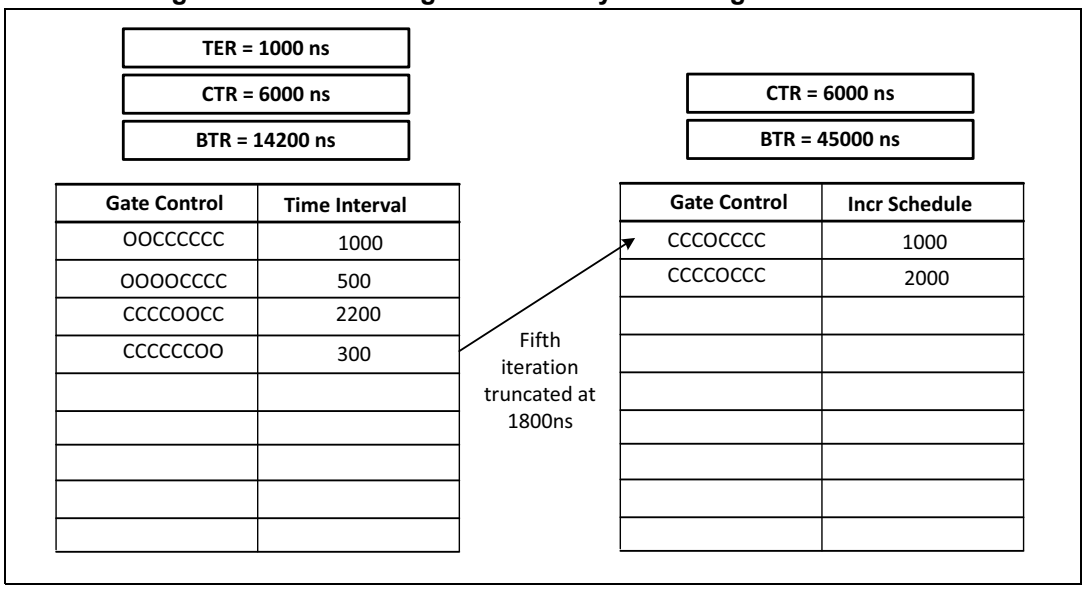

Table 1378. Switching to new list by extending the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

50.3.5.4.4 Impact of transmit scheduling algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are “Open” get priority, these algorithms are modified to treat “gate open” queues and “gate closed” queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously.

50.3.5.4.5 Programming guidelines for EST

For details about programming guidelines for EST, see *Section 50.5.15: Programming guidelines for EST on page 2207*.

50.3.5.5 Frame Preemption (FPE)

50.3.5.5.1 Overview of the Frame Preemption

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

If an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

50.3.5.5.2 Description of the Frame Preemption

You can select the Frame Preemption feature (FPE) feature during RTL configuration of the core. FPE feature can be selected independently with or without selecting the EST feature.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (pre-emptive) frame; the pre-emptive frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A pre-emptive MAC, called pMAC, which carries the pre-emptive traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the pre-emptive traffic, in the presence of express traffic:

- The MTL scheduler interrupts the pre-emptive traffic that is currently being transmitted.

  When the preemption capability is active, the MAC interrupts the transmission and reception of pre-emptive frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The pre-emptive frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met.

  However, interleaving of more than 1 pre-emptive packet is not permitted. This implies that if a pre-emptive packet is fragmented by an express packet, another pre-emptive packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of pre-emptive traffic.

  When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received.

50.3.5.5.3 Enabling the Frame Preemption

Enable the frame pre-emption feature by setting EFPE field of the MAC_FPE_CTRL_STS register.

50.3.5.5.4 GCL modification to support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the table below:

Table 1379. Gate control list when FPE is disabled

Gate control (up to 8 bits)	Time intervals (ns) 16, 20 or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
...	...
OCOCOCOO	T126
OOOOCCCC	T127

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval.

However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation.

To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control.

The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue is ignored and considered as always “Open”. So, even if the software writes a “0” (“C”), it is ignored for such queues.

Table 1380. Gate control list when FPE is enabled

Gate control (up to 7 bits)	Release/hold indication	Time interval (ns) < 16, 20 or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL “ha” ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register).

When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL “ra” ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register).

The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

50.3.5.5.5 Impact of preemption on CBS

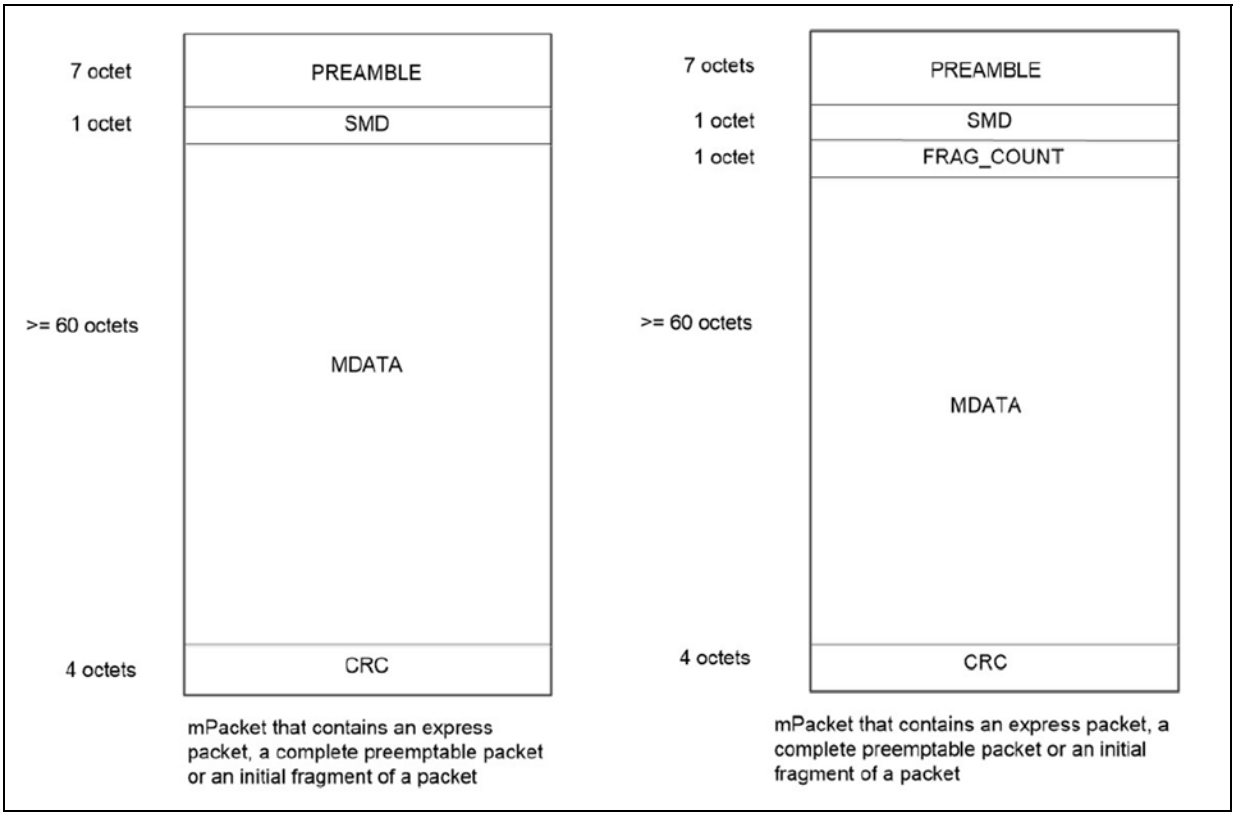
In CBS, the definition of “Transmit” is as follows:

- “True” for the duration of frame transmission from the queue
- “False” when frame transmission from the queue is complete

When CBS algorithm is used along with frame preemption, the value of “Transmit” is “True” only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of “Transmit” is FALSE until transmission of the frame commences or is resumed.

Also, the value of “Transmit” is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is “False”, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.



50.3.5.5.6 mPacket format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. An express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Figure 1293 shows the format of the mPacket. It contains an express packet, a complete preemptable packet or the initial fragment of a preemptable packet. The second part of the figure shows the format of an mPacket containing a continuation fragment of a packet.

Figure 1293. mPacket format

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet.

The table below shows the valid SMD values.

Table 1381. Possible SMD values of mPacket

mPacket type	Notation	Frame count	Value
Verify packet	SMD-V	—	0x07
Respond packet	SMD-R	—	0x19

Table 1381. Possible SMD values of mPacket (continued)

mPacket type	Notation	Frame count	Value
Express packet	SMD-E	—	0xD5
Preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
Continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 1382. Possible frag_count values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC

The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32-bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express packet
  7bytes of Preamble, SMD-E, Data, and CRC.
- Complete preemptable packet
  7 bytes of Preamble, <Current Preemptable packet SMD>, Data, CRC.
- Initial fragment (non-final) of preemptable packet
  7 bytes of Preamble, <Current Preemptable packet SMD>, Data, mCRC.
- Continuation fragments (non-final) of preemptable packet
  6 bytes of Preamble, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC.
- Final fragment of preemptable packet
  6 bytes of Preamble, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC.

SMD-C3	FC3	SMD-C3	FC0

50.3.5.5.7 Transmit preemption

50.3.5.5.7.1 MTL Tx preemption

To support preemption MAC should have more than 1 TX queue with at least 1 Queue designated as Express Queue. (and 1 queue designated as preemption queue). When FPE is enabled (setting EFPE = 1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a “hold” request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met.

Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_FPE_CTRL_STS register. Preemption does not occur until at least 64 $\times$ (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after “release” request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

Note: All the PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF:

- express frame
- preemption frame (full or fragment)
- continuation fragment (non-final or final)

Table 1385. Preemption control values on MTI interface for various frame types

Qualifier	Preemption control value	Frame type
SoF	00	Start express
SoF	01	Start preemption
SoF	10	Continuation fragment
SoF	11	Reserved
EoF	00	End of frame
EoF	01	End of fragment

If the mti_sof_o and mti_eof_o are sent in the same cycle on the MTI interface, the mti_preemp_ctrl (preemption control value) for EoF is taken as “00”, End of Frame.

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx fragment status section below.

50.3.5.5.7.2 MAC Tx preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in *Section 50.3.5.5.6: mPacket format*.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in *Table 1385*) and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

Tx Fragment status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets. To indicate a fragment status, bit-31 of the mti_txstatus_o field is set and all other values in the status field is set to ‘0’.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. The bit-31 of mti_txstatus_o is set to ‘0’ to indicate a Frame Status. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

50.3.5.5.8 Receive preemption

50.3.5.5.8.1 MAC receive preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing

an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket. If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress.
2. The frame count indicated by the SMD matches the frame count of the packet in progress.
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

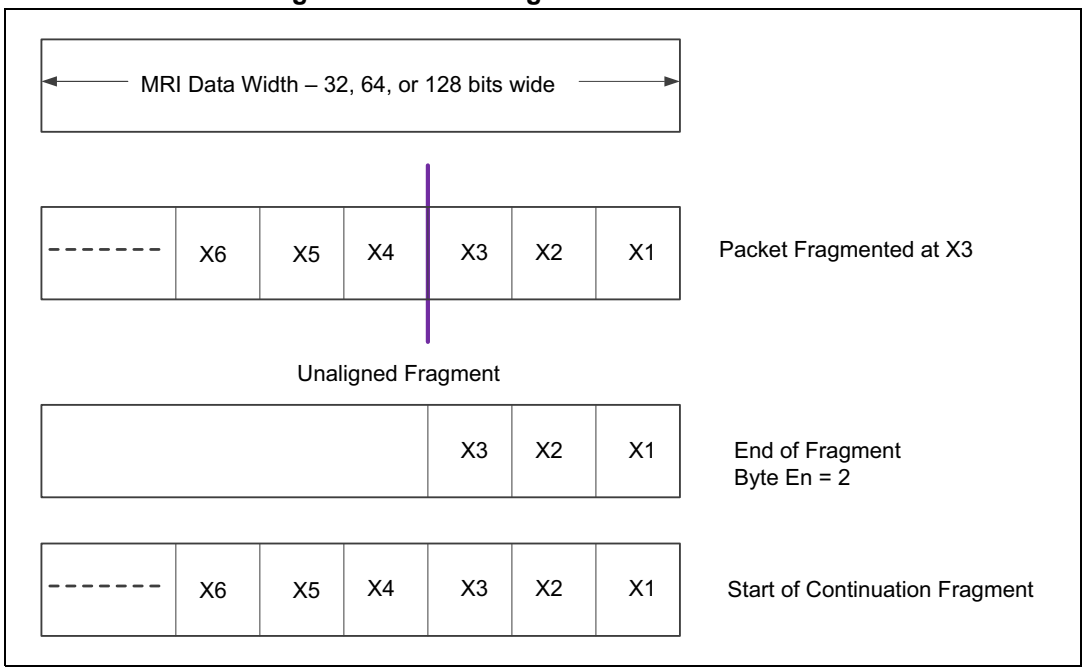
When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields and so on.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a “dummy status” (all zeros in mri_rxstatus_o) for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal on the MRI interface qualified by mri_sof_o and mri_eof_o:

- Express frame
- Preemption frame (full or fragment)
- Continuation fragment (non-final or final)

Table 1386. Preemption control values on MRI interface for various frame types



Qualifier	Preemption control value	Frame type
SoF	00	Start express
SoF	01	Start preemption
SoF	10	Continuation fragment
SoF	11	Reserved
EoF	00	End of frame
EoF	01	End of fragment

If the mri_sof_o and mri_eof_o are sent in the same cycle on the MRI interface, the mri_preemp_ctrl (preemption control value) for EoF is taken as '0' indicating End of Frame.

Data alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the figure below:

Figure 1294. Data alignment feature of MAC

MTL can choose to ignore the partial data (based on Byte Enable value) that comes with End of Fragment and instead use the "data width aligned" data received in the first beat of the next continuation fragment.

MTL receive preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable “Frame Preemption Residue Queue” (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 1387. Preemption control values on MRI Interface for various frame types

Preemption packet type	Queue routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets or when RA = 1	FPRQ

The express frames use Queue 0 as a default queue. So, in case of filter failures, Queue0 must not be used for receiving preemption frames.

When a fragment is received, it is pushed into its destination Rx queue. When this packet is preempted, and is followed by an express packet, it is pushed/stored in a different Rx queue. The MTL saves the context of the preempted frame, and processes one or more express frames. When the continuation fragment arrives, it restores the saved context and pushes the remainder of the fragmented frame into its Rx queue.

MTL receive arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/transfer of data in terms of chunks of “PBL” size of data which is almost similar to the concepts of “fragments”. Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

50.3.5.5.9 Received preemption frames support in offload engines

When Frame Preemption is enabled, all the packets processed by the Offload Engines (ARP, PTO) and PMT, PTP, PAUSE, and PFC packets must be received as express/normal packets. These offload engine logic and functions do not recognize preemption frames.

50.3.5.5.10 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission

of these frames, MAC clears the SVER/SRSP bits and sets the TVER and TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Note: For the preemption frames received with CRC error indication, ignore the following status fields:

- *Packet length*
- *Dribble error indication*
- *Runt frame indication*

Note: When FPE is configured, Forward Undersized Good Packets (FUP) bit of MTL_RxQ_Operation_ Mode register should not be set.

50.3.5.5.11 Frame preemption and MMC counter and interrupt registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature and any one of the existing MMC counters are selected during RTL configuration.

Table 1388. MMC counters and associated interrupt registers

Frame assembly error counter	Description	Associated MMC counter
Frame assembly error counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD error counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame	MMC_Rx_Packet_SMD_Err_Cntr
Frame assembly OK counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx fragment counter	A 32-bit counter that provides the number of additional mPackets received due to preemption	MMC_Rx_FPE_Fragment_Cntr
MAC Tx fragment counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption	MMC_Tx_FPE_Fragment_Cntr
MAC Tx fragment counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC	MMC_Tx_Hold_Req_Cntr

50.3.5.5.12 Additional registers associated with MMC interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

50.3.6 VLAN and double VLAN handling

The Ethernet module supports the double VLAN tagging feature in which the MAC can process up to two VLAN tags (inner and outer). The Ethernet module supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.
- Channel/queue based VLAN tag insertion on all transmitted packets.

50.3.6.1 VLAN processing in transmit path

Table 5-2 Double VLAN Processing Features in Tx Path5-2 describes the double VLAN processing features supported by the MAC on the Transmit side.

Table 1389. Double VLAN processing features in Tx path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_Inner_VLAN_Incl registers. The Ethernet module supports processing of any sequence of outer and inner VLAN tags. **Note:** The Ethernet module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: – The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. – The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. – The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. – The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.

Table 1389. Double VLAN processing features in Tx path (continued)

Feature	Description
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_INCL or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields.
- Insert or replace the VLAN Type and VLAN Tag fields. Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_INCL register as described in *Table 1390*.

Table 1390. VLAN insertion or replacement based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_INCL register) – VLAN Tag field with the Content of the VT field of Transmit context descriptor of the packet.
VLTI bit is reset	The MAC inserts or replaces the following: – VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_INCL register) – VLAN Tag field with the VLT field of MAC_VLAN_INCL register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets. To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_INCL register.
- Enabling VLAN insertion, replacement, or deletion for selective packets. To enable this feature for selective packets, Program the VTIR field of TDES2 Normal Descriptor.

50.3.6.2 VLAN processing in receive path

Table 1391 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 1391. Double VLAN processing in Rx path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

50.3.6.3 Queue/channel based VLAN tag insertion on Tx

Ethernet module supports channel/queue based VLAN tag insertion on all transmitted packets.

Queue/Channel specific VLAN tag registers are accessed using indirect addressing via the MAC_VLAN_INCL register. VLAN type and tag value can be independently programmed for each queue/channel.

When the CBTI field is set in the MAC_VLAN_INCL register, the VLAN tag is inserted on every packet that is transmitted from a queue/channel, with the programmed tag value taken from queue/channel specific VLAN tag register.

Refer to *Section 50.5.14: Programming sequence for queue/channel based VLAN inclusion register*.

50.3.7 Source address insertion, replacement, or deletion

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field.
- Replace the content of the SA field with the content of the MAC Address Registers.

