DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2044. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2045 through *Table 2048* show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 2045. DAC events and resultant updates, dual-issue case 1

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)

Table 2045. DAC events and resultant updates, dual-issue case 1 (continued)

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2046. DAC events and resultant updates, dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	**Event(s)**	**Result**
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction (7). No ESR update. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2046. DAC events and resultant updates, dual-issue case 2 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instruction (4). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b101. No ESR update. DSRR0 points to instruction (7). No debug event updates for instruction (7). **Note:** In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2047. DAC events and resultant updates, dual-issue case 3

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 2047. DAC events and resultant updates, dual-issue case 3 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	**Event(s)**	**Result**
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 2048. DAC events and resultant updates, dual-issue case 4

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	**Event(s)**	**Result**
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.

Table 2048. DAC events and resultant updates, dual-issue case 4 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

65.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be

recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

65.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

65.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ cannot be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

65.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when an EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

65.2.7 Interrupt Taken debug event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

65.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

65.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (that is before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

65.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (that is before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

65.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal

transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

65.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

65.2.13 Performance Monitor Interrupt debug event

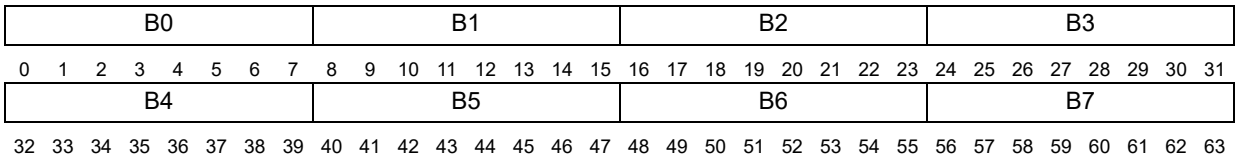
A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

65.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

65.3.1 Debug Address and Value registers



Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when

performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 2088*) corresponds to the byte data value transferred to/from memory byte offset such as 0, 8, and the least significant byte of the register (labeled B7 in *Figure 2088*) corresponds to byte offset such as 7, F. When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z420n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

SPR 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset: Unaffected

Figure 2088. DVC1, DVC2 registers

65.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z4256 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

65.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z4256 adds some implementation specific bits to this register, as seen in *Figure 2089*.

EDM	IDM	RST	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC2	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0	CIRPT	CRET	0

SPR - 308; Read/Write; Reset(1) - 0x0

Figure 2089. Debug Control Register 0 (DBCR0) register

1. $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

Table 2049 provides bit definitions for Debug Control Register 0.

Table 2049. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0.
		Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.

Table 2049. DBCR0 field descriptions (continued)

Bit	Name	Description
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved

65.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation. The DBCR2 register is shown in *Figure 2091*.

SPR - 310; Read/Write; Reset(1) - 0x0

Figure 2091. DBCR2 register

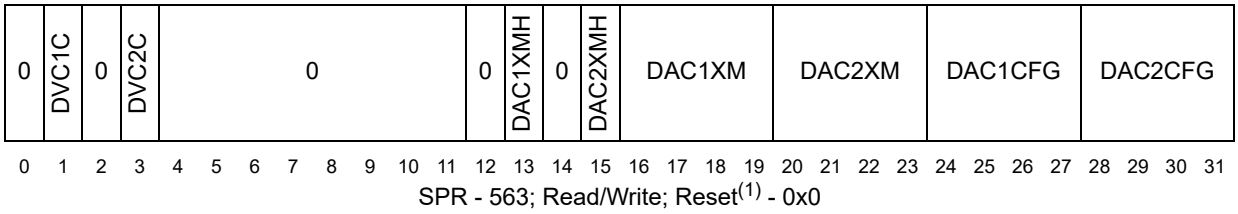
1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 2051 provides bit definitions for Debug Control Register 2.

Table 2051. DBCR2 field descriptions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table 2051. DBCR2 field descriptions (continued)



Bit	Name	Description
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.

Table 2051. DBCR2 field descriptions (continued)

Bit	Name	Description
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

65.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 2092*.

SPR - 563; Read/Write; Reset(1) - 0x0

Figure 2092. DBCR4 register

1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 2052 provides bit definitions for Debug Control Register 4.

Table 2052. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. Refer to details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits

Table 2052. DBCR4 field descriptions (continued)

Bit	Name	Description
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 2052. DBCR4 field descriptions (continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01*xx* Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01*xx* Reserved 1*xxx* Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

65.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 2093*

IAC5US	IAC5ER	IAC6US	IAC6ER	IAC56M	0	IAC7US	IAC7ER	IAC8US	IAC8ER	IAC78M	0
0 1	2 3	4 5	6 7	8 9	10 11 12 13 14 15	16 17	18 19	20 21	22 23	24 25	26 27 28 29 30 31

SPR - 564; Read/Write; Reset(1) - 0x0

Figure 2093. DBCR5 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 2053 provides bit definitions for Debug Control Register 5.

Table 2053. DBCR5 field descriptions

Bit	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)

Table 2056. DBCR8 field descriptions (continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

65.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 2097*.

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 2097. Debug Status Register (DBSR)

Table 2057 provides bit definitions for the Debug Status Register.

Table 2057. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred

Table 2057. DBSR field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is updated by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 2098*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 600; Read/Write; Reset - unaffected

Figure 2098. Debug Data Effective Address Register (DDEAR)

65.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in *Figure 2099*.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	DNI	DQM	0

13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 2058. EDBRAC0 field descriptions (continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable. **Note:** This bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors that have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** This bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored. 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 2059 shows which resources are controlled by EDBRAC0 settings.

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in *Table 2059* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

65.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. Refer to the "Data Acquisition ID Tag Field" section in the Core (e200z420n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 2100*.

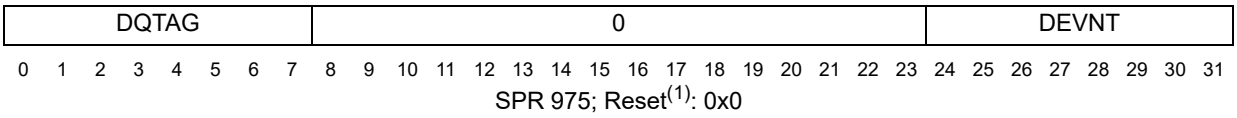

Figure 2100. Debug Event Select register (DEVENT) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.** Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

Table 2060 provides bit definitions for the Debug Event Register.

Table 2060. DEVENT field descriptions

Bit	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 No signal is asserted *xxxxxxx*1 **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock *xxxxxx*1*x* **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock *xxxxx*1*xx* **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock *xxxx*1*xxx* **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock *xxx*1*xxxx* **p_devnt_out[4]** is asserted for one clock *xx*1*xxxxx* **p_devnt_out[5]** is asserted for one clock *x*1*xxxxxx* **p_devnt_out[6]** is asserted for one clock 1*xxxxxxx* **p_devnt_out[7]** is asserted for one clock

65.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. Refer to the "Data Acquisition Messaging" section in the Core (e200z420n3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 2101*.

DDAM																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 576; Reset(1): 0x0

Figure 2101. Debug Data Acquisition Message (DDAM) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 2061 provides bit definitions for the Debug Data Acquisition Message Register.

Table 2061. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

65.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 2052*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, that is, after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 2052* and *Table 2055* in *Section 65.3.2, Debug Control and Status registers*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

65.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 65.2, Software debug events and exceptions* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

*It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the

$EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

65.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

65.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 2102*.

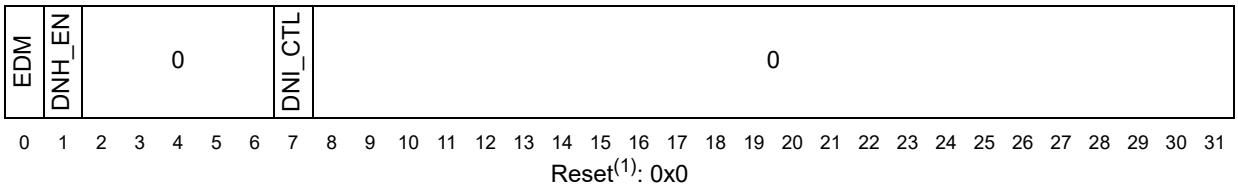

Figure 2102. External Debug Control Register 0 (EDBCR0)

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 2062 provides bit definitions for External Debug Control Register 0.

Table 2062. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	**dnh** Instruction Enable 0 Execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 Execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE}=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. **Note:** This control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1.
8:31	—	Reserved

65.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 2103*.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9 10 11	12	13	14	15	16	17 18 19 20	21	22	23	24	25	26	27	28 29 30	31

Read/Write; Reset(1) - 0x0000_0000

Figure 2103. External Debug Status Register 0 (EDBSR0)

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$=0.

Table 2063 provides bit definitions for External Debug Status Register 0.

Table 2063. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred

Table 2063. EDBSR0 field descriptions (continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A ‘1’ stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by

the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 2104*.

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

65.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 2105*.

Data Effective Address

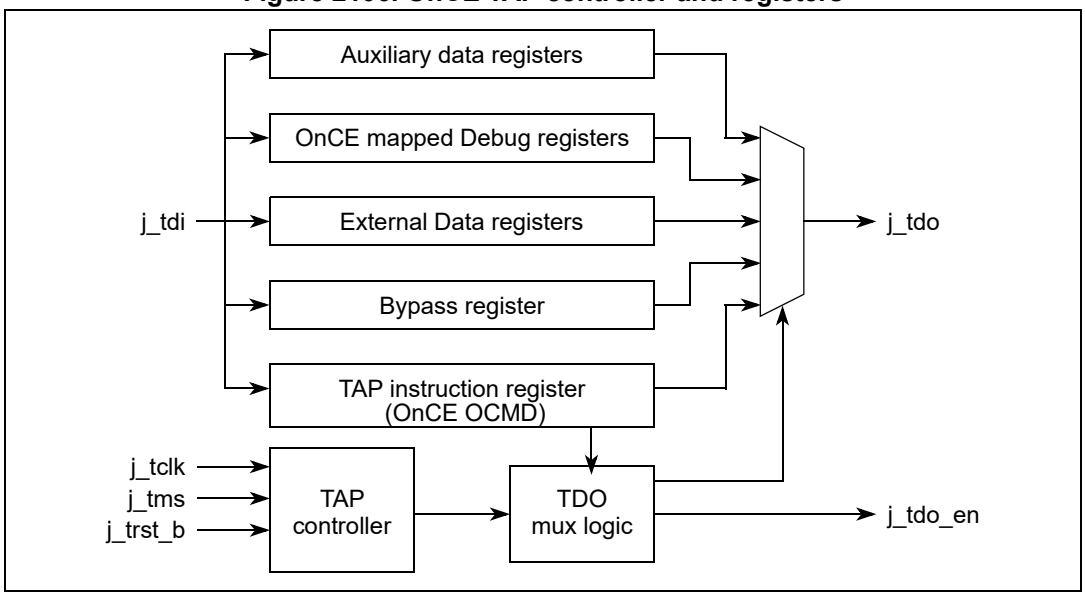
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

Read/Write; Reset: unaffected

Figure 2105. External Debug Data Effective Address Register (EDDEAR)

65.5.2 OnCE introduction

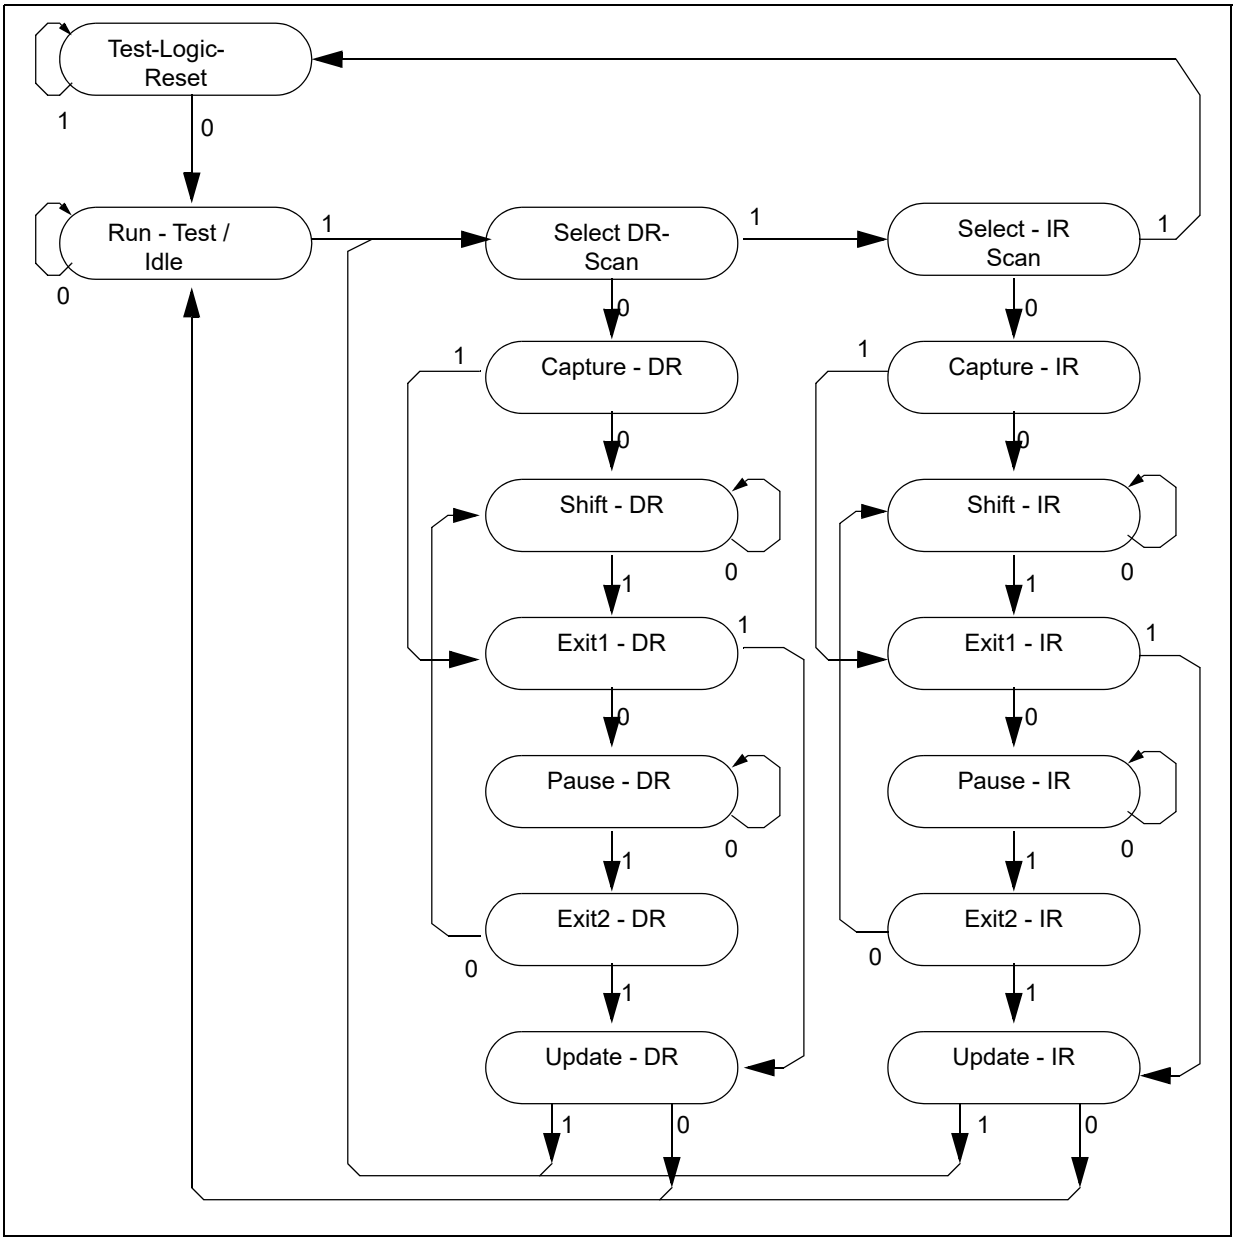
The e200z4256 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z4256 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction



functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.



The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 2106. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 2107. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 65.5.6.1, OnCE Status register*) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (refer to *Section 65.5.6.2, OnCE Command (OCMD) register*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

65.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

Table 2065 details the primary JTAG/OnCE interface signals.

Table 2065. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en(1)	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z420n3) Core Complex Overview.

65.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

65.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

65.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

65.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

65.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

65.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

65.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take effect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

65.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z4256 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

65.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. Refer to *Section 65.5.6.2, OnCE Command (OCMD) register* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

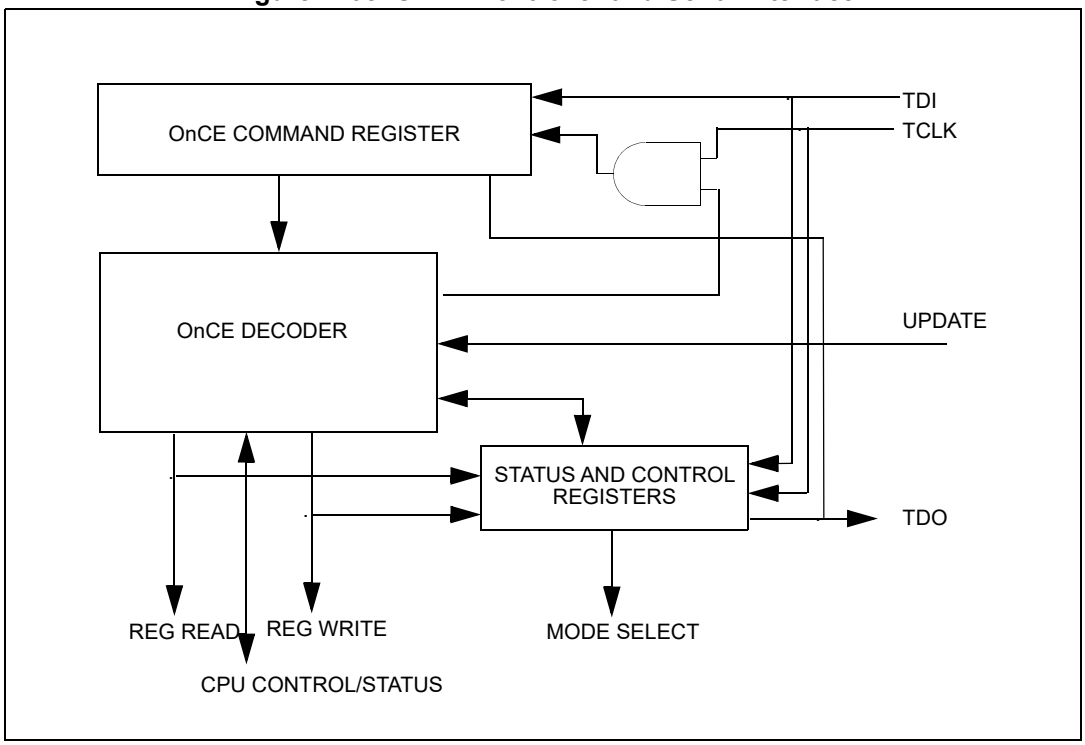
65.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z4256 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

65.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 2072* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

65.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)



This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

65.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 2108* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 2108. OnCE Controller and Serial Interface

65.5.6.1 OnCE Status register

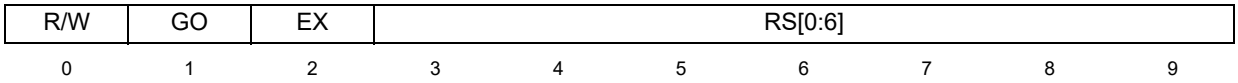
Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 2109. OnCE Status register

Table 2066 provides bit definitions for the OnCE Status register.

Table 2066. OnCE Status register field descriptions



Bit	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including such as External, Critical, machine check, Storage, Alignment, Program) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

65.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 2110*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as

such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step or exit functionality, or both, to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test_Logic_Reset state

Figure 2110. OnCE Command (OCMD) register

Table 2067 provides bit definitions for the OCMD.

Table 2067. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 65.5.9.6, Exiting Debug mode and interrupt blocking*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 2067. OCMD field descriptions (continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. **Note:** If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. Refer to *Section 65.5.9.6, Exiting Debug mode and interrupt blocking*.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 2068* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 2068 indicates the OnCE register addresses.

1. Causes assertion of the j_en_once_regsel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (such as interrupts, machine checks, bus error conditions) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

65.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z4256 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (refer to *Section 65.7, MPU operation during debug*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 2111*.

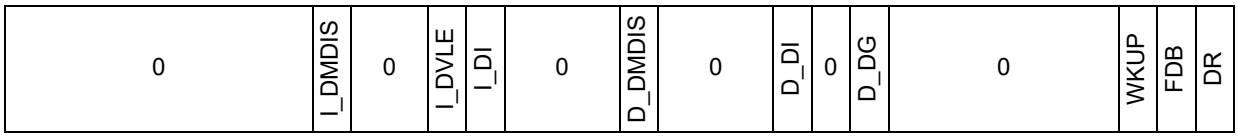

Figure 2111. OnCE Control Register (OCR)

Table 2069 provides bit definitions for the OnCE Control Register.

Table 2069. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug ‘G’ Attribute Bit This bit is used to provide the ‘G’ attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.

Table 2069. OCR field descriptions (continued)

Bit	Name	Description
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo-instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. **Note:** This bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

65.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z4256 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z4256 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z4256 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (such as DBSR) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 2070 provides a list of access requirements for OnCE registers.

Table 2070. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*(1)

Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	

Table 2070. OnCE register access requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	—	—	—	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

65.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input. Refer to *Section 65.5.5.1, OnCE Enable (jd_en_once)* for details.

65.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z4256 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z4256 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

65.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

65.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

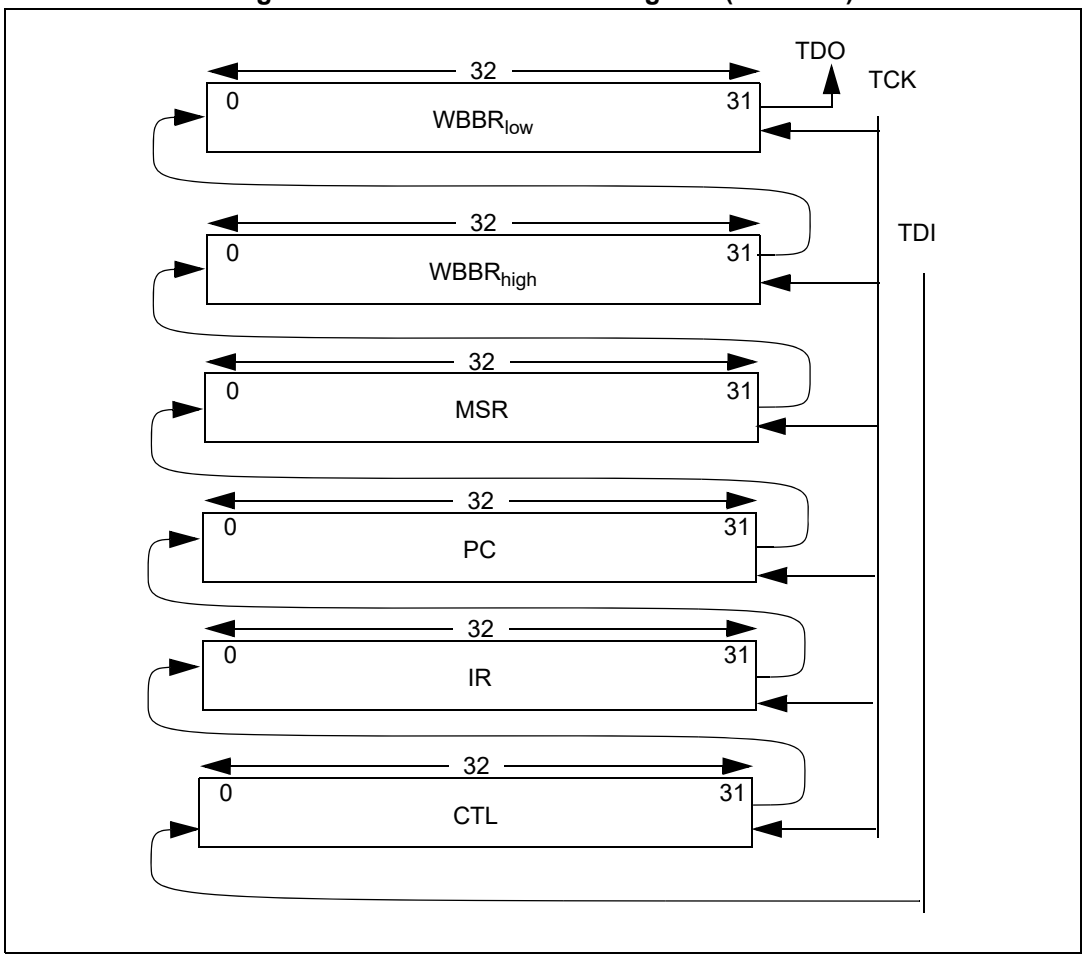
65.5.8.4 Debug request during Waiting, Halted, or Stopped state

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

65.5.8.5 Software request during normal activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z4256, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.



65.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z4256, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

65.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 2112* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 2112. CPU Scan Chain Register (CPUSCR)

65.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

65.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the

external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

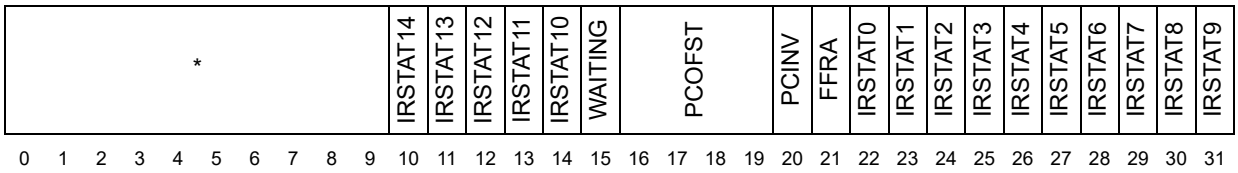


Figure 2113. Control State Register (CTL)

Table 2071. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, that is, when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. Refer to *Section 65.5.5.3: OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered

Table 2071. CTL field descriptions (continued)

Bit	Name	Description
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (Refer to PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR. For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of $WBBR_{lo}$ used as operand value.
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.

Table 2071. CTL field descriptions (continued)

Bit	Name	Description
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to ‘0’, and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU,

the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

65.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

65.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 65.5.9.2, Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

65.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used. This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

65.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

65.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device or system damage, or both, these registers should not be accessed.

65.6 Watchpoint support

e200z4256 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes (refer to the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter).

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 2072 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 2072. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]

Table 2072. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a '0' to a '1' while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.

Table 2072. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

65.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR *Section 65.5.6.3, OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 65.5.6.3, OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

65.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

65.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2, Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2, Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

66 Debug and Calibration Interface (DCI)

66.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

66.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

66.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using software debug mode.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

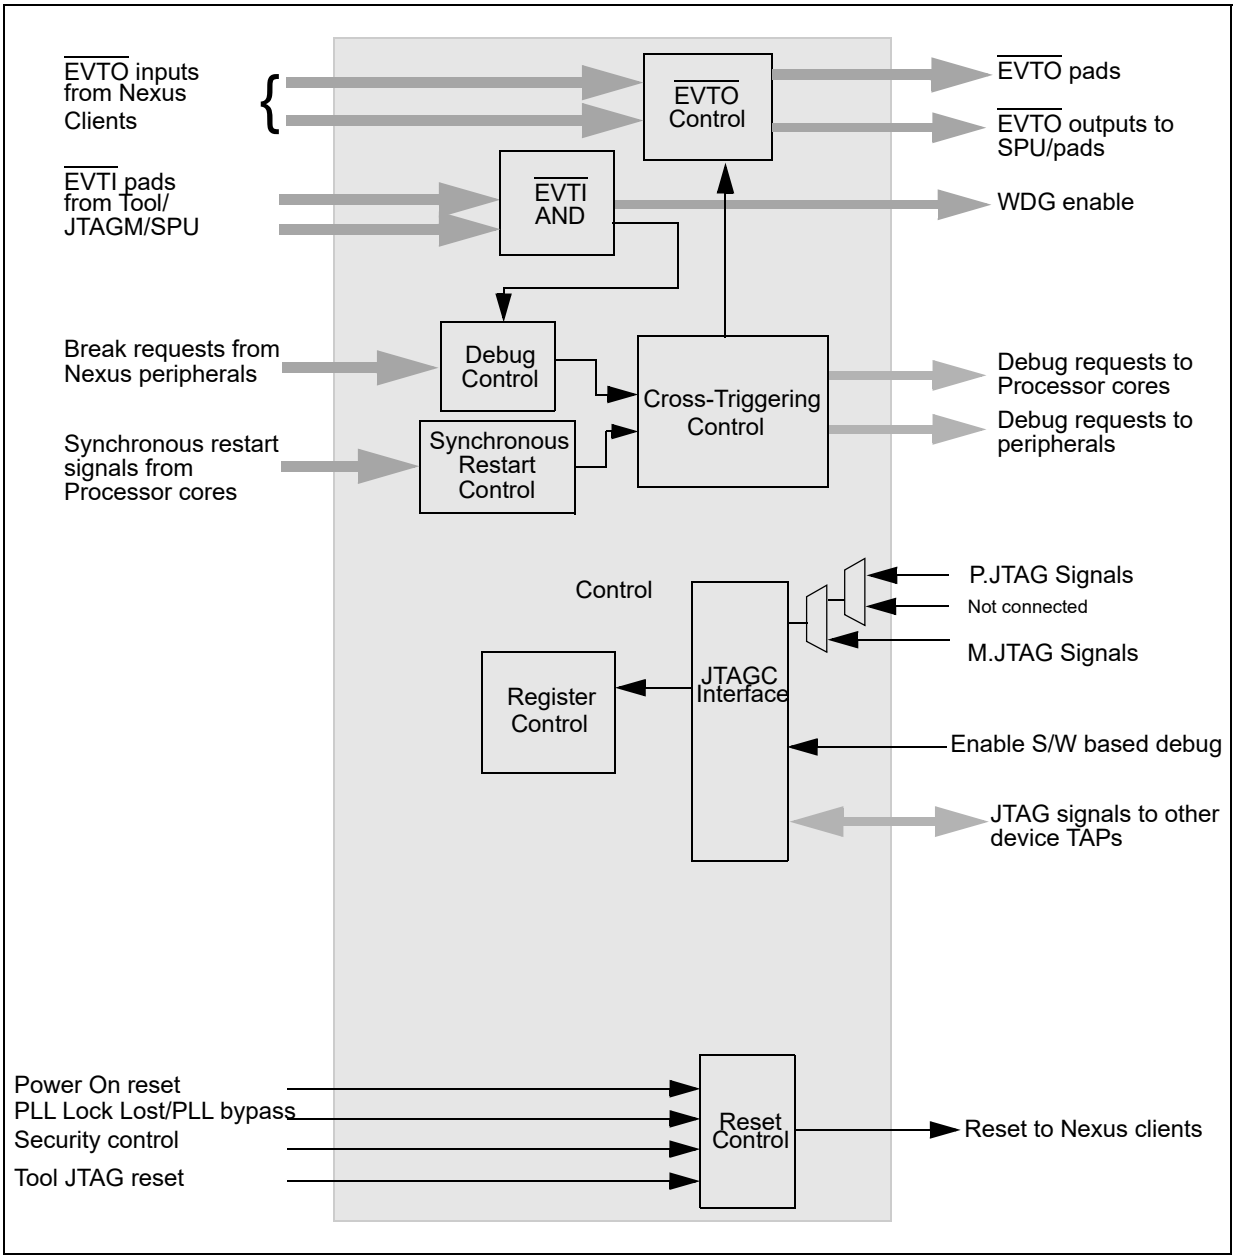
By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as SPU. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signal to the debug tool in case of the occurrence of any internal debug event.