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- To enable this feature for all packets, program the SARC field of the MAC_Configuration register.
- To enable this feature for selective packets, use the following method:
  Program the SA Insertion Control field (Bits[6:8] of TDES3 Normal Descriptor (Read Format)) in the first Transmit descriptor of the packet. When Bit 6 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 6 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.
- If both MAC_Configuration Register and TDES3 are programmed for SA insertion, then setting of MAC_Configuration register takes precedence.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

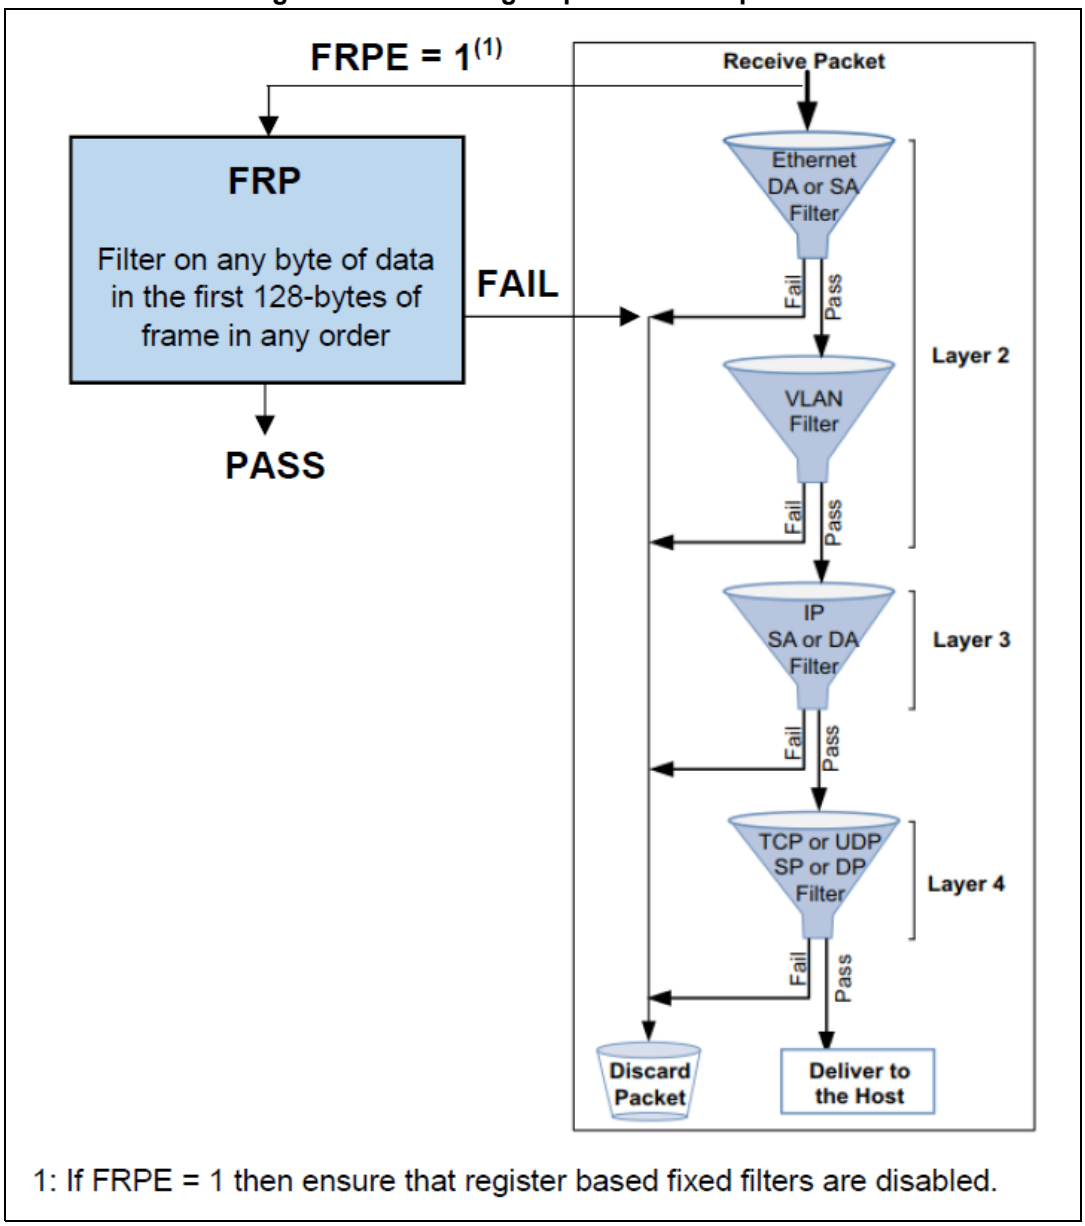
50.3.8 Packet filtering

The Ethernet module supports two types of RX filtering.

1. Fixed Filters
2. Flexible Receive Parsing based filtering (see *Section 50.3.8.6*)

Figure 1295 shows the filtering sequence for Rx packets.

The fixed filters sequence shown is valid when all the filters (L2, VLAN, L3, and L4) are active. If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters is discarded. However, the discarded packet can be forwarded to the host based on the register control. For example, when Bit RA of MAC_Packet_Filter register is set to 1, all discarded packets are forwarded to the host but with its packet status indicating the specific filter-failure. If RA=0, Bits VTFE and IPFE of MAC_Packet_Filter register controls if the packets that fail the VLAN filter and Layer 3-4 filter should be discarded or forwarded to the host.



When FRP feature is enabled then we have the option to have a programmable lookup table based flexible Parser for filtering and steering the Rx packets. All incoming packets are parsed as per the programmable instructions in the memory. We get more flexibility with FRP:

- Do partial/group DA/SA match (bit mask instead of byte mask).
- Do partial/group VLAN match (Only perfect match in register filter).
- Can link DA/SA filter with VLAN filter, that is if DA1 match, then check VLAN1 else if DA2 match, then check VLAN2, and so on); Register based filter does not give that flexibility (sequential links).

FRP is completely flexible and can do any of the register filter functions. Only difference is that, it can check for patterns sequentially (1 field at a time) unlike register filtering which can compare in parallel and at line rate.

When Flexible Receive Parser (FRPE bit in MTL_Operation_mode register) is enabled, all the MAC packet filtering features should not be enabled.

Figure 1295. Filtering sequence for Rx packets

50.3.8.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

50.3.8.1.1 Unicast destination address filtering

The MAC supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC of MAC_Packet_Filter register bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects Bit 63 of selected register, and a value of 11111 selects Bit 0 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

50.3.8.1.2 Multicast destination address filtering

To program the MAC to pass all multicast packets, set the PM bit in *Section 50.2.2.3: MAC packet filter register (MAC_PACKET_FILTER)*. If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the MAC_Packet_Filter register.

In Perfect filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bit CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 63 of selected register and a value of 111111 selects Bit 0 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

50.3.8.1.3 Hash or perfect address filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in *Section 50.2.2.3: MAC packet filter register (MAC_PACKET_FILTER)*. This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

50.3.8.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

50.3.8.1.5 Unicast source address filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 1 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

50.3.8.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 1392 and *Table 1393* summarize the DA and SA filtering based on the type of packets received.

Table 1392. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 1393. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

50.3.8.2 VLAN filtering

The Ethernet module supports the following types of VLAN filtering:

- VLAN Tag Perfect Filtering
- VLAN Tag Hash Filtering

50.3.8.2.1 VLAN tag perfect filtering

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. The VLAN packet status bit (Bit 21 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results.

50.3.8.2.2 VLAN tag hash filtering

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered

as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 1394 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of the MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in the MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail. In *Table 1394*, value *X* means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 1394. VLAN match status(1)

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

1. In this table, X represents any value.

Note: The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_Tag register. When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.

50.3.8.3 VLAN filter fail packets queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 and the enable bit (VFFQE) for the queue is set.

1. RA and VTFE bits are implemented in the MAC_Packet_Filter register.
2. VFFQ and VFFQE fields are implemented in the MAC_RxQ_Ctrl4 register.

The packets that pass the VLAN filtering are routed based on the VLAN TAG priority field. The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in

the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA = 0 or VTFE = 1. However when RA = 1 or VTFE = 0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE = 0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

The below table shows the Rx Queue routing table for Unicast tagged packets, with SA Filter enabled.

Table 1395. Rx queue routing table for unicast tagged packets

RA	VFTE	SA/DA filter results	VLAN filter result	VFFQE	Queue routing
X(1)	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ(2)/PSRQ
1	X	FAIL	X	1	UFFQ(2)/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

1. X: Don’t care condition.
2. When UFFQE is enabled else PSRQ.

50.3.8.4 Extended receive VLAN filtering and routing

The MAC Receiver can classify the received packets based on VLAN Tag and steer them to a specific Rx DMA channel. The MAC compares the received frame's VLAN Tag with all the enabled and relevant filters and provides a filtering result. If any of the perfect filters give a pass result and if the respective filter's DMA channel number is enabled, the frame is routed to that DMA channel.

In addition to filtering, routing can also be done. For more details about routing, refer to “Extended VLAN based DMA selection” in *Section 50.3.5.1.4.2: Dynamic (per packet) mapping*.

50.3.8.4.1 Comparison modes

For each VLAN Tag Filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only.

For example, if a filter is enabled for 16-bit comparison, SVLAN Type, and Outer VLAN Tag, any single or double VLAN Tagged frames with Outer SVLAN Tags are compared with this filter, and a pass or fail result is obtained.

Note: The inner VLAN Tag comparison is applicable only if Double VLAN Tag processing is enabled through the MAC VLAN Control Register bit.

50.3.8.4.2 Filtering

When Extended RX VLAN Filtering and Routing feature is enabled, the application can enable both Perfect and Hash Filtering. The overall VLAN Filter Result is based on the perfect filter result and the Hash Filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

50.3.8.4.3 Filter status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions in various configurations. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15: Outer VLAN Tag Filter Status
- Bit 14: Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15: Outer VLAN Tag Filter Status
- Bit 14: Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47: Outer VLAN Tag Filter Status
- Bit 46: Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the framefs Outer VLAN tag has matched one of the VLAN tag filters.
- If this bit is reset, it indicates that the framefs Outer VLAN tag has either failed the relevant Outer VLAN tag filters or bypassed them.
- If none of the filters are enabled for Outer VLAN tag comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the framefs VLAN tag has passed all the relevant VLAN tag filters. If it is reset, then it has failed at least one of or bypassed all the filters programmed for Outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the framefs Inner VLAN tag has matched one of the VLAN tag filters.
- If this bit is reset, it indicates that the framefs Inner VLAN tag has either failed the relevant Inner VLAN tag filters or bypassed them.
- If none of the filters are enabled for Inner VLAN tag comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the framefs VLAN Tag has passed all the relevant VLAN tag filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN tag comparison.
- This bit is valid for only Double VLAN tagged frames, when double VLAN processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Table 1396 and *Table 1397* show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Caption for the table:

- VTIM: VLAN Tag Inverse Match Enable. Bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison. bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison. Bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO: Perfect Filter comparison enabled for Outer VLAN Tag. Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI: Perfect Filter comparison enabled for Inner VLAN Tag. Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS: Outer VLAN Tag Filter Status.
- ITS: Inner VLAN Tag Filter Status.

Table 1396 shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 1396. OTS and ITS bit values with at least one perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 1397 shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 1397. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of *Table 1396* indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame does not pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of *Table 1396* indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

50.3.8.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.
- If the application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if Stripping is enabled for any of the tags, the tag can be put in the status. For this the application will have to enable the respective “VLAN Tag in Status” bit - 24 or 31 in the MAC VLAN Tag Control Register.

50.3.8.4.5 Programming guidelines for extended VLAN filtering and routing on receive

Refer to *Section 50.5.13: Programming guidelines for extended VLAN filtering and routing on Receive*.

50.3.8.5 Layer 3 and Layer 4 filtering

The Ethernet module supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the MAC_Configuration register to enable the Rx Checksum Offload Engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match.
  - At least one of the enabled field matches and other fields are bypassed or disabled.
- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets. The aborted or partial packets can be dropped in the MTL Rx FIFO. If the Rx FIFO operates in the Threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Note: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

50.3.8.5.1 Layer 3 and Layer 4 filters register set

The MAC implements a set of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as MAC_L3_L4_Control0, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address0
- MAC_Layer3_Address0_Reg0
- MAC_Layer3_Address1_Reg0
- MAC_Layer3_Address2_Reg0
- MAC_Layer3_Address3_Reg0

50.3.8.5.2 Layer 3 filtering

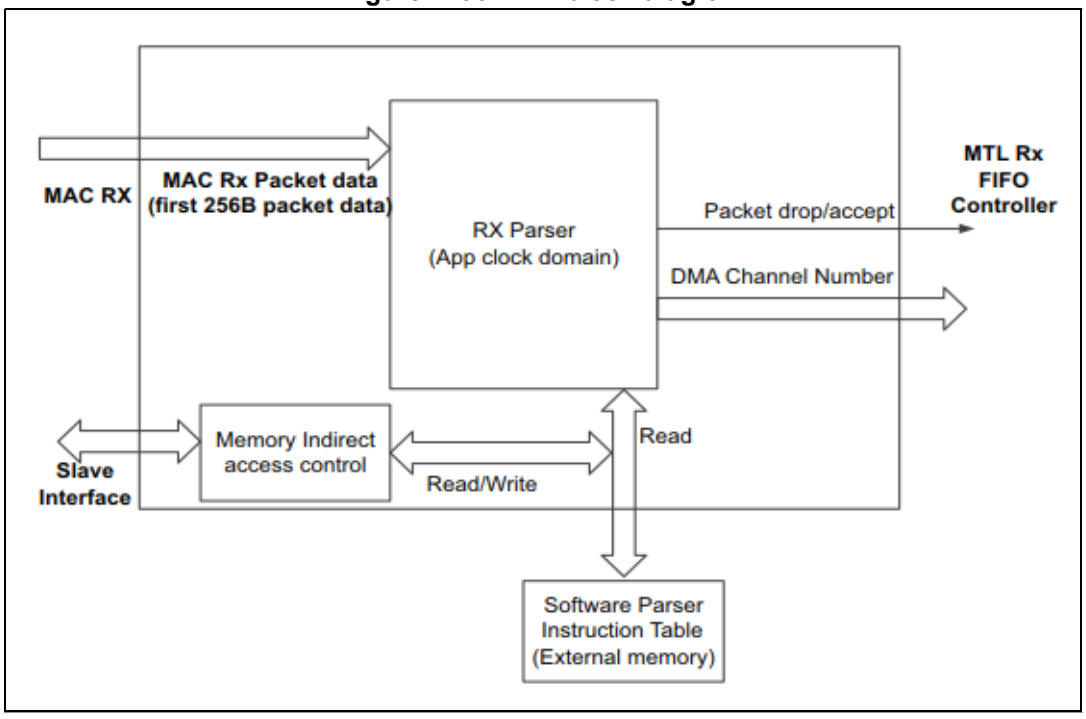
The Ethernet module supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

50.3.8.5.3 Layer 4 filtering

The Ethernet module supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.



The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

50.3.8.6 Flexible Receive Parser (FRP)

50.3.8.6.1 Overview of FRP

On enabling FRP, all incoming packets are parsed as per the programmable instructions in the memory. The Flexible Receive Parser operates over the first 128 bytes of the packet. The parser supports a maximum of 256 programmable instructions. The parser operates after the MAC receiver and before the MTL receiver FIFO controller. *Figure 1296* shows the functional block diagram of Flexible Receive Parser.

Figure 1296. FRP block diagram

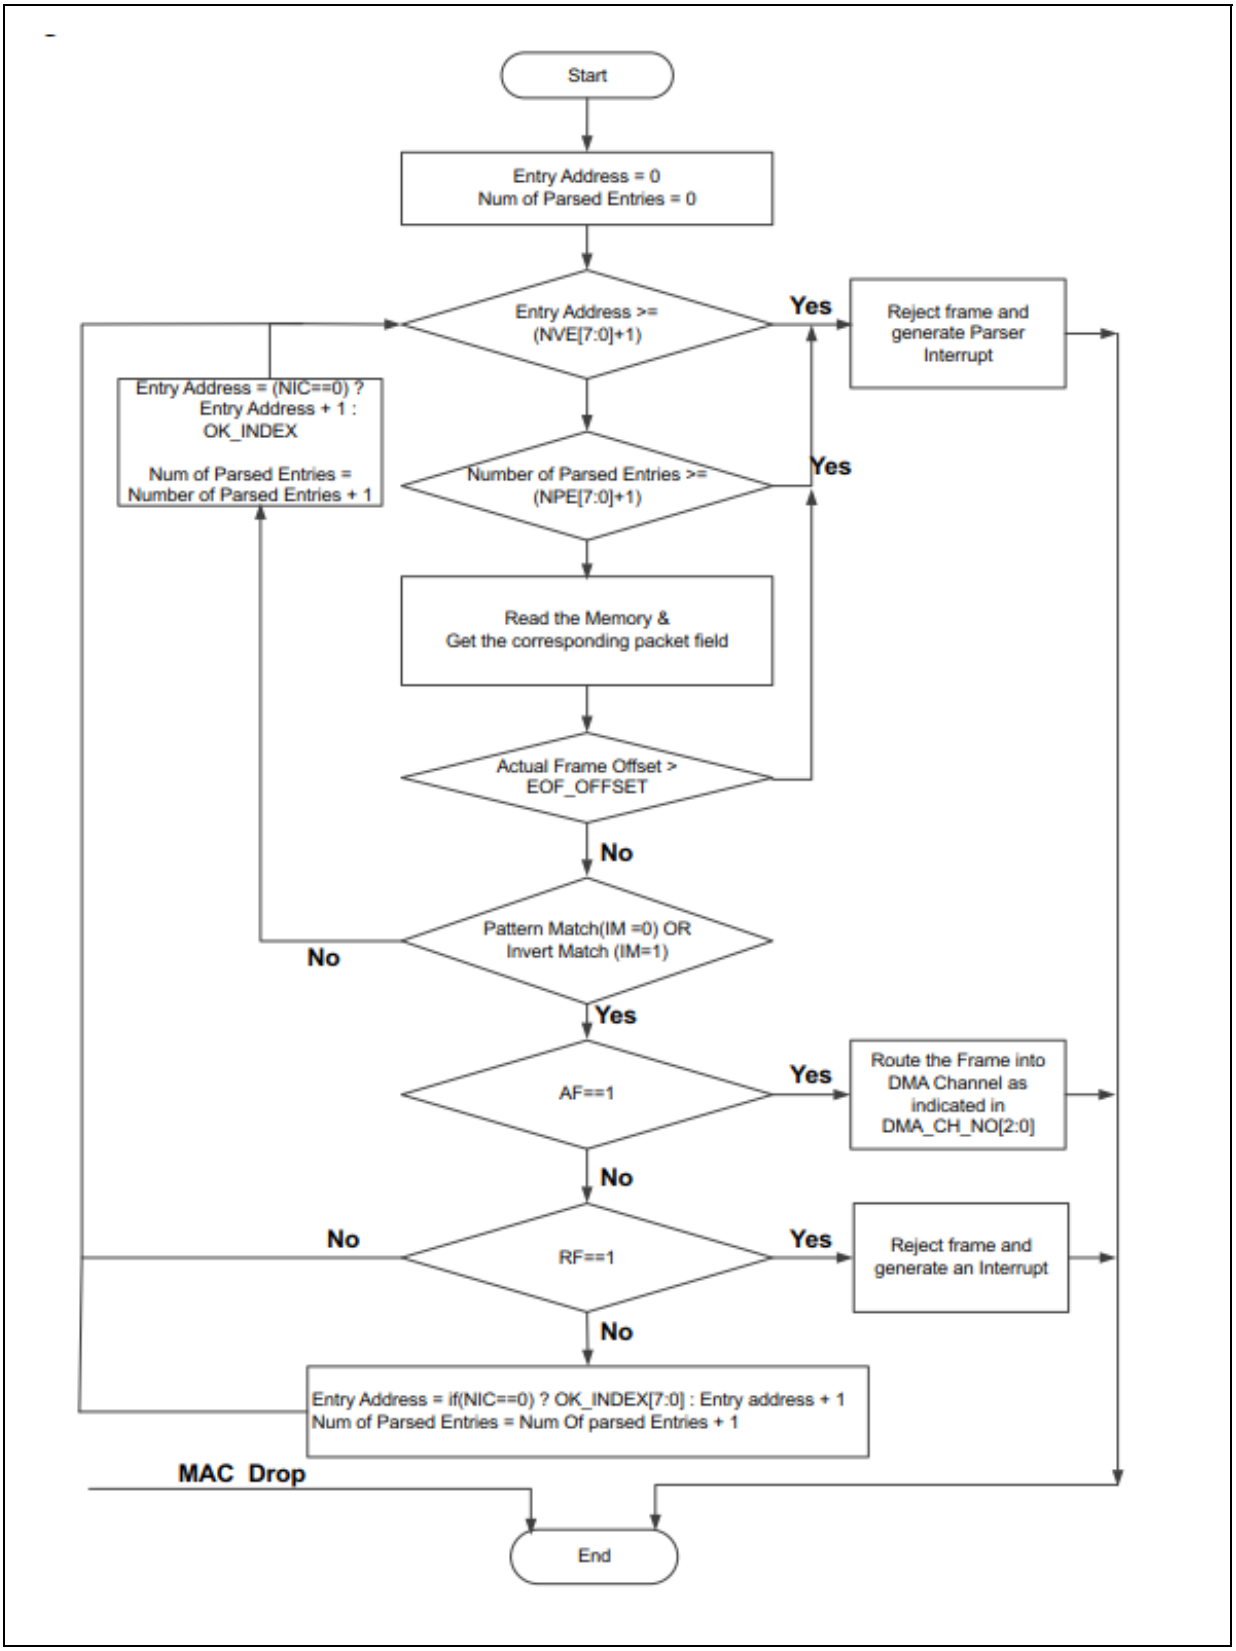
50.3.8.6.2 Instruction table format of the FRP

Before you enable the Flexible Receive Parser, ensure that the software has built the 96-bit wide instruction table for the parser. Each instruction is programmed as an entry in the Instruction memory. The format of each entry in the Instruction table is shown in *Table 1398*.

Table 1398. Instruction table

Field offset	Field name	Description
31:0	MATCH_DATA	The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness supported by IP on the slave interface. The programming of this instruction table should adhere to the same.
63:32	MATCH_EN	When the MATCH_EN is set to 1, the corresponding Packet data bit is used for comparing. Otherwise, corresponding data bit is don't care.
64	AF	AF = Accept frame RF = Reject Frame IM = Inverse match NIC= Next Instruction Control match = MATCH_DATA & MATCH_EN Bits == (Packet data[frame offset*8 + 8*4]) & MATCH_EN bits **If IM = 0** ENTRY_MATCH = match **If IM = 1** ENTRY_MATCH = !match **If ENTRY_MATCH** ==1 **If AF = 1**, then put frame into DMA Chanel (as indicated in DMA CH Number, the [95:88] of this table) **else if RF = 1**, then reject/drop frame **else if !(AF|RF)** **if (NIC == 0)** continue parse from OK Index **else // (NIC == 1)** continue sequentially (parse the next entry in the instruction table) If ENTRY_MATCH == 0 **if (NIC == 1)** continue parse from OK Index **else //(NIC == 0)** continue sequentially (parse the next entry in the instruction table) **Note:** AF and RF should not be programmed together. However, if both AF and RF are programmed together, AF gets the priority in case of ENTRY_MATCH.
65	RF	
66	IM	
67	NIC	
71:68	Reserved	

Table 1398. Instruction table (continued)



Field offset	Field name	Description
79:72	Frame Offset	[77:72] indicates the frame offset in terms of 4 bytes. ([79:78] are always 0). Frame offset in the packet data to be compared for Match. This is in terms of 4 bytes. Value Actual Frame offset in bytes 0 0 1 4 2 8 … 31 124 Others Reserved The max value programmed in this instruction table should not exceed 31 (only 128 byte frame buffer).

87:80	OK Index	If (NIC==0)
		Memory Index to be used next when ENTRY_MATCH==1 and neither AF or RF is set to 1
		If (NIC==1)
		Memory Index to be used next when ENTRY_MATCH==0

95:88	DMA CH NO	Indicate the DMA Channel Number (1-bit for each). This will be used when ENTRY_MATCH == 1 and AF = 1 (Accept frame) The encoding is given by the following: bit[0]: DMA Channel Number 0 bit[1]: DMA Channel Number 1 bit[2]: DMA Channel Number 2 bit[7:4]: Reserved The DMA Channel number is encoded using bit wise as IP support multicasting/broadcast across DMA Channels.

The parser begins parsing from the zeroth entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the parser result of the current entry. *Figure 1297* shows the detailed flow.

Figure 1297. Instruction flow

The EOF_OFFSET in flowchart is equal to the least among the following:

- Actual Packet size
- 128, when frame pre-emption feature is not enabled
- 128, when frame pre-emption feature is enabled and packet is pre-emptible
- 64, when frame pre-emption feature is enabled and packet is Express Packet

50.3.8.6.3 Number of Valid Entries (NVE)

Indicates the number of valid entries in the instruction table. The default value is set to 256. Software can override this value by writing into MTL_RXP_Control_Status registers field NVE[7:0]. While parsing, if the Entry address is found to be is greater than NVE[7:0] + 1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[0], NVEOVIS (Number of Valid Entries overflow status). The IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

50.3.8.6.4 Number of Parsable Entries (NPE)

NPE indicates the number of entries that can be parsed on an incoming packet. The default value is set to 256. Software can override this value by writing into MTL_RXP_Control_Status registers field NPE[7:0] (Number of Parsable Entries) bits [23:16]. While parsing, if the number of parsed entries is more than NPE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[1], NPEOVIS (Number of Parsable Entries Overflow Status). The IP generates an interrupt status MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

While NVE[] indicates the number of valid entries in the Rx parser memory built by software, NPE[] indicates the worst-case parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

50.3.8.6.5 Frame Offset

Indicates the frame offset, in terms of 4 bytes; used while comparing against the current table entry. In an entry, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[2], FOOVIS (Frame Offset Overflow Interrupt Status) in any of the following cases:

When frame offset is more than:

- Packet size.
- 128 if pre-emption is disabled.
- 128 if pre-emption is enabled and packet is pre-empitble.
- 64 if pre-emption is enabled and packet is an Express packet.

IP set an interrupt status (MTL_Interrupt_Status bit[23]) and MTLPIS (MTL Parser Interrupt Status).

If the frame ends after the (frame_offset*4) bytes but before ((frame_offset*4) + 4) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (via MASK bits) for the non-received bytes; from (frame_offset*4) to ((frame_offset*4) + 4).

50.3.8.6.6 Frame Reject

In case an entry matches (considering the Inverse match, IM bit in the instruction table) and Frame Accept bit is not set, and Frame Reject bit (RF) is set, the frame is dropped. When a

frame is dropped due to RF = 1, the IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

50.3.8.6.7 Out of Order processing

The Rx parser flow can be out of order. The decision tree needs not be based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[]/FRAME_OFFSET[]) can be less than the current entry address and current Frame Offset.

For example, one can look for matching/mismatching IP header and then look for Ethernet Header to decide on Filtering/Channel Selection. Also, it can skip from higher address entry to lower address entry in the table.

50.3.8.6.8 Ethernet Line Speed dependency

To enable the maximum parsing ability the Rx parser block uses the application clock domain. It is assumed that the application clock frequency is higher enough than the MAC line rate clock frequency.

Example: Worst Case Processing Rate: 64B back-to-back (with 8B preamble and 12B IPG). A total of 84 cycles in 125MHz(8ns) clock. So, the requirement is one packet to be processed every 84 cycles of 8ns clock 672ns).

Initial Overhead (O) = 4 cycles. This is for the initial memory read latency and other overheads.

Jump Instruction Latency (J) = 3 cycles.

- Number of available cycles = ((64 + 8 + 12)*(RGMII clock period))/Application clock period (both periods in ns).
- Number of available cycles @ 125MHz RGMII and 200MHz Application clock = (84 * 8ns) / 5ns = 134.
- Number of entries that can be processed (Best Case) = (Number of available cycles) – O = 134-4 = 130.
- Number of entries that can be processed (Worst Case) = (Number of available cycles/J) – 4 = (134/3) – 4 = 40.

To summarize:

The IP supports a maximum of 256 entries in the Instruction table. To keep the line rate at 1 Gbps the maximum number of instructions that can be processed is as follows:

- At 1 Gbps, 200 MHz Application clock, 64 byte back-to back with 12 byte IPG and 8 byte Preamble.
- 0% Jumps Best Case = 130 entries (No Jumps).
- 100% Jumps Worst Case = 40 entries (All Jumps).
- 50% Jumps Case = 82 entries.
- 25% Jumps Case = 103 entries.

If packet parsing is not complete even after reaching the immediate next packet's end of the packet (EOP), the packet is dropped and considered as NPE[] overflow.

50.3.8.6.9 DMA channel selection

The MAC/MTL also determines the DMA channel number based on incoming packet fields. When the Rx parser is enabled (FRPE bit[16] is set to 1 in MTL_Operation_Mode register) the Rx parser overrides the DMA selection criteria of the MAC. When the Rx parser is disabled (FRPE bit[16] is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

50.3.8.6.10 Receive Queue selection

The Rx Queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the Rx Parser. This is because the Rx parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause/PFC feature.

When there are multiple queues and multiple DMA channels are enabled, a particular DMA channel might receive out of order packets. This is because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on Rx parser. If in-order packet reception is necessary, you must program Single Queue configuration.

50.3.8.6.11 MAC Packet Filtering/Drop/Error handling

The MAC does the packet filtering based on the received packet fields. Disable the Packet Filtering features inside the MAC when the Rx parser is enabled. To disable the Packet Filtering features inside the MAC:

1. Set Promiscuous Mode (PR, bit[0] of MAC_Packet_Filter register).
2. Set all other bits in the MAC_Packet_Filter register to their default values.

When MAC decides to drop the packet (due to Rx MAC dependent Error) the packet is dropped irrespective of the Rx parser decision. The MAC issues the following errors:

- GMII error
- Receive Watch Dog error
- CRC error
- Giant Frame error

50.3.8.6.12 PAD Strip/ CRC Strip handling

The PAD Strip and CRC Strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the Rx parser instructions accordingly.

50.3.8.6.13 VLAN Strip handling

The MAC supports stripping the VLANs, outer as well as inner VLAN. When MAC is programmed to strip the VLAN, the Rx parser considers those VLAN tags to be part of the incoming packet.

50.3.8.6.14 Multicast and Broadcast support

The IP supports multicast and broadcast only when PDC (packet duplication control) is enabled and the packet is routed to the highest queue number. When Rx Parser is enabled, the packet routing is decided by the DMA Channel Numbers (DMA CH NO, Bits[95:88]) in the Instruction table.

When Rx Parser is disabled, the packet routing is determined by DCS (DMA Channel Select) field of the MAC_AddressX_High register. For more details, see “Broadcast/Multicast Packet Duplication”.

DCS/DMA CH NO field is per DMA Channel control and therefore, multiple DMA channels can be selected for routing the packet.

50.3.8.6.15 Pre-emption support

The Rx parser supports 128 bytes parsing on all the incoming packets. So, it has 2 x 128 bytes storage. This is because, while parsing the current packet, the next packet needs to be stored.

When pre-emption is enabled, the pre-emptible packets might get fragmented just after 64 bytes in the middle of the parsing and the remaining data is expected to arrive after Express packet gets over; also, multiple back to back Express packets need to be processed till then. So, the context of the pre-emptible parser and associated data buffers need to be maintained while IP is still able to process back to back Express packets. This demands another 128 bytes storage. However, by keeping the total storage limit to 2 x 128 bytes. Following limitations apply to the parsable number of bytes for the Express Traffic:

- FRP Buffer size = 128
- Number of Bytes the Rx Parser can operate on the Express Traffic = 64
- Number of Bytes the Rx Parser can operate on the Pre-emptible Traffic = 128

The reduction of the parsing ability of the Express packet is done considering packet parameters that are well known in advance (via stream reservation protocol). The packets are generated and consumed within the LAN, and does not need deep frame parsing.

Note: The Express packet queue is always different from the pre-emptible queue.

50.3.8.6.16 Software access to the FRP memory

Software can read/write into the Rx parser memory, using the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

IP collects 4 x 32-bit data (parser table width) before initiating the writes. It also collects 4 x 32-bit (parser table width) data in advance before responding to the first read. For more details, see “Register Descriptions”.

50.3.8.6.17 Statistical counters

Following counters are available when flexible receive parser is enabled.

1. MTL_RXP_Drop_Cnt
   This counter is incremented when the Rx parser drops a packet due to RF = 1. For more details, see “Register Descriptions”.
2. DMA_RXP_Error_Cnt
   This counter is incremented when Rx parser encounters an error. The error scenarios are:
   – Entry address >= NVE[]
   – Number of parsed entries >= NPE[]
   – Frame offset in bytes > EOF / FRP_BUF_SIZE (for pre-emptible packet) / (FRP_BUF_SIZE/2) (for Express packet) data entry address
   – Parsing is not complete even after receiving next packet’s EOP

   For more details, see “Register Descriptions”.
3. DMA_CHn_Rxp_Accept_cnt (for n = 0 to 2)
   This is a per DMA channel counter. This counter is incremented when Rx parser accepts a packet due to AF = 1. For more details, see “Register Descriptions”.

50.3.8.6.18 Changing the instruction table by Software

Software can update the instruction table in the memory in the following ways:

- Disable the MAC Receiver and Receive Parser by setting the RE field of the MAC_Configuration register to 0 and FRPE bit of MTL_Operation_mode register to 0. Wait for Rx Parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Program in the Entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory) where it is programmed to reject or accept all packets.

50.3.8.6.19 Receive Cut-Through functionality

In the case of cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received (RTC field in the MTL_RxQx_Operation_Mode register. The RTC can take values 16, 32, 64, and 128). However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as follows: The Rx controller attempts to transfer packet to DMA after at least RTC number of bytes have been received and Rx parser results are available.

50.3.8.6.20 Receive Packet Drop indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's Rx parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the Application Interface and status is indicated accordingly. For more details, see RDES2, bit 16(RXPD) in “Receive Normal Descriptor (Write-Back Format)”.

50.3.8.6.21 Runt Packet handling

The Rx parser is designed for worst case minimum packet size to be of 64 B. If the runt packet is received (should be indicated by MAC), the Rx parser assumes that it gets

dropped in the MAC. This is because, back-to-back runt packets (< 64 B) cannot be handled in the Rx parser.

50.3.8.6.22 Uncorrectable ECC Error handling

When the parser detects an uncorrectable ECC error while parsing the parser memory, the packet is not dropped. Instead, the packet is sent to the application with an Error Indication. The RXPI (RX Parser Incomplete) is set in the packet status along with Error Summary (ES) bit. For more details, see “Receive Normal Descriptor (Write-Back Format)”.

50.3.8.6.23 Enabling/Disabling the FRP

To enable the Flexible Receive Parser, set bit[16] (FRPE, Flexible Rx Parser Enable) to 1, in the MTL_Operation_Mode register. You must disable the MAC receiver (block the traffic on the receiver) before enabling or disabling the flexible receive parser. To disable the MAC Receiver, set the RE (bit[0]) bit of MAC_Configuration Register to 0.

50.3.9 IEEE 1588 timestamps

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The Ethernet module supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet module provides programmable support for both standards. It supports the following features:

- Supports both timestamp formats.
- Provides an option to take snapshot of all packets or only PTP type packets.
- Provides an option to take snapshot of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent.
- Provides an option to select the node to be a master or slave for ordinary and boundary clock.
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

50.3.9.1 Clock types

The Ethernet module supports the following clock types defined in the IEEE 1588-2008:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

50.3.9.1.1 Ordinary clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled.
- Maintains the data sets such as timestamp values.

Table 1399 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 1399. Ordinary clock: PTP messages for snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control register.

50.3.9.1.2 Boundary clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

50.3.9.1.3 End-to-End transparent clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in the bullet points below. The snapshot is taken by setting the SNAPTYPSEL bits to ‘10’ in the MAC_Timestamp_Control register.

End to End transparent clock: PTP messages for snapshot:

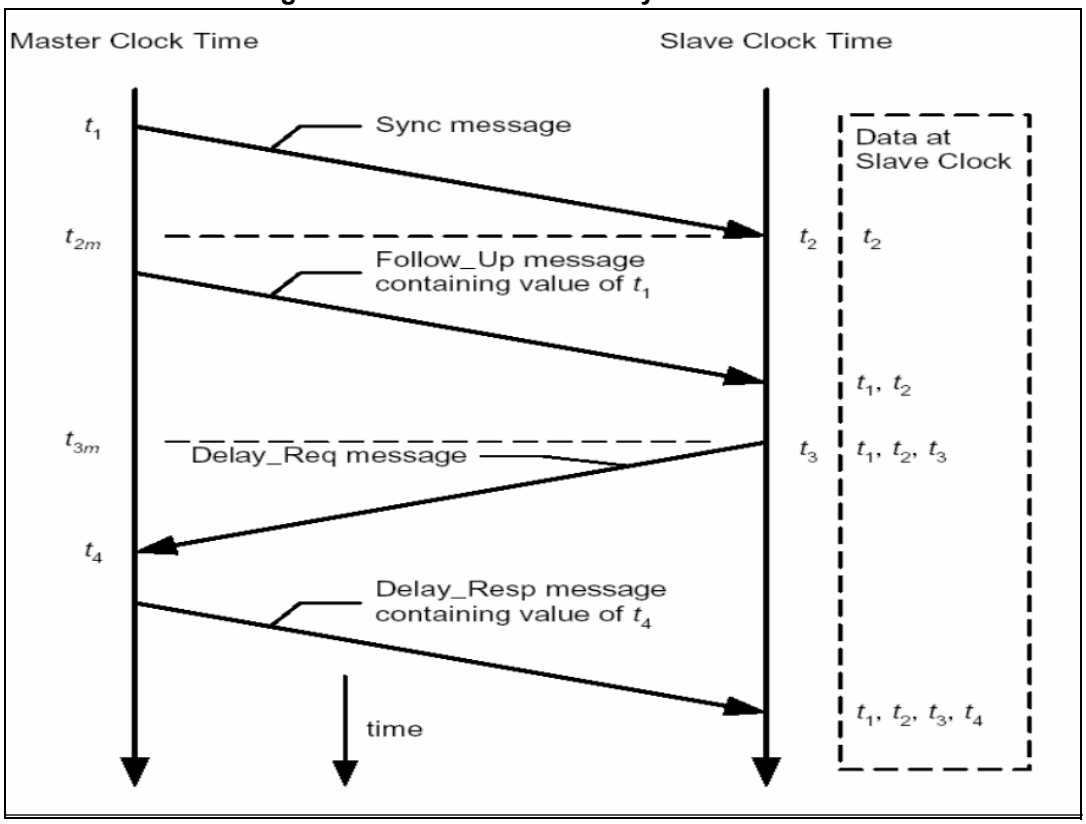
- SYNC
- Delay_Req

50.3.9.1.4 Peer-to-Peer transparent clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as mentioned in the below bullet points.

Peer-to-Peer transparent clock: PTP messages for snapshot



- SYNC
- Pdelay_Req
- Pdelay_Resp

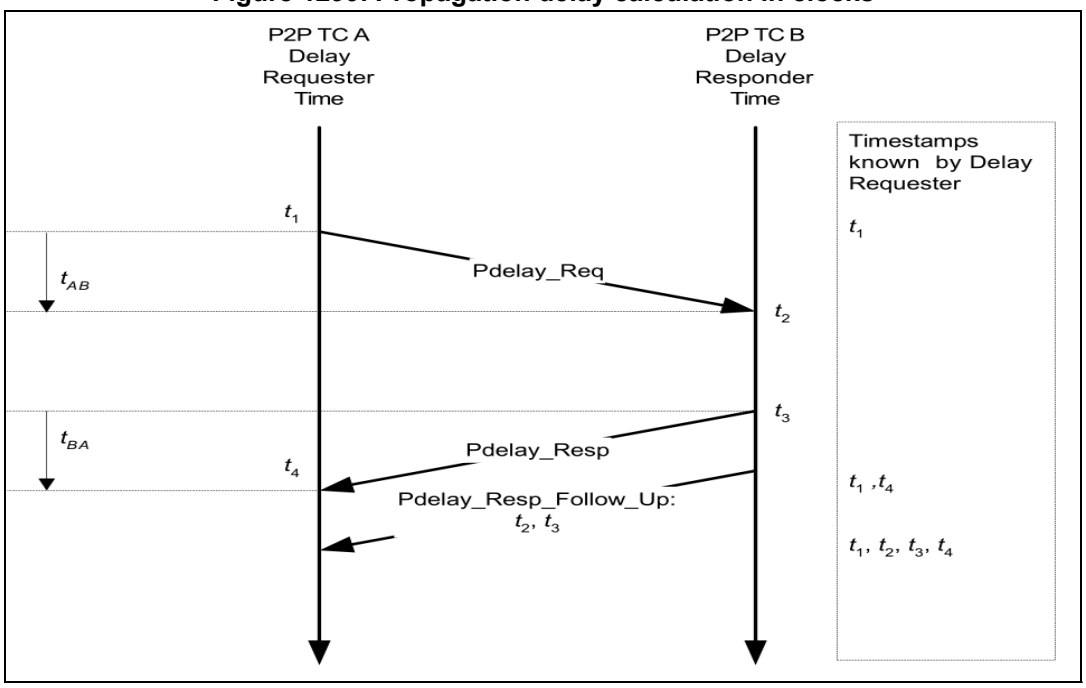
The snapshot is taken by setting the SNAPTYPESEL bit to ‘11’ in MAC_Timestamp_Control register.

50.3.9.2 Delay Request-Response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. *Figure 1298*, shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 1298. Networked time synchronization

As shown, the PTP uses the following process:



1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

50.3.9.3 Peer-to-Peer PTP Transparent Clock (P2P TC) message support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. *Figure 1299* shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 1299. Propagation delay calculation in clocks

As shown, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.