Figure 2114 shows the DCI block diagram.

Figure 2114. DCI block diagram



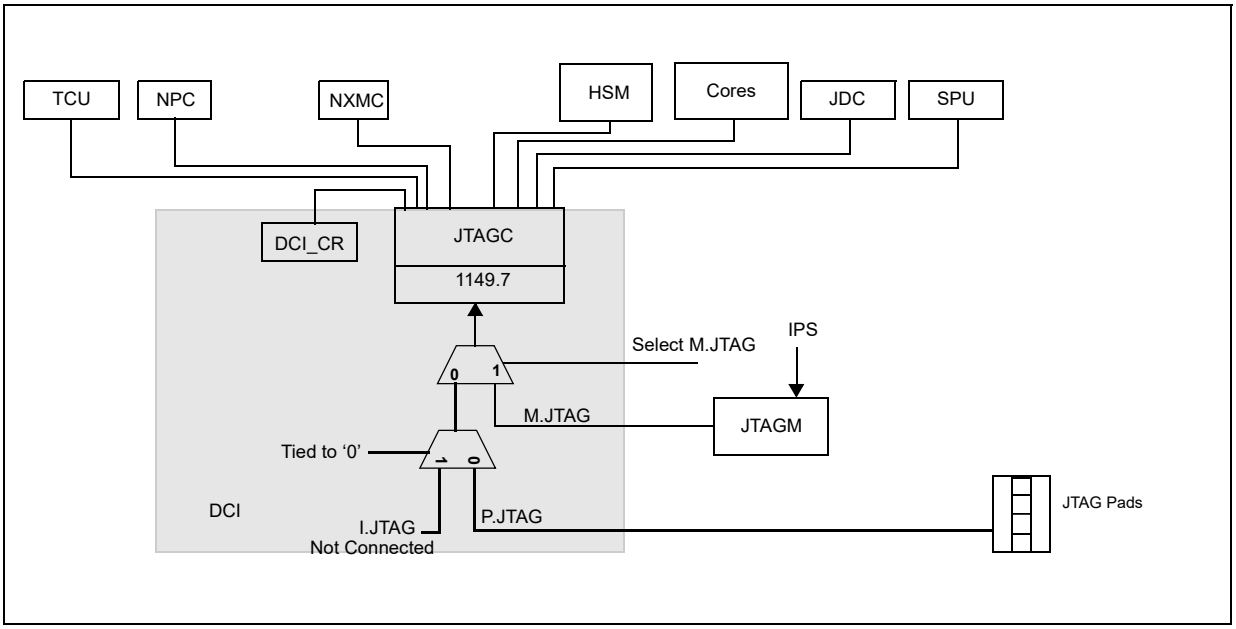


Figure 2115 shows the DCI configuration for the standard production package.

Figure 2115. DCI in a standard configuration

66.1.3 Operating modes

Selection between various JTAG sources is done using a JTAGM register bit, JTAGM_MCR[DTM]. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when JTAGM_MCR[DTM] is set.

Table 2073 shows a summary of the configuration options.

Table 2073. DCI JTAG source selection

JTAGM_MCR[DTM]	DCI Source	JCOMP
0	P.JTAG (Standard JTAG)	Asserted
1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 2074 contains the operating mode descriptions.

Table 2074. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.

66.1.3.1 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

66.1.3.2 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug

functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset. If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 2075. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

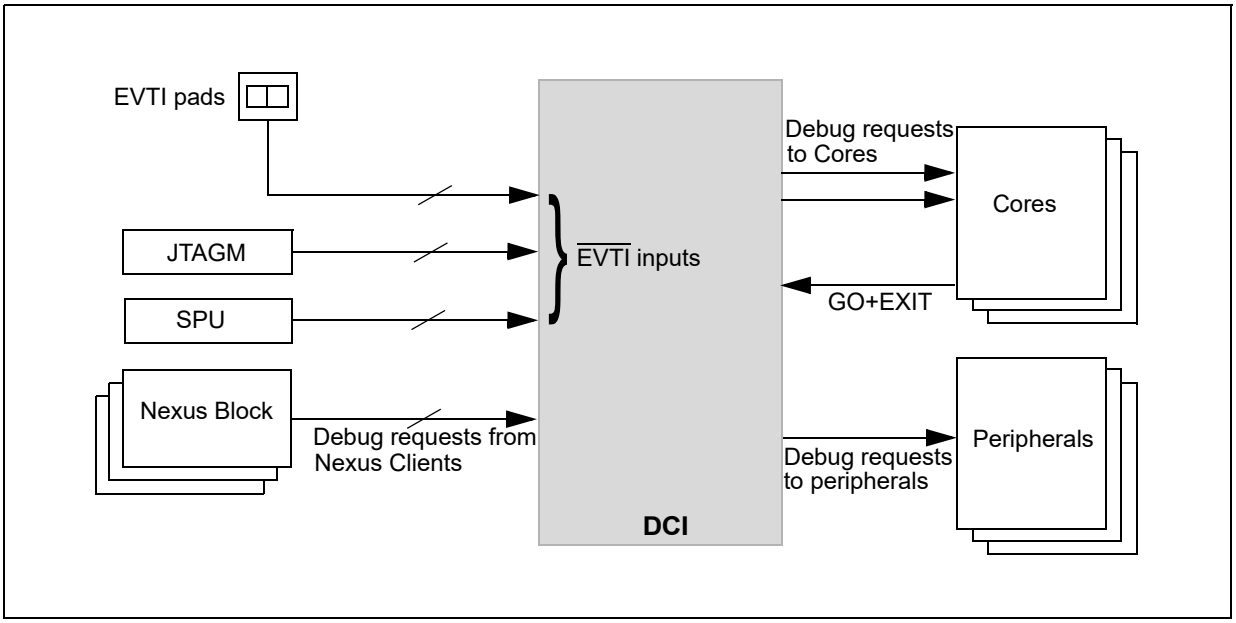
66.1.3.3 SWT control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

Please note that debugger should check the SWT counter to confirm if SWT has actually stopped or not, otherwise repeat the sequence mentioned above to disable the SWT.

66.1.3.4 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as DMA, Watchdog and other peripherals.



There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[0] signal from EVTI pad
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

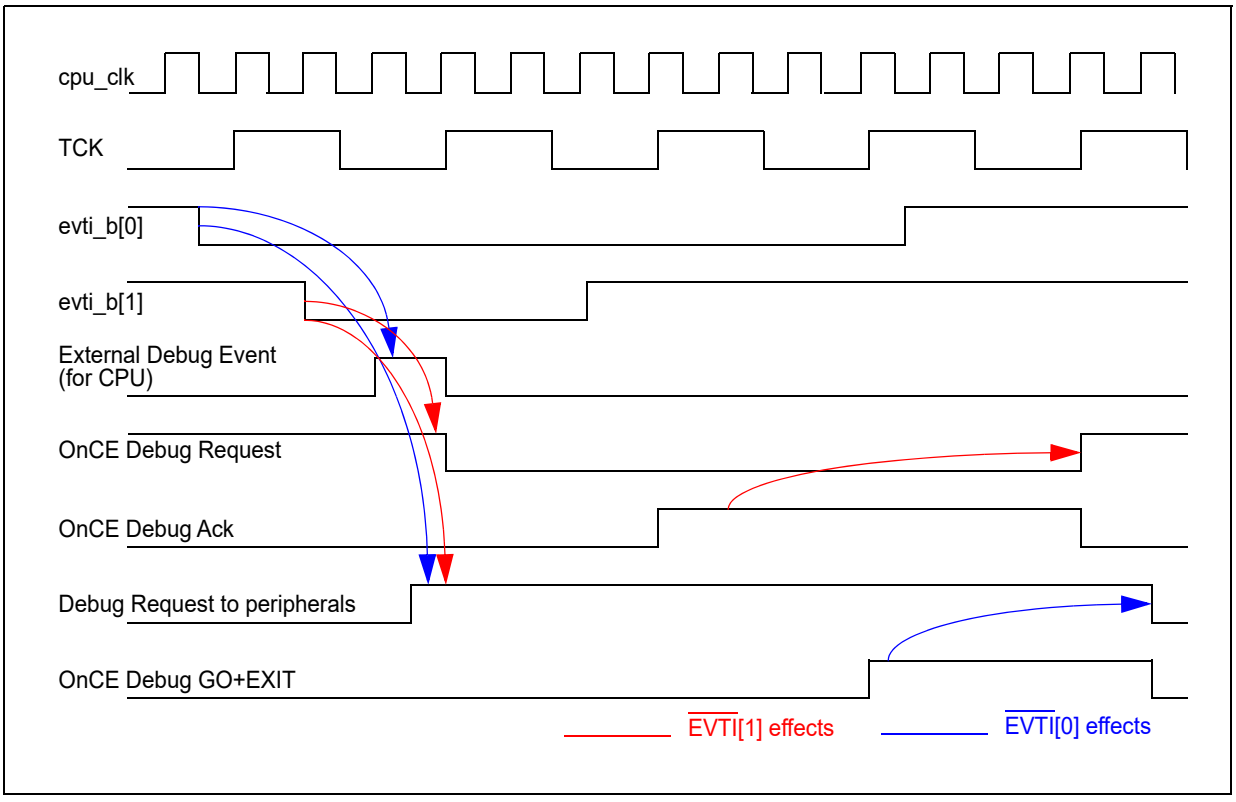
The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 2116. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$ inputs are synchronized and logically ANDed in the DCI to generate the following:

- debug requests for each processor core
- external debug requests for each processor core
- debug request for all non-CPU peripherals



The $\overline{\text{EVTI}}$[0] from the EVTI pads, SPU and JTAGM are used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The $\overline{\text{EVTI}}$[1] from the SPU and JTAGM, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted. The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command. The $\overline{\text{EVTI}}$[0] signal coming from the pad is enabled for debug control using DCI_CR[4] bit.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 2117 shows the timing sequence.

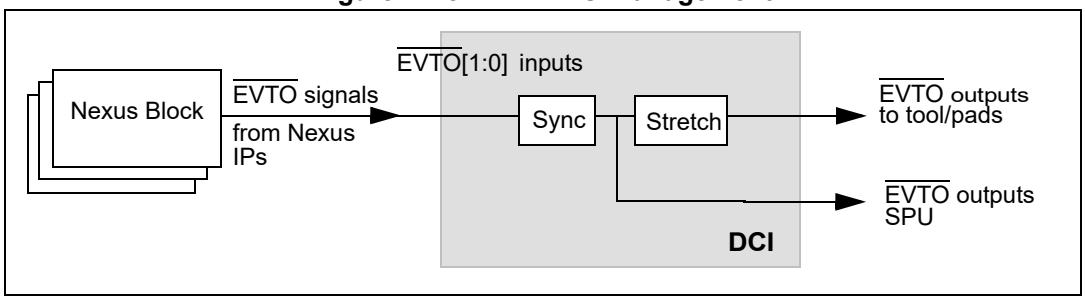
Figure 2117. DCI debug signal generation

66.1.3.5 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

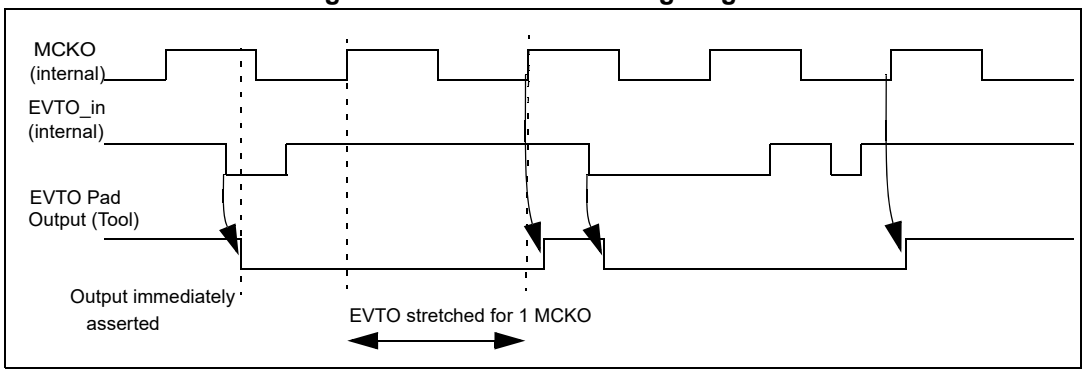
66.1.3.6 Synchronous restart control



The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (that is set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

66.1.3.7 EVTO management



The EVTO management block diagram is presented in *Figure 2118*.

Figure 2118. DCI EVTO management

The DCI module controls distribution of the EVTO output from all Nexus Clients including the cores that produce EVTO[0] signals. The DCI uses a high frequency clock to sample EVTO signal coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[0] signals from any Nexus client, the DCI immediately asserts EVTO[0] outputs and stretches it for a minimum of one output clock period for the output to the tool (*Figure 2119*). The DCI also generates EVTO output in other device clock domains so that other Nexus clients can receive EVTO input without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

Figure 2119. DCI EVTO timing diagram

66.1.3.8 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset

control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

66.1.3.9 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

66.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

66.3 Register description

The DCI module contains one registers, DCI_CR, which is present inside the JTAGC module. This register is only controlled using the JTAGC TAP and no memory-mapped registers are present.

66.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 2120* shows the format of the DCI_CR.

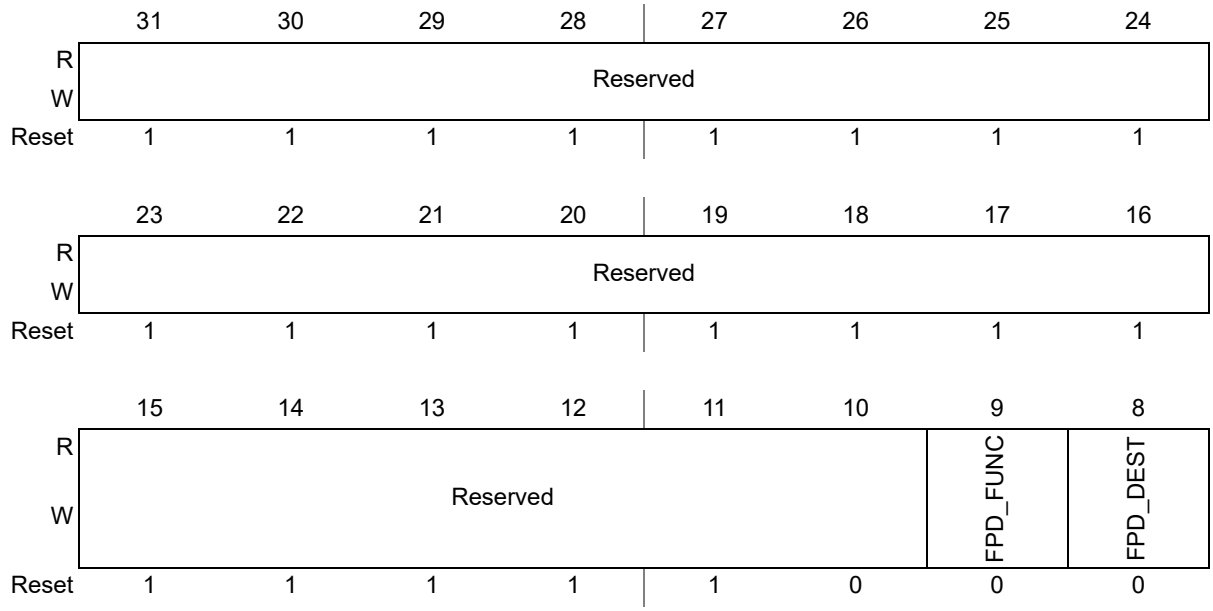


Figure 2120. DCI control register (DCI_CR)

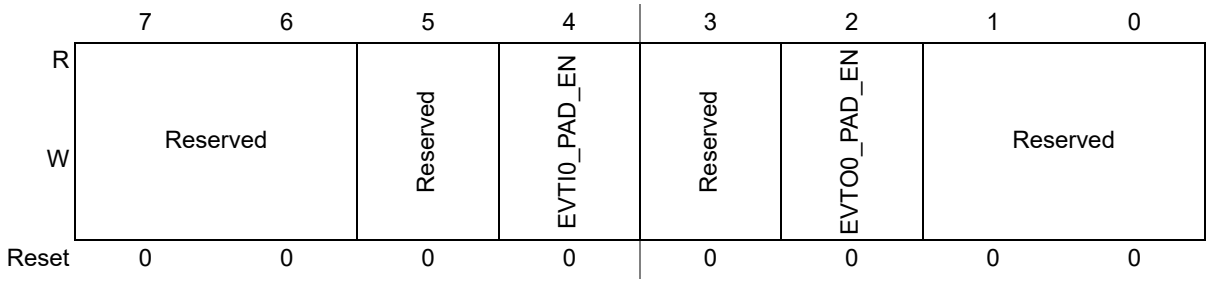

Figure 2120. DCI control register (DCI_CR) (continued)

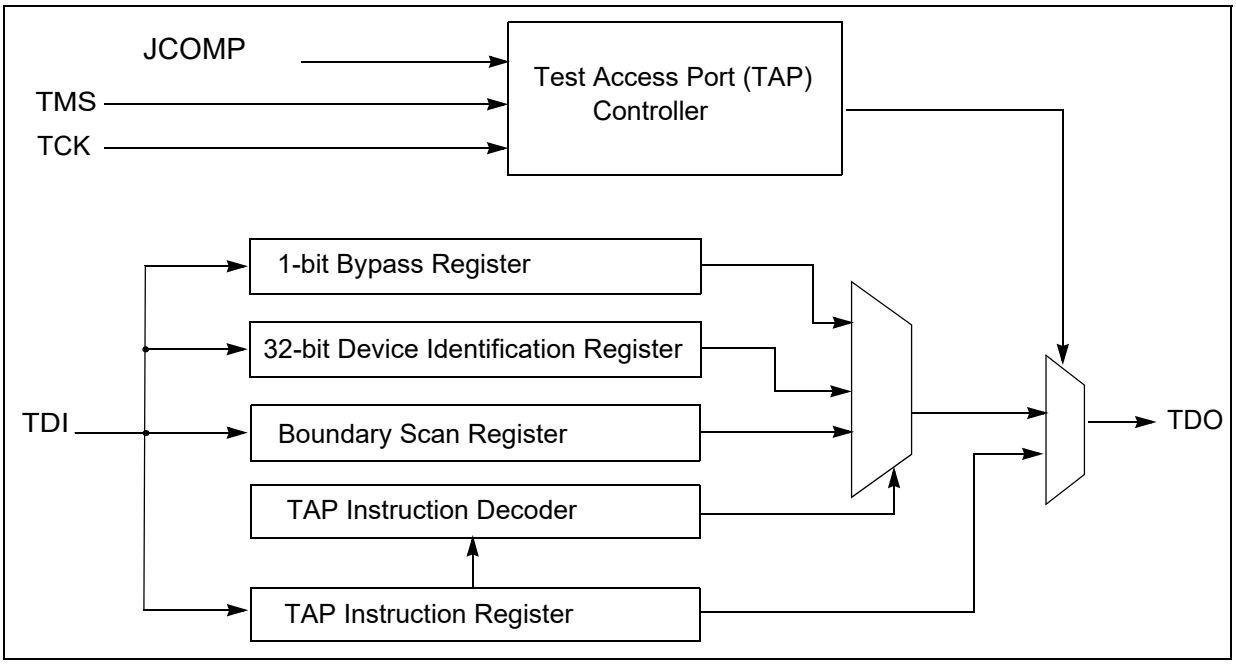
The DCI_CR is described in *Table 2076*.

Table 2076. DCI_CR field descriptions

Field	Description
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
4 EVTI0_PAD_EN	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled

67 JTAG Controller (JTAGC)



67.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

67.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 2121. JTAG (IEEE 1149.1) block diagram

67.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 2080* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

67.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

67.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

67.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 67.4.4*.

67.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

67.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 2077. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

67.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

67.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

67.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 67.4.3*.

67.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

67.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

67.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

67.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	0	1	2	3	4	5
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

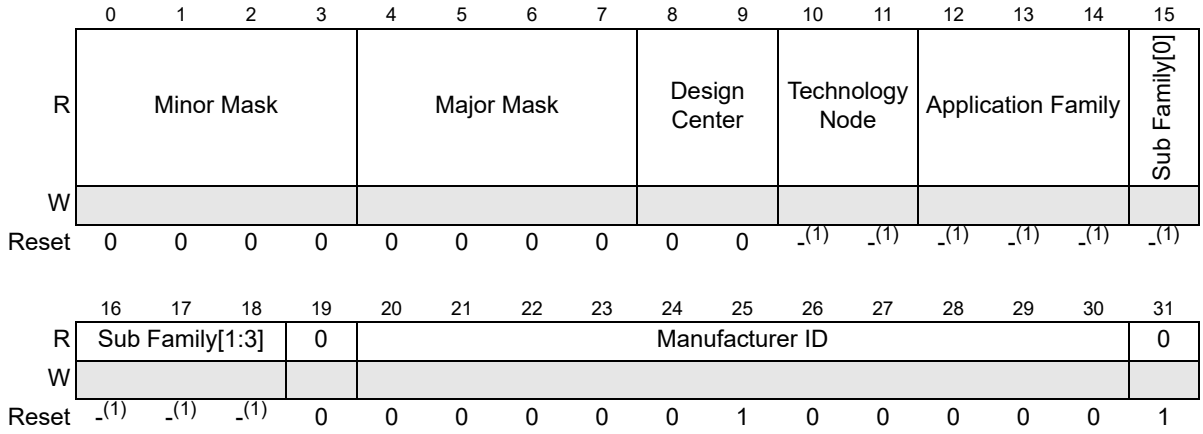


Figure 2122. 6-bit instruction register

67.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

67.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

1. The value is shown in *Table 2078*

Figure 2123. Device identification register

The following table describes the device identification register functions.

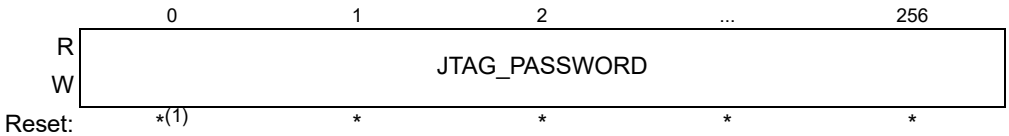

Table 2078. Device identification register field descriptions

Field	Description
0:3 Minor Mask	Minor Mask These bits contain the minor mask of the part
4:7 Major Mask	Major Mask These bits contain the major mask of the part
8:9 Design Center	Design Center These bits indicate the device design center
10:11 Technology Node	Technology Node These bits indicate the device technology node 01 40nm
12:14 Application Family	Application Family These bits indicate the device application family 000 SPC58N - Powertrain 40nm
15:18 Sub Family	Sub Family These bits indicate the device sub family 1000 SPC58NE84C3 , SPC58NE84E7
20:30 Manufacturer ID	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID 00000100000: STMicroelectronics

67.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine

is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 2124. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 2079. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

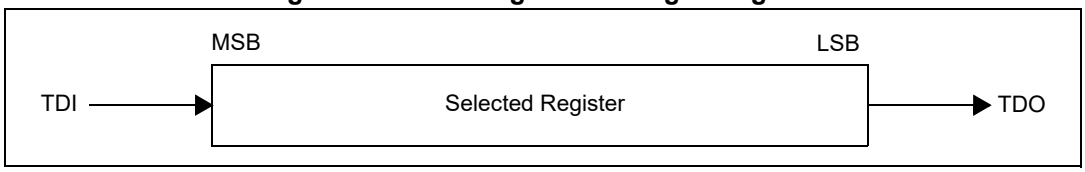
67.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 67.4.5*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

67.4 Functional description

This section explains the JTAGC functional description.

67.4.1 JTAGC reset configuration



While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

67.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 67.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

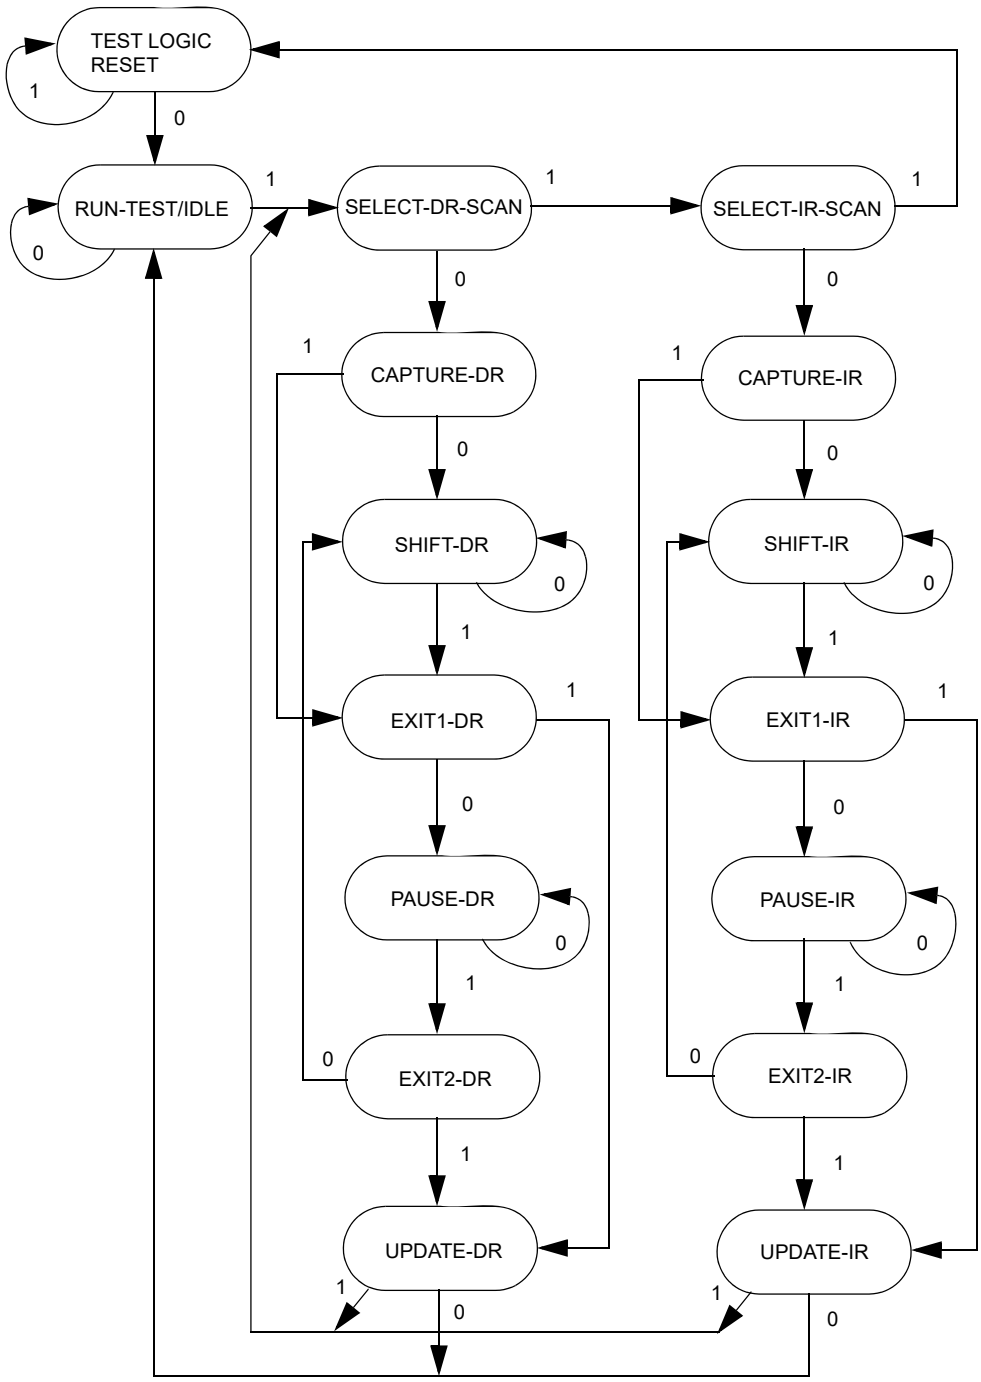


Figure 2125. Shifting data through a register

67.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 2126. IEEE 1149.1-2001 TAP controller finite state machine

Note: The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

67.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

67.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

67.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 2080. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Reserved	000101	Reserved
Reserved	000110	Reserved
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Reserved	001010	Reserved
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NPC_PD	100001	Enables access to the NPC TAP controller on production device

Table 2080. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100001	Reserved
Reserved	100010	Reserved
Reserved	100011	Reserved
Reserved	100100	Reserved
Reserved	100101	Reserved
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller, to access the HSM challenge and response registers
ACCESS_AUX_HSM	100111	Enables access to the HSM core TAP controller
ACCESS_AUX_CORE_0	101000	Enabled access to E200 Core 0
ACCESS_AUX_CORE_1	101001	Enables access to E200 Core 1
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101011	Reserved
ACCESS_AUX_BUS_MON_5	101100	Enables access to NXMC Client 5 TAP controller
ACCESS_AUX_BUS_MON_6	101101	Enables access to NXMC Client 6 TAP controller
ACCESS_AUX_BUS_MON_7	101110	Enables access to NXMC Client 7 TAP controller
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
Reserved	110011	Reserved
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
ACCESS_AUX_BUS_MON_2	110110	Enables access to NXMC Client 2 TAP controller
ACCESS_AUX_BUS_MON_3	110111	Enables access to NXMC Client 3 TAP controller
ACCESS_AUX_BUS_MON_4	111000	Enables access to NXMC Client 4 TAP controller
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported

2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

67.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

67.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

67.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

67.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

67.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

67.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (for example high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

67.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

67.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

67.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

67.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

67.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, must be loaded the appropriate instruction for the test or action to be performed.

68 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG)

68.1 References

- IEEE Std 1149.1-2001 (R2008), Standard Test Access Port and Boundary-Scan Architecture
- IEEE Std 1149.7, Standard for Reduced-Pin and Enhanced-Functionality Test Access Port and Boundary-Scan Architecture

68.2 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backward compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

68.2.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- Compliant
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- Extended
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” – IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- Advanced
  - Two-pin operation using the “Advanced Protocol” – signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

68.2.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

68.2.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in *Table 2081*. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

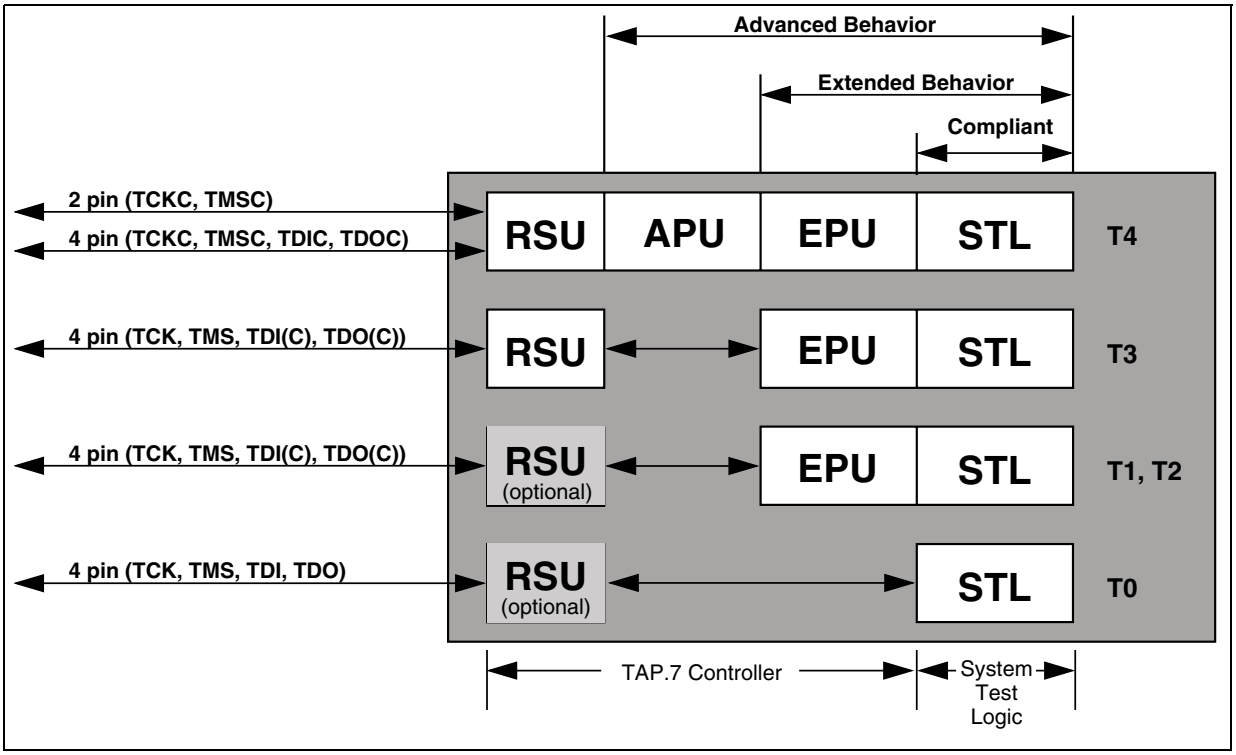
The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC, and nTRST pins.

Table 2081. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4



68.2.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in *Figure 2127*. It is described with the hardware layers listed below:

- **STL System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

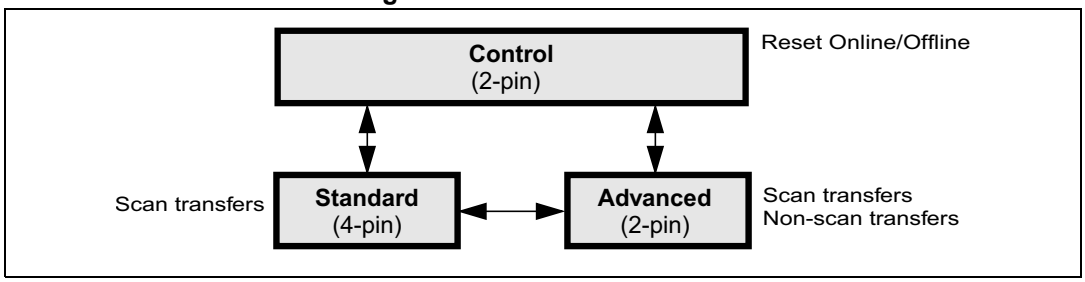


Figure 2127. TAP.7 Controller Architecture

68.2.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in *Figure 2128*.

Figure 2128. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in *Table 2082*.

Table 2082. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

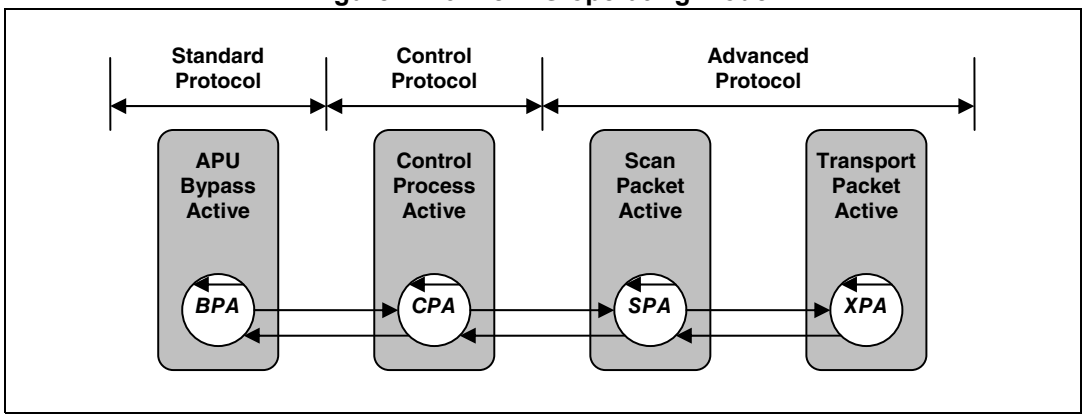
The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

68.2.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

68.2.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.



68.2.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

68.3 Operating models

Figure 2129 illustrates a simplified view of the CJTAG operating model.

Figure 2129. CJTAG operating model

68.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

68.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

68.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

68.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

68.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

68.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

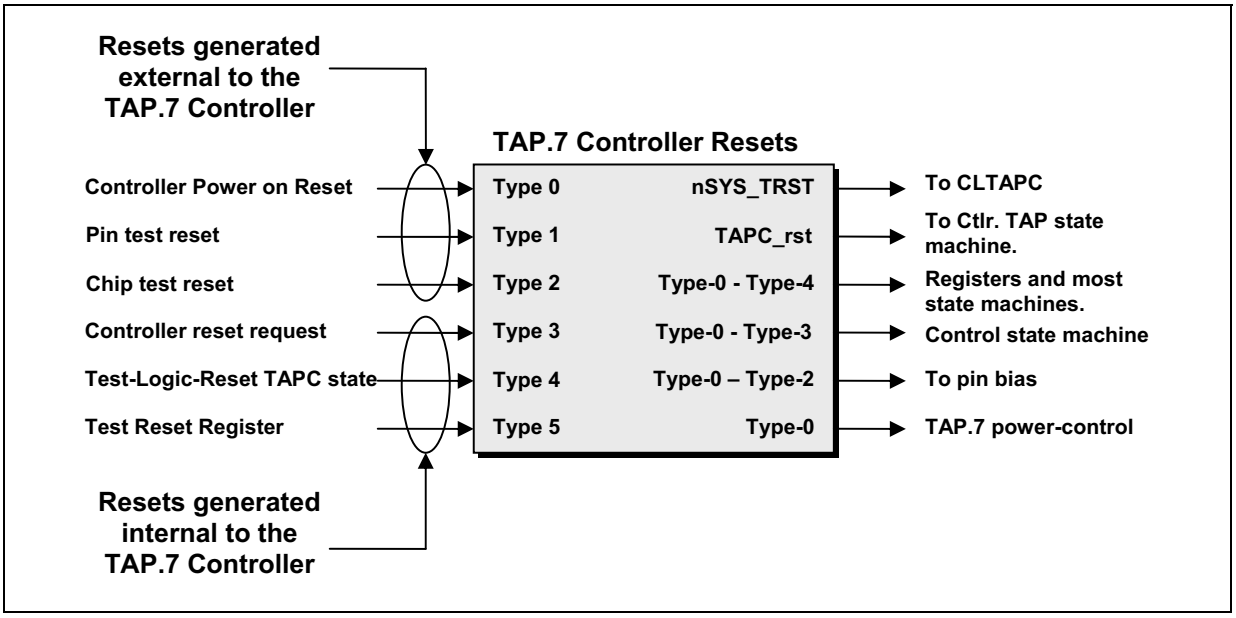
68.5 Ancillary services

68.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine



68.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 2130. Conceptual view of the EPU reset logic and state machines

68.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

68.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

68.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

68.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

68.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

68.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

68.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 2131. Reset state machine

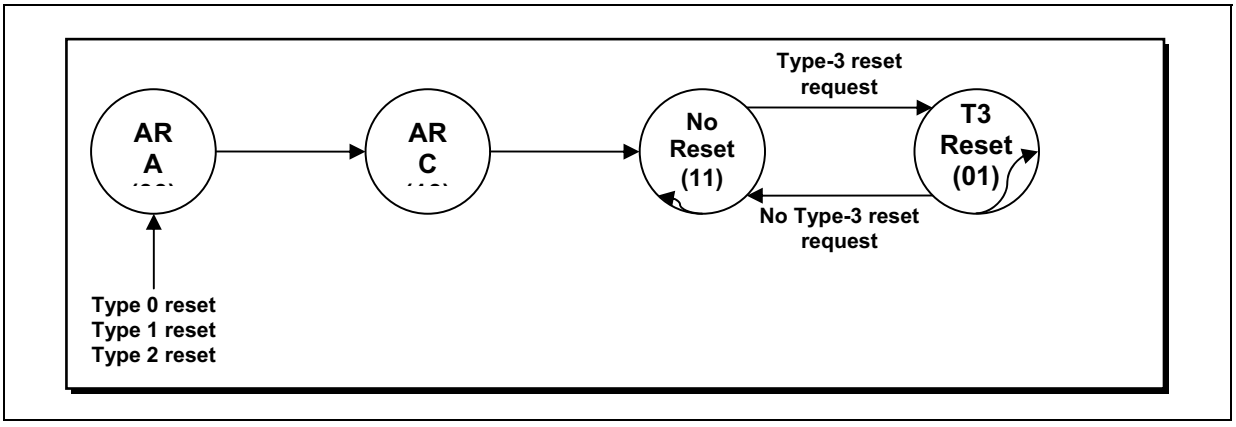


Table 2083. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in *Table 2084*.

Table 2084. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

68.5.3 Start-up Options

68.5.3.1 Overview

The TAP.7 start-up options are shown in *Table 2085*. The only startup option currently supported by the CJTAG module is 1149.1 compliant.

Table 2085. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

68.5.3.2 1149.1 Compliant start-up

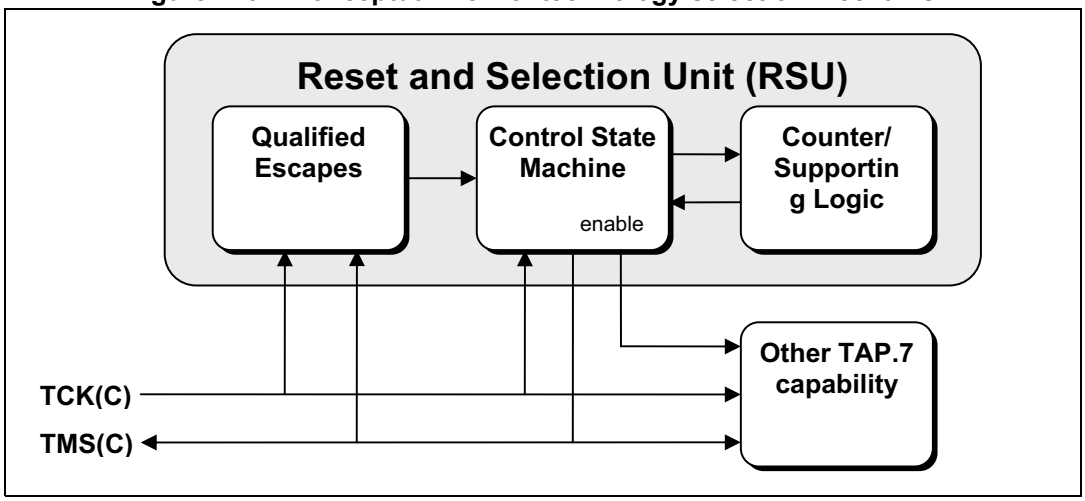
Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine
- The TDIC and TDOC pins are present and provide the TDI and TDO function
- The CLTAPC is coupled at start-up

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 2086. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU



68.5.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

68.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in *Figure 2132*.

Figure 2132. Conceptual view of technology selection mechanism

68.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

68.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset).

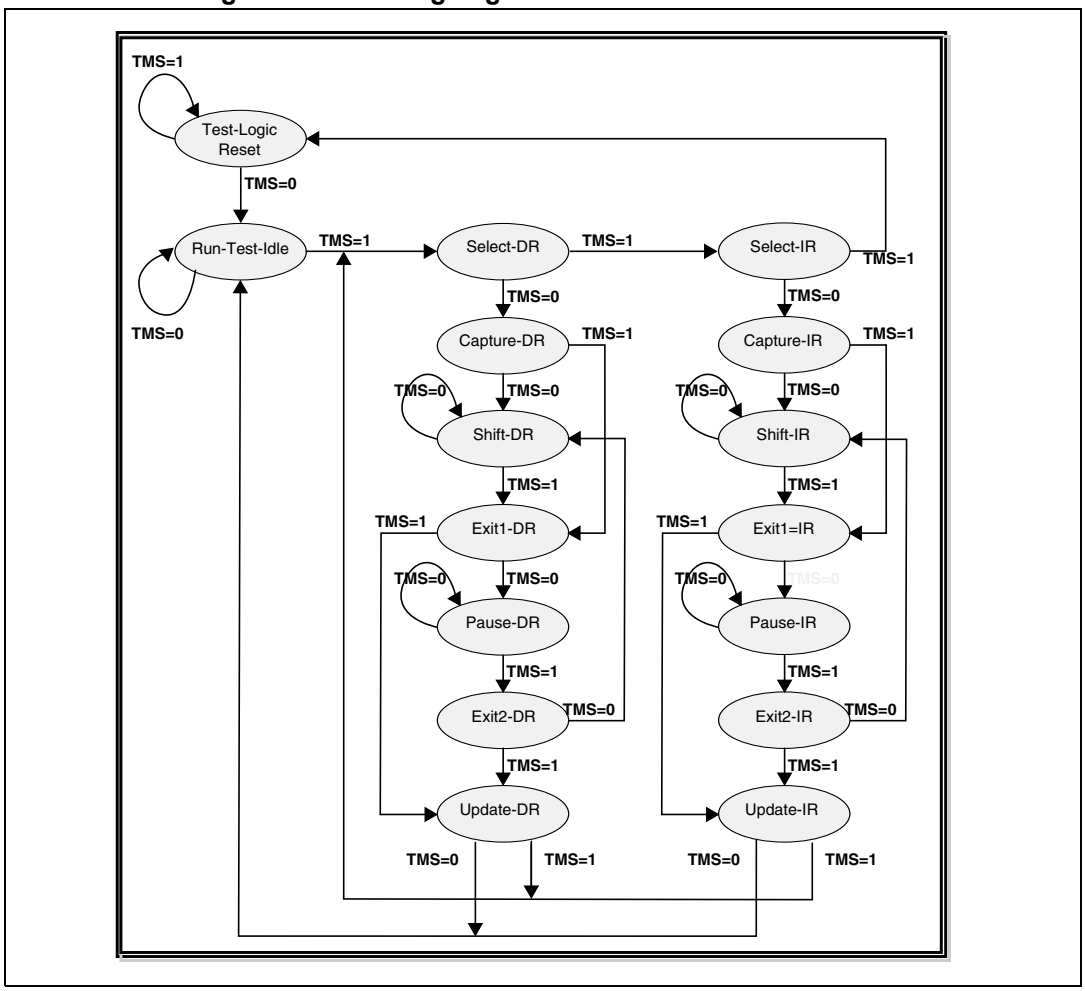
The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

68.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.



68.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occurs with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

68.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 2133. Falling edge TAP controller state machine

68.6 EPU (Extended Protocol Unit) Operation

68.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

68.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

68.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be

incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

68.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

68.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

68.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

68.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

68.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created.
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

68.6.2 EPU Registers

68.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose.

These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

68.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers. There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back.

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 2087. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
		1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Options Select	Local Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge

Table 2087. TAP.7 controller register list (managed with commands) (continued)

Register type	Global/ local	Width	Register mnemonic	Name
		32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
Read-only	Local	M = Mandatory register O = Optional register		

68.6.2.3 Registers

68.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

68.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the “System Path” (STL) is used.

- **1** – Suspend use of control levels. Enables “System Path.”
- **0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

68.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- **1** – Inhibit ZBS detection.
- **0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

68.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 2088. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state

Table 2088. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

68.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

68.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance

the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the “Global Register.”

68.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

68.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

68.6.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0x** – TDI and TDO have JTAG function.
- **1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

68.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

68.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

68.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0.

68.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 2089. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format
6:5	2	PWRMODE	Power-control Modes
7	1	FRESET	Functional Reset

	32	CNFG0	Configuration Register 0				

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

68.6.3 EPU Commands

There are two command types:

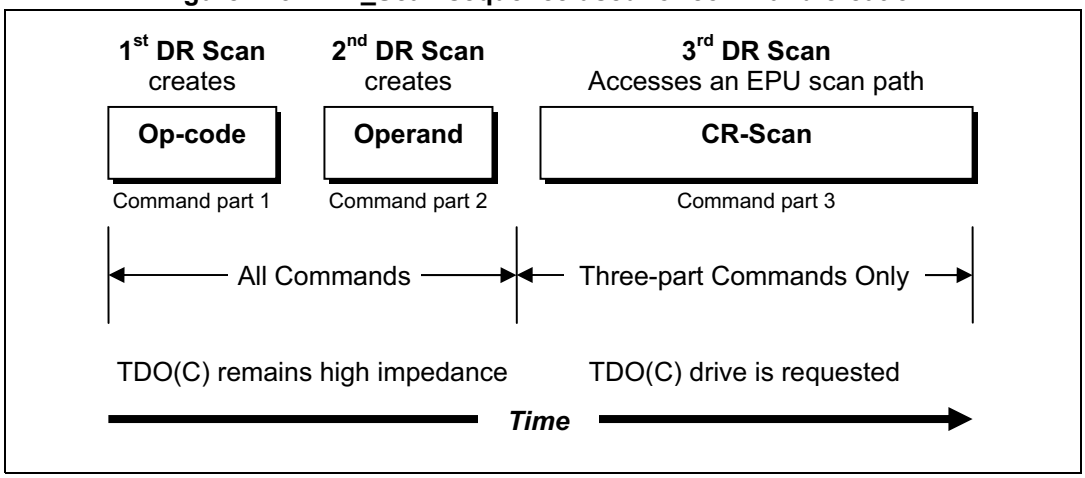
- Two-Part Commands
- Three-Part Commands

Any number of two-part and three-part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

68.6.3.1 Two-Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two).

The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.



68.6.3.2 Three-Part Commands

Some commands are used to send or receive, or both, data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

68.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in *Figure 2134*.

Figure 2134. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two-part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two-part commands, but only 3 three-part commands, each having a special purpose.

68.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in *Table 2092*.

Table 2092. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate(1)	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

68.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

68.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

68.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

68.6.3.5 Command Definitions

68.6.3.5.1 Store Commands

68.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 2093. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	—	SGC = y
				1	—	CGM = y
		010	RdyCtl	-	—	RDYC = xy
		011	DlyCtl	-	—	DLYC = xy
		100	ScnFunc	0	—	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	—	—	Reserved
		110		—	—	
		111		—	—	

68.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 2094. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	—	SREDGE = v
			001	—	Reserved
			010	—	TRESET = v
			011 – 111	—	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

68.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 2095. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	Operand	c	bb	CAPE	Description
00010	c bb vv	0	00	—	Reserved
			01	—	STCKDC = vv
			10	—	APFC = vv
			11	—	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

68.6.3.5.1.4 Store Scan Format (STFMT)

Table 2096. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

68.6.3.5.2 Select Commands

68.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 2097. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

68.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 2098. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

68.6.3.5.3 Scan Commands

68.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 2099. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

68.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

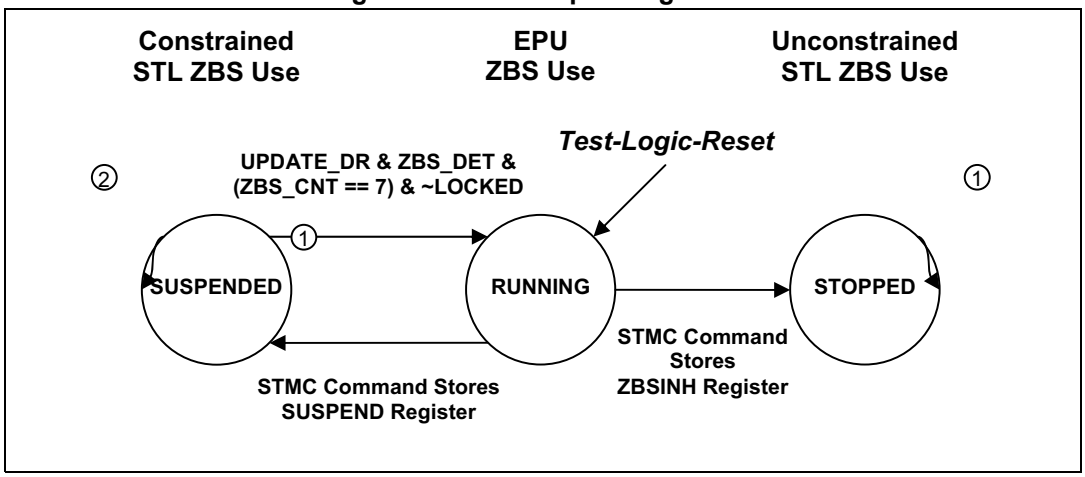


Table 2100. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

68.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in *Figure 2135*.

Figure 2135. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in *Table 2101*. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 2101. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

68.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path.
- **Bit** – Supports set and test bit operations (a 1-bit shift register).
- **String** – Support 32-bit reads or 32-bit writes.
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s.
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

68.7 APU (Advanced Protocol Unit) Operation

68.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

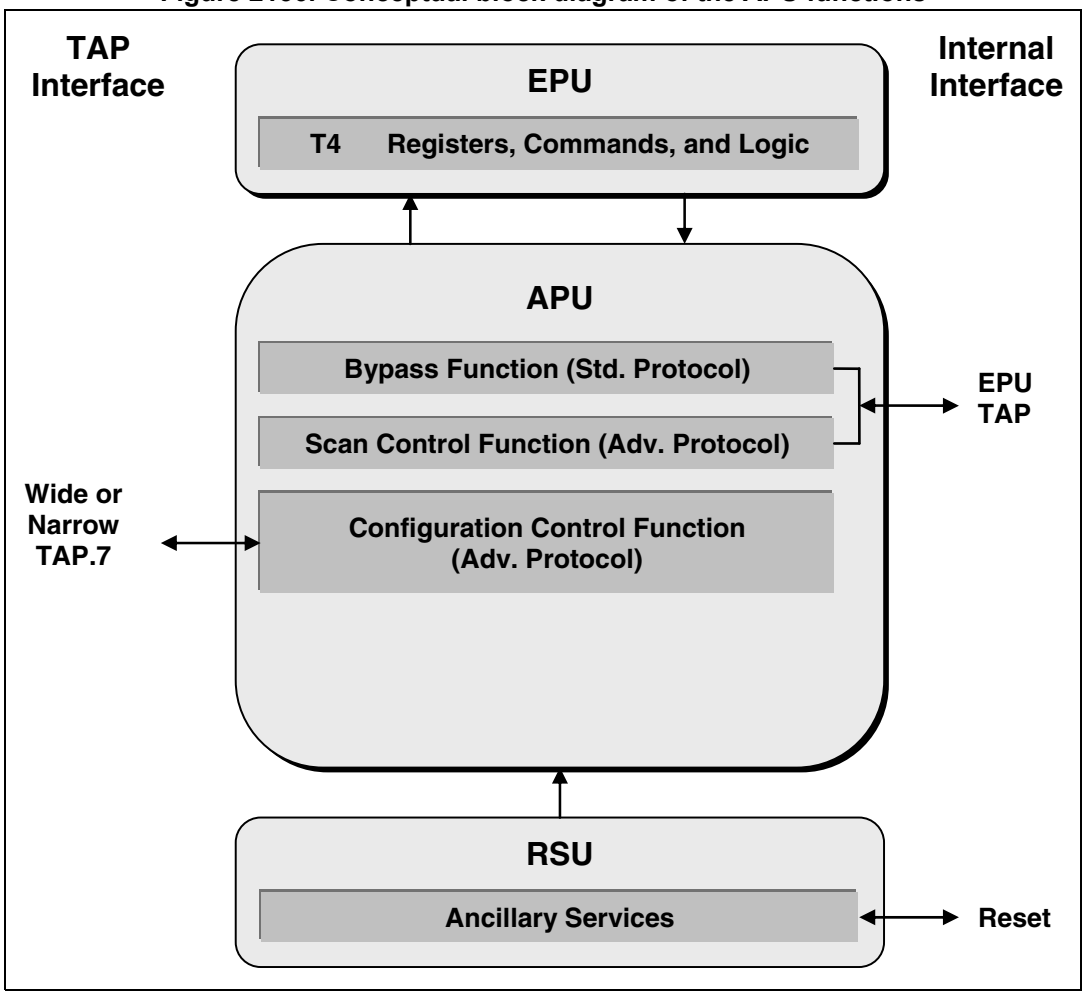
The entire EPU infrastructure (that is, ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.



The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

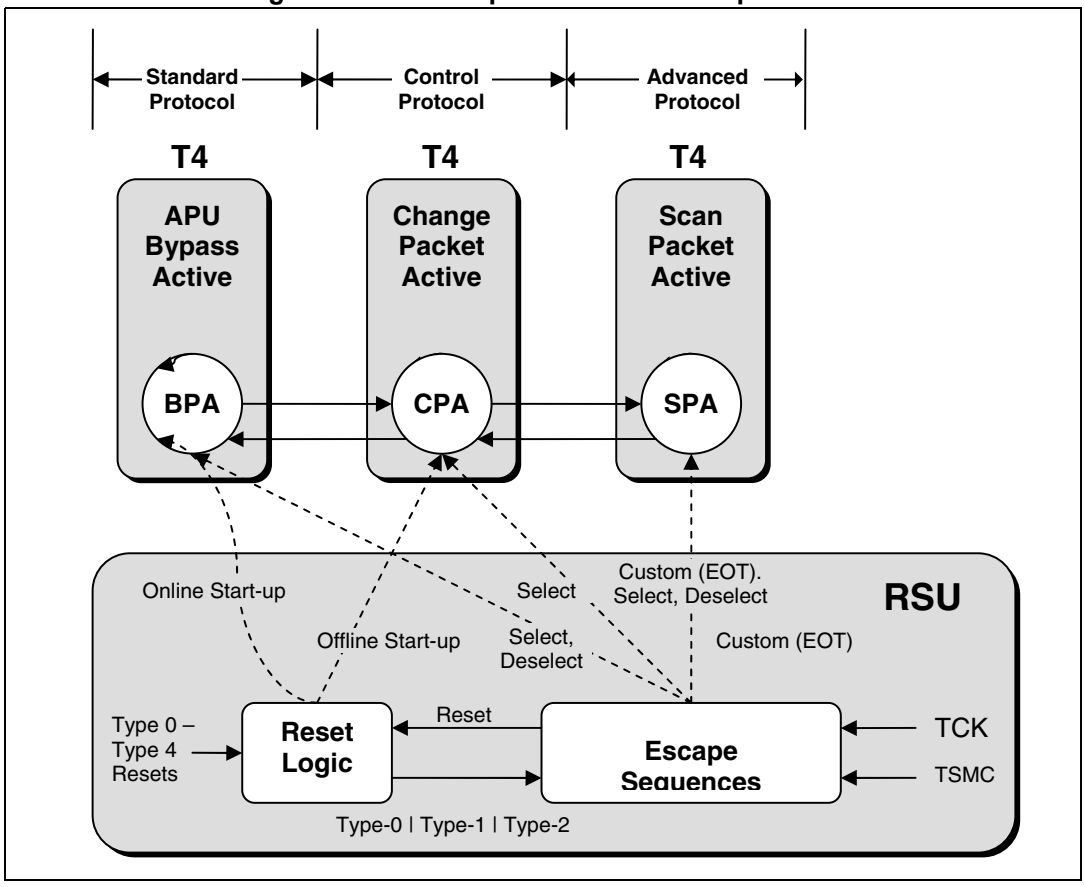
- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 2136. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function



When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

68.7.2 Operation

The conceptual view of the APU operation is shown in *Figure 2137*.