To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

a) Difference between the timestamps t2 and t3 in the Pdelay_Resp message
b) Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
c) Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

50.3.9.4 Reference timing source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

50.3.9.4.1 Internal reference time

Ethernet module provides the following options for using the reference timing source in a node:

- External Timestamp Input

  This option takes an external 64-bit timing reference and its clock as input. The clock input is used to synchronize the timing reference to the MAC clock domain.
- Internal Reference Time (80-bit)

  This option takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The Ethernet module provides an Internal Reference Time (80-bit). It takes the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

- UInteger48 secondsField: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bit wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002.
- UInteger32 nanosecondsField: The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001.

The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

Note: These modes are set through TSCTRLSSR bit in MAC_Timestamp_Control register.

50.3.9.4.2 External timestamp input

The 64-bit timing reference is split into the following two 32-bit signals:

- Upper 32-bits providing the time in seconds.
- Lower 32-bits providing the time in nanoseconds.

This timing reference is used to timestamp the packets.

50.3.9.4.3 IEEE 1588 higher word register

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. You can read the values of the upper 16-bits of the seconds field from the CSR register.

Note: This Higher Word Register can be invoked only when the “System Time Source” is “Internal”.

50.3.9.4.4 Fixed Pulse-Per-Second output

The Ethernet module supports the pulse-per-second (PPS) output that is given to indicate 1 second interval (default). You can change the frequency of the PPS output by setting the PPSCTRL0 field in the MAC_PPS_Control register.

50.3.9.4.5 Flexible Pulse-Per-Second output

The Ethernet module also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. The Ethernet module provides the following features with the flexible PPS output:

- Supports programming the start or stop time in terms of system time.
- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Supports programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed.
- Supports programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programmed in the MAC_Sub_Second_Increment register. You can program the width of pulse from 1 to 2^{32}-1 units of sub-second increment value.
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^{32}-1 units of sub-second increment value .
- Provides the option to cancel the programmed PPS start or stop request.
- Indicates error if the start or stop time being programmed has already elapsed.

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of MAC_Timestamp_Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated (using incr_sub_sec_reg shown in Figure 1300).

50.3.9.4.5.1 PPS Start or Stop time

You can initially program the start time in the Target Time register. If required, you can again program the start or stop time but you can do it only after the earlier programmed value is synchronized to the PTP clock domain. Bit 0 of MAC_PPS*n*_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

50.3.9.4.5.2 PPS width and interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

50.3.9.4.6 Auxiliary snapshots with external events

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the ptp_aux_ts_trig_i sideband signal.

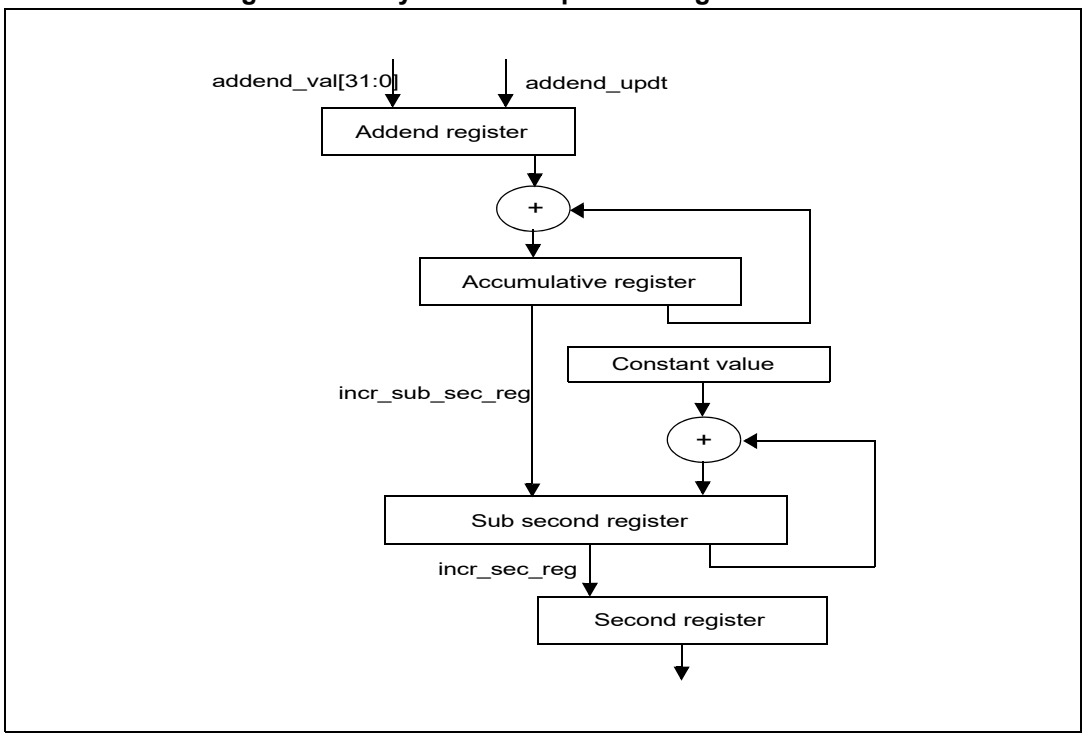
The Ethernet module has two auxiliary snapshot inputs and depth 4 of a single common auxiliary snapshot FIFO. The snapshots taken for any input are stored in a common FIFO. The application can read the MAC_Timestamp_Status register to know the timestamp of which input is available for reading at the top of this FIFO.

The MAC stores these snapshots in a FIFO. Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from the MAC_System_Time_Higher_Word_Seconds register. When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the MAC_Timestamp_Status register. This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When an application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in MAC_Auxiliary_Control register. When multiple snapshots are present in the FIFO, the count is indicated in Bits[4:6] of MAC_Timestamp_Status register.

50.3.9.4.7 System time register module

The 64-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the MII interface.



The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in *Figure 1300*. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

This algorithm is shown in *Figure 1300*.

Figure 1300. System time update using fine method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^{32} / 1.32) must be programmed.

In 5-12, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32}$ / FreqDivisionRatio

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is
  $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  $FreqCompensationValue_n = FreqScaleFactor_n \times FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

50.3.9.5 Transmit path functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can do this by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

50.3.9.6 Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Note: The Ethernet module also supports the PTP messages over VLAN packets.

50.3.9.7 Timestamp correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock ***clk_ptp_ref_i***) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

50.3.9.7.1 Ingress correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programmed in the Ingress Correction register. The value that needs to be programmed in the ingress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value as follows:

```
INGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp as follows:

```
Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY
```

Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

It is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programmed value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <ingress_correction_value> represented in binary.

50.3.9.7.2 Egress correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value)

programmed in the Egress Correction register. The value that needs to be programmed in the egress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value as follows:

When Enable one step timestamp feature is selected,

```
EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)
```

Otherwise,

```
EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp as follows:

```
Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY
```

Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The value must not exceed 0x3B9A_C9FF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programmed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 0 to 31 and bits 1:31 containing <egress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 0 to 30 and bits 1:31 containing 2^31 - <egress_correction_value> represented in binary.

50.3.9.8 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains, that is, from the MAC clock domain to the application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

50.3.9.8.1 Maximum PTP clock frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

50.3.9.8.2 Minimum PTP clock frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the MII clock domain. This relationship is given in the following equation:

Equation 34

3 × PTP clock period + 4 × MII clock period <= Minimum gap between two SFDs

The MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in *Table 1400*.

Note: It is recommended that you use a clock that has constant frequency, preferably a divided application clock.
When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Increment register limits the minimum PTP frequency that can be used to ~4 MHz.

Table 1400. Minimum PTP clock frequency example

Mode	Minimum gap between two SFDs	Minimum PTP frequency with internal timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
10 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	5 MHz
100 Mbps half duplex	48 MII clocks (8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	5 MHz
1000 Mbps full duplex	84 GMII clocks (64 clocks for a 64-byte packet + 12 clocks of min IFG + 8 clocks of preamble)	5 MHz

50.3.9.9 PTP processing and control

Table 1401 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 1401. Message format defined in IEEE 1588-2008

Bits								Octets	Offset
0	1	2	3	4	5	6	7		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField(1)								1	32
logMessageInterval								1	33

1. ControlField is used in version 1. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets over IPv4Packets over IPv4
- PTP Frames over IPv6Frames over IPv6
- PTP Packets over EthernetPackets over Ethernet

50.3.9.9.1 PTP packets over IPv4

Table 1402 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1402*.

Table 1402. IPv4-UDP PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP

Table 1402. IPv4-UDP PTP packet fields required for control and status (continued)

Field matched	Octet position	Matched value	Description
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP Primary multicast address: 224.0.1.129 PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	0x013F: PTP event message(1) 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only).

50.3.9.9.2 PTP frames over IPv6

Table 1403 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in *Table 1403*.

Table 1403. IPv6-UDP PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [0:3])	0x6	IP version is IPv6
Layer 4 Protocol	20(1)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57(1)	0x013F, 0x140	0x013F: PTP event message 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94(1)	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management (version1)
PTP Message Type Field (IEEE 1588 version 2)	62(1) (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The Extension Header is not defined for PTP packets.

50.3.9.9.3 PTP packets over Ethernet

Table 1404 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, *Annex D* and the message format defined in Table 5-12 Message Format Defined in IEEE 1588-2008n 5-12.

Table 1404. Ethernet PTP packet fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Destination Multicast Address(1)	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses(2): 01-1B-19-00-00-00 01-80-C2-00-00-0E(3)
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	0x00: SYNC 0x01: Delay_Req 0x02: Follow_Up 0x03: Delay_Resp 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	0x0: SYNC 0x1: Delay_Req 0x2: Pdelay_Req 0x3: Pdelay_Resp 0x8: Follow_Up 0x9: Delay_Resp 0xA: Pdelay_Resp_Follow_Up 0xB: Announce 0xC: Signaling 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	0x1: Supports PTP version 1 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, *Annex F.*
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

50.3.9.10 One-step timestamp

The Ethernet module supports the one-step timestamp feature. When this feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application at that offset.

You can enable the one-step timestamp feature for a packet by setting Bit 11 (OSTC) in ATI Control Word. The inserted timestamp consists of 80-bits, the 64-bit TSSL and TSSH received from the application and the content of higher 16 bits of Higher Timestamp Word register.

Note: The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets because the timestamp insertion happens in the MAC and the IP payload checksum needs to be updated. However, the checksum computation happens in the MTL.

50.3.9.10.1 MAC transmit PTP mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- Correction Field in the PTP header of messages
- OriginTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 1405 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the *Section 50.2.2.153: Timestamp control register (MAC_TIMESTAMP_CONTROL)* and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Table 1405. MAC transmit PTP mode and one-step timestamping operation

Programming			Mode	Per packet control(1)			Messages processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE	OSTC	TTS	
X	X	X	N/A	1	X	X	Timestamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
2'b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)

Table 1405. MAC transmit PTP mode and one-step timestamping operation (continued)

Programming			Mode	Per packet control(1)			Messages processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE	OSTC	TTS	
2’b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2’b01	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

1. The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.

Note: Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp. When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy. Clocks supporting peer delay mechanism does not use delay request or response, but it is included in OST for flexibility.

50.3.10 TCP/IP offloading features

50.3.10.1 IPv4 ARP offload

The Ethernet module supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. The Ethernet module generates the ARP reply packets for appropriate ARP request packets**.** The ARP packet for IPv4 is L2 layer packet with Length/Type of 0x0806.

The ARP offloading process is as follows:

1. The MAC receiver gets an ARP request if the Target Protocol Address of request matches the IPv4 address programmed in the L3 register of the MAC.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   – DA field of the Ethernet packet header.
   – Target Hardware Address field of the ARP reply packet.
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   – SA field of the Ethernet packet header.
   – Sender Hardware Address field of the ARP reply packet.
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for generated ARP reply packet.
9. The MAC transmitter sends the ARP reply.

The MAC processes only one ARP request at a time. It does not store the fields of multiple ARP requests. If the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC does not generate the ARP reply for new ARP request. The MAC forwards the new ARP request packet to application with ARP Reply Not Generated (Bit 21) status bit set. However, in power-down mode, if the MAC receives an ARP request when it is already processing an earlier ARP request, the MAC drops the new ARP request.

If the Disable CRC check bit of the MAC Extension Configuration bit is set, then the MAC does not check for valid CRC of an ARP request Packet. The ARP request Packet must always have a valid CRC. It can generate an ARP response packet if the other conditions are valid.

50.3.10.2 Checksum offload engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path.

Note: On the transmit path the Checksum Offload Engine is present in Queue0 only.

50.3.10.2.1 Transmit checksum offload engine

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[14:15]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the Ethernet module is configured for Threshold (cut-through) mode.
You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. When reading starts, the COE fails and consequently all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the following number of bytes in size: TXFIFO_SIZE – ((PBL + N) × (DATAWIDTH/8)), Where N= 5

50.3.10.2.1.1 IP header checksum engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 31). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

50.3.10.2.1.2 TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine

includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.

- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 19). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 1406 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Note: You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 1406. Transmit checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2 K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes

Table 1406. Transmit checksum offload engine functions for different packet types (continued)

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Routing (with segment left 0)	Not applicable	No
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Authentication	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

50.3.10.2.2 Receive checksum offload engine

You can enable the Receive Checksum Offload Engine (Rx COE) by setting the IPC bit of MAC_Configuration register. When enabled, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is sent in the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum

Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 1407 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as “No” in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status, as described in *Table 1418*.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 1407. Receive checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1522 bytes (2000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers		
Hop-by-hop options (in IPv6 main header)	Not applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not applicable	No
Destinations options	Not applicable	Yes
Routing (with segment left 0)	Not applicable	Yes
Routing (with segment left > 0)	Not applicable	No
TCP, UDP, or ICMP	Not applicable	Yes
Any other next header field in main or extension headers	Not applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels		
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels		
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes

Table 1407. Receive checksum offload engine functions for different packet types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

50.3.10.2.2.1 Splitting header on receive

Optionally, the incoming receive packet header can be split such that the header and the payload are stored in different buffers in the system memory.

Header splitting is also useful for non-IP packets such as AVB traffic which are generally multicast type. This enables the application to store the packet header of AVB streams and payload for AVTP (Audio Video Transport Protocol) packets and the DMA can process the header and payload of the received packets separately.

Table 1408 shows how DMA processes a packet depending upon its type and the value of the SPLM bit.

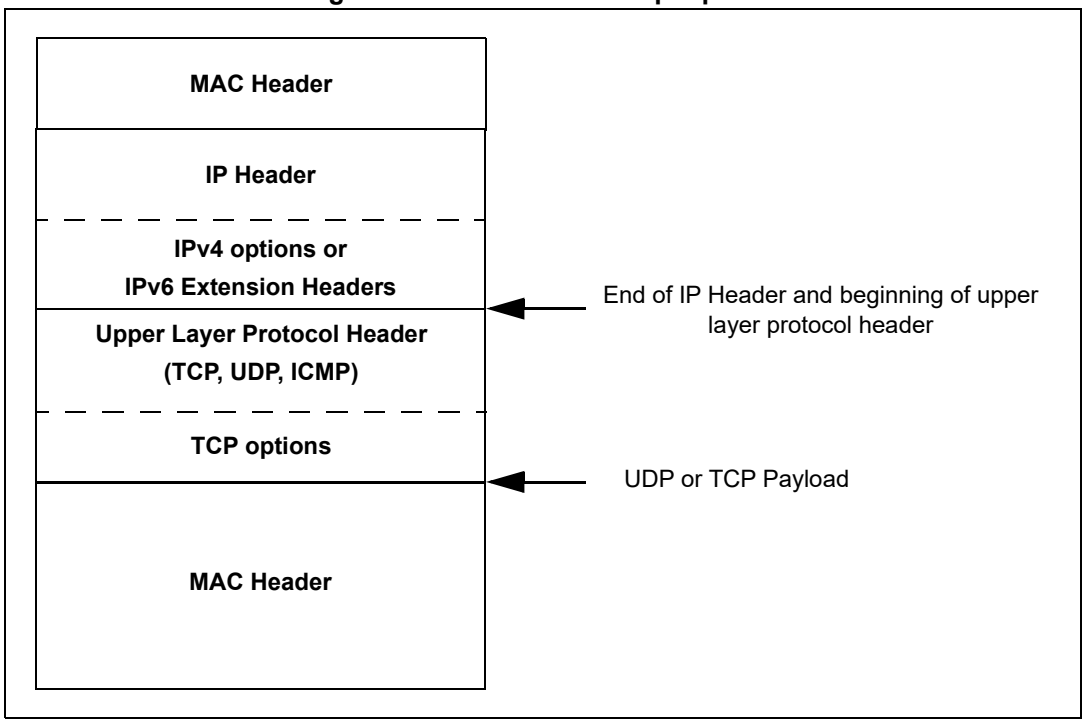
Table 1408. Split header support depending on the packet type

Packet type	SPLM	Description
TCP or UDP packet	00 (L3/L4 split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
IP packet and non IP packet	01 (L2 split)	The DMA writes the Ethernet header based on split offset (SPLOFST) into the header buffer.
IP packet	10 (combination of L2 or L3/L4 split)	L3/L4 split
Non-IP packet		L2 split
NA	11	Reserved

Note: L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped.

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames. The points at which the L3/L4 header is split are shown in the below figure.

Figure 1301. L3/L4 header split points



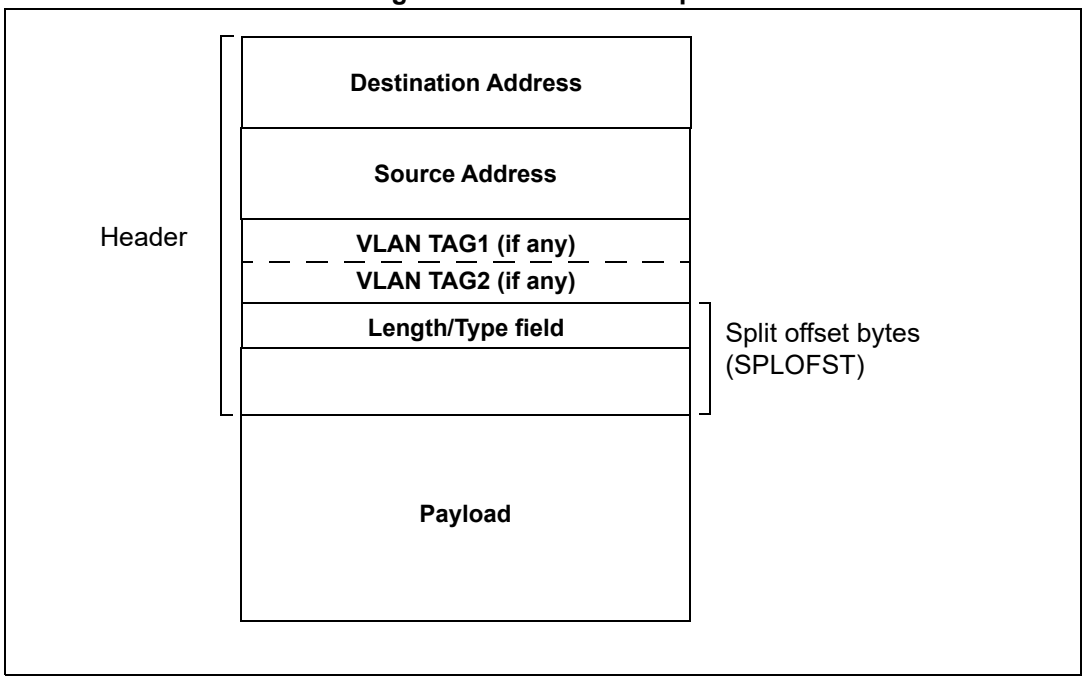


Figure 1302 shows the IP header split for L2. The split is based on SPLM filed which is a programmable 2-bit field of MAC_Ext_Cfg1 register. The programmable offset field allows the frames to be split at a fixed length starting from the Length/Type field, which is indicated by the SPLOFST field of the MAC_Ext_Cfg1 register. For more details, refer to *Section 50.2: Memory map and registers description*.