Figure 2137. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

68.7.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

68.7.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

68.7.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

68.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

68.7.4 Signal behaviors

The TCKC signal:

- The test clock

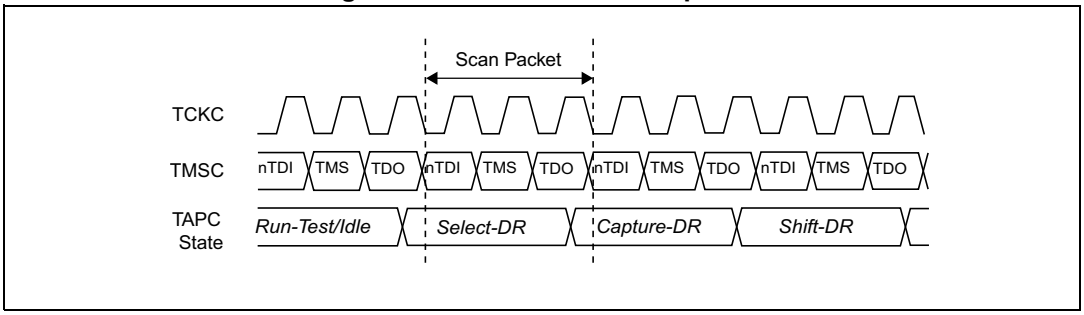
The TMSC signal:

- An input when the Standard Protocol is used
- Bidirectional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

68.7.5 APU Functions



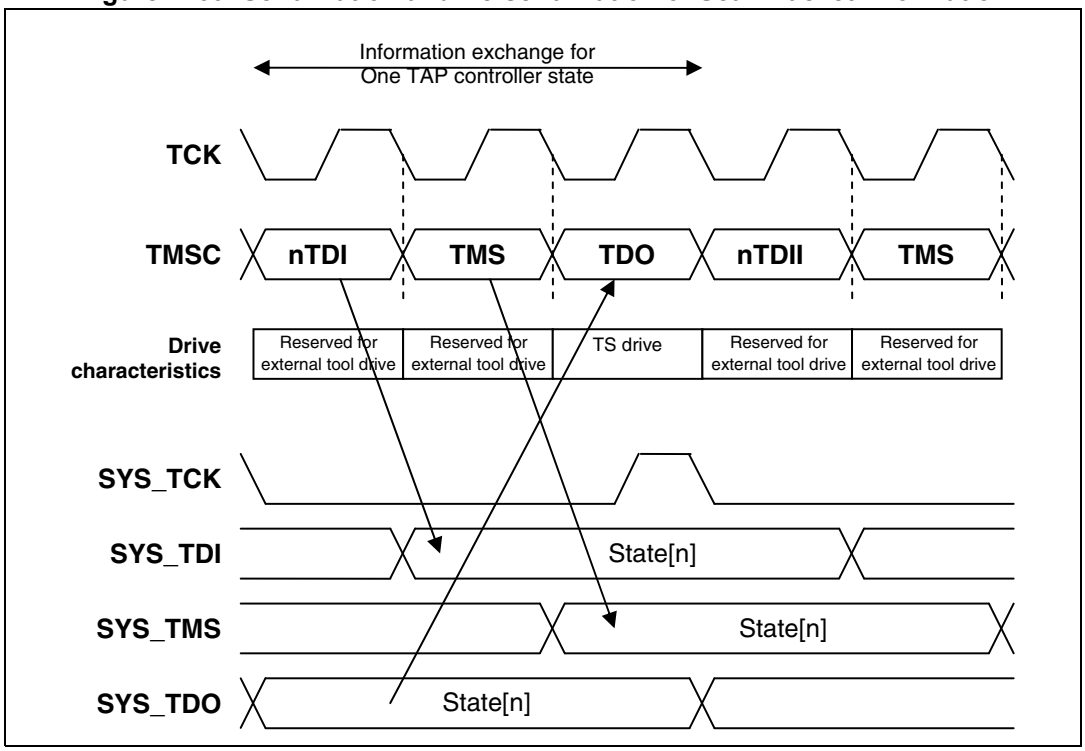
68.7.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (for example, a narrow TAP.7, or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

68.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in *Figure 2138*. There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 2138. Scan Packet sequence



A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in *Figure 2138*. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

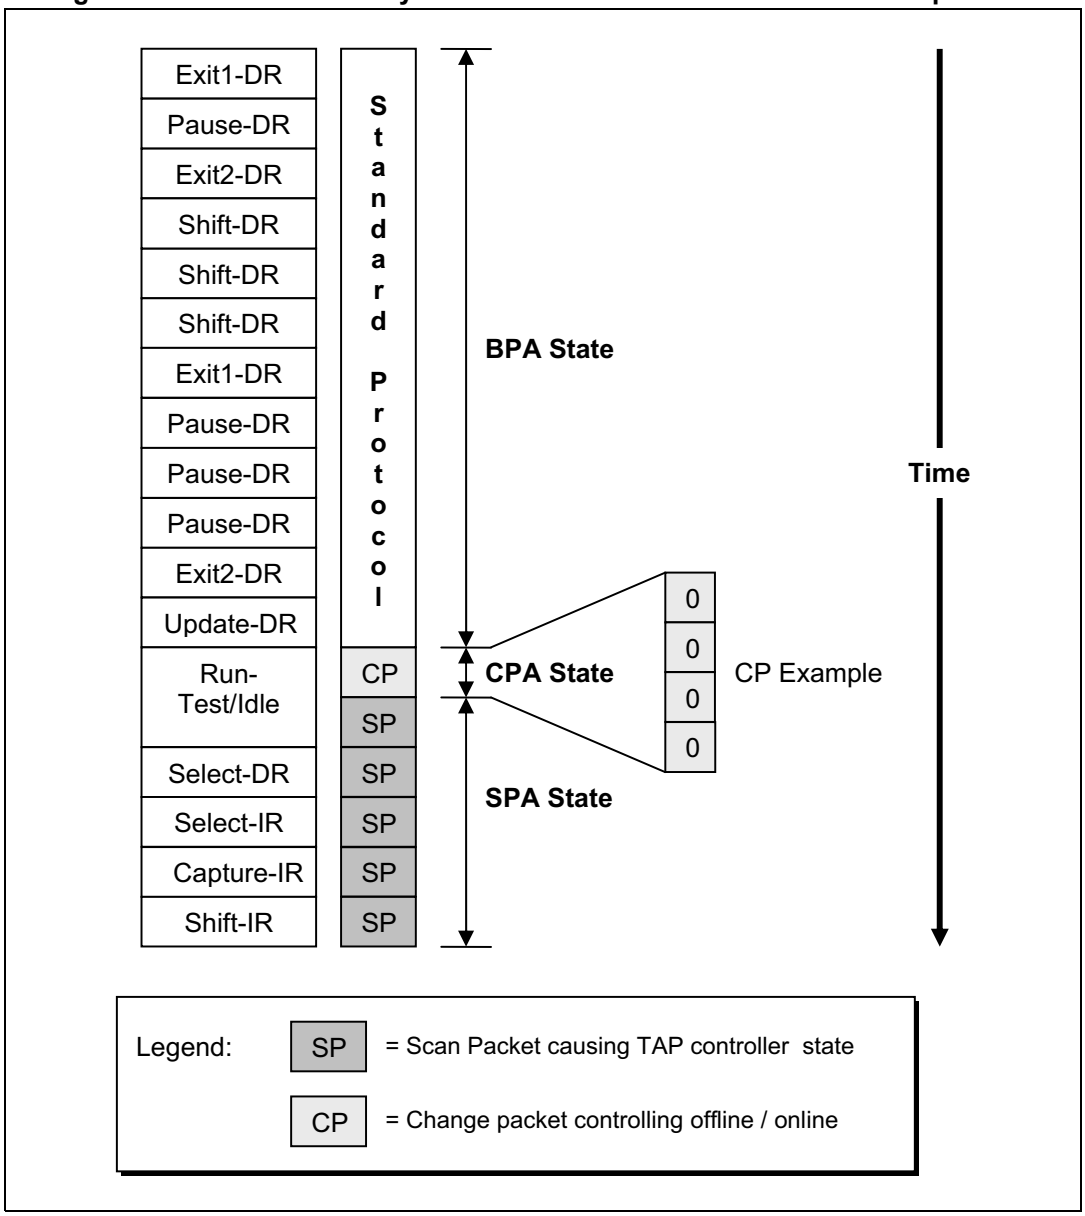
Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 2139. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats).

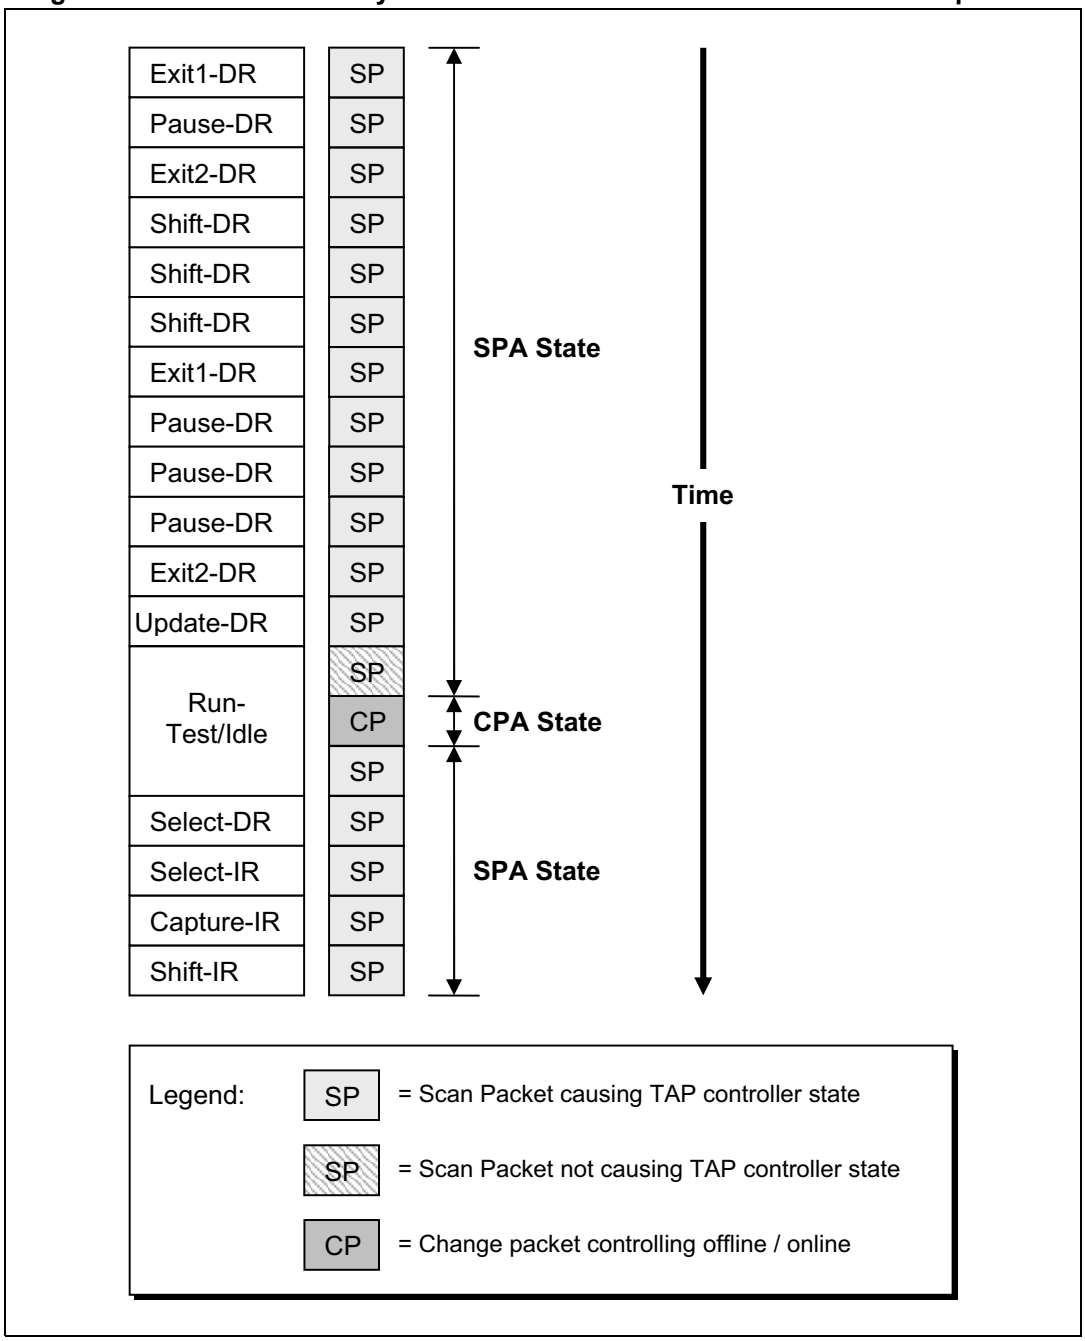
The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.



With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

68.7.5.3 Control Process Active (CPA) Function



While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

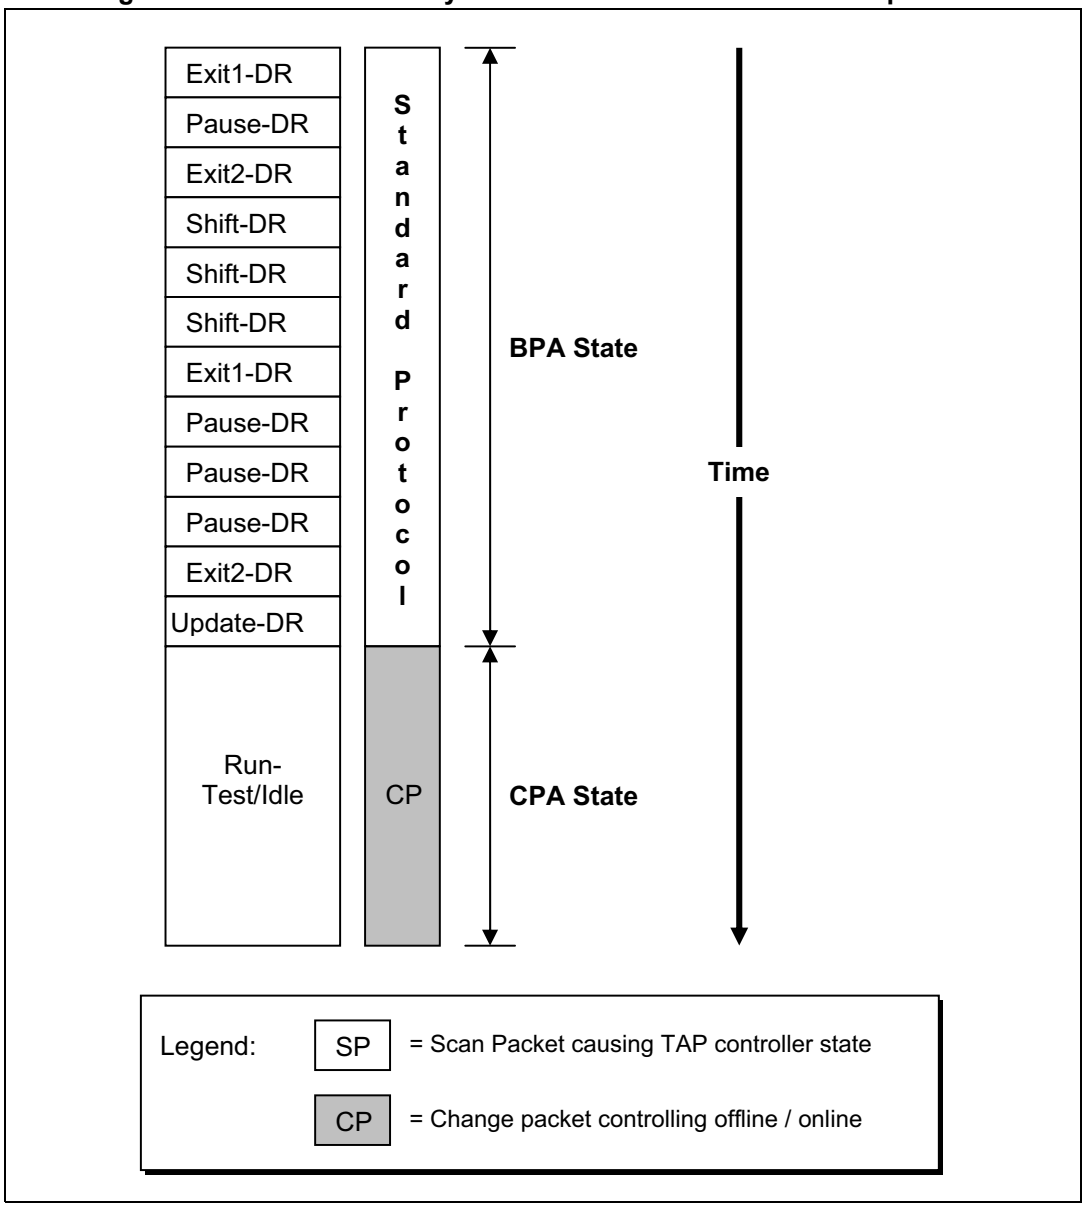
Figure 2140. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 2141. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 2142. CPA State Entry from the BPA State with Offline Operation



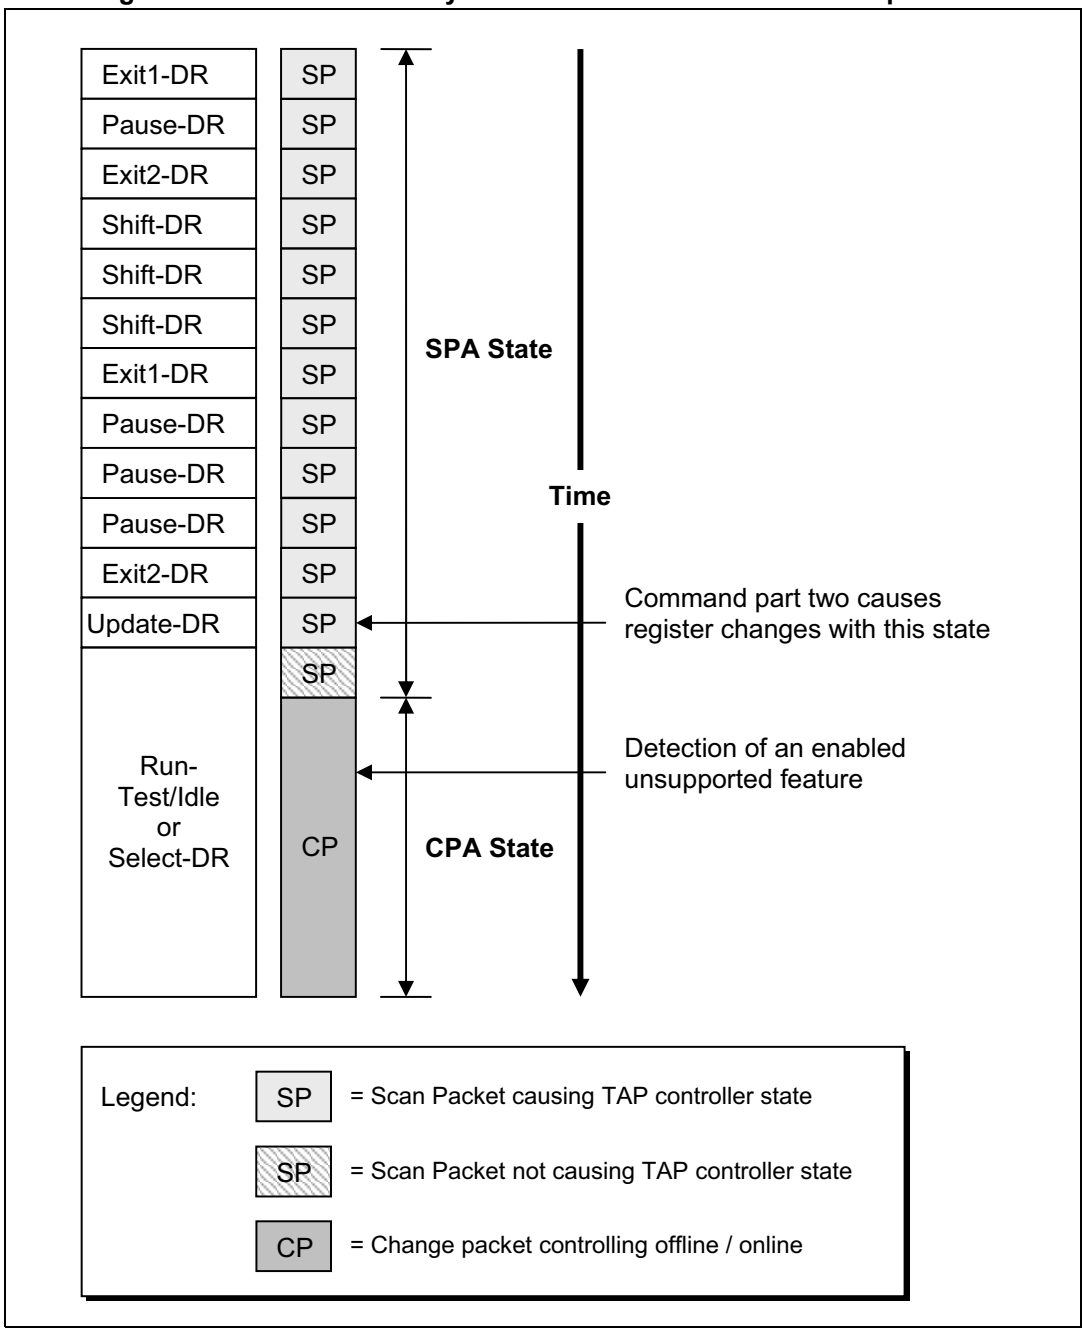


Figure 2143. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

68.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives:
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit)
- **Post amble** – A 1-bit value that is a don't care. This bi t facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

68.7.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof).
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

68.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

68.7.8.1 Payload Element Content

68.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

68.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in *Table 2102*.

Table 2102. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

68.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

68.7.8.3 Scan Formats

68.7.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in *Table 2103* and *Table 2105*, respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

68.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

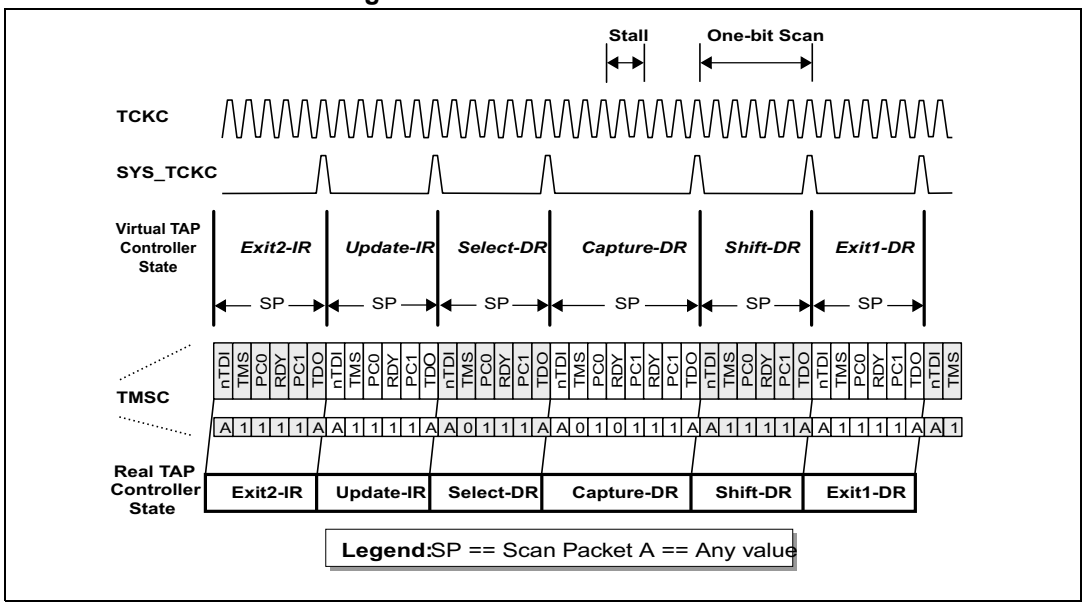

Table 2103. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 2104. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

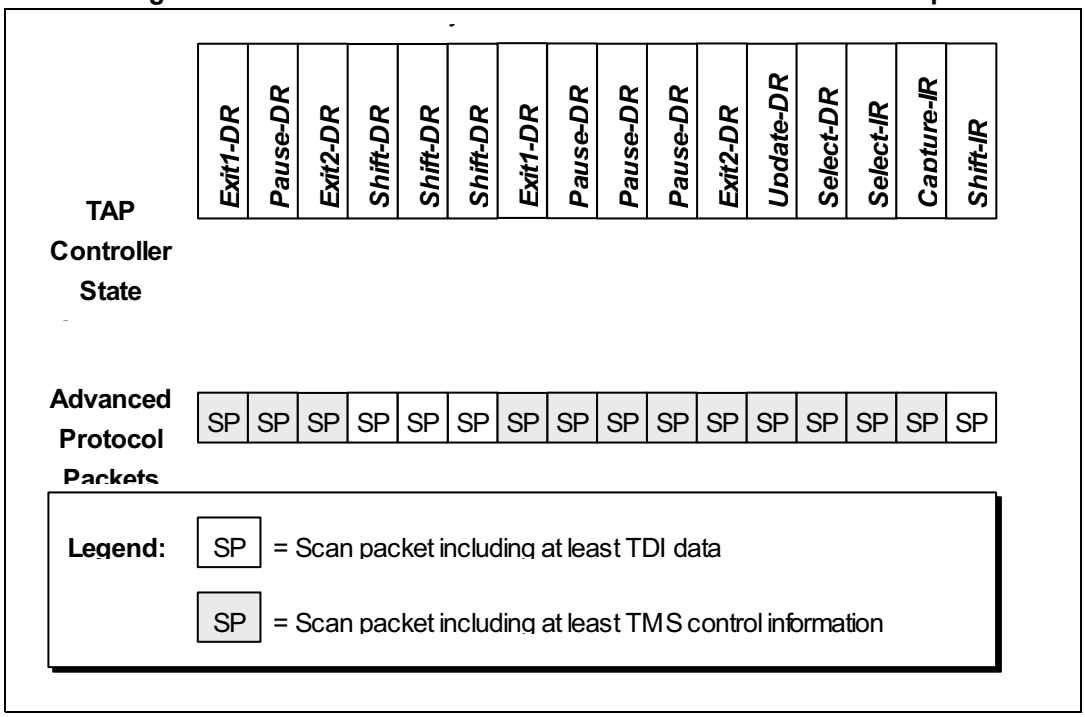

Figure 2144. MScan Transaction

68.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 2145. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in *Table 2105*.

Table 2105. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 2106. OScan Scan Format "Payload"

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO
OScan1	nTDI	TMS	—	TDO		nTDI	TMS	—	TDO

Note 2: Following Shift-xR Scan Packet.

68.8 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

68.8.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in *Section 68.6.1.4: Control levels*.

After the control level is set to control level 2, TAP.7 commands can be executed as described in *Section 68.6.3: EPU Commands*. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in *Section 68.7.5.3: Control Process Active (CPA) Function* and *Section 68.7.6: Configuration Change Packets (CP)*. Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in *Section 68.6.3.5.1.3: Store Conditional 2-bit (STC2)*.

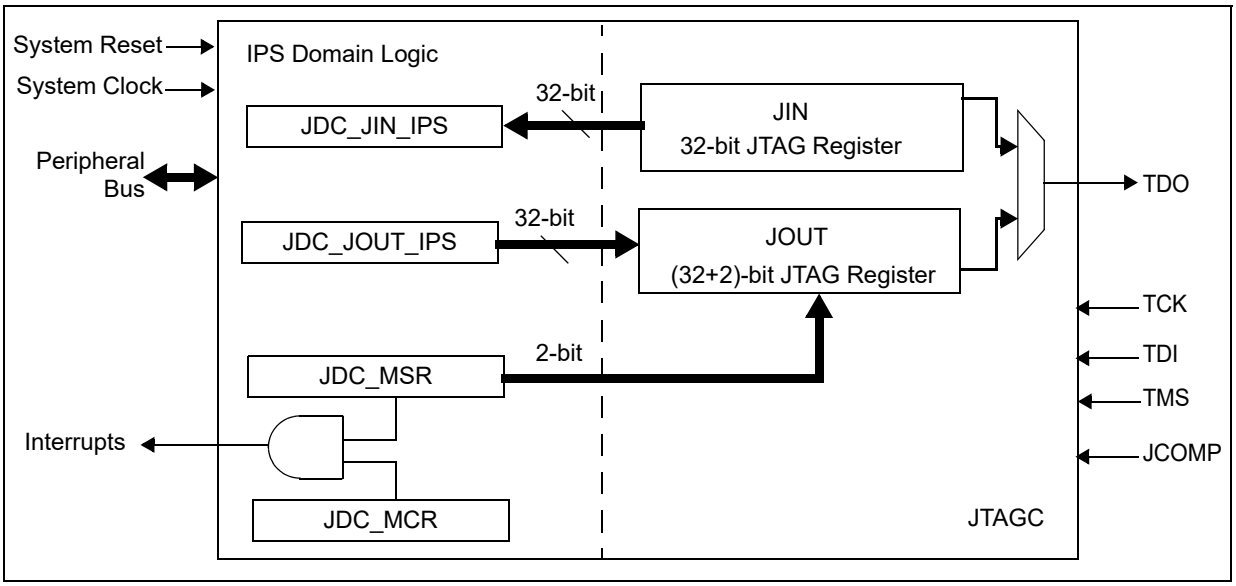
69 JTAG Data Communication (JDC)

69.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

69.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.



The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 2146*.

Figure 2146. JDC block diagram

69.3 Register definition

Table 2107 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 2107. JDC memory map

Address offset	Register	Access	Reset value	Location
0x0	Module Configuration Register (JDC_MCR)	R/W	0x0000_0000	*Section 69.3.1.1*

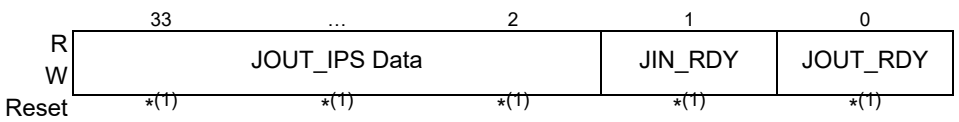
0:31 DATA	Contains JIN_IPS data.



69.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

69.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JDC_JIN_RDY and JDC_JOUT_RDY status bits. *Figure 2151* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

Figure 2151. JOUT JTAG register

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in *Table 2112*.

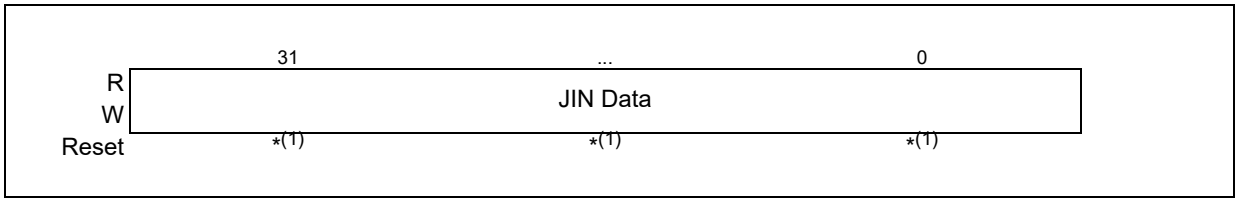


Table 2112. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

69.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 2152* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

Figure 2152. JIN JTAG Register

1. The reset value of the JIN register is 32'b0.

The JIN register is described in *Table 2113*.

Table 2113. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JDC_JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

69.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data

is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

69.4.1 IPS register access

IPS access is available to the registers described in *Section 69.3.1*.

69.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

69.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 2114*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 2114. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

69.5 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The JDC_MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate

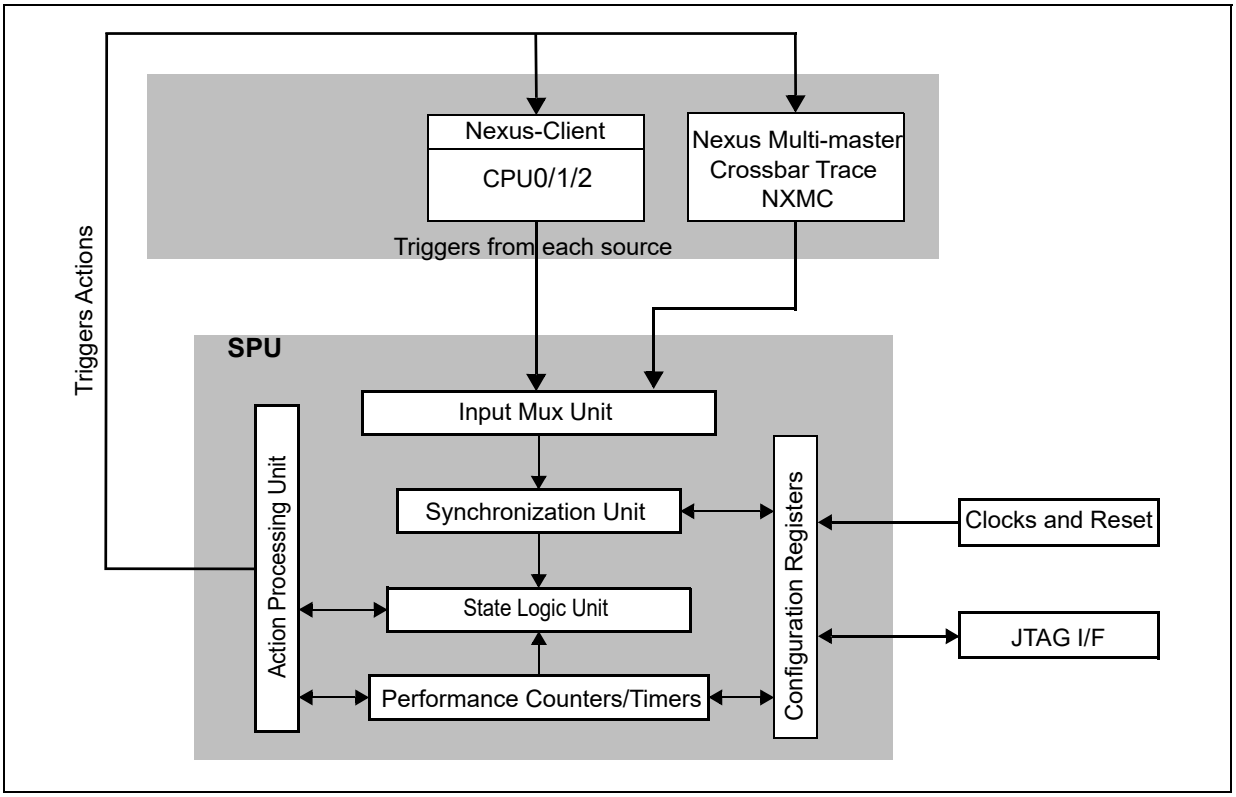
the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the JDC_MCR[JOUT_IEN] is set.

7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

70 Sequence Processing Unit (SPU)

70.1 Introduction



The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

70.1.1 SPU block diagram

Figure 2153 shows a top-level block diagram of the SPU.

Figure 2153. SPU block diagram

70.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 2192*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 2193*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 2194* and *Figure 2195*. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU writes to VariableB. If CPU writes a value to VariableB which is 0x100, then enable trace for the halt CPU.

The SPU consists of the following sub-blocks:

- Input Mux Unit: receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 2192*.
- State Logic Units (SLU): responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan's law, allows for generalized signal combinations. This is shown in *Figure 2193*.
- Action Processing Unit: takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers: the SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

70.1.3 Features

The features of the SPU are as follows:

- clients:
  - 3 CPUs
  - 2 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics
  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action

  - Access to timer/counter values via JTAG
- Prescaler for timer mode only
  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces
  - CPU
  - System bus
  - DCI
- Configuration registers: 32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions: SPU block triggers various actions based on the derived events, these actions are defined in *Section 70.2*

70.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Halt1: single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2: single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Single interrupt for INTC to interrupt a CPU: de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin: output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source: Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals): four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

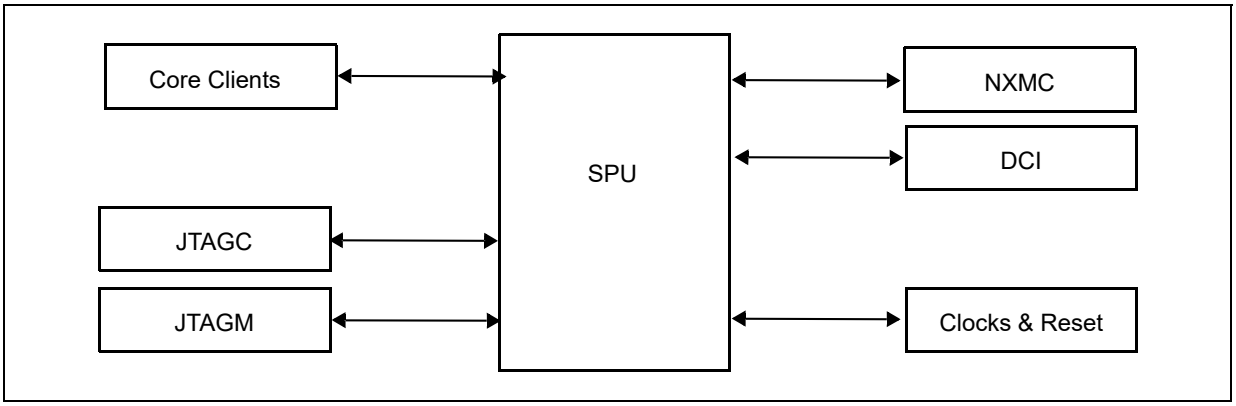
In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

70.3 Operation mode

70.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:



- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

70.4 SPU module interface

The SPU is connected to many clients such as the cores, system bus and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 2154*.

Figure 2154. SPU module interface

70.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 2115 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x01–0x49) registers is 4'h3.
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x01–0x72) is 4'h2.

70.5.1 Registers description

70.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 2192*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

70.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 2155 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see Calibration and Debug (or Debug and Trace) chapter that describes how the modules are configured.

70.5.1.1.14 CPU0 interrupt priority selection (C0PIS)

Figure 2168 shows the format of the C0PIS register. The SPU compares the input CPR vector from CPU0 with the value programmed to the C0PIS register and generates a match signal if necessary. The typical use case would be for posedge detection on match (to detect when the priority level is set to the compare value) or high detection while match remains.

70.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 70.5.1.1: Level1 input Mux configurations registers*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 2192* for State0. Similar logic is provided for States 1 to 7.

Figure 2171. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

70.5.1.3 Sequence unit registers

70.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 2176* shows the format of the IOICn register where the state number, n = 0 to 7.

70.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 2177* shows the format of the SCTRL register.

Table 2129. SCTRL register field descriptions (continued)

Field	Description
25:27 S1ST2	Sequence 1 End State 000 State 0 is the Stop state for sequence 1 001 State 1 is the Stop state for sequence 1 010 State 2 is the Stop state for sequence 1 011 State 3 is the Stop state for sequence 1 100 State 4 is the Stop state for sequence 1 101 State 5 is the Stop state for sequence 1 110 State 6 is the Stop state for sequence 1 111 State 7 is the Stop state for sequence 1
28:30 S1ST1	Sequence 1 Start State 000 State 0 (Always)
31 S1ST0	Sequence1 Enable/Disable(2) Once enabled, this bit is disabled at the end of the Sequence 1. 0 Sequence 1 is disabled 1 Sequence 1 is enabled

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.
2. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.

70.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 2178 shows the format of the SnGC register where the state number, n = 0 to 7.

Offset: 0x40 +n*0x1 (n= 0 to 7) Access: Read/Write

Figure 2178. State n goto control (SnGC)

The SnGC register fields are described in *Table 2130*.

Table 2130. SnGC register field descriptions

Field	Description
24:26 NF	Next State on False Condition Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
27 FE	GOTO Control of State Under False Condition Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5]. If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition. 0 Disable Goto control 1 Enable Goto control
28:30 NT	Next State on True Condition Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
31 TE	GoTo Control of State Under True Condition Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition. 0 Disable Goto control 1 Enable Goto control

70.5.1.4 SLU status register (SS)

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. *Figure 2179* shows the format of the SS register.

Offset: 0x48 Access: User read/write

Figure 2180. SPU enable register (SE)

The SE register fields are described in *Table 2132*.

Table 2132. SE register field descriptions

Field	Description
30 DIV	Div Option Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required
31 SED	SPU Enable/Disable This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled

Note: Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

70.5.1.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

70.5.1.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example, if there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

70.5.1.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in *Section 70.2*.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in *Section 70.2*, becomes redundant with Div4 option.

70.5.1.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 70.2*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 2133* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 2133. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment

11	Reserved						

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

70.5.1.7.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a true condition of every state. All the possible actions and their encoding are listed in *Table 2133*. A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

Figure 2181 shows the format of the SnTA0 register where the state number, n = 0 to 7.

70.5.1.7.5 Trace group configuration registers (DTMTGC, PTMTGC, OTMTGC, WTMTGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace: clients are configured with the DTM trace group configuration (DTMTGC) register
- PTM trace: clients are configured with the PTM trace group configuration (PTMTGC) register
- OTM trace: clients are configured with the OTM trace group configuration (OTMTGC) register
- WTM trace: clients are configured with the WTM trace group configuration (WTMTGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 2185 shows the format of the trace group configuration registers.

Offset: 0x21 (DTMTGC), 0x22 (PTMTGC), 0x23 (OTMTGC), 0x24 (WTMTGC)

31 ENABLE	Enable 0 Counter disabled 1 Counter enabled

70.5.1.9 Counters compare n registers (CCMPn)

A 32-bit comparator value can be programmed for each of the counters. This value is compared with the corresponding counter/timer to generate an event for the SPU. *Figure 2188* shows the format of the CCMPn registers where the counter number, n = 0 to 15.

Offset: 0x36 + n*0x1 (n = 0 to 15) Access: Read/Write

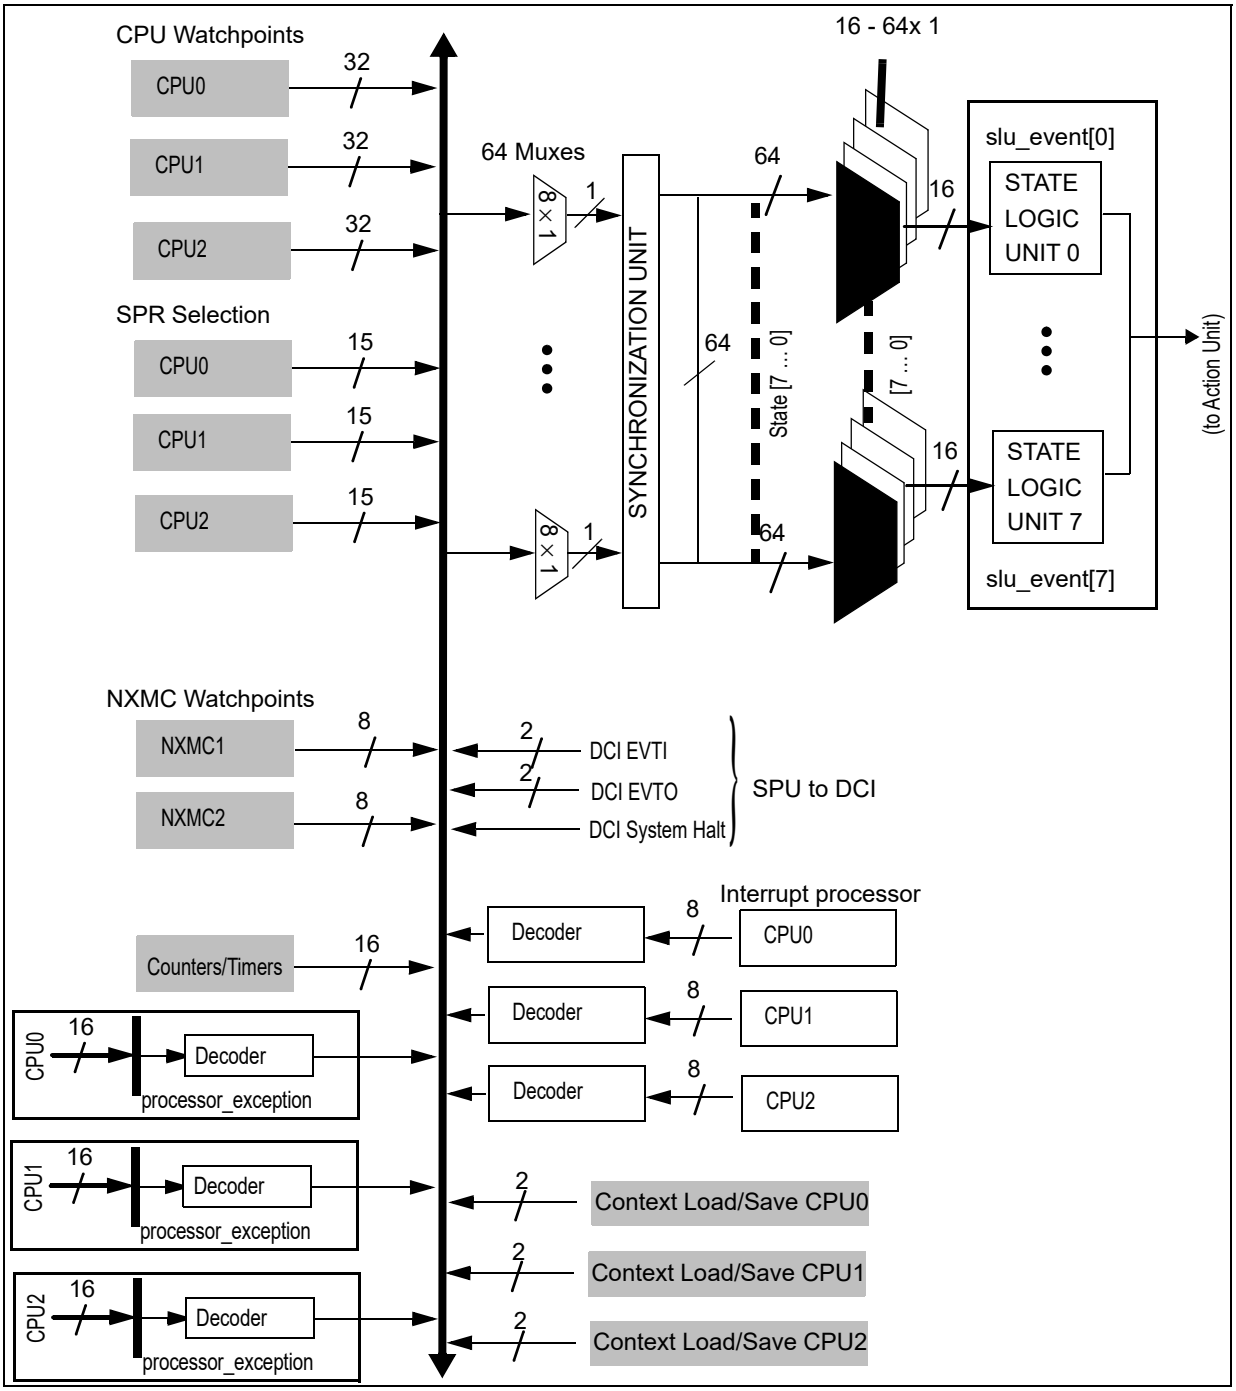
70.6 Functional description

70.6.1 Input Mux unit



The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client

input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two levels of muxing both of which are shown in *Figure 2192*.

- Level 1 Muxing: At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 2192*.
- Level 2 Muxing: At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.
  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be taken to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16×8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 2192*.

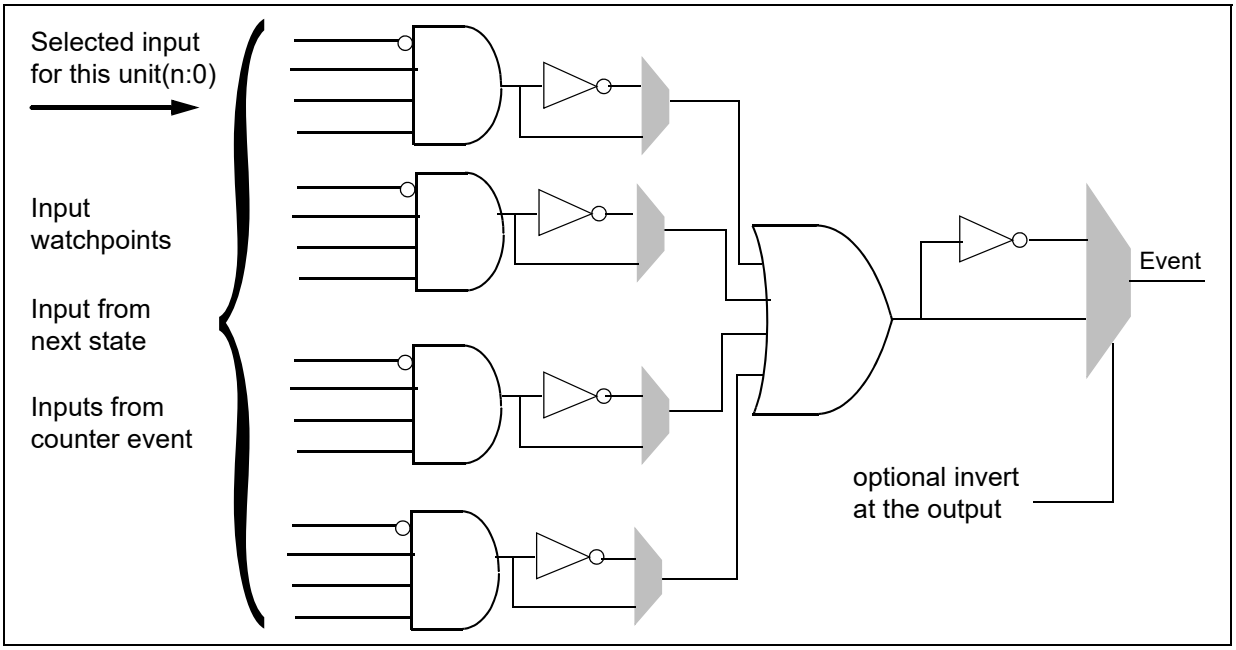
Figure 2192. Input Mux unit block diagram

70.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input

condition as shown in *Table 2145*. The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0 to 2) registers as shown in *Table 2145*.

Table 2145. Processor exception processing conditions



CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input: autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input: autovectored

0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input: vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input: vectored

70.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 2193*.

Figure 2193. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

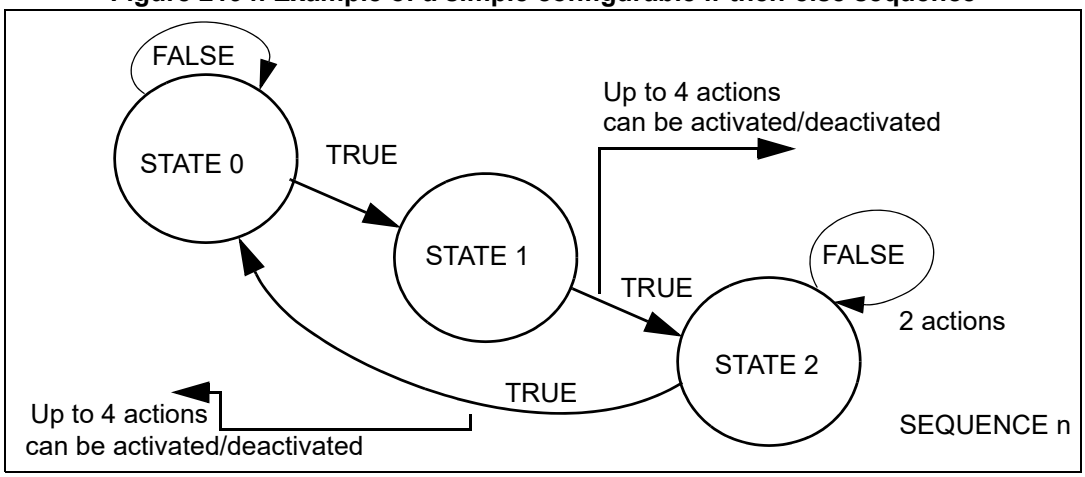
An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

70.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.



For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 2194*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic.

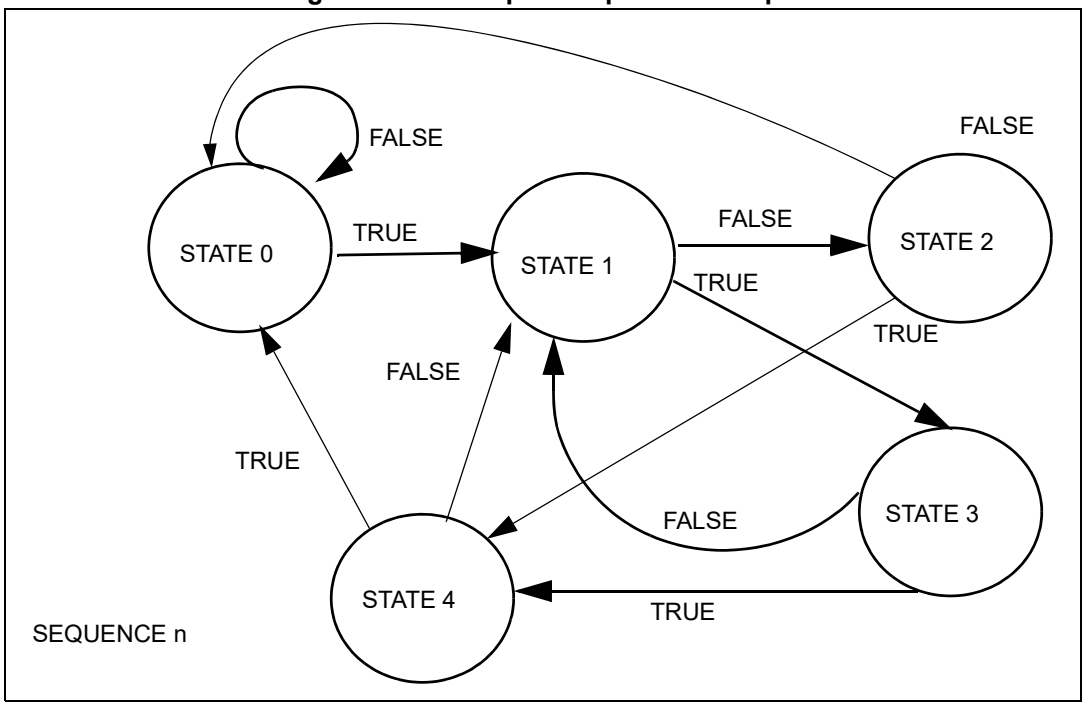


Figure 2194. Example of a simple configurable if-then-else sequence

70.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 2195*.

Figure 2195. Complex sequence example

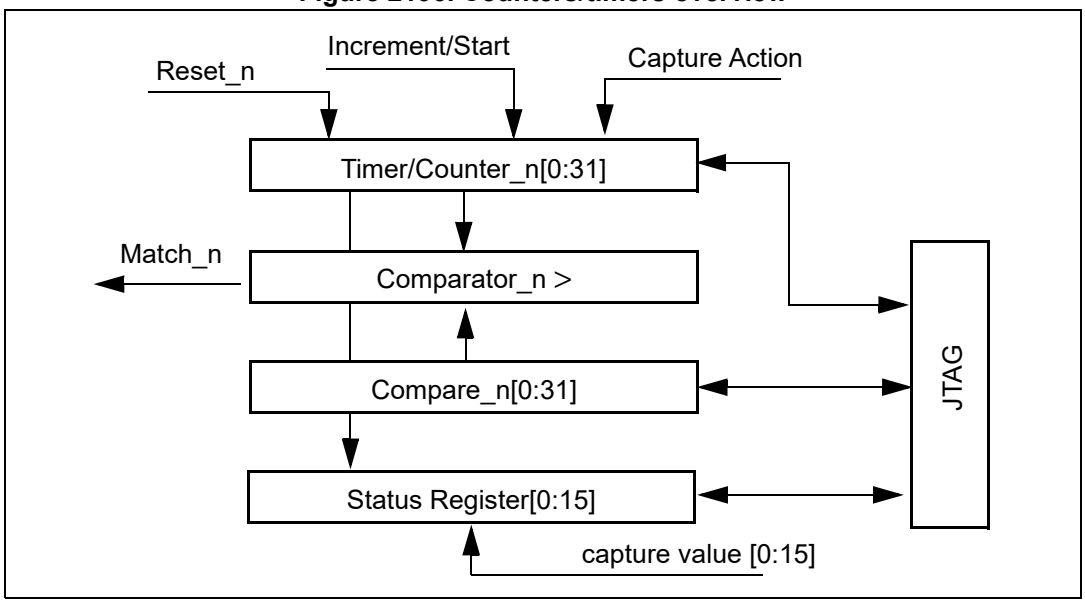
70.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurrence of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

70.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:



- States: each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register
- Sequence status: each sequence has a field indicating the active state of the state machine. This is a read only field

70.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 2196*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

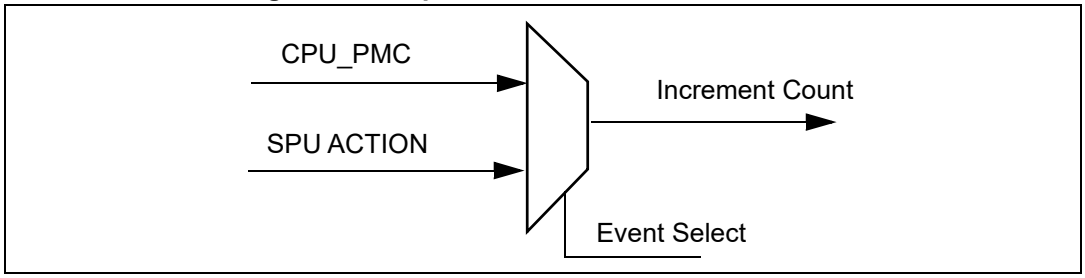
Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 2196. Counters/timers overview

70.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are type write 1 to clear (W1C).

There are two classes of signals, actions and events:



- Actions: each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.
- Event: on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

70.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 2197*. These inputs include signals from the primary SPU muxes or SPU events of counters.

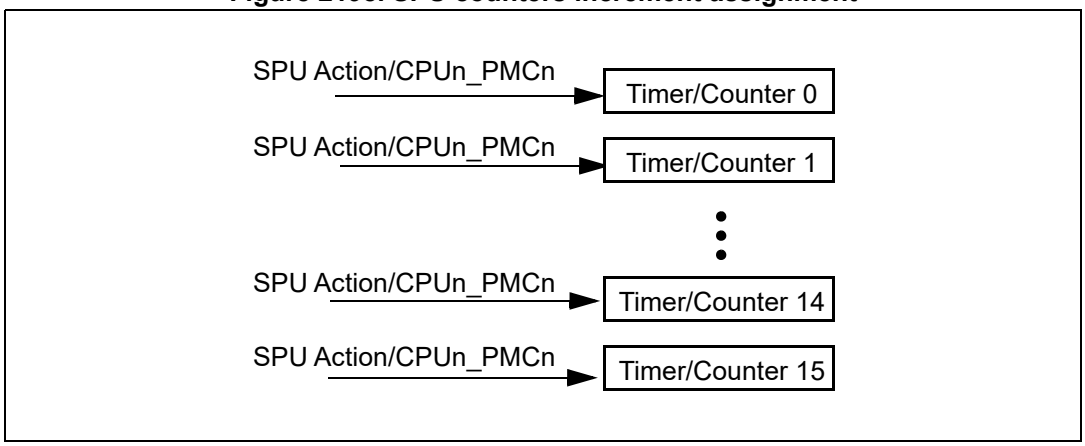


Figure 2197. nput selection for count increment

70.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 2198*.

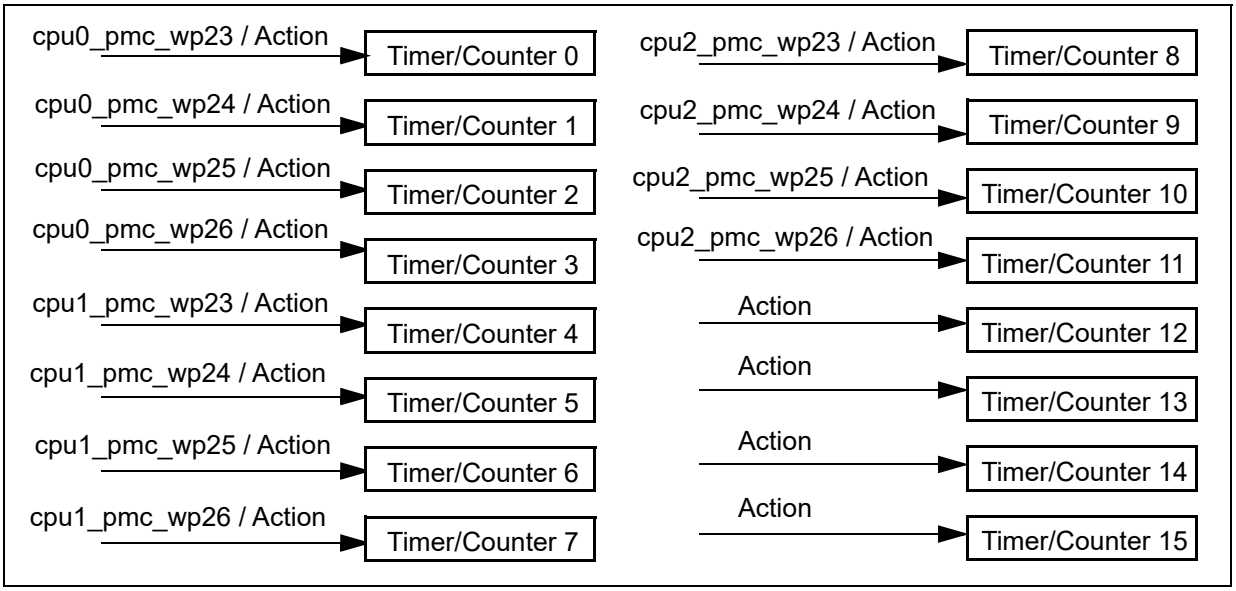

Figure 2198. SPU counters increment assignment

70.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 2199*.

Figure 2199. CPU PMC mapping inside the SPU unit

70.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 70.2*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers**.** Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

70.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers, defined in *Table 2138*, are available where the user can group the different traces from same or different clients.

70.6.8 Format for CKSRC & CKDATA Values

The format of the CKSRC is defined for the SPU Peripheral (as In-Circuit trace client):

Table 2146. CKSRC format

ICT CLIENTS	CKSRC Value
SPU Counter Trace Client	b00_0000
Reserved	b00_0001–b11_1111

The format for the CKDATA field for the SPU Counter trace client is:

Table 2147. CKDATA format

CKDATA	
CKDATA[CTR_Index]	CKDATA[CTR_VALUE]
4 bits	32-bits

71 JTAG Master (JTAGM)

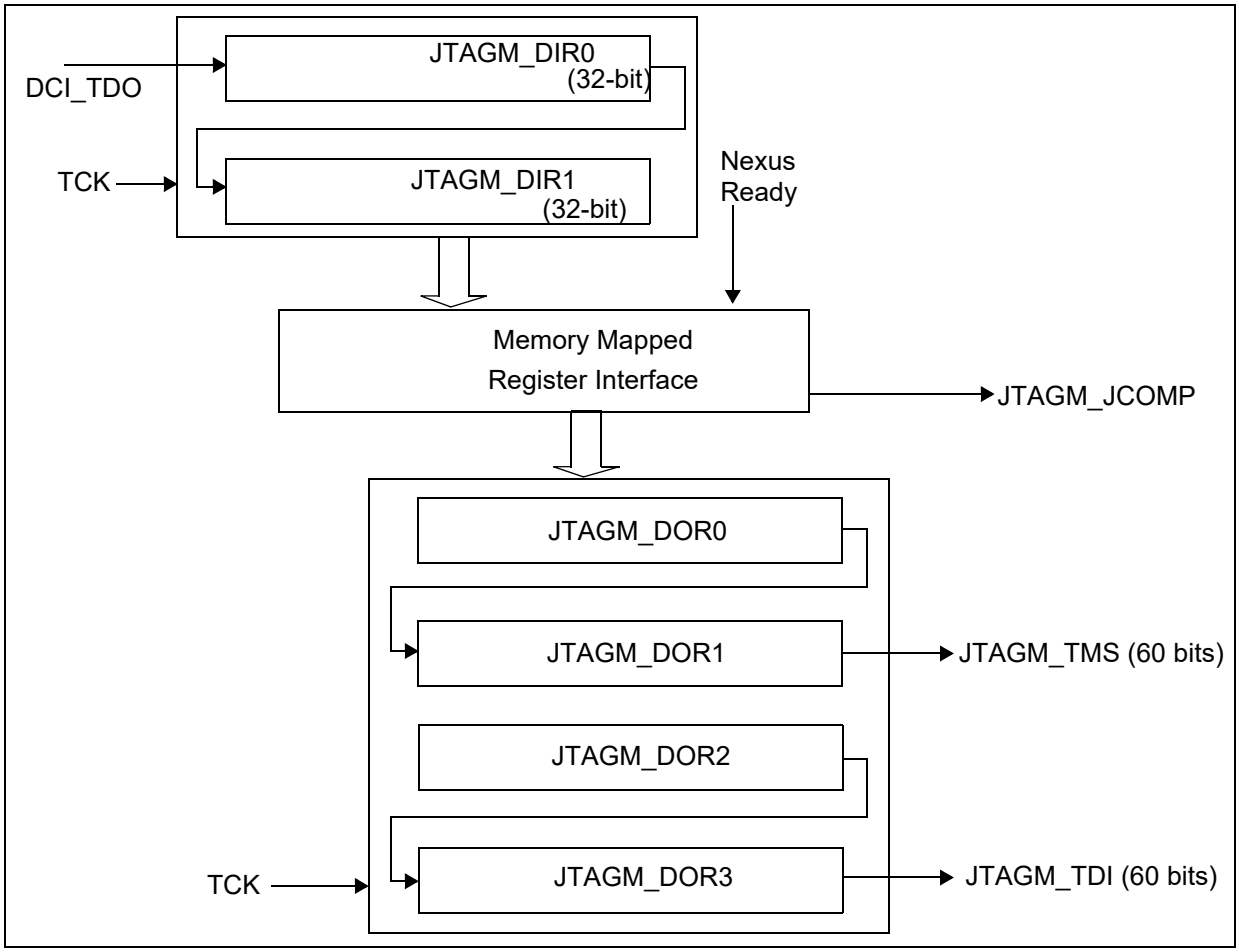
71.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

71.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- Two data input registers

All these registers, described in detail in *Section 71.4*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 2200 shows the block diagram of the JTAGM.