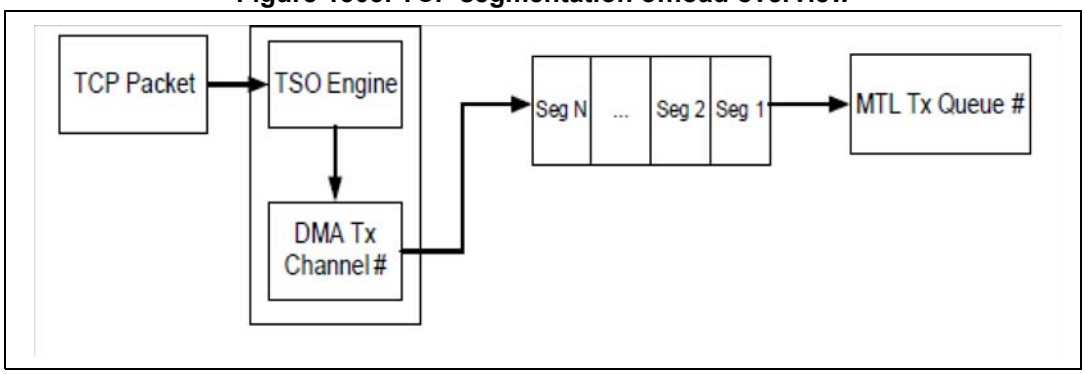
Figure 1302. L2 header split

Refer to *Section 50.5.11: Programming guidelines for split header on Receive*.

50.3.10.3 Using the TCP/IP Segmentation Offload (TSO) engine

50.3.10.3.1 Introduction to the TSO engine



The TCP Segmentation Offload (TSO) engine is useful in offloading the TCP segmentation functions to the hardware.

It also supports UDP Segmentation Offload (USO) in which the UDP payload is segmented in the hardware. There are no sequencing/ordering controls available or updated in the segments, so it can be used in point to point applications in which out of order packets are not expected by the receiver. The description and flow of TSO mentioned in this section is same as USO, any deviation is provided as notes.

50.3.10.3.2 Description of TCP segmentation offload engine

In the TCP segmentation offload (TSO) feature, the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in *Figure 1303*.

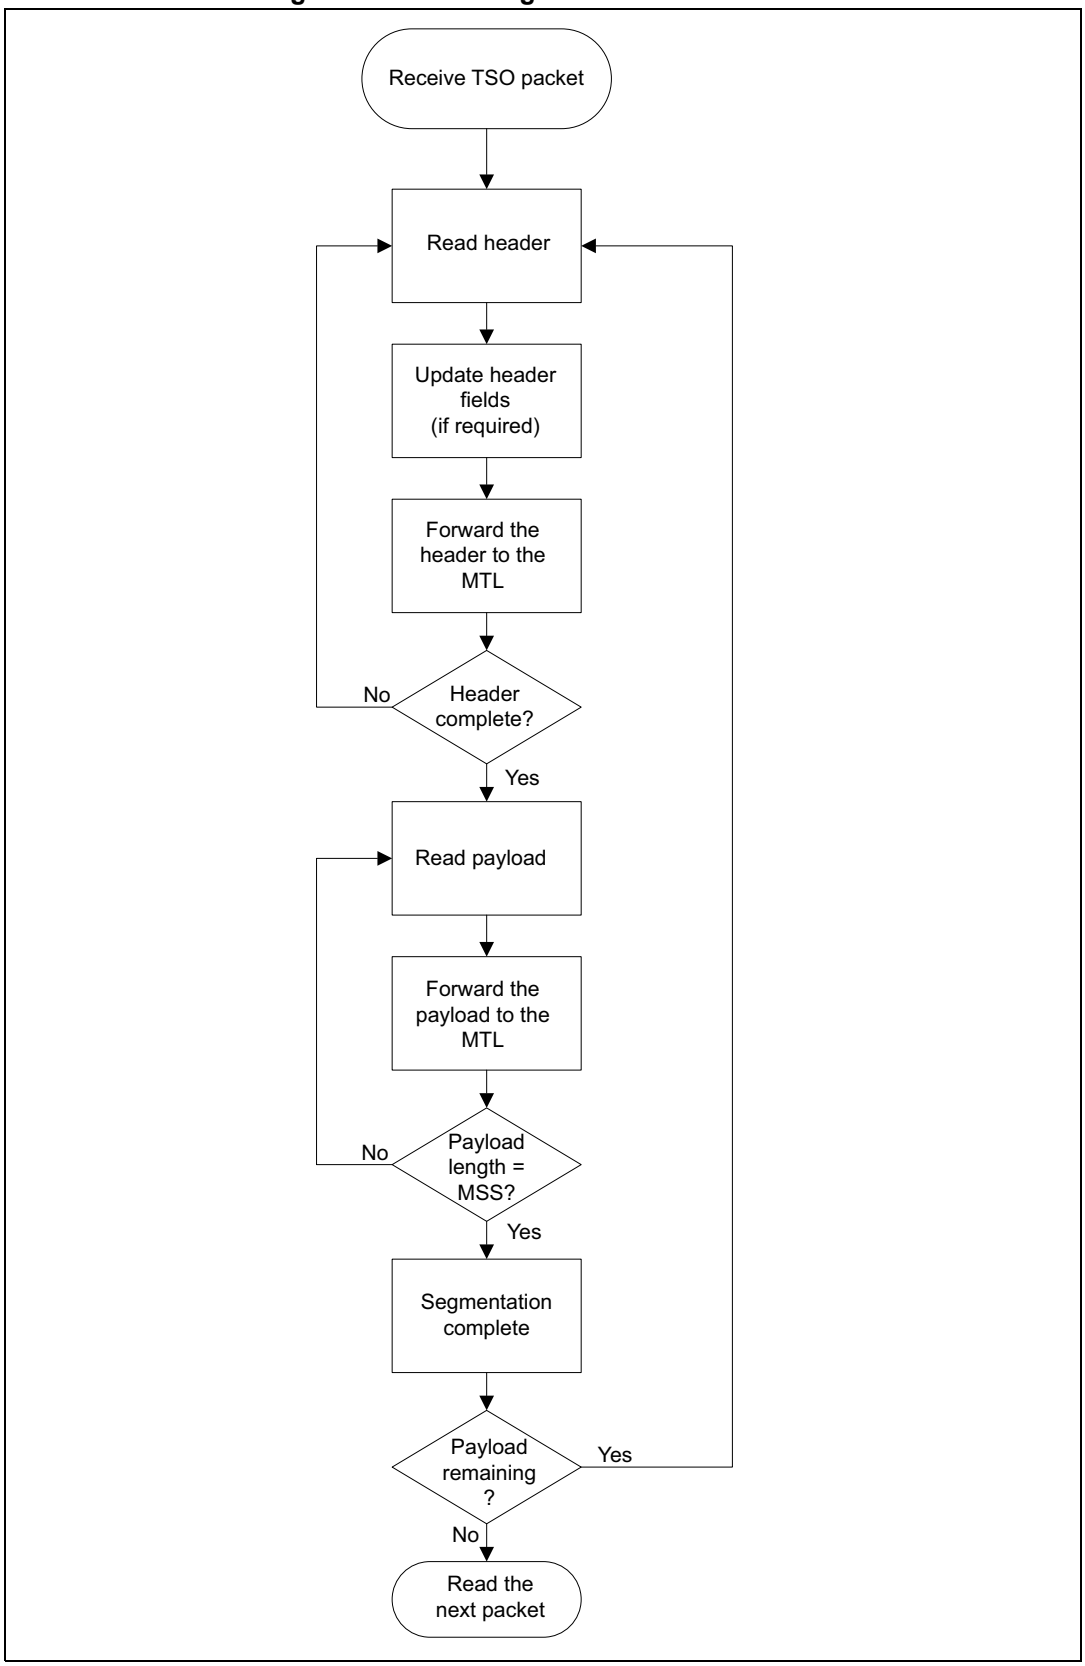


Figure 1303. TCP segmentation offload overview

50.3.10.3.2.1 DMA operation with TSO feature

Figure 1304 shows the TSO flow.

Figure 1304. TCP segmentation offload flow

For the TSO feature, the Tx DMA operation is as follows:

1. The application sets up the Transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application increases the offset value of the Descriptor Tail pointer of the DMA Tx channel.
3. While in the Run state, the DMA fetches the next available descriptor and does one of the following:
   a) If the descriptor is a context descriptor and the context is not between the first and last descriptors of a packet, the DMA stores the context values.
   b) If the descriptor is a context descriptor and the context is between the first and last descriptors of a packet, the DMA closes the context descriptor indicating a Context Descriptor Error (TDES3[23]) and fetches the next descriptor.
   c) If the descriptor is a normal descriptor, the DMA checks for the TSE bit. If TSE bit is not set, the DMA continues with the default mode of operation or OSF operation (if enabled).
4. The DMA calculates the number of segments from the TCP payload length(TDES3[17:0]) and the MSS value.
5. The DMA goes through channel arbitration to fetch the data buffers. The DMA fetches the header and payload separately.
6. For the first segment, the DMA fetches the header from the system memory and stores it in the TSO memory (if present and when the length of header is not greater than the TSO memory size).
   If the current segmented packet is not the first segment, the DMA fetches the header from the local TSO memory if available. Otherwise, it will fetch the header buffer in system memory again, as done for the first segment. In such cases (header not available is TSO memory), the DMA will not close the first descriptor containing the header buffer until the header for last segment is fetched.
7. The required fields in the header bytes are modified/updated as per the segmentation requirements and written into the corresponding MTL TxQ.
8. The DMA then takes the payload buffer pointer, fetches the MSS number of payload bytes from the system memory and directly pushes it into the MTL TxQ. In case the buffer(s) in the descriptor do not have enough data for the MSS payload (except for the last segment), the DMA closes this descriptor.
9. The DMA jumps to Step 3 and repeats the process until the last segment is written into the TxQ.
10. The DMA closes the last descriptor and also the first descriptor (containing the header buffer when it is not stored in TSO memory) and then moves on to the next packet transfer.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

Note: The TSO engine determines whether to perform TSO or USO operation based on the THL field (TCP Header Length) in TDES3 of first Normal Tx descriptor for the packet. The value of 2 indicates USO and any value greater than or equal to 5 indicates TSO.

The DMA repeats all these steps if more descriptors are available. When no descriptor is available, the DMA enters the suspend state.

50.3.10.3.2.2 TCP/IP header fields

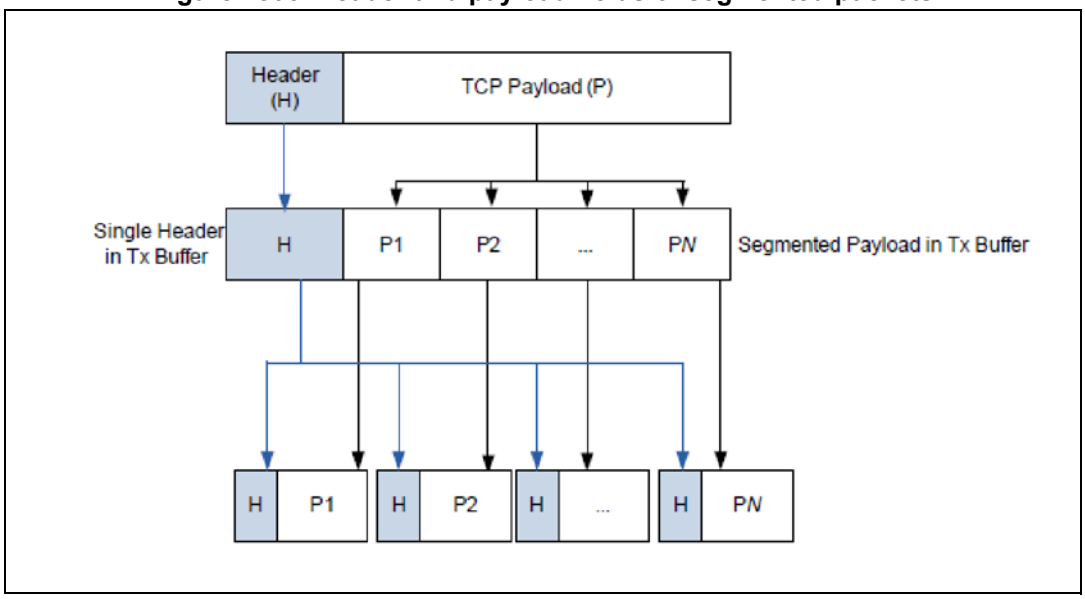
While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 1409* describes how the TCP and IP headers are updated.

Table 1409. TSO: TCP and IP header fields

Packet sequence	TCP header	IP header
First packet	– The sequence number is not updated. The value provided in the header is used. – The TCP checksum is calculated again. – If set, the FINand PSH flags are cleared.	– IPv4 Header – Total Length = MSS + TCP Header Length + IP Header Length – Identification field is not modified It is sent as per the header provided by the software – IPv4 Header Checksum is recalculated. – IPv6 Header Payload Length = MSS + TCP Header Length + IP Extension Header Length
Subsequent packets	– The sequence number is updated. The MSS value is added to the sequence number value of previous segment. – If set, the FINand PSH flags are cleared. – The TCP checksum is calculated again.	– IPv4 Header – Total Length = MSS + TCP Header Length + IP Header Length – Identification field = Previous Identification Field + 1 – IPv4 Header Checksum is recalculated – IPv6 Header Payload Length = MSS + TCP Header Length + IP Extension Header Length
Last packet	– The sequence number is updated. The MSS value is added to the sequence number value of previous segment. – If FINand PSH flags were set in original header, these flags are set. – The TCP checksum is calculated again.	– IPv4 Header – Total Length = Remaining payload + TCP Header – Identification field = Previous Identification Field + 1. – IPv4 Header Checksum is recalculated – IPv6 Header Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length

Note: In case of USO, the engine updates only the following fields in the IP-UDP headers:

- *Total Length, Identification Field, and Header Checksum field in IPv4 header*
- *Payload Length field in IPv6 header*
- *Length and Checksum field in UDP header*



50.3.10.3.2.3 Header and payload fields of segmented packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in *Table 1409*. *Figure 1305* shows how the same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When

the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Figure 1305. Header and payload fields of segmented packets

50.3.10.3.2.4 Context descriptor sequence

You can use the context descriptor to provide the MSS value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application wants to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset.

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this MSS value for all subsequent packets that have the TSO Enabled through the TSE bit of TDES3 normal descriptor.

50.3.10.3.3 Building the descriptor and the packet for the TSO feature

Set the TSE bit of TDES3 of first normal descriptor. If the TSE bit is set in TDES3 for a non TCP/IP packet, the DMA behavior is unpredictable.

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 KB.

Note: The TDES3[22:19] field is used as slot number in case of AV configurations. If both TSO and AV are enabled for the same DMA Tx channel (TSE bit is set in DMA_Tx_Control_Register), then you must not enable slot checking for that DMA Tx Channel (do not set ESC bit in DMA_CH[n]_Slot_Function_Control_Status).

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in the DMA_CH#_Control register or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in DMA_CH#_Tx_Control register should be lesser than the Tx Queue size programmed in TQS field of MTL_TxQ#_Operation_mode register. Synopsys recommends a MSS+header equal to half the programmed Tx Queue size.

The DMA also supports segmentation of VLAN Tagged TCP/IP frames, so if the TCP packet has a VLAN Tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN Tag insert/replace control bits are used for all segments.

If the Double VLAN Feature is selected, then the DMA passes both the tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN Tag Insert/Replace control bits for both tags is applicable for all segments.

If Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

If the TSE bit is set in TDES3 for the packet and TCP header length provided is less than 5 (meaning an invalid TCP header because it is less than 20 bytes), the DMA does not perform segmentation, instead it transmits the entire packet as a single packet. In this scenario, the CRC pad control bits are forced by DMA to 2'b00 (MAC does CRC and padding) and checksum insertion control bits are forced to 2'b11 (Hardware does the checksum calculation for both header and payload).

50.3.11 Memory access in Debug mode

The Ethernet module supports the debug access to the FIFO memory. When you enable this feature, you must program the entire selected Tx memory to Tx Queue 0 and Rx memory to Rx Queue 0. In addition, the offload features such as Checksum Offload Engine and IEEE timestamp should not be enabled with this feature.

When this feature is enabled, the MAC insert the pad (if required) and computed CRC in the Transmit packet. The FIFOs operate in the store-and-forward mode.

50.3.11.1 Slave mode access

You can use this mode to send or receive a packet through a slave interface. The following sections describe how to transmit or receive a packet through a slave interface.

50.3.11.1.1 Transmitting packets through a slave interface

To write a packet to the Tx memory through a slave interface, complete the steps given in *Table 1410*.

Table 1410. Steps to write a packet to Tx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the Packet control word.
MTL_DBG_CTL	Complete the following: a. Set the PKTSTATE field to Control field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Reset the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write the SOP, the first word of the packet data.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to SOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.
MTL_FIFO_DEBUG_DATA	Write subsequent data words.
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to Packet Data. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL and MTL_DBG_STS	Repeat Write subsequent data words. and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). till the penultimate word of the packet data.
MTL_FIFO_DEBUG_DATA	Write the last data word in the FDBGDATA field.

Table 1410. Steps to write a packet to Tx memory through a slave interface (continued)

Register name	Step number and description
MTL_DBG_CTL	Complete the following steps: a. Set the PKTSTATE field to EOP. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Set the number of valid bytes in the field.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations.

After Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field to know the number of free locations. in *Table 1410*, the core automatically initiates the packet transmission. The status of the packet transmission can be obtained as explained in *Table 1410*. To get the status of a Tx packet, complete the steps given in *Table 1411*.

Table 1411. Steps to get the status of a Tx packet

Register name	Step number and description
MTL_DBG_STS	Wait for the STSI interrupt bit to set.
MTL_DBG_CTL	Complete the following steps: a. Set the FIFOSEL field to Tx Status FIFO. b. Reset the FIFWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_CTL	Read the FIFOBUSY bit and wait till this bit is low.
MTL_FIFO_DEBUG_DATA	Read the FDBGDATA field.

50.3.11.1.2 Receiving packets through a slave interface

To read a packet from the Rx memory through a slave interface, complete the steps given in *Table 1412*.

Table 1412. Steps to read a packet from Rx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for slave access by using the DBGMOD and FDBGEN fields.
MTL_DBG_STS	Wait for the PKTI interrupt.
MTL_DBG_CTL	Complete the following: a. Set the FIFOSEL field to Rx FIFO. b. Reset the FIFOWREN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low.

Table 1412. Steps to read a packet from Rx memory through a slave interface

Register name	Step number and description
MTL_DBG_CTL	Read the PKTSTATE and fields.
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field to know the number of available locations.
MTL_DBG_STS, MTL_DBG_CTL, MTL_FIFO_DEBUG_DATA	Repeat Read the FIFOBUSY bit and wait till this bit is low. through Read the LOCR field to know the number of available locations. till the complete packet, along with the Rx status, is received. **Note:** The format of the received packet is as follows First (One or multiple words) Last Status Word (One Word. Acts as delimiter between the status and data) Frame Data Word (multiple) Last Frame Data Word (One Word. Acts as a delimited among subsequent packets on the received Queue)

50.3.11.2 Debug mode access

Debug mode enables you to do both the following operations:

- Write and Read back the Tx Queue
- Read and Write to the Tx Queue

This mode is useful for Memory BIST applications.

50.3.11.2.1 Writing to FIFO memory in debug mode

To write to FIFO memory in the debug mode, complete the steps given in *Table 1413*.

Table 1413. Steps to write to FIFO memory in debug mode

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields.
MTL_FIFO_DEBUG_DATA	Write the data in the FDBGDATA field.
MTL_DBG_CTL	Complete the following: – Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. – Reset the FIFORDEN bit. – Set the FIFOWREN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_DBG_CTL - MTL_DBG_STS	Repeat Complete the following: and Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). twice to write one complete data word in 64-bit mode.

50.3.11.2.2 Reading from FIFO memory in debug mode

To read from FIFO memory in the debug mode, complete the steps given in *Table 1414*.

Table 1414. Steps to read from FIFO memory in debug mode

Register name	Step number and description
MTL_DBG_CTL	Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO, or TSO FIFO. b. Reset the FIFOWEN bit. c. Set the FIFORDEN bit.
MTL_DBG_STS	Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_DEBUG_DATA	Read the data in the FDBGDATA field.
MTL_DBG_STS	Read the LOCR field (if required).
MTL_DBG_CTL, MTL_DBG_STS, MTL_FIFO_DEBUG_DATA	Repeat Complete the following: and Read the LOCR field (if required). twice to read one complete data word in 64-bit mode.

50.3.12 Loopback

The MAC supports Loopback of transmitted packets to its receiver. By default, the MAC Loopback function is disabled. You can enable this feature by programming the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block. The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip, you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.
- The MAC does not process ARP or PMT packets that are looped back.