Figure 2200. JTAGM block diagram

71.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG

71.2 Functional description

71.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

71.2.2 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available.

71.2.2.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

71.2.2.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

71.2.3 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

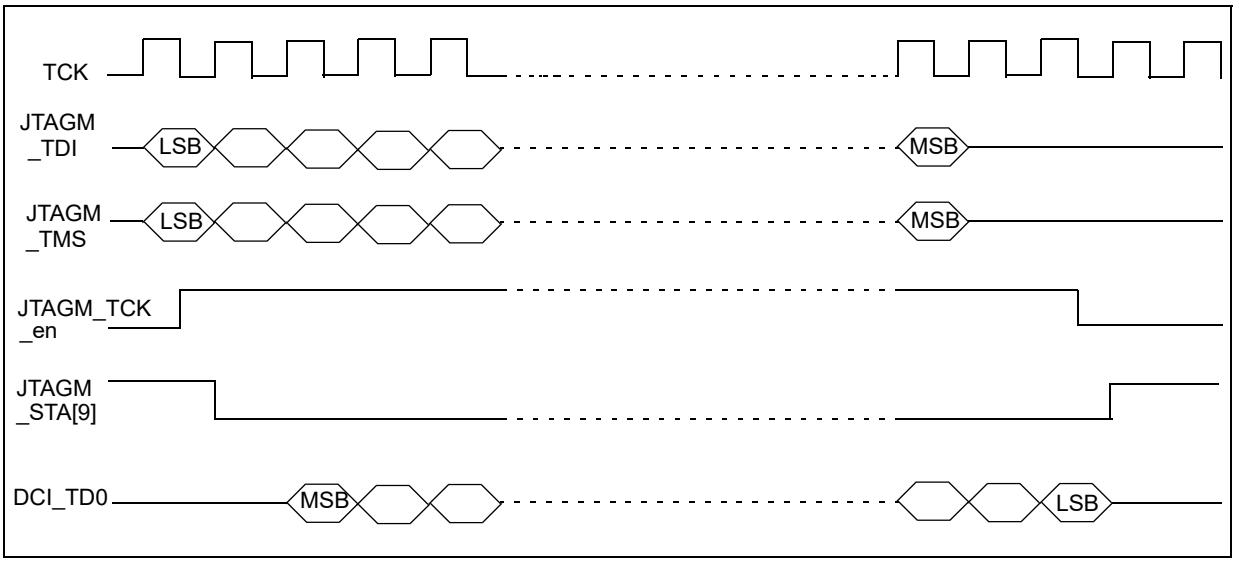
The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is a CPU interrupt.

The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI.

Note: EVTI generation and EVTO detection bits of JTAGM can be used by debugger to detect EVTI assertion and to generate EVTO. This method is useful when EVTI/O pins are not available on SoC PADs.



71.2.4 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 71.2.2.1: Status register ready bit*). The status register also includes status bits provided by the DCI module.

71.2.5 JTAGM to DCI serial interface

Figure 2201 shows the data transfer timings between JTAGM and DCI.

Figure 2201. JTAGM to DCI serial interface diagram

71.2.6 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

71.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

71.4 Memory map and register definition

Table 2148 contains the memory map of the JTAGM registers.

Table 2148. Memory map

W									evto0_ clr	evto1_ clr						
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Figure 2203. JTAGM_SR register

The JTAGM_SR register is described in *Table 2150*.

Table 2150. JTAGM_SR register field descriptions

Field	Description
8:15 dci_status	Status information from the DCI. The composition of these bits is as follows: bit 8 Reserved to 0 bit 9 Reserved bit 10 DCI JTAG port enable bit 11 Reserved bit 12 DCI JTAG safe mode bit 13 Reserved bit 14 Reserved bit 15 DCI tool present, set when a debug tool is connected
16 evto0_edge	In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO0}}$ 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO0}}$

Table 2150. JTAGM_SR register field descriptions (continued)

Field	Description
17 evto1_edge	In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO1}}$ 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO1}}$
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to '1' when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready **Note:** 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24 evto0_clr	Used for clearing the evto0_edge bit.
25 evto1_clr	Used for clearing the evto1_edge bit.

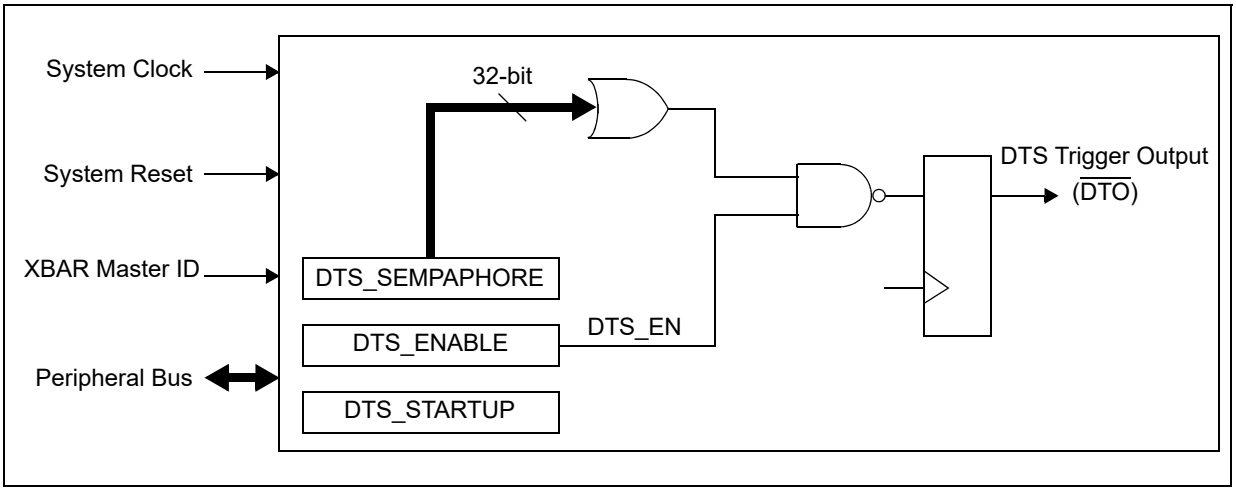
72 Development Trigger Semaphore (DTS)

72.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.



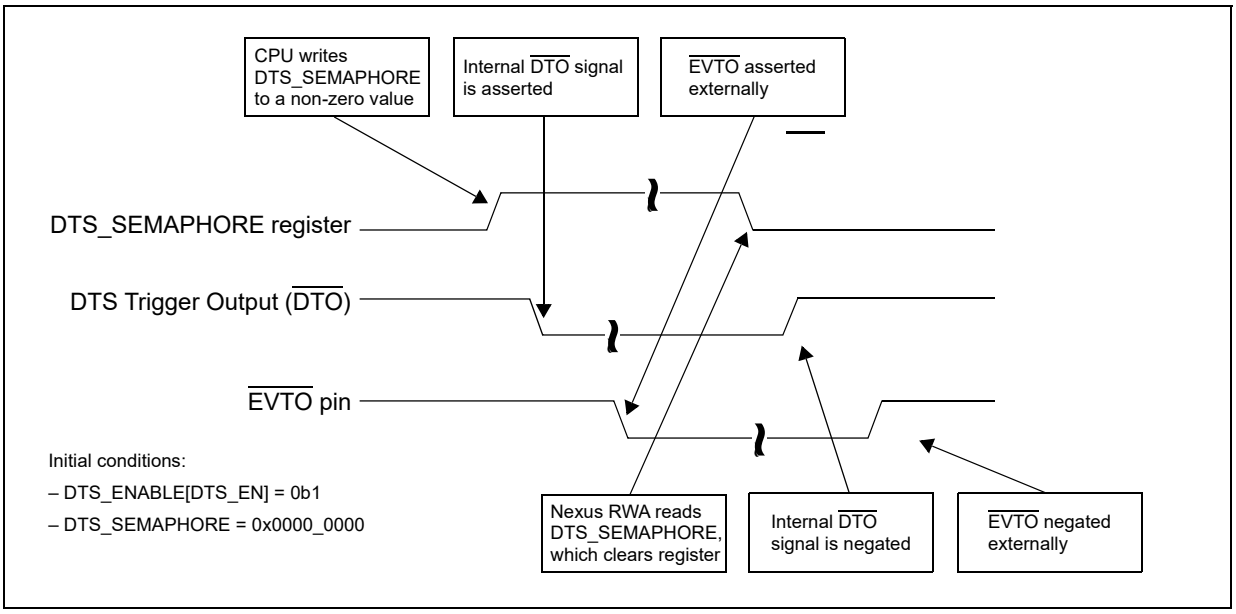
72.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal, DTS Trigger Output ($\overline{\text{DTO}}$). The registers are as follows:

- DTS_SEMAPHORE register: Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_STARTUP register: This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register: This register provides an enable/disable capability for the DTS feature.

The architecture is shown in *Figure 2210*.

Figure 2210. DTS block diagram



The DTS Trigger Output ($\overline{\text{DTO}}$) signal is connected to one of the $\overline{\text{EVTO}}$ inputs of the Debug and Calibration Interface (DCI). The other $\overline{\text{EVTO}}$ inputs are connected to the other Nexus modules in the device. $\overline{\text{DTO}}$ is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and $\overline{\text{EVTO}}$ becomes the $\overline{\text{DTO}}$. Unlike the $\overline{\text{EVTO}}$ function that only asserts for one clock, the $\overline{\text{DTO}}$ function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 2211 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

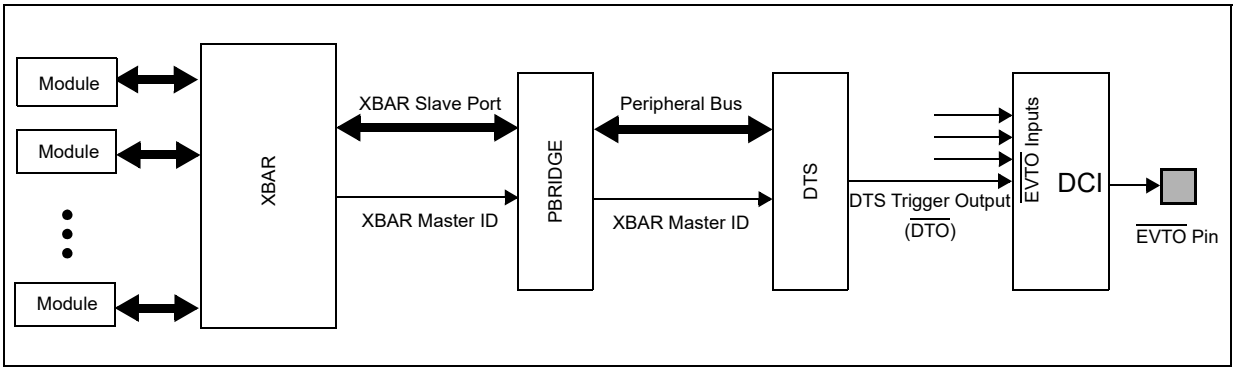


Figure 2211. $\overline{\text{DTO}}$ event sequence example

72.3 DTS device connections

Figure 2212 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 2212. DTS device connections

The registers have limited access as described in *Section 72.3.1: DTS register access*. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore register is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool or debug Zipwire can clear bits in the semaphore register (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access or debug Zipwire.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

72.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in *Table 2157*. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 2157. DTS register access effects

Register	32-bit read				32-bit write			
	RWA(1)	Core	eDMA	Other crossbar masters	RWA(1)	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear(2)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore register by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: The XBAR Master ID should not be confused with the Master Port number of the XBAR. See Chapter 17: Crossbar switch (XBAR), for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core or debug Zipwire. External tool accesses through either core appear as if the access is

via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

72.4 Memory map and register definition

Table 2158 shows the memory map of the DTS module registers.

Table 2158. DTS memory map

Offset address	Register name	Access	Reset Value	Location
0x0000	DTS Output Enable register (DTS_ENABLE)	Restricted R/W(1)	0x0000_0000	*Section 72.4.1.1*
0x0004	DTS Startup register (DTS_STARTUP)	Restricted R/W(1)	0x0000_0000	*Section 72.4.1.2*
0x0008	DTS Semaphore Register (DTS_SEMAPHORE)	Restricted R/W(1)	0xFFFF_FFFF	*Section 72.4.1.3*
0x000C	DTS Semaphore Extension (DTS_SEMAPHORE_B)	Restricted R/W(1)	0xFFFF_FFFF	*Section 72.4.1.4*

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

72.4.1 Register descriptions

72.4.1.1 DTS output enable register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{DTO}$) and whether $\overline{DTO}$ is active on the $\overline{EVTO}$ output pin of the device. *Figure 2213* shows the format of the DTS_ENABLE register. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA) or debug Zipwire.

Note: Access to the DTS_SEMAPHORE and DTS_STARTUP registers are unaffected by the state of this register.

Offset 0x0000 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

Figure 2213. DTS output enable register (DTS_ENABLE)

Table 2159. DTS_ENABLE field descriptions

Field	Description
31 DTS_EN	DTS Enable Controls whether the DTO signal is routed to the EVTO pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external RESET or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal (DTO).

72.4.1.2 DTS startup register (DTS_STARTUP)

Figure 2214 shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA modules and other crossbar masters but can only be updated by a Nexus Read Write Access (RWA) or debug Zipwire.

Offset 0x0004 Access: Restricted R/W(1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The DTS_STARTUP register can be read by the cores, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

Figure 2214. DTS startup register (DTS_STARTUP)

Table 2160. DTS_STARTUP field descriptions

Field	Description
0:31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access or debug Zipwire to update the contents of this register. **Note:** A device reset (either from the RESET pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

72.4.1.3 DTS semaphore register (DTS_SEMAPHORE)

Figure 2215 shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the DTO signal on the device EVTO pin. A one in any

bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Offset 0x08 Access: Restricted R/W

Figure 2215. DTS semaphore register (DTS_SEMAPHORE)

Table 2161. DTS_SEMAPHORE field descriptions

Field	Description
0:31 ST	Semaphore Trigger. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.4.1.4 DTS semaphore extension (DTS_SEMAPHORE_B)

Figure 2216 shows the format of the DTS_SEMAPHORE_B register. The DTS_SEMAPHORE_B register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

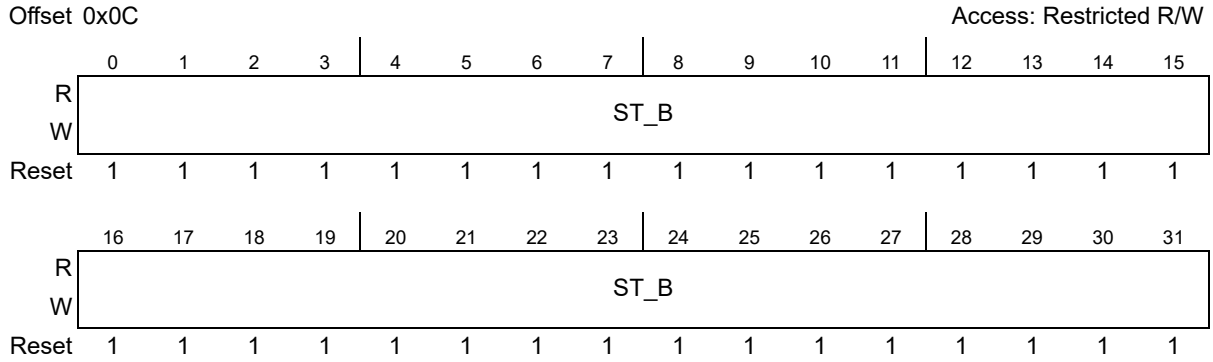

Figure 2216. DTS Semaphore extension register (DTS_SEMAPHORE_B)

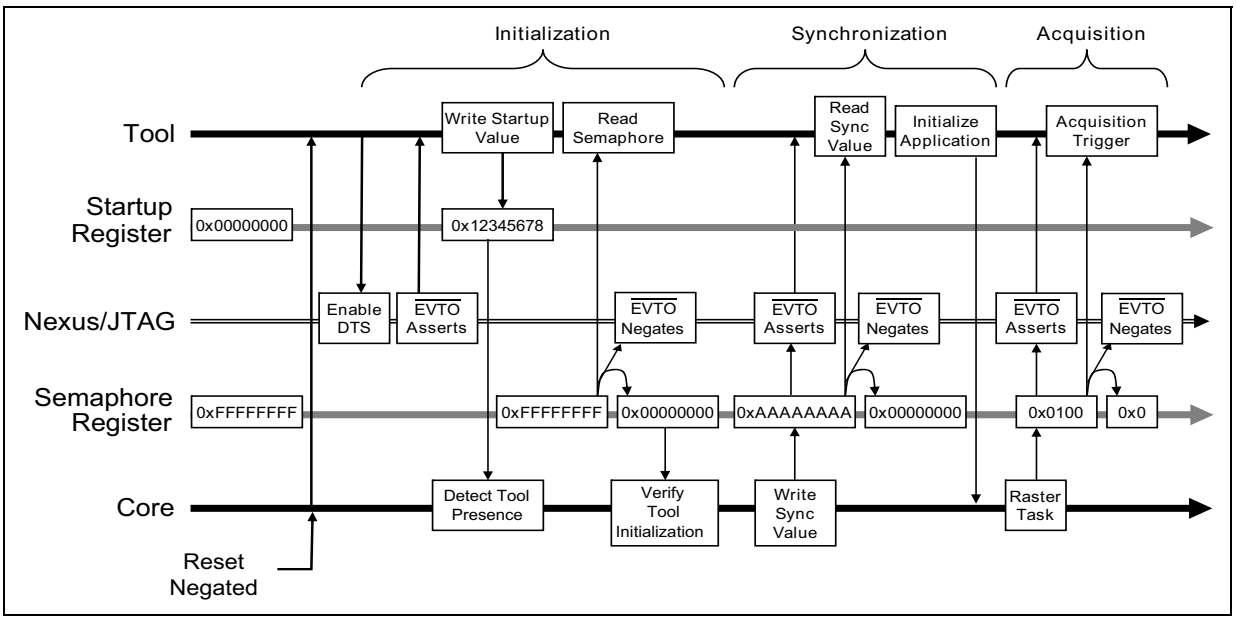
Table 2162. DTS_SEMAPHORE_B field descriptions

Field	Description
0:31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. – All register bits are set to '1' by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.



In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note: It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

Figure 2217 shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA, all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 2217. DTS startup sequence example

73 Nexus Port Controller (NPC)

73.1 Information specific to this device

This section presents device-specific parameterization, customization, and feature availability information not specifically referenced in the remainder of this chapter.

73.1.1 Parameter values

The following table provides the parameter values for this device.

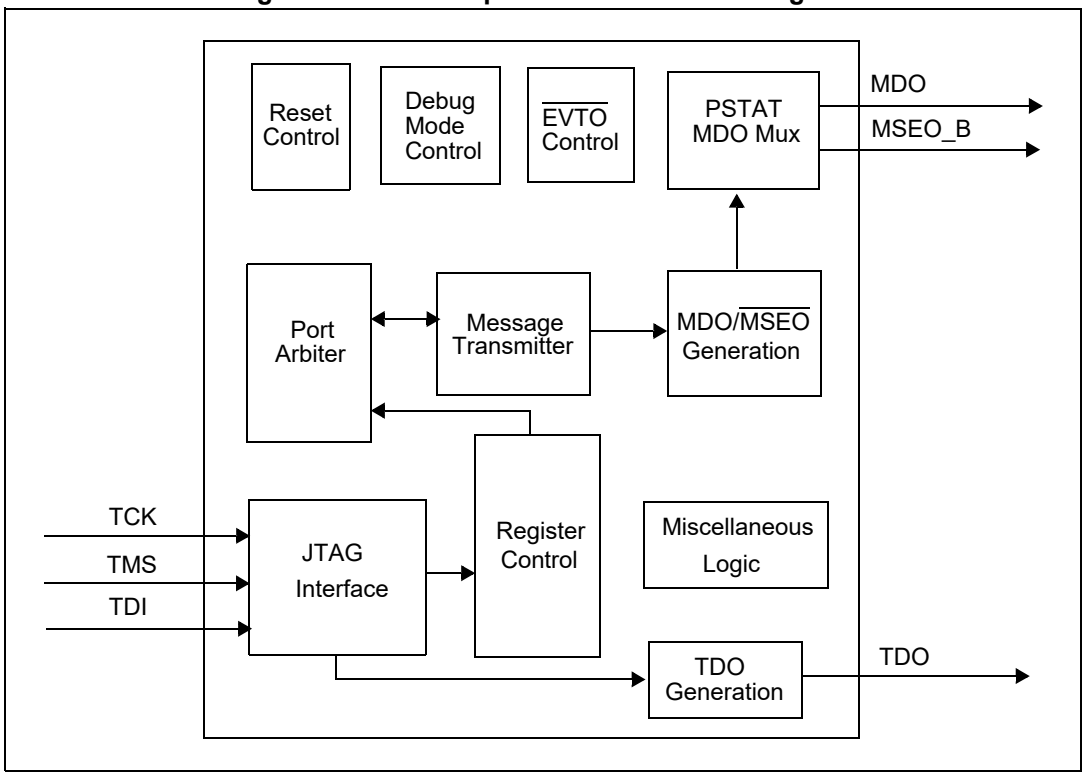


Table 2163. Device parameter values

Parameter	Value
Number of MDO pins available in reduced-port mode	4
Number of MDO pins available in full-port mode	12
Number of $\overline{\text{MSEO}}$ pins available	2

73.2 Introduction

The following figure shows the Nexus Port Controller (NPC) block diagram.

Figure 2218. Nexus port controller block diagram

73.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2003 standard. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

73.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Auxiliary Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Generates power-on reset status
- Provides Nexus support for censorship mode
- $\overline{\text{RDY}}$ pin support to increase the transfer rate of the IEEE 1149.1 port for large data read requests

73.2.3 Modes of operation

The NPC block uses the censorship status and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

73.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, the device enters censored mode, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The auxiliary output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset or censored mode only)
- Registers default back to their reset values

73.2.3.2 Disabled-Port mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages cannot be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

73.2.3.3 Full-Port mode

Full-port mode (FPM) is entered by asserting the MCKO_EN and FPM bits in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

73.2.3.4 Reduced-Port mode

Reduced-port mode (RPM) is entered by asserting the MCKO_EN bit and deasserting the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

73.2.3.5 Censored mode

When the device is in censored mode, reading the contents of internal flash externally is not allowed. To prevent Nexus modules from violating censorship, the NPC is held in reset when in censored mode, asynchronously holding all other Nexus modules in reset as well. This prevents Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

73.2.3.6 Nexus Double Data Rate mode

Nexus double data rate (DDR) mode is enabled by asserting the DDR_EN bit in the PCR. DDR mode is only supported for MCKO_DIV settings of sys_clk/2, sys_clk/4 and sys_clk/8. In double data rate mode, message data is updated between the edges (both rising and falling) of MCKO, effectively doubling message throughput.

73.3 External signal description

73.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table.

Table 2164. NPC signal properties

Name	Port	Function	Reset state	Pull(1)
EVTO	Auxiliary	Event Out pin	0b1	—
MDO	Auxiliary	Message Data Out pins	0	—
MSEO	Auxiliary	Message Start/End Out pin	0b1	—
TCK	JTAG	Test Clock Input	—	Down
TDI	JTAG	Test Data Input	—	Up
TDO	JTAG	Test Data Output	High Z(2)	—
TMS	JTAG	Test Mode Select Input	—	Up
RDY	JTAG	Data ready for transfer to/from NRRs	—	—

1. The pull is not implemented in this block. Pullup/pulldown devices are implemented in the pads.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

73.3.2 Detailed signal descriptions

This section describes each of the signals listed in *Table 2164* in more detail. The JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

73.3.2.1 $\overline{\text{EVTO}}$ - Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

73.3.2.2 MDO - Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

73.3.2.3 MSEO_B - Message Start/End Out

Message Start/End Out ($\overline{\text{MSEO}}$) is one output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample $\overline{\text{MSEO}}$ on the rising edge of MCKO.

73.3.2.4 TCK - Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

73.3.2.5 TDI - Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

73.3.2.6 TDO - Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

73.3.2.7 TMS - Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

73.3.2.8 $\overline{\text{RDY}}$ - Data ready for transfer

The $\overline{\text{RDY}}$ pin exists to increase the transfer rate of the IEEE 1149.1 port. It is used to signal when data are ready to be transferred to and from NRRs. This may eliminate the need to poll NRRs for status information for synchronization purposes. This capability becomes especially important when performing read/write access transfers to different speed target memories.

The $\overline{\text{RDY}}$ pin asserts (asynchronously) a logic low whenever the read/write access transfer has completed without error and then deasserts when the IEEE 1149.1 state machine has reached the CAPTURE_DR state.

73.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

Table 2165 shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers. Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 2165. NPC registers

Index	Register
0	Device ID Register (DID)
127	Port Configuration Register (PCR)

73.4.1 Register descriptions

This section contains the NPC register descriptions.

73.4.1.1 Bypass Register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

73.4.1.2 Instruction Register

The NPC block uses a 4-bit instruction register as shown in *Figure 2219*. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

Figure 2219. 4-bit Instruction Register

	0	1	2	3
R	Previous Instruction Opcode			
W	Instruction Opcode			
Reset:	BYPASS Instruction Opcode (0xF)			

73.4.1.3 Nexus Device ID Register (DID)

The device identification register allows identification information of the part to be determined through the auxiliary output port.

Register index: 0

73.4.1.4 Port Configuration Register (PCR)

The PCR is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

Note: The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Register index: 127

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2221. Port Configuration Register (PCR)

Table 2167. PCR field descriptions

Name	Description
0 FPM	Full Port Mode The value of the FPM bit determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 1 All MDO pins are used to transmit messages 0 A subset of MDO pins are used to transmit messages
1 MCKO_GT	MCKO Clock Gating Control This bit is used to enable or disable MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 1 MCKO gating is enabled. 0 MCKO gating is disabled.
2 MCKO_EN	MCKO Enable This bit enables the MCKO clock to run. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 1 MCKO clock is enabled. 0 MCKO clock is driven to zero.
3:5 MCKO_DIV[2:0]	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. *Table 2168* shows the meaning of MCKO_DIV values. In this table, SYS_CLK represents the system clock frequency.
6 EVT_EN	$\overline{\text{EVTO}}$/$\overline{\text{EVTI}}$ Enable This bit enables the $\overline{\text{EVTO}}$/$\overline{\text{EVTI}}$ port functions. 0 $\overline{\text{EVTO}}$/$\overline{\text{EVTI}}$ port disabled 1 $\overline{\text{EVTO}}$/$\overline{\text{EVTI}}$ port enabled

Table 2167. PCR field descriptions (continued)

Name	Description
7 DDR_EN	Double Data Rate Mode Enable This bit enables Nexus Double Data Rate (DDR) mode. In DDR mode, message data is updated on both rising and falling edges of MCKO, effectively doubling message throughput. 1 DDR mode enabled 0 DDR mode disabled
16 LP_DBG_EN	Low Power Debug Enable This bit enables debug functionality on exit from low power modes on supported devices. 1 Low power debug enabled 0 Low power debug disabled
22 LP2_SYN	Low Power Mode 2 Synchronization This bit is used to synchronize the entry into low power mode between the device and debug tool. Supported devices set this bit before a pending entry into low power mode. After reading the bit as set, the debug tool then clears the bit to acknowledge to the device that it may enter the low power mode. 1 Low power mode entry pending 0 Low power mode entry acknowledged
23 LP1_SYN	Low Power Mode 1 Synchronization This bit is used to synchronize the entry into low power mode between the device and debug tool. Supported devices set this bit before a pending entry into low power mode. After reading the bit as set, the debug tool then clears the bit to acknowledge to the device that it may enter the low power mode. 1 Low power mode entry pending 0 Low power mode entry acknowledged

Table 2168. PCR[MCKO_DIV] values

MCKO_DIV[2:0]	MCKO frequency
0d (000b)	SYS_CLK(1)
1d (001b)	SYS_CLK/2
2d (010b)	SYS_CLK/3(2)
3d (011b)	SYS_CLK/4
4d (100b)	Reserved
5d (101b)	Reserved
6d (110b)	Reserved
7d (111b)	SYS_CLK/8

1. The SYS_CLK setting for MCKO frequency should only be used if this setting does not violate the maximum operating frequency of the auxiliary port pins.
2. SYS_CLK/3 setting must not be used in DDR mode.

73.5 Functional description

73.5.1 NPC reset configuration

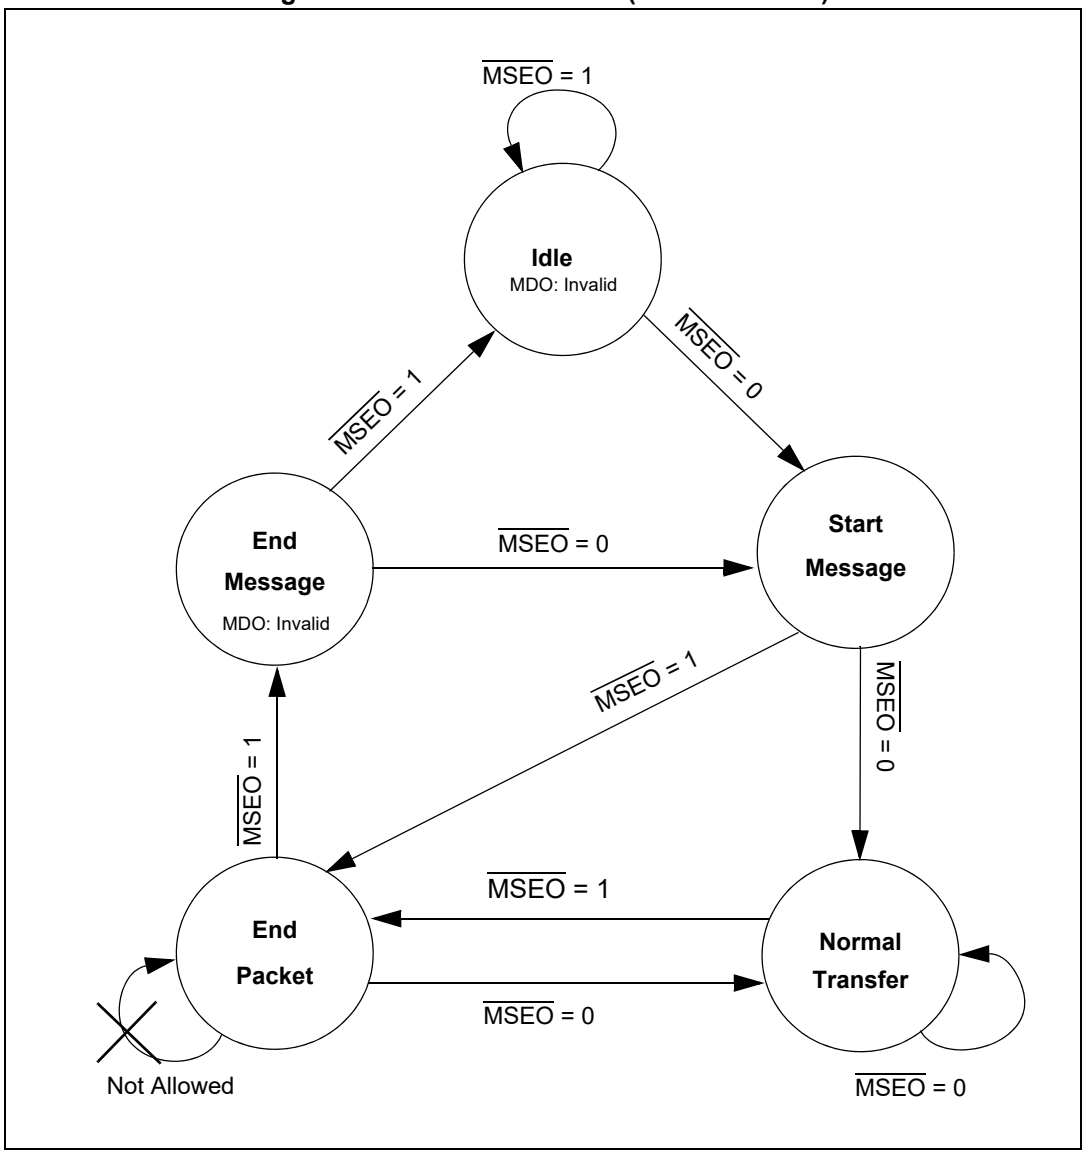
The NPC is placed in disabled mode upon exit of reset. If message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

The following table describes the NPC reset configuration options.

Table 2169. NPC reset configuration options

NPC_PCR[MCKO_EN]	NPC_PCR[FPM]	Configuration
X	X	Reset
0	X	Disabled
1	1	Full-Port mode
1	0	Reduced-Port mode

73.5.2 Auxiliary output port



The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

73.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the MSEO functions. The MSEO pin is used to signal the end of variable-length packets and the end of messages. It is not required to indicate the end of fixed-length packets. MDO and MSEO are sampled on the rising edge of MCKO.

Figure 2222 illustrates the state diagram for MSEO transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 2222. $\overline{\text{MSEO}}$ transfers (for 1-bit $\overline{\text{MSEO}}$)

73.5.2.2 Output messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register and the port replacement output message on the MDO pins. The device ID message can also be sent out serially through TDO.

Table 2170 describes the device ID and port replacement output messages that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

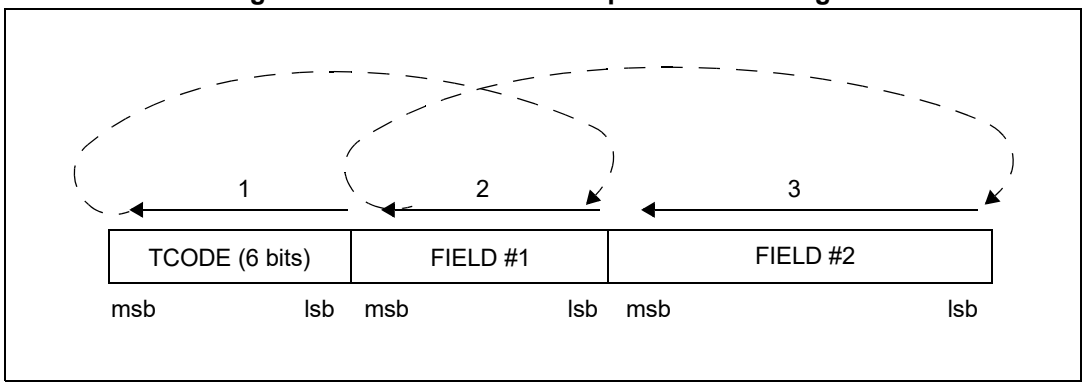
Table 2170. NPC output messages

Message name	Packet				
	Size (bits)		Type	Name	Description
	Min	Max			
Device ID Message	6	6	fixed	TCODE	Value = 1
	32	32	fixed	ID	DID register contents

Figure 2223 shows the various message formats that the pin interface formatter has to encounter. Note that for variable-length fields, the transmitted size of the field is determined from the range of the least significant bit to the most significant non-zero-valued bit (that is most significant zero-valued bits are not transmitted).

Figure 2223. Message field sizes

Message	TCODE	Field #1	Field #2	Field #3	Field #4	Field #5	Size (bits)	
							Min(1)	Max(2)
Device ID Message	1	Fixed = 32	—	—	—	—	38	38



1. Minimum information size. The actual number of bits transmitted depends on the number of MDO pins.
2. Maximum information size. The actual number of bits transmitted depends on the number of MDO pins.

The double edges in *Figure 2223* indicate the starts and ends of messages. Fields without shaded areas between them are grouped into super-fields and can be transmitted together without end-of-packet indications between them.

73.5.2.3 Rules of message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. *Figure 2224* shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

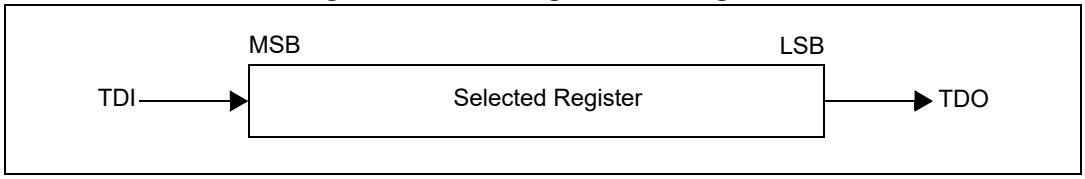
Figure 2224. Transmission sequence of messages

73.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 TAP for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in *Figure 2226*. The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in *Figure 2227*.



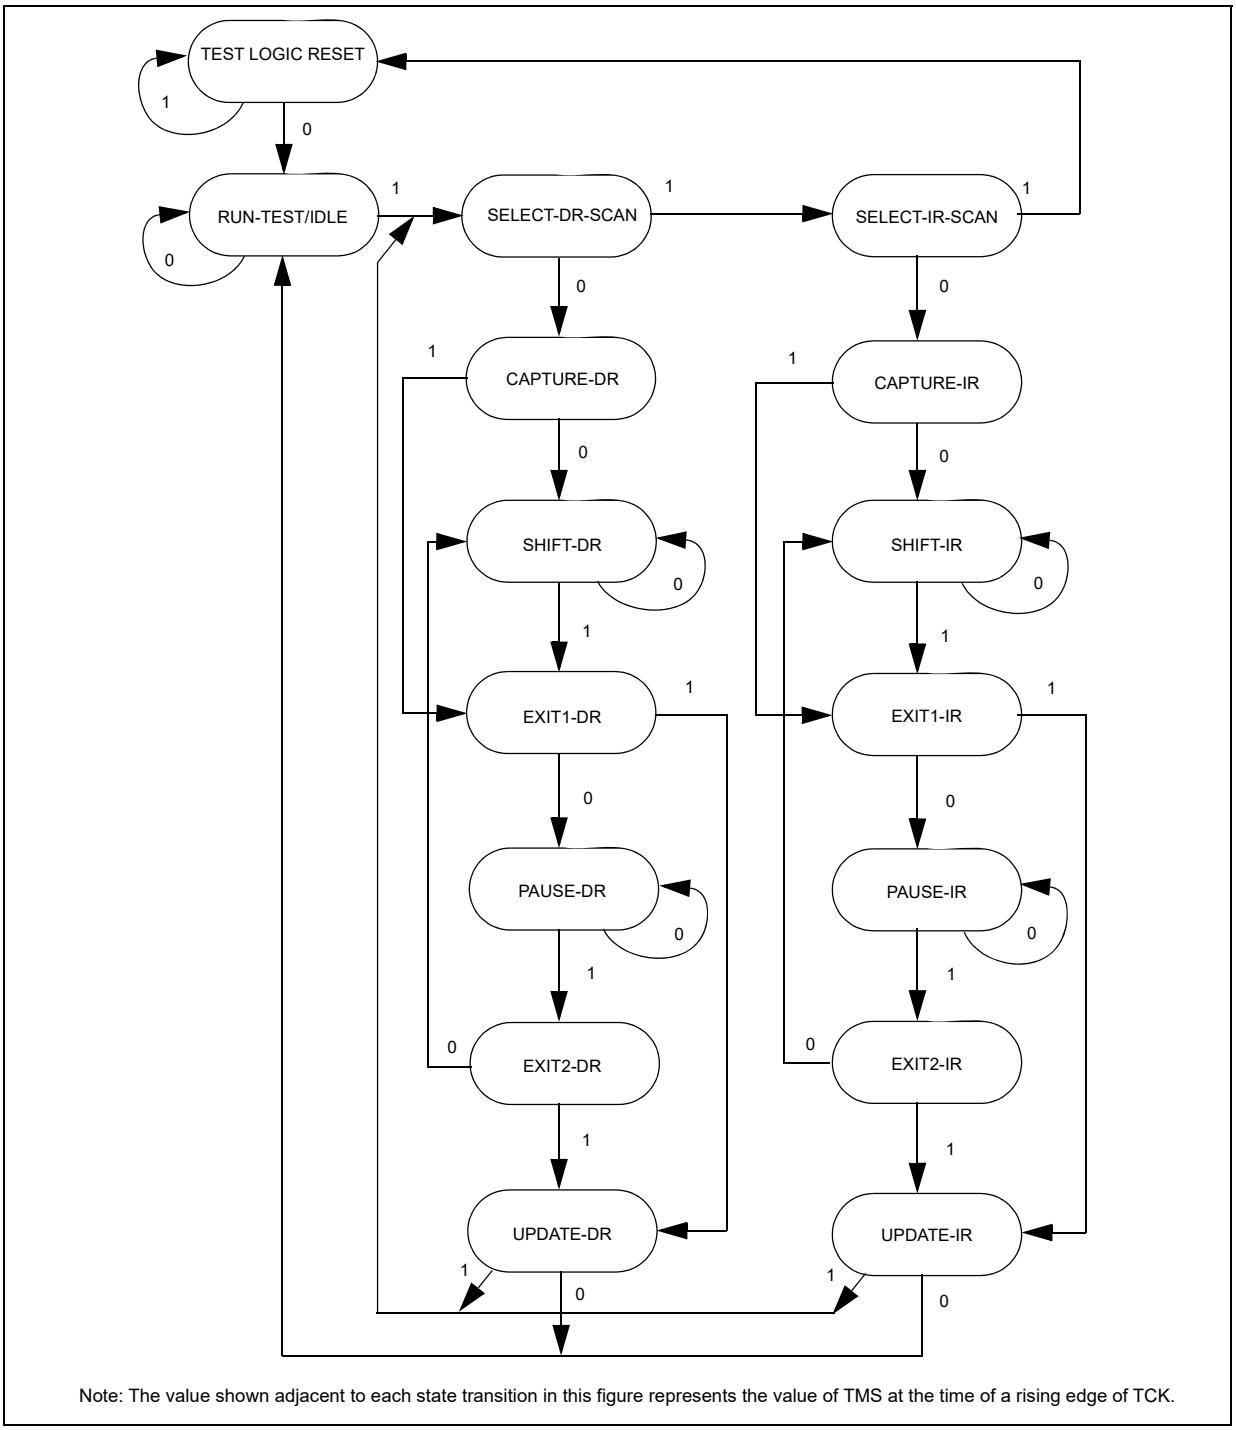
The instructions implemented by the NPC TAP controller are listed in *Table 2171*. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

Table 2171. Implemented instructions

Instruction name	Private/Public	Opcode	Description
NEXUS-ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in *Figure 2225*. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2225. Shifting data into register



73.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or entry into censored mode resets the NPC TAP controller.

When not in power-on reset or censored mode, the NPC TAP controller is enabled exiting the Test-Logic-Reset state loading the NEXUS-ENABLE instruction in NPC TAP controller.

Figure 2226. IEEE 1149.1-2001 TAP controller state machine

Note: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

73.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the auxiliary output port or shifted out serially by accessing the Nexus Device ID register through the TAP. Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled. Transmission of the device identification message serially via TDO is achieved by performing a read of the register contents as described in *Section 73.5.3.4: Selecting a Nexus client register*.

73.5.3.3 Loading NEXUS-ENABLE instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2227*, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. *Table 2172* illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 2227. NEXUS controller state machine

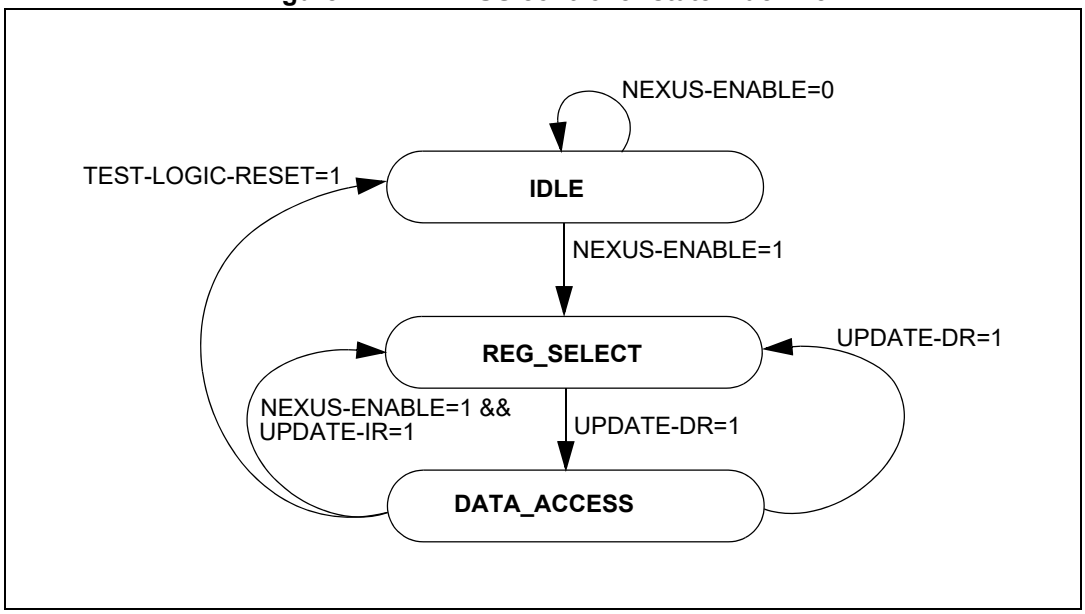


Table 2172. Loading NEXUS-ENABLE instruction

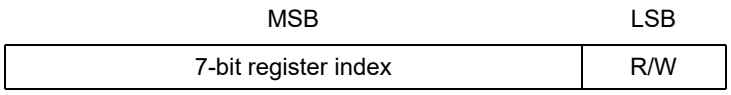
Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in

Table 2172. Loading NEXUS-ENABLE instruction (continued)

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers



73.5.3.4 Selecting a Nexus client register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2228*. The read/write control bit is set to '1' for writes and '0' for reads.

Figure 2228. IEEE 1149.1 controller command input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 2173. Write to a 32-bit Nexus Client Register

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register

Table 2173. Write to a 32-bit Nexus Client Register (continued)

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

73.5.4 Nexus JTAG port sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

73.5.5 MCKO and ipg_sync_mcko

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1.

73.5.6 $\overline{\text{EVTO}}$ sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

73.6 Initialization/Application information

73.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2003 standard for more detail.

74 Nexus handshake module (NPC_HNDSHK)

This module enables debug entry/exit across low-power modes (Stop, Halt, Standby).

The NPC_HNDSHK supports:

- Setting and clearing of the NPC PCR sync bit on low-power mode entry and exit
- Putting the core into debug mode on low-power mode exit
- Generating a falling edge on the JTAG TDO pad on low-power mode exit

74.1 Entry into STOP/STANDBY from RUN modes

For the device to be in debug mode on low-power exit, the debugger should set the LP_DBG and LP1_SYNC bit in the NPC PCR register.

On STOP, STANDBY entry, the MC_ME asserts the lp_mode_entry_req input after the clock disable process has completed and before the processor enters its stopped state. The mode transition will then not proceed until the lp_mode_entry_ack output has been asserted.

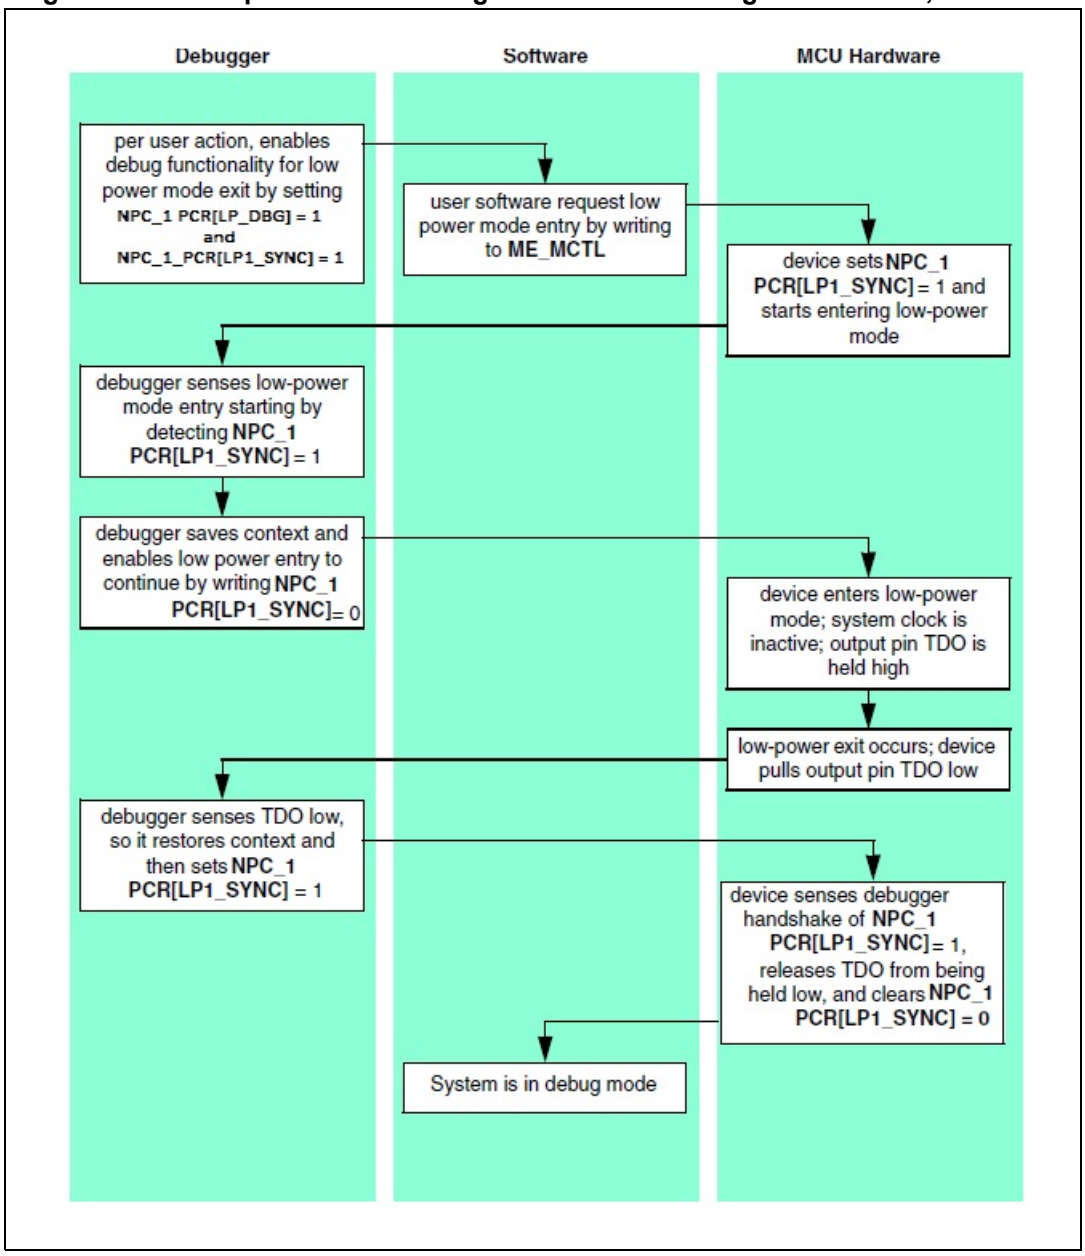
The notification to the debugger of a low-power mode entry consists in setting the NPC PCR [LP1_SYNC] bit by the NPC Handshake module.

The debugger acknowledges that the transition into a low-power mode may proceed by clearing NPC PCR[LP1_SYNC] bit.

The device enters into the low-power modes. In anticipation of the low-power mode exit notification, the TDO pad is driven to '1'.

74.2 Exit from STOP/STANDBY into RUN modes

On STOP mode exit, the MC_ME asserts the lp_mode_exit_req input after ensuring that the regulator and memories are in normal mode and before the processor exits its stopped state. The mode transition will then not proceed until the lp_mode_exit_req has been acknowledged. The MC_RGM asserts the exit_from_standby input when executing a reset sequence due to a STANDBY exit. The reset sequence will then not complete until the lp_mode_exit_req has been acknowledged.



The notification to the debugger of a low-power mode exit consists in driving the TDO pad to '0'.

The debugger acknowledges that the transition from a low-power mode can continue by setting the NPC PCR[LP1_SYNC] bit.

Further, the NPC PCR[LP1_sync] bit is de-asserted by the hardware and the lp_mode_exit_ack output is sent to the MC_ME.

Note: The debugger clock multiplexer may not guarantee glitch free switching. Therefore, TCK should be disabled from when the debugger clears the sync bit in ENTRY_CLR until the debugger senses the falling edge of TDO in TDO_SET.

Figure 2229. Low-power mode debug handshake flow diagram for STOP, STANDBY

75 e200z4256 Nexus 3 module

The e200z4256 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

75.1 Introduction

75.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

75.1.2 Terms and definitions

Table 2174 contains a set of terms and definitions associated with the Nexus 3 module.

Table 2174. Terms and definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM or DWM, or both.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 2174. Terms and definitions (continued)

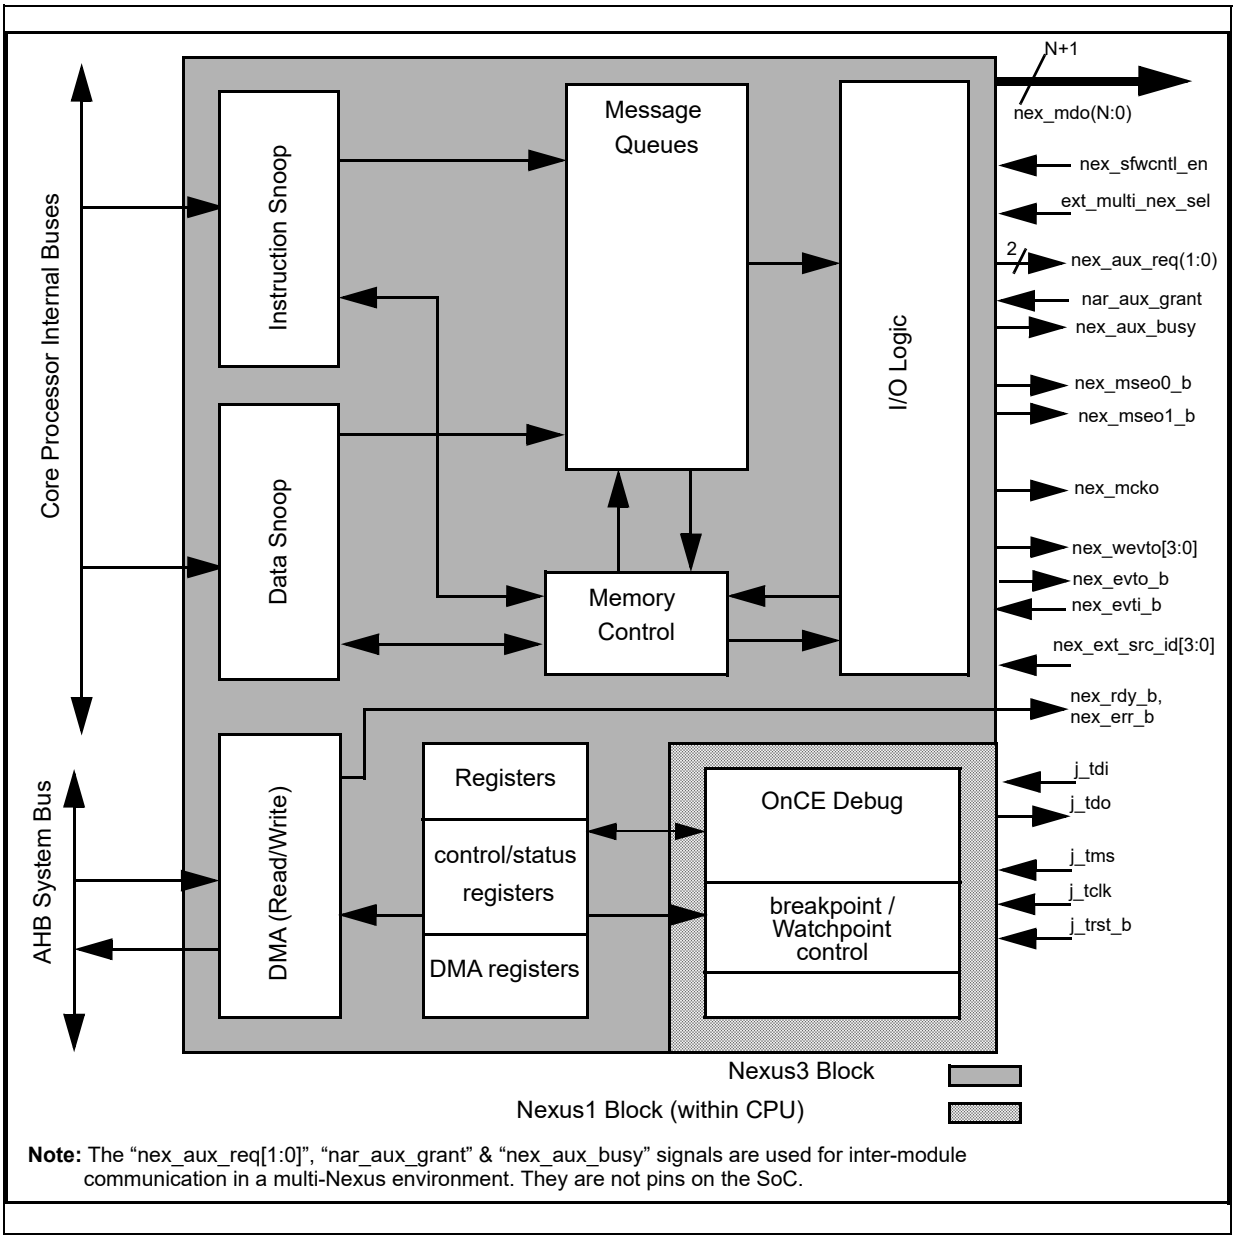
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number or size of packets, or both, to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

75.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (such as direct and indirect branches, exceptions), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins.
- Watchpoint Trigger enable of Program or Data Trace Messaging, or both.
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging.
- Auxiliary interface for higher data input/output.
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**).



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

75.1.4 Functional block diagram

Figure 2230. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

Note: NAR is not supported on this device

75.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the

Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

75.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

75.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 2175*.

Table 2175. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2180*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2175. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2180*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message with Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2175. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch Message with Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2180*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 2180*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 2178*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (Refer to *Section 75.12.4: Resource Full Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 2175. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (Refer to *Section 75.12.1: Branch Trace Messaging types*)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch History Message with Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (Refer to *Section 75.12.1: Branch Trace Messaging types*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated with program flow (Refer to *Table 2179*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (Refer to *Section 75.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (Refer to *Section 75.12.5: Program Correlation Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 75.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 2176 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 2176. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (such as Debug Status messages)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 2177 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 2177. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 2178 shows the encodings used for resource codes for certain messages.

Table 2178. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 2179 shows the event code encodings used for certain messages.

Table 2179. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 2180 shows the data trace size encodings used for certain messages.

Table 2180. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

75.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. Refer to *Section 75.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 75.6: Nexus 3 Register Access via Software* for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 2181 details the register map for the Nexus 3 module.

Table 2181. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—	
Port Configuration Register (PCR)(3)	PCR_INDEX(2)	R/W	—	—	
Development Control 1 (DC1)	0x2	R/W	0x04	0x05	368
Development Control 2 (DC2)	0x3	R/W	0x06	0x07	369
Development Control 3 (DC3)	0x4	R/W	0x08	0x09	370
Development Control 4 (DC4)	0x5	R/W	0x0A	0x0B	371
Reserved	0x6	R/W	0x18	0x19	—
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F	—
Reserved	0x8	R/W	0x18	0x19	—
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13	—
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15	—
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17	375
Reserved	0xC	R/W	0x18	0x19	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.

2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

75.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Reserved				CS			
7	6	5	4	3	2	1	0

Nexus Reg# 0x1; Read-only; Reset: 0x0

Table 2182. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

75.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

OPC	0	MCK_EN	MCK_DIV	0

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

75.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 2233* and its fields are described in *Table 2184*.

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 75.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 75.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

75.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 2234* and its fields are described in *Table 2185*.

75.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

Figure 2237. Development Status (DS) register

Table 2188. DS field descriptions

25:0	—	Reserved for future functionality (read as 0)

75.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allow the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program or Data Trace, or both, enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace or data trace in DC1, or both, will override these controls, and trace will remain enabled until another direct write to DC1 to disable program or data trace, or both, occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between

enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

75.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0

Nexus Reg# 0x15; DCR: 408; Read/Write; Reset: 0x0

Figure 2253. Data Trace End Address 4 register

Table 2197 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2197. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (that is when the instruction prefetch is discarded).