50.3.13 MAC flow control

This section describes the flow control for Transmit and Receive paths.

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

In the Receive path, the Flow Control is functional only in the full-duplex mode. The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

50.3.13.1 Transmit flow control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

The Transmit Flow Control is enabled independently for each Rx queue when TFE bit is set in MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

The software can request the MAC to send a Pause packet or initiate backpressure by setting the FCB_BPA bit in the corresponding MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register.

The hardware can automatically trigger TX flow control based on the Rx Queue Threshold**.** The hardware flow control operation of the MAC is enabled when the EHFC bit of the corresponding MTL_RxQ*n*_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in the RFA field of the MTL_RxQ*n*_Operation_Mode register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field.

Table 1415, describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE bit of the MAC_Q0_Tx_Flow_Ctrl register
- DM bit of the MAC_Configuration register
- RFA field of the MTL_RxQ0_Operation_Mode register
- RFD field of the MTL_RxQ0_Operation_Mode register
- FCB_BPA bit of the MAC_Q0_Tx_Flow_Ctrl

Flow control is similar for Queue1.

Table 1415. TX MAC flow control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	0	The MAC transmitter performs backpressure when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX performs backpressure when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the pause packet when FCB_BPA of the MAC_Q0_Tx_Flow_Ctrl register is set.
1	1	1	The MAC transmitter sends the pause packet when FCB_BPA of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC TX sends a pause packet when the Rx Queue level crosses the threshold set by the RFA field of the MTL_RxQ0_Operation_Mode register.

50.3.13.1.1 Flow control in full-duplex mode

In full-duplex mode, the Ethernet module uses IEEE 802.3x Pause packets for flow control. *Table 1416*, describes the fields of a Pause packet. When the FCB_BPA bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Table 1416. Pause packet fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets
PT	Contains Pause time specified in the PT field of the MAC_Q0_Tx_Flow_Ctrl /MAC_Q1_TX_Flow_Ctrl register

50.3.13.1.2 Flow control in half-duplex mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

50.3.13.2 Receive flow control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet. You can enable the Pause flow control by setting the RFE bit in the MAC_Rx_Flow_Ctrl register. *Table 1417*, describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 1417. RX MAC flow control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

When the RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   – Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001).
   – Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set.
   If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.
2. The MAC decodes the following fields of the received packet:
   – Type field: This field is checked for 16'h8808.
   – Opcode field: This field is checked for 16'h0001 (Pause packet).
   – Pause Time: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).
3. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register.
4. If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value.

50.3.14 MAC management counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the CSR. Each register is 32-bit wide. The width of each MMC counter is 32-bit.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, you should set Bit 31 in the MAC_Packet_Filter register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets.

The following definitions define the terminology.

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered “good” if none of the following errors exists:
  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - MII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1518
  - VLAN Frame maxsize = 1522
  - Jumbo Frame maxsize = 9018
  - JumboVLAN Frame maxsize = 9022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in *Table 1418*

Table 1418. Size of the maximum receive packet size

JE	S2KP	GPSLCE	EDVLP	Untagged frame maxsize in bytes	Single VLAN frame maxsize in bytes	Double VLAN frame maxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

50.3.15 Low power modes

This chapter describes the low power modes supported by the Ethernet module. It contains the following sections:

- Energy Efficient Ethernet
- Power Management

50.3.15.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities, negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Note: The EEE feature is not supported when the MAC is configured to use the RMII PHY interface. Even if the MAC supports multiple PHY interfaces, you should activate the EEE mode only when the MAC is operating with the MII interface.
According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the LPI mode is supported only in the full-duplex mode. Therefore, you should not enable the LPI mode when the MAC Transmitter is configured for the half-duplex mode.

50.3.15.1.1 Transmit path functions

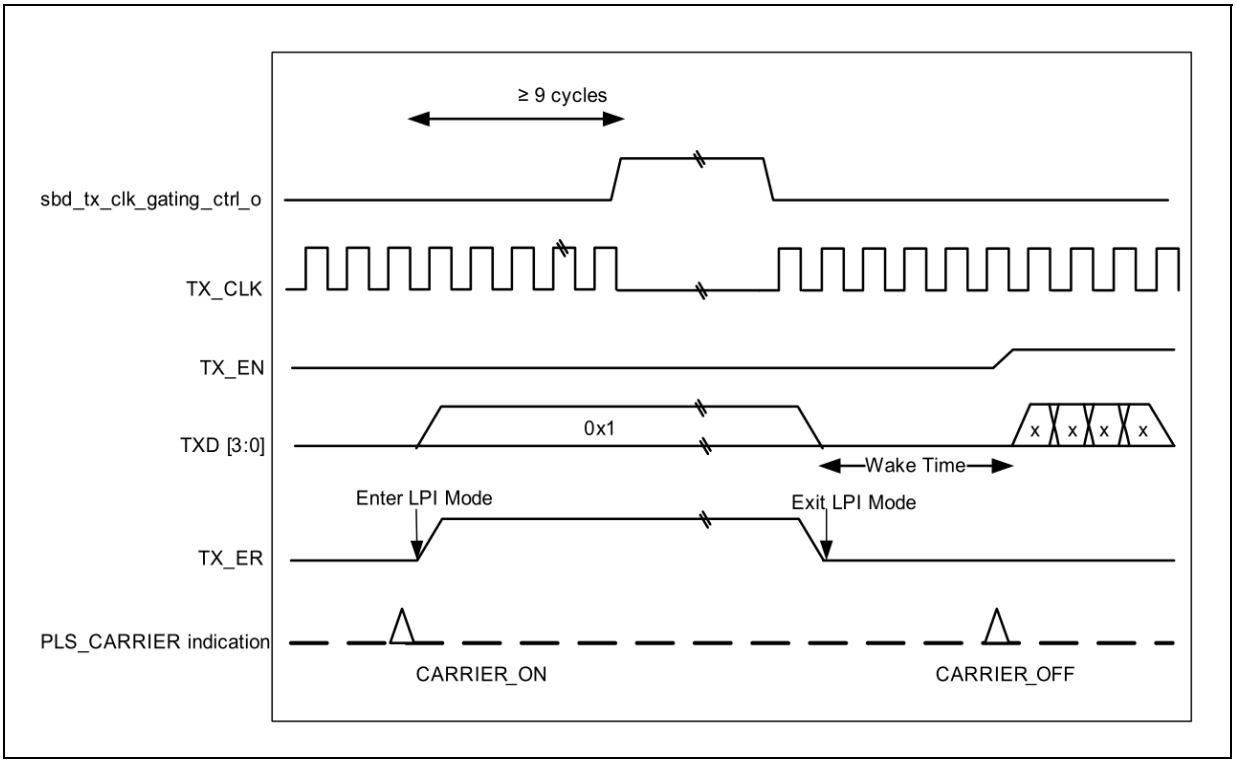
In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Timers_Control register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

Note: According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN.
2. Asserts TX_ER.
3. Sets TXD[3:0] to 0x1 (for 100 Mbps).
4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt.

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:



1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER
   The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC_LPI_Timers_Control register.
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt.

Figure 1306 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

Note: The MAC maintains the same state as the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

The MAC does not stop the TX_CLK clock. You can stop this clock (as shown in Figure 1306) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after 9 Tx Clock Cycles, one Pulse Synchronizer delay (BCM22), and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status Register.
If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.

Figure 1306. LPI transitions (transmit)

50.3.15.1.1.1 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[12]) and LPITXEN (Bit[15]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[11] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

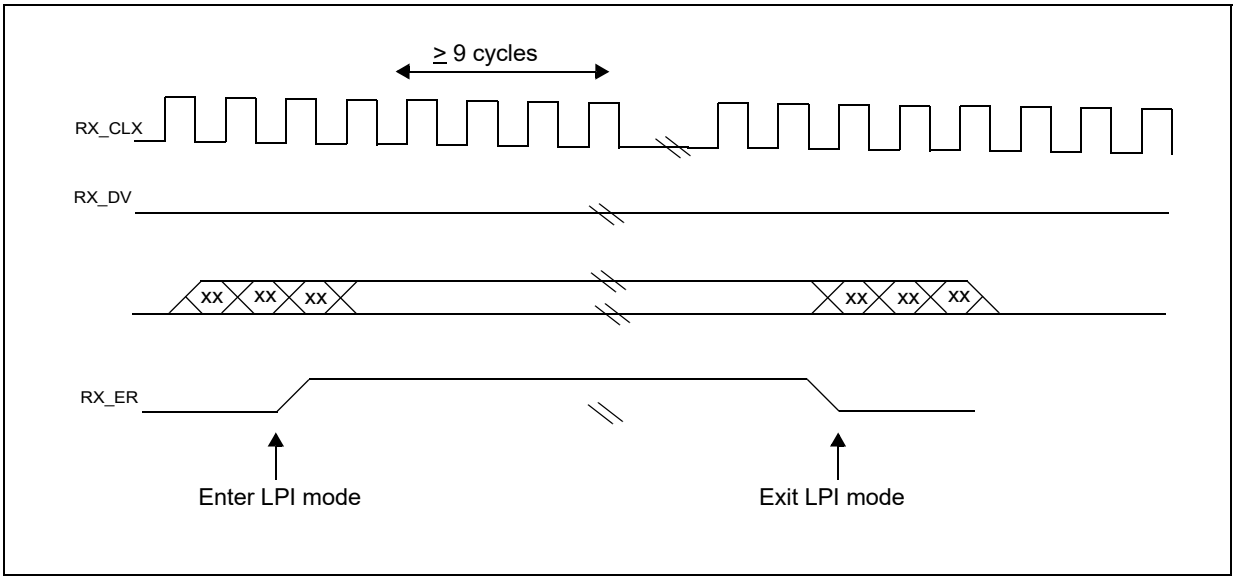
When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

50.3.15.1.2 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV.
4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt.

Note: If the LPI pattern is detected for a very short duration (that is, less than 2 cycles of Rx clock), the MAC does not enter the Rx LPI mode.
If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than 2 cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.



The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 1307 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

Figure 1307. LPI transitions (receive)

Note: If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than 9 clock cycles after the start of the LPI state as shown in Figure 1307.
If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.
If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.
When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.

50.3.15.1.3 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER: The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. Software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.
  This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in Bits[6:15] of the MAC_LPI_Timers_Control register. The MII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.
- LPI TW TIMER: The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[16:31] of MAC_LPI_Timers_Control register. The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal

operation after the TW timer reaches the terminal count.
The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µs.

- LPI AUTO ENTRY TIMER: This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

50.3.15.2 Power management

The power management (PMT) block supports the reception of network (remote) wake-up packets and magic packets. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up packets and magic packets that the MAC receives.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up packet is received and the corresponding detection is enabled.

The PMT block is available in the receive path of MAC. You can select both types of power management packet (remote wake-up packet and magic packet). You can use the RWKPKTEN and MGKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

Note: The magic packet feature is implemented based on the Magic Packet Technology white paper. The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

50.3.15.2.1 PMT block registers

The following are the PMT block registers:

- MAC_PMT_Control_Status
- MAC_RWK_Packet_Filter

50.3.15.2.2 Remote wake-up packet detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status, the normal operation is resumed after a remote wake-up packet is received. The application writes all eight wake-up filter registers, by performing a sequential Write to address (00C4H). The application enables remote wake-up by writing 1 to the RWKPKTEN bit of the MAC_PMT_Control_Status register.

The PMT block supports 4 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wake-up packet.

The Filter Offset determines the offset from which the packet is to be examined. The Filter Byte Mask determines which bytes of the packet must be examined. The bit 0 of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up packet is checked only for length error, FCS error, dribble bit

error, MII error, and collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wake-up packet detection is updated in the PMT Control and Status register for every remote wake-up packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wake-up packet.

Note: The watchdog timeout limit for a remote wake-up frame is 2048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a remote wake-up frame only when Enable IPv4 ARP Offload is selected in the configuration.

50.3.15.2.3 Magic packet detection

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wake-up packet data format of 6 bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wake-up by writing 1 to the MGKPKTEN bit of the MAC_PMT_Control_Status register. The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48’hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48’hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48’hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

Destination Address Source Address …….. FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

The Ethernet module checks the remote wake-up packet only for length error, FCS error, dribble bit error, MII error, collision. In addition, the remote wake-up packet is checked to

ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, the Ethernet module considers it a valid packet.

The magic packet detection is updated in the MAC_PMT_Control_Status register for the received magic packet. A PMT interrupt to the Application triggers a read to the MAC_PMT_Control_Status register to determine whether a magic packet has been received.

Note: The watchdog timeout limit for a magic packet is 2048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.
The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet only when Enable IPv4 ARP Offload is selected in the configuration.

50.3.15.2.4 System considerations during power down

The Ethernet module neither gates nor stops clocks when the power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during the power-down mode, because it is involved in the magic packet or remote wake-up packet detection. However, the application path clock can be gated during the power-down mode. The transmit Path clock must be gated during the power-down mode only if ARP Offload is not enabled.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt [Bit 31 of the register] is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC_Configuration register.
3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. You can do this by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter the Power-Down mode.
6. Gate the application and transmit clock (transmit clock must be gated only if ARP Offload is not enabled) inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid remote wake-up packet, the Ethernet module asserts the pmt_intr_o signal and exits the Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

50.3.16 Interrupts

Interrupt can be generated as a result of various events in the Ethernet IP core. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (interrupt) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the DMA_Interrupt_Status register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX and RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH*n*_STATUS register
- MTL_INTERRUPT_STATUS register
- MAC_INTERRUPT_STATUS register

The interrupt is a level signal and will get de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

50.3.16.1 DMA interrupts

The DMA_CHn_STATUS register captures all the interrupt events of that TxDMA and RxDMA channel pair. The DMA_CH*n*_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[16:17] of DMA_CHn_STATUS register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[25] of DMA_CHn_STATUS register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the register for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of the DMA_Interrupt_Status register are cleared.

50.3.16.1.1 Periodic scheduling of DMA Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet IP gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[0]) once for every “required” number of packets to be transmitted.
2. Similarly, set the IOC (RDES3[1]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.

In addition to above, an interrupt timer (DMA_CHn_RX_INTERRUPT_WATCHDOG_TIMER) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a

non-zero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[1]) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH*n*_Interrupt_Enable register. The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

50.3.16.1.2 Per DMA channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CHn_STATUS register. The TI bit is set whenever the Tx DMA channel closes the a descriptor in which the IOC (Interrupt On Completion - TDES2[0]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[1]) bit is set.

The common interrupt output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH*n*_Interrupt_Enable register.

50.3.16.2 MTL interrupts

In MTL, the interrupts are mainly related to exception events in the TxQ or RxQ in the Transmit and Receive paths respectively. The interrupt status are captured and organized in a hierarchical manner in order to identify the root cause quickly.

The MTL_INTERRUPT_STATUS register identifies the top level modules that can cause the interrupt to be asserted.

- Bits[30:31] identify 2 Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Q*n*_Interrupt_Status register to identify the exact cause and set the corresponding bits to 1 to clear the interrupt event. The assertion of interrupt due to these events is enabled by the corresponding enable bits in MTL_Q*n*_Interrupt_Enable register.
- Bit[15] is made high in case the event is present in the MAC core. The application should in turn read the MTL_INTERRUPT_STATUS register to identify the cause.
- Bit[14] is related to indirect access completion events to the TxFIFO and RxFIFO memory in Debug Mode.

50.3.16.3 MAC interrupts

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_INTERRUPT_STATUS register describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the MAC_INTERRUPT_ENABLE register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, Bit 26 of the MAC_INTERRUPT_STATUS register indicates that

the LPI interrupt status has changed. You must read the TLPIEN bit of MAC_LPI_Control_Status register to clear this interrupt event.

The interrupts from the MAC are combined (OR'ed) and given as the MACIS bit in the DMA_Interrupt_Status register.

50.3.16.4 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt mci_intr_o (interrupt in EQOS-DMA configurations) is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the mci_intr_o (interrupt in EQOS-DMA configurations), the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. You can use the lpi_intr_o signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state. If you do not want to gate-off the application clock during the Rx LPI state, you can leave the lpi_intr_o signal unconnected and use the mci_intr_o (interrupt in EQOS-DMA configurations) signal to detect Rx LPI exit.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately after the MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSR clock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

50.3.16.5 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. In addition to the interrupt, the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode.

You can use the pmt_intr_o interrupt to trigger the external clock-gating circuitry to restore the application clock and Tx clock to the MAC. If you do not want to gate-off these clocks during the power-down mode, you can leave the pmt_intr_o signal unconnected and use the interrupt to detect the MAC wake-up operation.

The pmt_intr_o signal is generated in the Rx clock domain. It is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the Ethernet module is operating in the 10 Mbps mode.

When software resets the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

50.3.16.6 Overview of interrupt for MDIO transaction completion

This is to generate an interrupt on completion of MDIO read or write transactions. The application does not need to poll the GMII Busy bit of MAC_MDIO_Address register to know the completion of MDIO commands.

50.3.16.6.1 Related registers

The following are the registers are modified for the design changes:

- MAC_INTERRUPT_STATUS
- MAC_INTERRUPT_ENABLE

50.3.17 PHY interfaces

Refer to the Device Configuration chapter for PHY interfaces configuration.

50.3.17.1 Station management agent

50.3.17.1.1 Introduction to station management agent

The application can access the PHY registers through the Station Management Agent (SMA) module. SMA is a two-wire Station Management interface (MIM).

50.3.17.1.2 Functional description of station management agent

In the ethernet module core, the gmii_mdc_o clock is derived from the APB clock, using a divider-counter. The divide factor depends on the clock range setting (CR field) in the MAC_MDIO_Address register.

Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register, to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, there is a provision to select a different divider.

The MDIO frame structure is as follows:

Table 1419. MDIO clause 45 frame structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2’b00
OPCODE	– 2’b00 – 2’b01 – 2’b10 – 2’b11
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices

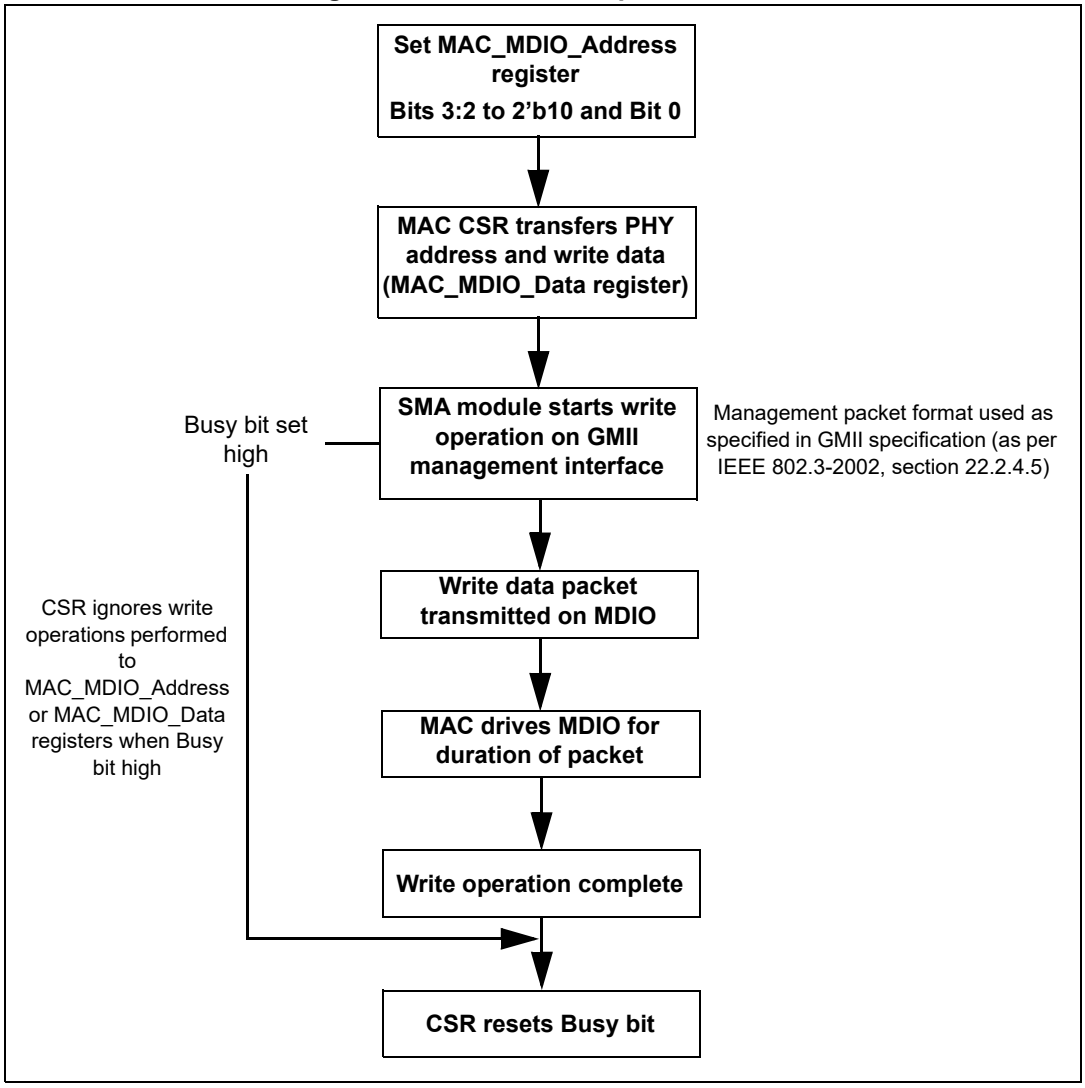
Table 1419. MDIO clause 45 frame structure (continued)

Field	Description
TA	Turnaround – 2'bZ0: Read and post-read increment address – 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value: For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. – In address and data write cycles, the ethernet module drives the MDIO line during the transfer of these 16 bits. – In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Address register can be programmed to enable Clause 22 or Clause 45 mode of operation. The table below shows the Clause 22 frame format.

Table 1420. MDIO clause 22 frame structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2'b01
OPCODE	– 2'b01 for Write – 2'b10 for Read
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address to select the register within each MMD
TA	Turnaround – 2'bZ0: Read and post-read increment address – 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	Any 16-bit value: – In a write operation, the ethernet module drives MDIO. – In read operation, the PHY drives MDIO.



In addition to normal read and write operations, the SMA also supports post-read increment address while operating in Clause 45 mode.

50.3.17.1.2.1 GMII/MII management write operation

After the Station Management Agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a write operation to the PHY registers.

The following figure illustrates the flow for a Write operation from the SMA module to the PHY registers.

Figure 1308. SMA write operation flow

When you set Bit[3:2] to 2'b01 and Bit 0 in the MAC_MDIO_Address register, the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MAC_MDIO_Data register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MAC_MDIO_Address register or the MAC_MDIO_Data register during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit.

The packet format for the Write operation is shown in the following figure:

Figure 1309. Packet format for the write operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD...DDD	Z

50.3.17.1.2.2 GMII/MII management read operation

After the Station Management Agent receives the PHY address and the register address in the PHY from the MAC CSR module, the SMA initiates a Read operation to the PHY registers.

The flow of a Management read operation is as follows:

1. Set Bit[3:2] to 2'b11 and Bit 0 in the MAC_MDIO_Address register.
2. The MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers.
3. The SMA module starts a Read operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).
4. When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MAC_MDIO_Address or MAC_MDIO_Data register during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface.
5. When the Read operation is complete, the SMA indicates this to the CSR.
6. The CSR resets the Busy bit and updates the MAC_MDIO_Data register with the data read from the PHY.

For more information about the communication from the application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.

The packet format for the Read operation is as follows:

Figure 1310. Packet format for the read operation

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDD...DDD	Z

Note: The MAC drives the MDO on negedge of MDC so that it can be sampled on posedge with sufficient setup or hold time (half cycle of MDC). Similarly, the PHY can drive MDI on negedge so that the MAC samples it on posedge, thus providing half cycle setup or hold time.

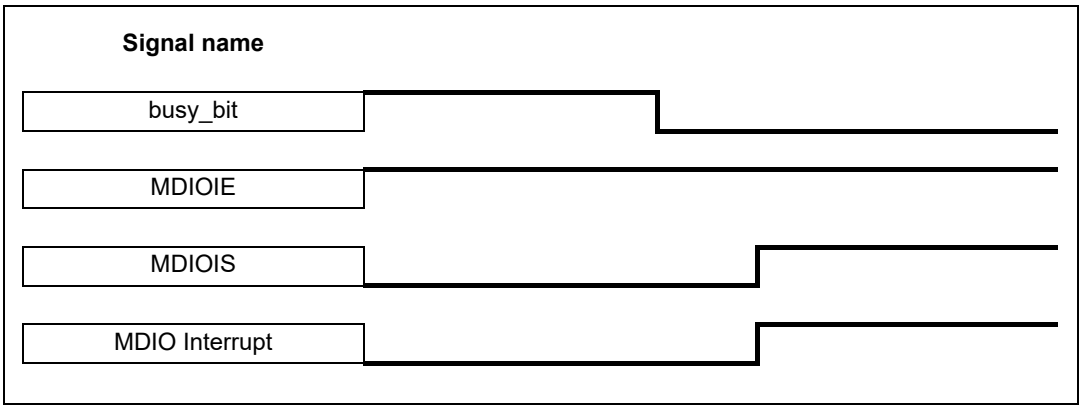
50.3.17.1.2.3 Preamble suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The ethernet module provides controls to support preamble suppression, it will transmit MDIO frames with only 1 preamble bit. The preamble suppression can be enabled by setting PSE bit of MAC_MDIO_Address register.

50.3.17.1.2.4 Trailing clocks and back to back transactions

The ethernet module drives MDC clock on the gmii_mdc_o port for duration of the MDIO frame. There is no clock driven during the idle period. The trailing clocks feature can be used if the PHY needs the MDC clock to be active for some cycles after the MDIO frame. The NTC field in MAC_MDIO_Address register allows programming of trailing clocks from 0 to 7.

The ethernet module supports Back to Back transactions which allows start of next MDIO frame even before the trailing clocks are completed for previous MDIO frame. This feature can be enabled by setting BTB bit in MAC_MDIO_Address register when trailing clocks feature is also enabled. When Back to Back transactions is enabled, the GMII Busy will be cleared immediately after MDIO frame completion allowing the software to issue next command, which will be executed by ethernet module while trailing clocks are still on for previous MDIO frame. When Back to Back transactions is not enabled, the GMII Busy will be cleared after the trailing clocks are completed for MDIO frame.



50.3.17.1.3 Interrupt for MDIO transaction completion

The application does not need to poll the GMII Busy bit of MAC_MDIO_Address register to know the completion of MDIO commands.

GMII busy bit is set to instruct the SMA to initiate a Read or Write access to the MDIO slave. After the completion of the command, the busy signal is de-asserted to indicate the completion of MDIO transaction.

A pulse generated at the falling edge of the busy signal is used to set the MDIO interrupt status bit of MAC Interrupt Status register. The interrupt is generated only if the MDIO Interrupt Enable bit of MAC Interrupt Enable bit is set.

Figure 1311. MDIO interrupt timing diagram

50.3.17.2 Reduced Gigabit Media Independent Interface

50.3.17.2.1 Introduction to Reduced Gigabit Media Independent Interface (RGMII)

The RGMII block has the following characteristics:

- Supports 10 Mbps, 100 Mbps, and 1000 Mbps operation rates.
- Extracts the in-band (link speed, link status, and duplex mode) status signals from the PHY and provides them to the MAC for link detection.

50.3.17.2.2 Signal conversion

The RGMII block performs the following conversions as described in the sections below.

50.3.17.2.2.1 Transmit data conversion

As defined in the RGMII specification, multiplexing of data and control in Gigabit mode is accomplished by using both edges of the Transmit clock. The RGMII block accepts the 8-bit GMII transmit data from the MAC GMII (gmii_txd[7:0]) on the rising edge of clk_tx_i. For Gigabit operation, the RGMII block then converts gmii_txd[7:0] to two 4-bit nibbles and transmits the data on the RGMII transmit data port (rgmii_txd_o[3:0]) as follows:

- At the rising edge of clk_tx_i, rgmii_txd_o[3:0] contains gmii_txd[3:0].
- At the falling edge of clk_tx_i (rising edge of clk_tx_180_i), rgmii_txd_o[3:0] contains gmii_txd[7:4].

For 10/100 mode, the Transmit data to the PHY is 4 bits. Therefore, for 10/100 mode, the RGMII block drives the gmii_txd[3:0] data to the PHY on rgmii_txd_o[3:0] at the rising edge of clk_tx_i.

50.3.17.2.2.2 Transmit control signal conversion

The RGMII block accepts the GMII transmit control signals (gmii_txen and gmii_txer) from the MAC GMII on the rising edge of clk_tx_i. The RGMII block then multiplexes gmii_txen and gmii_txer onto the rgmii_tctl_o output (as required by the RGMII specification) as follows:

- At the rising edge of clk_tx_i, rgmii_tctl_o is gmii_txen.
- At the falling edge of clk_tx_i (rising edge of clk_tx_180_i), rgmii_tctl_o is the logical XOR of gmii_txen and gmii_txer.

The table below shows the mapping of the PLS_DATA.request parameters from the MAC to the corresponding signaling on the GMII and RGMII control and data signals.

Table 1421. Encoding of gmii_txen, gmii_txer, rgmii_tctl_o, and rgmii_txd_o signals

gmii_txen	gmii_txer	gmii_txd(1)	rgmii_tctl_o (2)	Description	PLS_DATA.request Parameter
0	0	0x00–0xFF	0,0	Normal inter-packet	TRANSMIT_COMPLETE
0	1	0x00	0,1	Reserved	ZERO, ONE (8 bits)
0	1	0x01	0,1	LPI pattern	TRANSMIT_LPI in EEE mode
0	1	0x02–0x0E0,1	0,1	Reserved	
0	1	0x0F	0,1	Carrier extend	EXTEND (8 bits)
0	1	0x10–0x1E	0,1		
0	1	0x1F	0,1	Carrier extend	EXTEND_ERROR (8 bits)
0	1	0x20–0xFF	0,1	Reserved	

Table 1421. Encoding of gmii_txen, gmii_txer, rgmii_tctl_o, and rgmii_txd_o signals (continued)

gmii_txen	gmii_txer	gmii_txd(1)	rgmii_tctl_o (2)	Description	PLS_DATA.request Parameter
1	0	0x00–0xFF	1,1	Normal data transmission	ZERO, ONE (8 bits)
1	1	0x00–0xFF	1,0	Transmit error propagation	No applicable parameter

1. If the RGMII interface is configured to transmit the configuration during the IPG, rgmii_txd[3:0] reflects the Duplex Mode, Port Select, Speed (encoded as 00 for 10 Mbps, 01 for 100 Mbps, and 10 for 1000 Mbps), and Link Up/Down bits of the MAC_Configuration register during this period.
2. Values at rising, falling edges of clk_tx_i

50.3.17.2.2.3 Receive data conversion

For 1000 Mbps mode, the RGMII block registers the 4-bit data on the rgmii_rxd_i[3:0] signal at both edges of the Receive clock (clk_rx_i) and transfers the resulting 8-bit data to the ethernet module GMII on the rising edge of clk_rx_i clock, as follows:

- gmii_rxd[3:0] is the value received on rgmii_rxd_i[3:0] at the rising edge of clk_rx_i
- gmii_rxd[7:4] is the value received on rgmii_rxd_i[3:0] at the falling edge of clk_rx_i (rising edge of clk_rx_180_i)

For 10/100 mode, the RGMII block registers the 4-bit data on rgmii_rxd_i[3:0] only at the rising edge of clk_rx_i and transfers the data to the ethernet module GMII on the rising edge of clk_rx_i, as follows:

- gmii_rxd[3:0] is the value received on rgmii_rxd_i[3:0] at the rising edge of clk_rx_i
- gmii_rxd[7:4] is 0x0

50.3.17.2.2.4 Receive control signal conversion

The RGMII block samples the rgmii_rctl_i signal from the PHY at both edges of the clk_rx_i clock and drives the resulting GMII receive control signals to the ethernet module GMII as follows:

- gmii_rxdv is the value received on rgmii_rctl_i at the rising edge of clk_rx_i.
- gmii_rxer is the logical XOR of the following two signals/
  - The value received on rgmii_rctl_i at the rising edge of clk_rx_i (gmii_rxdv).
  - The value received on rgmii_rctl_i at the falling edge of clk_rx_i (rising edge of clk_rx_180_i).

50.3.17.2.2.5 Receive status signal conversion

To generate the GMII link status signals, the RGMII block decodes the rgmii_rxd_i[3:0] value sampled at the rising edge of clk_rx_i when the value of rgmii_rctl_i is 0 for both the rising and falling edges of clk_rx_i (normal inter-packet value). The following are the decoded status signals:

- link_status is the value of rgmii_rxd_i[0]
- link_speed is the value of rgmii_rxd_i[2:1]
- link_mode is the value of rgmii_rxd_i[3]

The table below shows the mapping of the PLS_DATA.indicate parameters from the ethernet module to the corresponding signaling on the GMII and RGMII control and data signals. In addition, the RGMII block asserts gmii_crs to the ethernet module GMII when any of the following conditions is true:

- The gmii_rxdv is true.
- The gmii_rxdv is false, gmii_rxer is true, and the value of gmii_rxd is 0xFF
- a carrier extend, carrier extend error, or false carrier occurs in Gigabit mode (see table below).
- Afalse carrier occurs in 10/100 mode.
- The RGMII is transmitting data, carrier extend, or carrier extend error on the RGMII transmit outputs.

The RGMII block asserts gmii_col to the MAC GMII when both of the following conditions are true:

- The RGMII is transmitting data, carrier extend, or carrier extend error on the RGMII transmit outputs.
- The RGMII is asserting either gmii_crs or gmii_rxdv signal.

Table 1422. Decoding of rgmii_rctl_i and rgmii_rxd_i

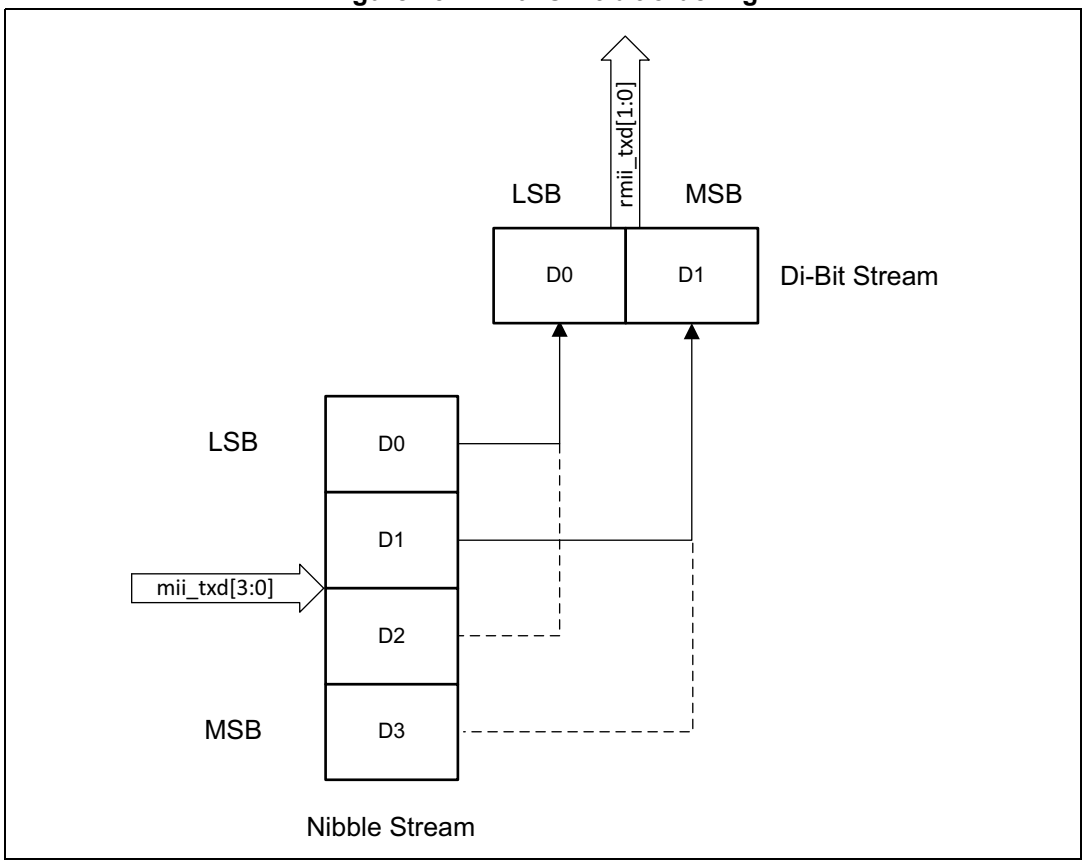
rgmii_rctl_i	gmii_rxd[7:0] ([3:0] in 10/100 mode)(1)	gmii_rxdv	gmii_rxer	Description	PLS_DATA.indicate or PHY_status Parameter
0,0	XXXXXXX0 or XXXXXXX1	0	0	Normal inter-packet	Indicates link status: 0 down 1 up
0,0	XXXXX00X or XXXXX01X or XXXXX10X or XXXXX11X	0	0	Normal inter-packet	Indicates Receive clock frequency: 00 2.5 MHz 01 25 MHz 10 125 MHz 11 Reserved
0,0	XXXX1XXX or XXXX0XXX	0	0	Normal inter-packet	Indicates duplex status: 0 half-duplex 1 full-duplex
0,1	0x01 (or 0x1 in 10/100 mode)	0	1	Low Power Idle (LPI)	Remote MAC in LPI in the Energy Efficient Ethernet (EEE) mode
0,1	0x0E (or 0xE in 10/100 mode)	0	1	False carrier indication	False carrier present
0,1	0x0F	0	1	Carrier extend	EXTEND (8 bits)
0,1	0x1F	0	1	Carrier extend error	ZERO, ONE (8 bits)
0,1	0xFF (or 0xF in 10/100 mode)	0	1	Carrier sense	PLS_Carrier.Indicate
1,1	0x00–0xFF	1	0	Normal data reception	ZERO, ONE (8 bits)
1,0	0x00–0xFF	1	1	Data reception error	ZERO, ONE (8 bits)

1. Values at rising, falling edges of clk_rx_i

50.3.17.3 Reduced Media Independent Interface

50.3.17.3.1 Introduction to Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode).



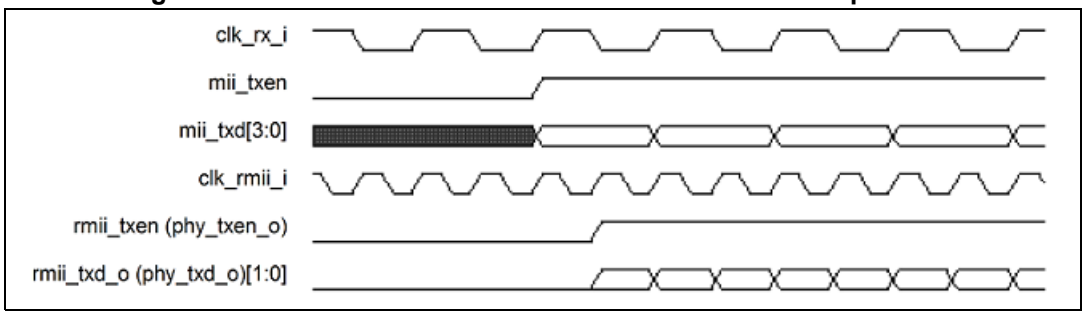
The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bit wide Transmit and Receive paths.

50.3.17.3.1.1 Transmit bit ordering

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in below figure. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

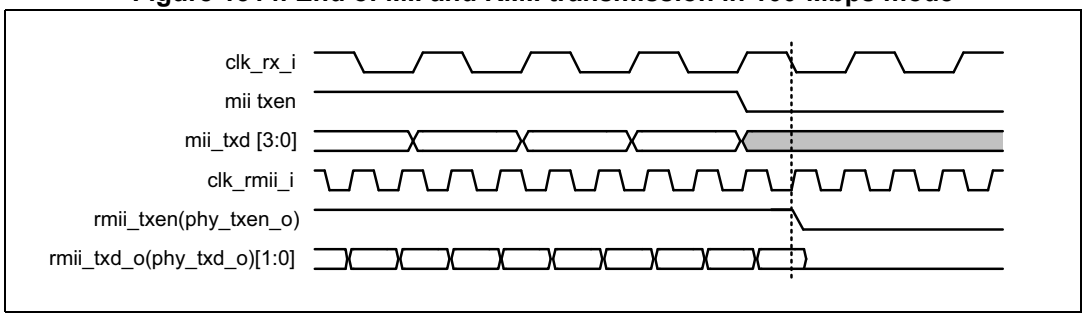
Figure 1312. Transmit bit ordering



50.3.17.3.1.2 RMII transmit timing diagrams

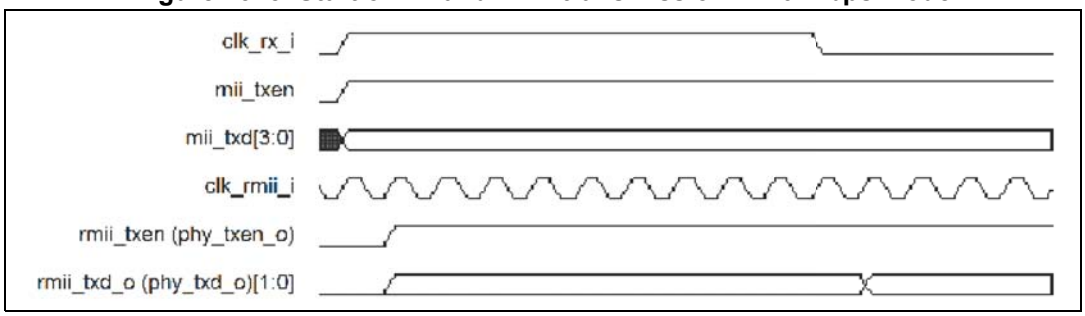
RMII transmit timing diagrams depict the various MII transmissions.

Figure 1313 through *Figure 1316* show MII-to-RMII transaction timing.



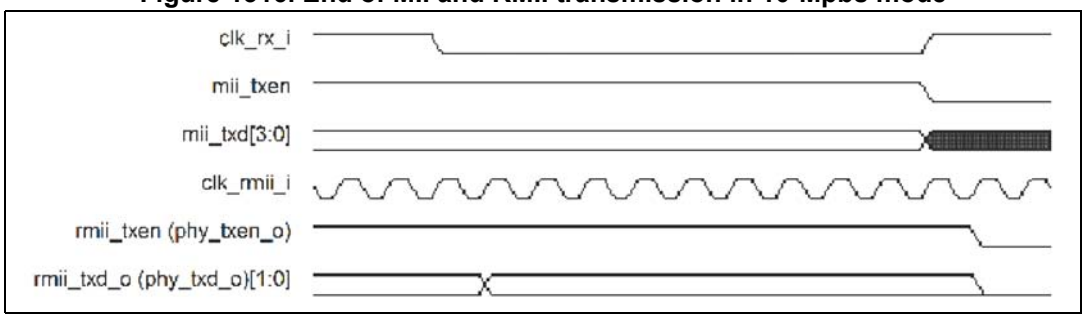
The figure below shows the start of MII transmission and the following RMII transmission in 100-Mbps mode.

Figure 1313. Start of MII and RMII transmission in 100-Mbps mode



The figure below shows the end of packet transmission for MII and RMII in 100-Mbps mode.

Figure 1314. End of MII and RMII transmission in 100-Mbps mode



The figure below shows the start of MII transmission and the following RMII transmission in 10-Mbps mode.

Figure 1315. Start of MII and RMII transmission in 10-Mbps mode

The figure below shows the end of MII transmission and RMII transmission in 10-Mbps mode.

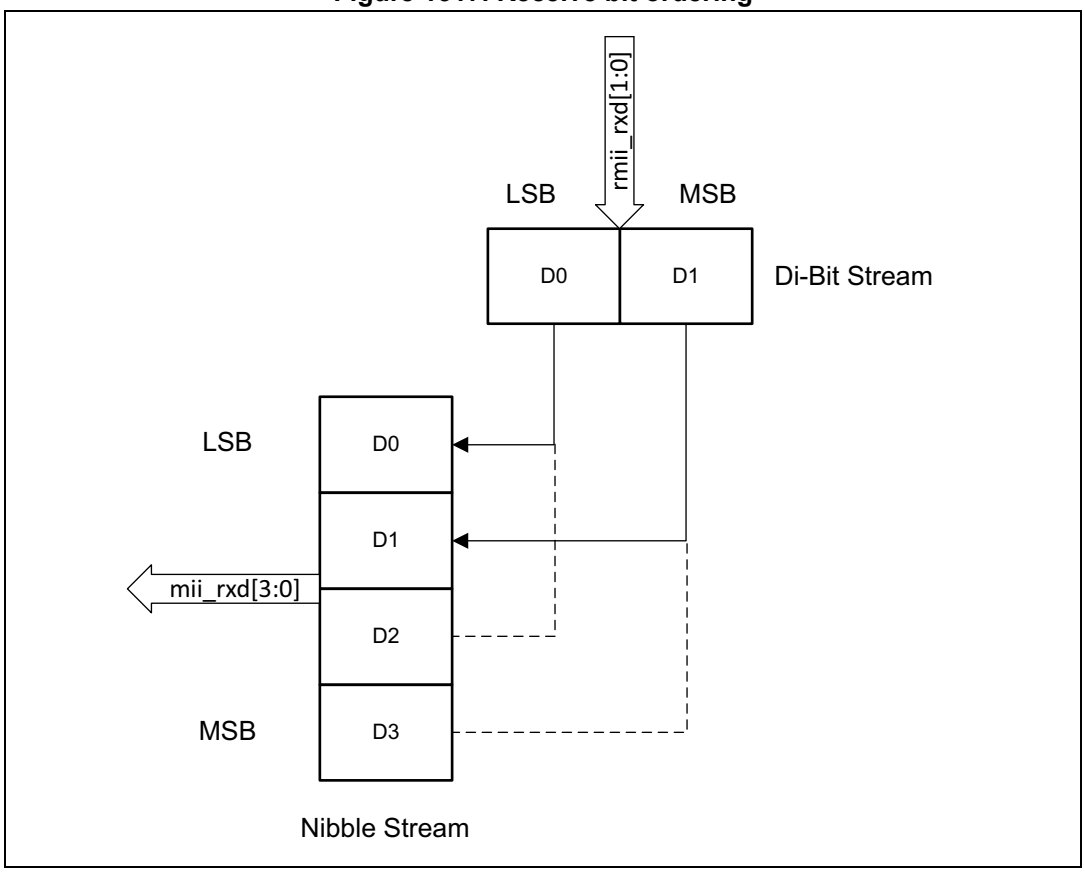


Figure 1316. End of MII and RMII transmission in 10-Mpbs mode

50.3.17.3.1.3 Receive bit ordering

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in the below figure. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 1317. Receive bit ordering

50.3.18 Safety

To make an IP better suited for applications in the automotive space, functional safety has been considered throughout the IP development process. ISO 26262 addresses functional safety and requires the hardware components to be analyzed with respect to their ability to detect and/or control the effects of random hardware faults. Random hardware faults can occur at any point in time during the life-cycle of the hardware component. They can take the form of permanent faults, or transient faults, and require safety mechanisms to be in place to ensure that severe consequences do not occur as a result of those faults.

The module includes the internal safety mechanisms which assist in detecting and handling random hardware faults. These complement the mechanisms already defined in the module protocol. The automotive safety features are targeted to improve the reliability and reduce

the time taken to detect faults in the controller. The module supports the following features for automotive safety:

- Error Correction Code (ECC) Protection for all Memories
- On-Chip Data Path Parity Protection
- FSM Parity and Timeout Protection
- AHB Master Interface Timeout Protection

50.3.18.1 Error Correction Code (ECC) Protection for Memories

50.3.18.1.1 Overview

Error Correction Code (ECC) protects all local memories of the module. ECC can correct single-bit error and detect double-bit error.

At the write interface, ECC check bits are computed on the contents of the data bus and respective write address. These ECC check bits are appended with the data that is written to the memory.

At the read interface, ECC check bits are recomputed on the content of the read data and the respective read address. This recomputed ECC is compared with the ECC check bits received from memory. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

50.3.18.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_ECC_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first erred memory address is reported or the latest erred memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors.
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected and the corresponding interrupt enable bits are set.
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Interrupt_Status registers.
- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

50.3.18.1.3 Handling the Uncorrectable Errors

Recovery from an uncorrectable error is based on the memory block and the operating mode of Ethernet module.

50.3.18.1.3.1 MTL Tx memory

If an uncorrectable error is detected, the packet is terminated with a forcible EOF. A CRC error is introduced by MAC for the transmitted packet, and the remaining packets in the FIFO are flushed and flush status (Bit 13) is indicated to the application in the TDES3 write-back descriptor belonging to that queue.

When an uncorrectable error is detected and reported by asserting the safety uncorrectable interrupt, reset the module to ensure proper functionality.

50.3.18.1.3.2 MTL Rx memory

When an uncorrectable error is detected, reset the module to ensure proper functionality.

50.3.18.1.3.3 MTL EST memory

This section is applicable only if the module configuration supports EST feature.

When an uncorrectable error is detected in the MTL EST memory, the module follows this sequence of actions for recovery:

1. The module disables the EST feature by resetting the EEST bit of MTL_EST_Control register. It sets all the gates to open state, generates an interrupt, and sets the status in the MTL_ECC_Interrupt_status register. This allows the software to reprogram the correct value in the EST memory.
2. The location of the uncorrected error in the EST memory is available in the ESTUEA/ESTCEA field of the MTL_EST_ECC_Err_Addr_Status register.

50.3.18.1.3.4 MTL Rx Parser memory

This section is applicable only if the module configuration supports FRP feature.

When an uncorrectable error is detected in the MTL Rx Parser memory, an error indication is provided to the Rx Parser block. The parser halts the parsing of the corresponding packet and all subsequent packets are accepted and marked as 'Parsing Incomplete (RXPI)' in the packet status of descriptor.

50.3.18.1.4 ECC Error Injection Capabilities

The module supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection.
- Two bits to indicate the type of error to be injected:
  - 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for:

- Tx/Rx FIFO memory are specified in the MTL_DBG_CTL register.
- EST memory are specified in the MTL_EST_GCL_Control register. Applicable only if the module configuration has EST feature enabled.
- RX parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register.
- Applicable only if the module configuration has EST feature enabled.

While using debug mode for ECC error injection:

- There should be no traffic.
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write maintains the same value for the error injection control word.

50.3.18.2 On-Chip Data Path Parity Protection

50.3.18.2.1 Overview

This feature provides parity protection for Transmit and Receive data paths, where feasible. For every byte of data, one bit parity is generated.

At the transmit side, the data from the host memory is protected with parity until it is written into the MTL Tx FIFO.

At the receive side, data from the MTL Rx FIFO read side is protected with parity until it is sent to the host.

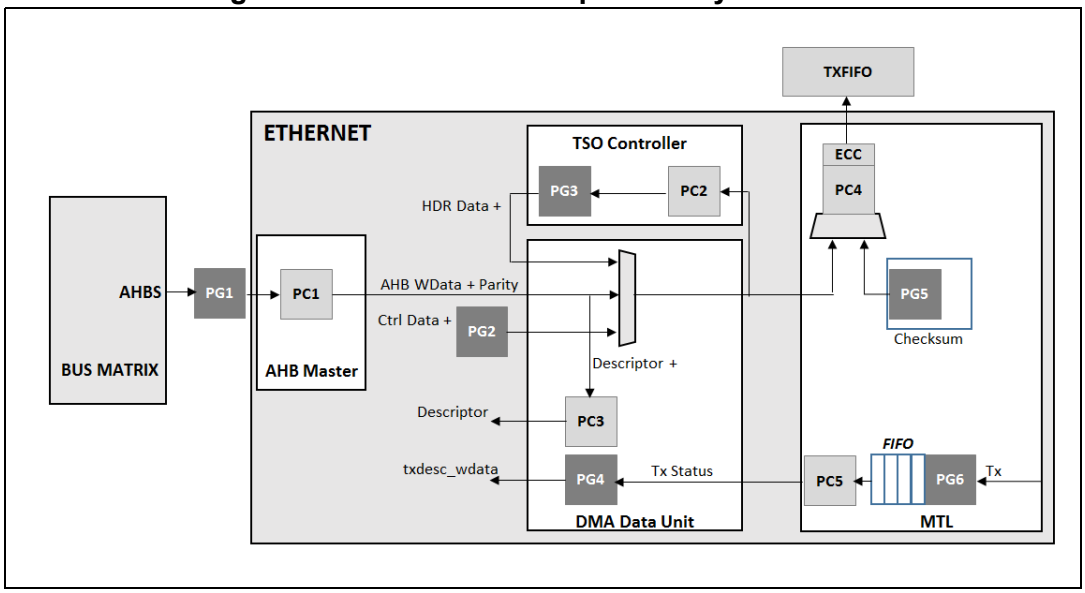
By default, even parity generation/detection is enabled. You can program to select odd parity generation/detection (OPE bit of MTL_DPP_Control register). It is recommended to keep the default value that is even parity.

Module does not support parity protection for data paths in MAC and MTI/MRI interface side in MTL. This is because data manipulation and offloading is performed on the data.

50.3.18.2.2 Transmit Datapath Parity Protection

The transmit DMA fetches the data packet and descriptors from the host memory through the AHB Master interface. The descriptors are consumed in the transmit DMA.

When the TSO feature is enabled, the transmit DMA modifies some of the header fields of the packet for segmentation. So the header data from TSO controller and the control data from the data transmit module are multiplexed with data from host memory and sent on the ATI interface, to MTL.



When the TSO feature is not enabled, the fetched packet is transferred by the transmit DMA to the MTL TXFIFO after aligning/concatenating the fetched data (when necessary) into different burst transfers. The transmit DMA also generates and pushes the “control words” for each packet in the same data path before the start of a packet.

In the MTL, when TX Checksum Offload Engine is enabled, the data packet is stored/written into the TXFIFO memory. The calculated checksums and the generated control signals are also written into the TXFIFO memory. Therefore, the input data from the ATI interface along with the internally generated checksum control word are multiplexed and then written into the MTL TX FIFO.

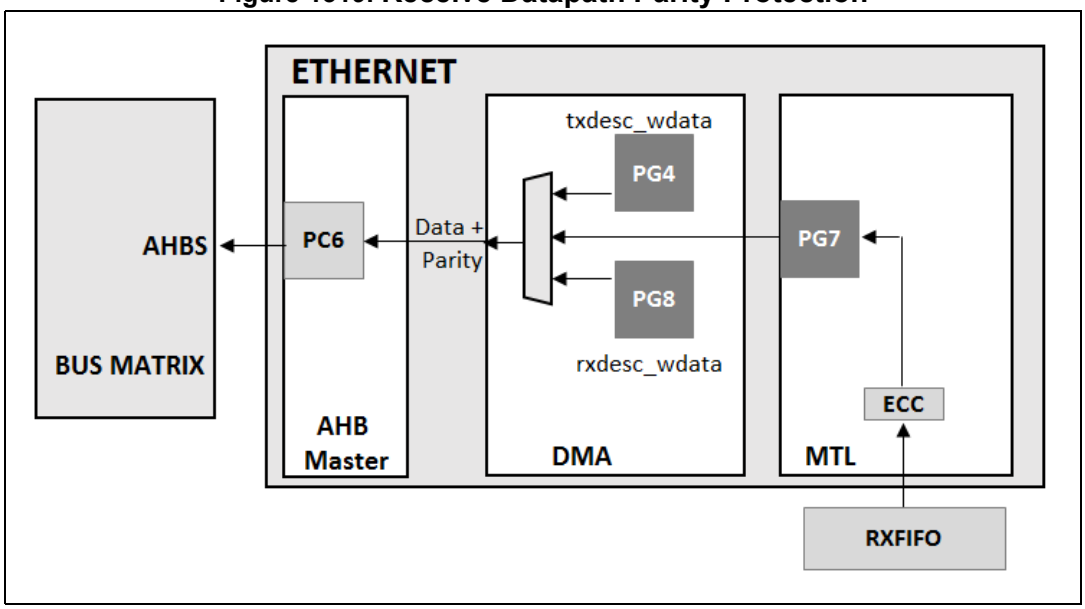
Transmit status received from MAC is written into a FIFO and sent to the DMA where it is updated along with the descriptor write-back status and then written to the host memory.

Figure below describes the locations of parity generators and checkers in the transmit data path:

Figure 1318. Transmit Datapath Parity Protection

Following are the locations of the parity generators and checkers in the transmit data path:

- Parity is generated on the input data port, PG1.
- A parity check is performed on the input parity data received from the application interface, PC1, and the respective error status is specified in the ATPES field of MAC_DPP_FSM_Interrupt_status register. This check identifies if the fault is internal or external to Ethernet module.
- A parity is generated on the control data received from the data transmit module, PG2.
- When TCP segmentation is enabled, parity is generated on the modified header data provided by the DMA TSO controller, PG3.
- When TCP segmentation is enabled, parity check is performed on the feedback header data, PC2, which is originally generated from the DMA TSO controller. The respective parity error is reported in the TPES field of MAC_DPP_FSM_Interrupt_status register.
- As the read descriptor data is consumed in both data transmit and data receive modules, parity check is performed on this data, PC3. The respective parity error is reported in RDPES field of MAC_DPP_FSM_Interrupt_status register.
- Parity is generated on the modified Tx write-back status which is generated from DMA data unit, PG4.
- When the checksum offloading is enabled parity is generated on the checksum data generated in MTL, PG5.
- Parity check is performed at the transmit write controller in MTL, PC4 before writing the data to TX FIFO. The parity generation is terminated at this checker because the ECC protection for memories feature protects the external memory paths. The respective



parity error status is reported in MPES field of MAC_DPP_FSM_Interrupt_status register.

- If transmit Status drop disabled in MTL, parity is generated on the status received from MAC, PG6
- If transmit Status drop is disabled in MTL, parity check is performed on the Tx Status which is transferred on ATI interface, PC5. The respective parity error status is reported in MTSPES bit of MAC_DPP_FSM_Interrupt_Status register.

50.3.18.2.3 Receive Data Path Parity Protection

On the receive side, the data packet and status from the MTL Rx FIFO are sent to DMA where it is multiplexed with the descriptor write-back status from the data transmit/receive module, before transferring to the host.

Figure 1319. Receive Datapath Parity Protection

Following are the locations of parity generators and checkers in the receive data path:

- Parity is generated on the MTL Rx FIFO read data, PG7 after ECC correction.
- Parity is generated on the DMA Rx write-back descriptor status after the update by the DMA data unit, PG8.
- Parity check is performed on the output data of AHB Master interface, PC6 and the respective parity error status is reported in the ARPES field of MAC_DPP_FSM_Interrupt_Status register.

50.3.18.2.4 Parity Error Injection

Each parity generator supports a control to inject parity error. When enabled, the parity of the first valid data at the generators are flipped. Application must set the appropriate bit in the MTL_DPP_Control register; after the respective parity bit is flipped the hardware clears the same. After the generator inserts error in the generated parity data, the subsequent parity checker should detect the mismatch and report the error status in the MAC_DPP_FSM_Interrupt_Status register.

For example, to insert an error in the input data at parity generator PG1, the sequence of operations are as follows:

1. Application sets the IPEID bit of MTL_DPP_Control register.
2. The parity generator PG1 inserts an error in the parity bits generated for the first valid data.
3. After the error is inserted, IPEID field of the MTL_DPP_Control register is reset.

As the data traverses through multiple paths, the subsequent checkers PC3 or PC4 in this example detects the parity mismatch and reports the error status in MAC_DPP_FSM_Interrupt_Status register and generates the sbd_sfty_ue_intr_o interrupt.

50.3.18.2.5 Interrupt for Parity Error

Ethernet module generates an interrupt, sbd_sfty_ue_intr_o to indicate to the application if any parity error is detected. Appropriate status is indicated in DMA/MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status registers. All the parity errors reported by the different checkers are logged in the MAC_DPP_FSM_Interrupt_Status register.

50.3.18.3 FSM Parity and Timeout Protection

The FSM protection feature supports FSM parity and FSM time out protection.

50.3.18.3.1 FSM State Parity Protection

The module implements one-hot encoding scheme for holding the state register. Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.