75.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 2199*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Table 2198. RWCS field descriptions (continued)

Bits	Name	Description
RWCS[21:18]	ATTR	Access Attributes 0xxx Reserved 1xxx Reserved x0xx **p_d_hprot[4]** driven to 0 for accesses x1xx **p_d_hprot[4]** driven to 1 for accesses xx0x **p_d_hprot[3]** driven to 0 for accesses xx1x **p_d_hprot[3]** driven to 1 for accesses xxx0 **p_d_hprot[2]** driven to 0 for accesses xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR (2)	Read/Write Access Error (Refer to *Table 2199*)
RWCS[0]	DV(2)	Read/Write Access Data Valid (Refer to *Table 2199*)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 2199. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

75.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 2255. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 2200* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 2200. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:
"X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 2201 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 2201. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	AHB[7:0]
Byte @001	0 0 1	—	—	—	AHB[15:8]
Byte @010	0 1 0	—	—	—	AHB[23:16]
Byte @011	0 1 1	—	—	—	AHB[31:24]
Byte @100	1 0 0	—	—	—	AHB[39:32]

Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table 2201. RWD byte lane mapping (continued)

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Doubleword @000 first RWD pass second RWD pass	0 0 0	AHB[31:24] AHB[63:56]	AHB[23:16] AHB[55:48]	AHB[15:8] AHB[47:40]	AHB[7:0] AHB[39:32]

Table Notes:
"—" indicates byte lanes that will contain unused data.

75.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 2256. Read/Write Access Address (RWA) register

75.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 2181*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (Refer to *Section 75.22: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (Refer to *Table 2181*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 2257. JTAG DR format

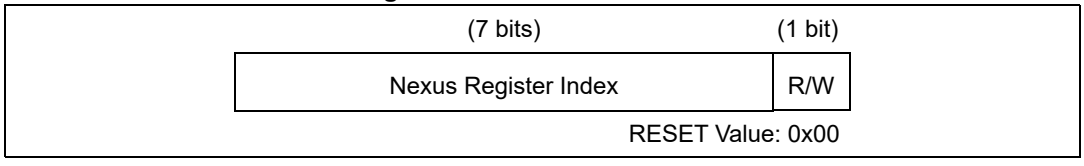

Table 2202. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 2181*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

75.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 2181* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

75.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

75.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

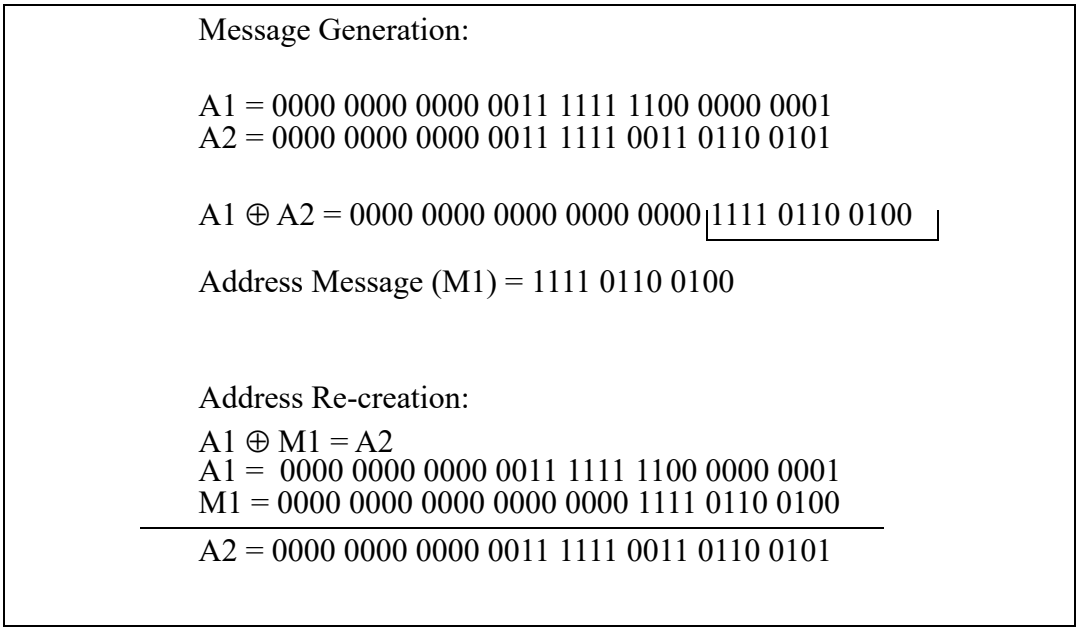
75.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

75.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 2258. Relative address generation and recreation

75.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization

messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

75.7.5 Timestamp Field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the **nex_tsen** input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of **nex_tsmode[0:1]** and the timestamp value is based on the **nex_timebase[0:29]** inputs. These signals are first synchronized to the **nex_clk** clock domain, and for **nex_timebase[0:29]**, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they enter the message queues. Leading zeros in the timestamp value are removed. *Table 2203* shows the **nex_tsmode[0:1]** encodings used for the timestamp mode.

Table 2203. nex_tsmode[0:1] Timestamp mode encoding

nex_tsmode[0:1]	Timestamp mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

75.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

75.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming

messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

75.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 75.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

75.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 75.8.1: Message Queue Overrun*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

75.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstance:

- More than three messages are generated in the same cycle

Table 2204 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 2204*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM $\rightarrow$ DQM $\rightarrow$ PCM_{PIDMSG} $\rightarrow$ OTM $\rightarrow$ BTM $\rightarrow$ DTM) $\rightarrow$ Instruction1 (newer instruction) (WPM $\rightarrow$ DQM $\rightarrow$ OTM $\rightarrow$ BTM $\rightarrow$ DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 2204. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A(1)
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

75.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

75.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

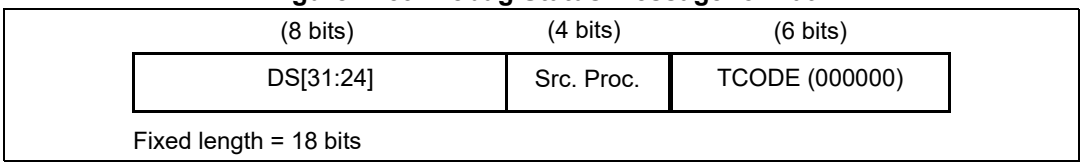
75.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

75.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



75.8.9 Data Trace Message Priority Loss Response

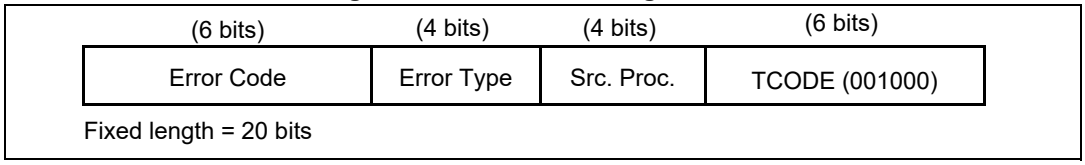
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

75.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 2259. Debug Status message format

75.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also, refer to *Table 2176* and *Table 2177*):

Figure 2260. Error message format

75.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

75.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

75.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z425n3) processors contain a <asisitalic>PowerISA 2.06 defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

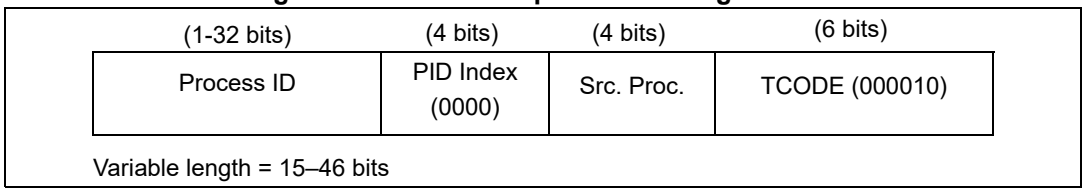
Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

SPR — 517; Read/Write; Reset: 0

Figure 2261. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.



The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 2262. Ownership Trace Message format

75.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z4256 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z425n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

75.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction,

taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. (**evsel**) Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

75.12.1.1 Indirect Branch Message instructions

Table 2205 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 2205. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfci, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

75.12.1.2 Direct Branch Message Instructions

Table 2206 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 2206. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

75.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. (**evsel**)

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

75.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

75.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

75.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to ‘1’, indirect branch information is messaged out in the following format:

Figure 2263. Indirect branch message (history) format

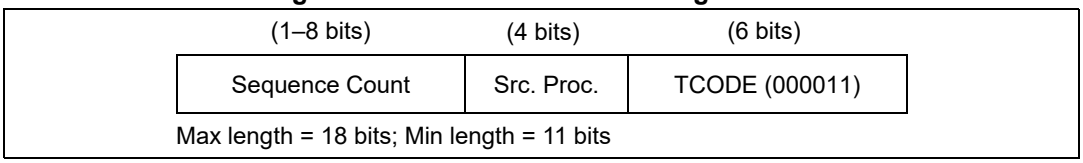
(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

75.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to ‘0’, indirect branch information is messaged out in the following format:

Figure 2264. Indirect branch message format



(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

75.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 2265. Direct branch message format

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

75.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

75.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a with sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

75.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 2207. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

75.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

75.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 2266. Resource Full Message format

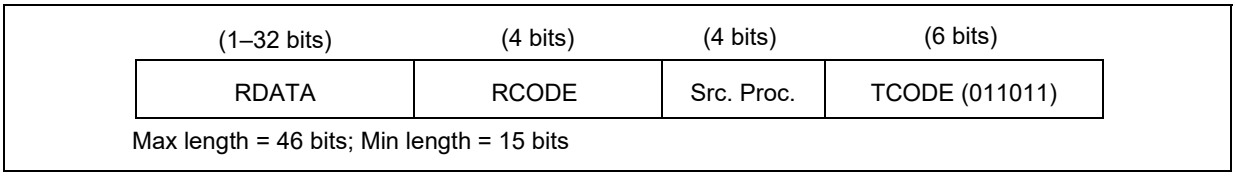


Table 2208 shows the RCODE encodings and RDATA information used for Resource Full Messages.

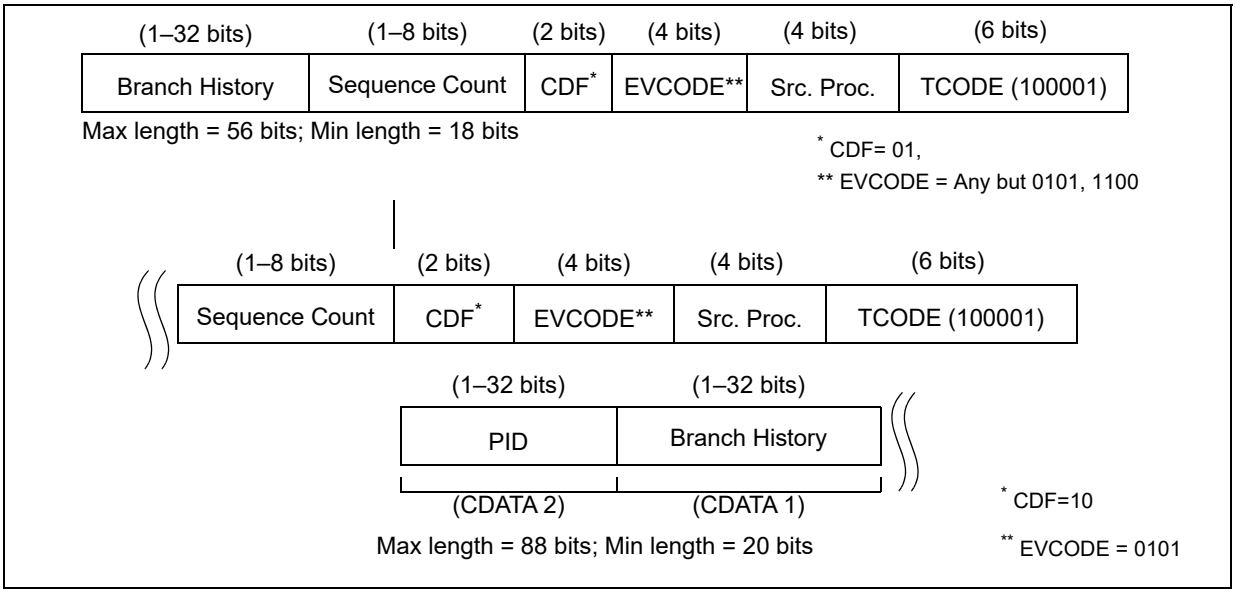
Table 2208. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch History. This type of packet is terminated by a stop bit set to 1 after the last history bit.

75.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions).
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 2179* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 2267. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.12.5.1 Program Correlation message generation for PID updates

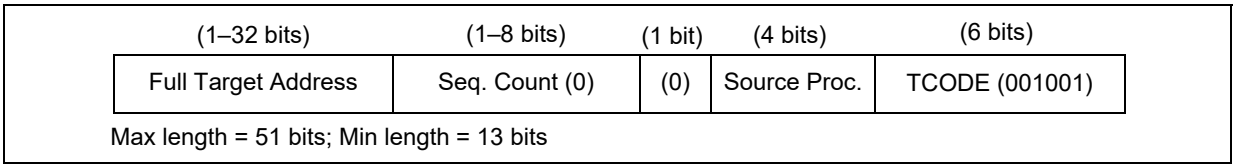
When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

75.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

75.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.



Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (refer to *Table 2209*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 2268. .Program Trace Synchronization message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in *Table 2209*.

Table 2209. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address

of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

75.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (refer to *Table 2209*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent with Sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 2269. Direct/Indirect Branch with Sync message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync Messages is as follows:

Figure 2270. Indirect Branch History with Sync message format

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a with Sync message type are summarized in *Table 2210*.

Table 2210. Program Trace Exception Summary for with Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch with Sync Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch with Sync Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the with Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch with Sync Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

75.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of the below ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

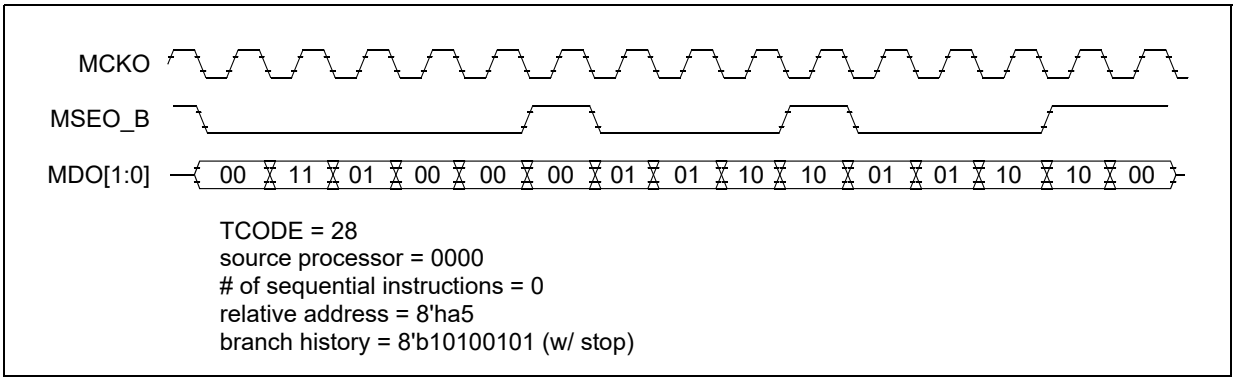

Figure 2273. Program Trace — Direct Branch (traditional) & Error messages

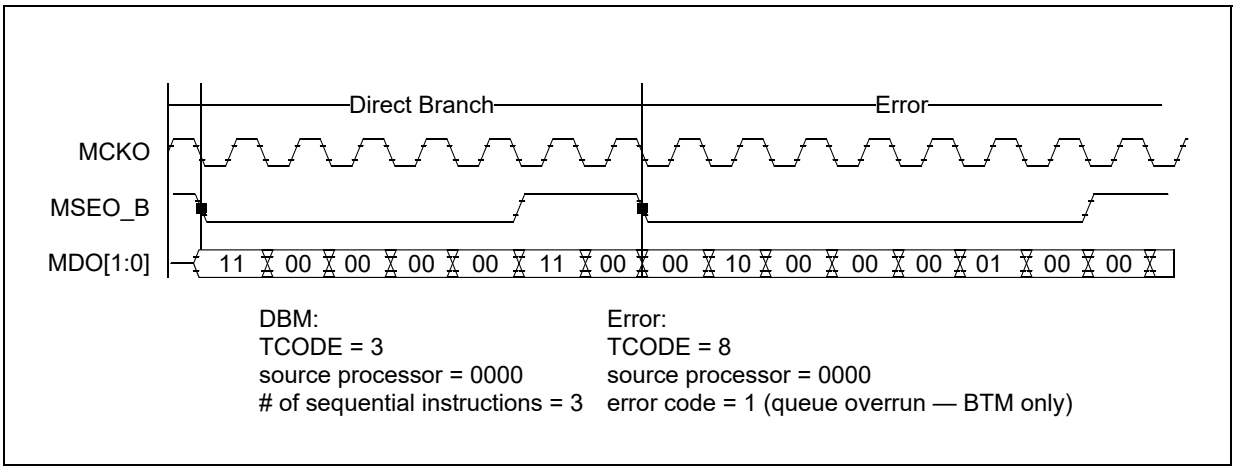

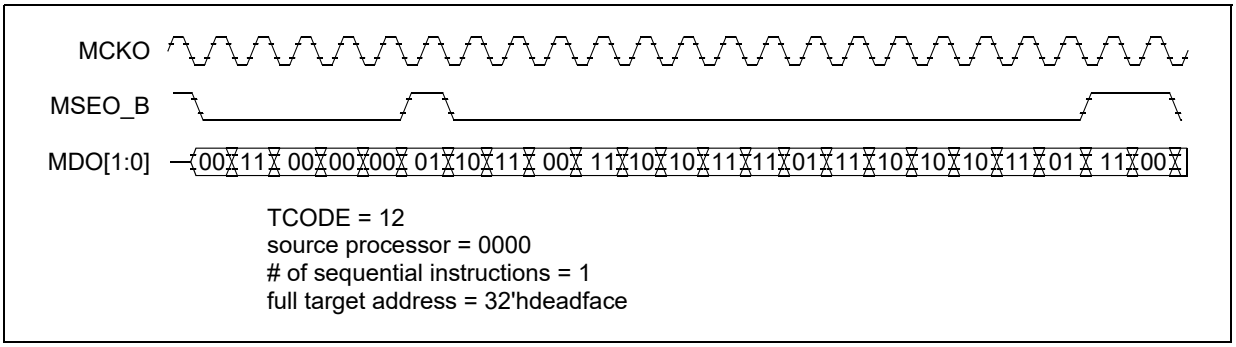

Figure 2274. Program Trace — Indirect Branch with Sync message

75.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

75.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z425n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**).

75.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

75.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 2275. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 2276. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

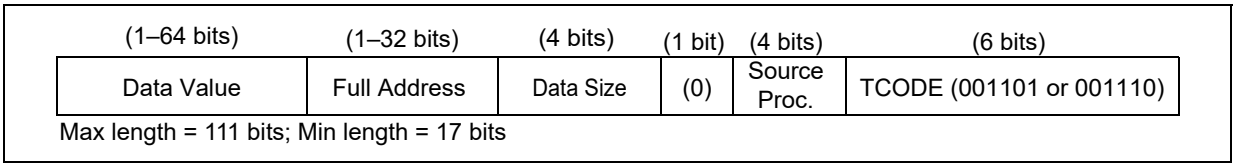
Max length = 111 bits; Min length = 17 bits

*Note: Core (e200z425n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the*

Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

*For Core (e200z425n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

The debug/development tool will need to distinguish the two cases based on the family of processor.



75.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (refer to *Table 2211*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's with security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync Messages is as follows:

Figure 2277. Data Write/Read with Sync message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in *Table 2211*.

Table 2211. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read with Sync Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read with Sync Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read with Sync Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read with Sync Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write with Sync Message.

75.13.3 DTM operation

75.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

75.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

75.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

75.13.3.4 Bus cycle special cases

Table 2212. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)[1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

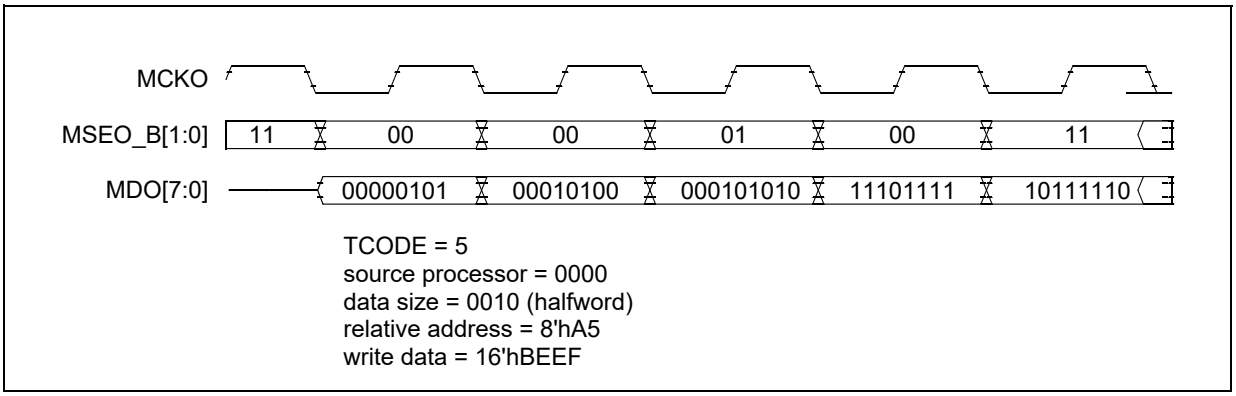
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (that is word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (Refer to the Data Trace Port section in the Core (e200z425n3) Core Debug Support chapter.)

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

75.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 2278. Data Trace — Data Write message



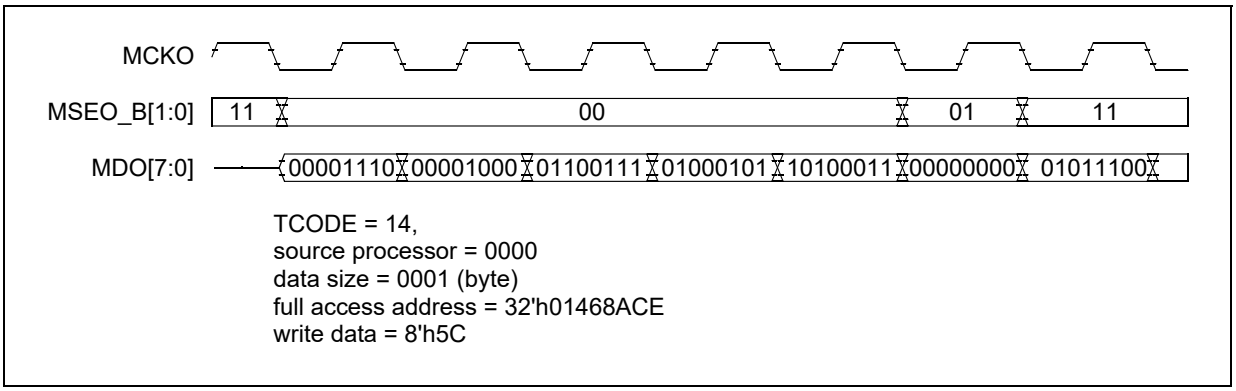


Figure 2279. Data Trace — Data Read with Sync message

75.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

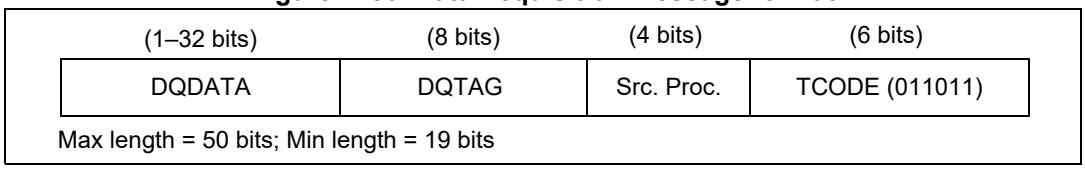
Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

75.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

75.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.



75.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

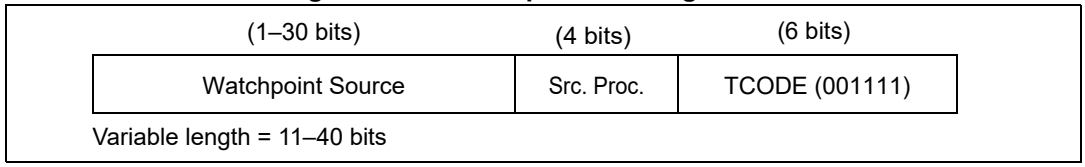
There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z425n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 2280. Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.15 Watchpoint Trace messaging



Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Refer to the Core (e200z425n3) Core Debug Support chapter for details on watchpoint initialization.

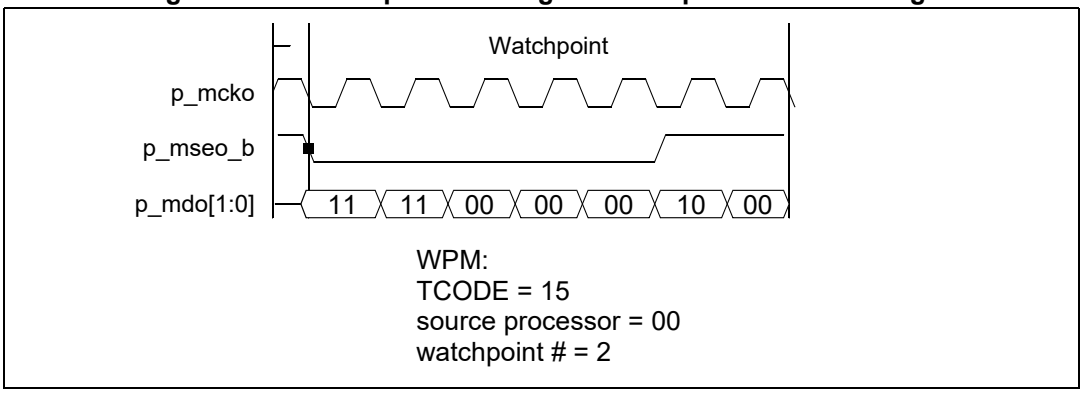
When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. Refer to *Table 2216* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 2281. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 2213. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1	Watchpoint #0 enabled for WTM

Figure 2282. Watchpoint Message & Watchpoint Error message

75.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 2214* details the external hardware trigger signals.

Table 2214. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 2214. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

75.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

75.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (refer to *Table 2216* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

*Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

75.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 75.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 75.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

75.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (refer to *Table 2216* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*.

*Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

75.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 75.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (refer to *Table 2216* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (refer to *Table 2216* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 75.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (that is doubleword read = two word reads from the RWD).

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

75.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

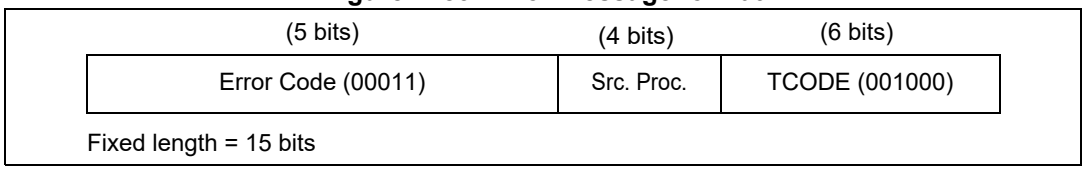
75.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

75.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD or RWA, or both, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

75.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 2283. Error message format

75.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

75.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 2216*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (refer to *Section 75.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z425n3) Core Debug Support chapter.

Table 2215. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 2216*.

Table 2216. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2’b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2’b01

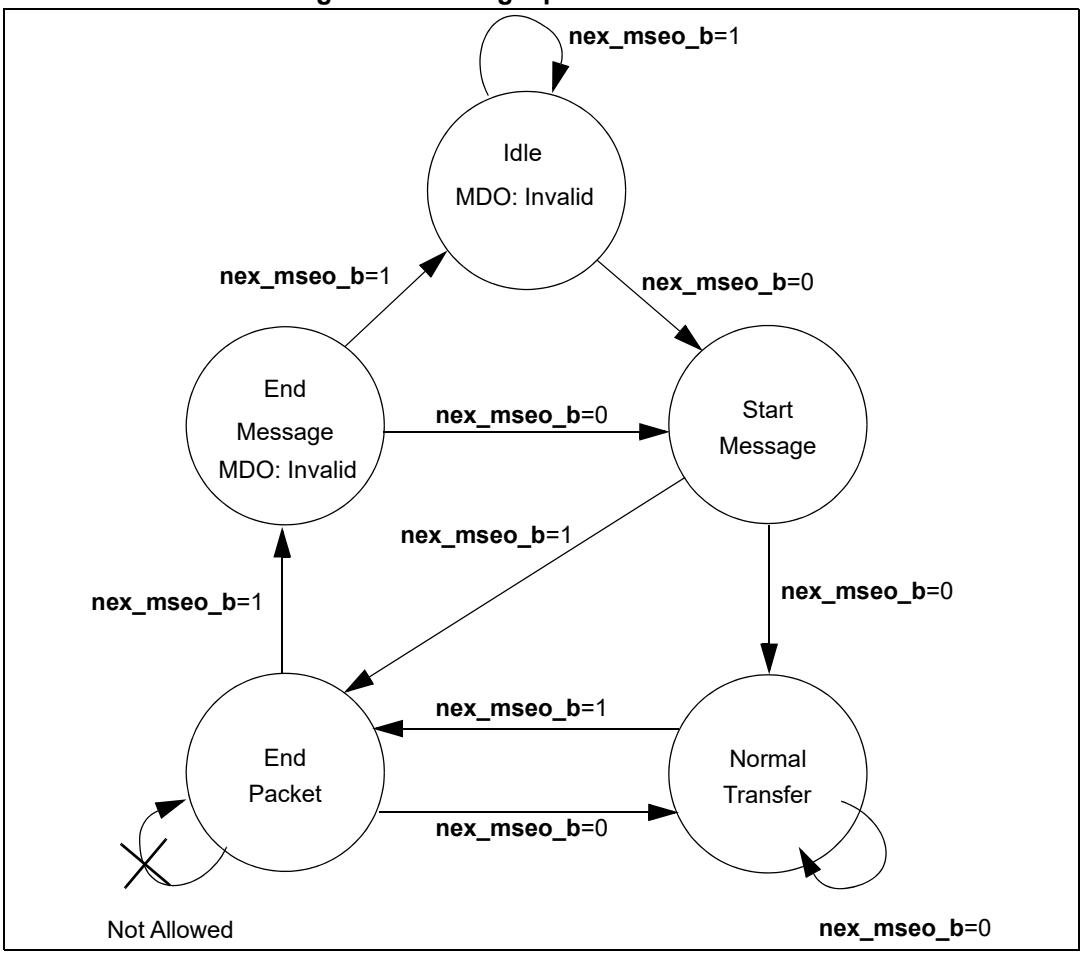
Table 2216. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

75.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 2217*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



Single pin MSEO is not supported on the SPC58xHx.

Table 2217. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 2284 illustrates the state diagram for single pin MSEO transfers.

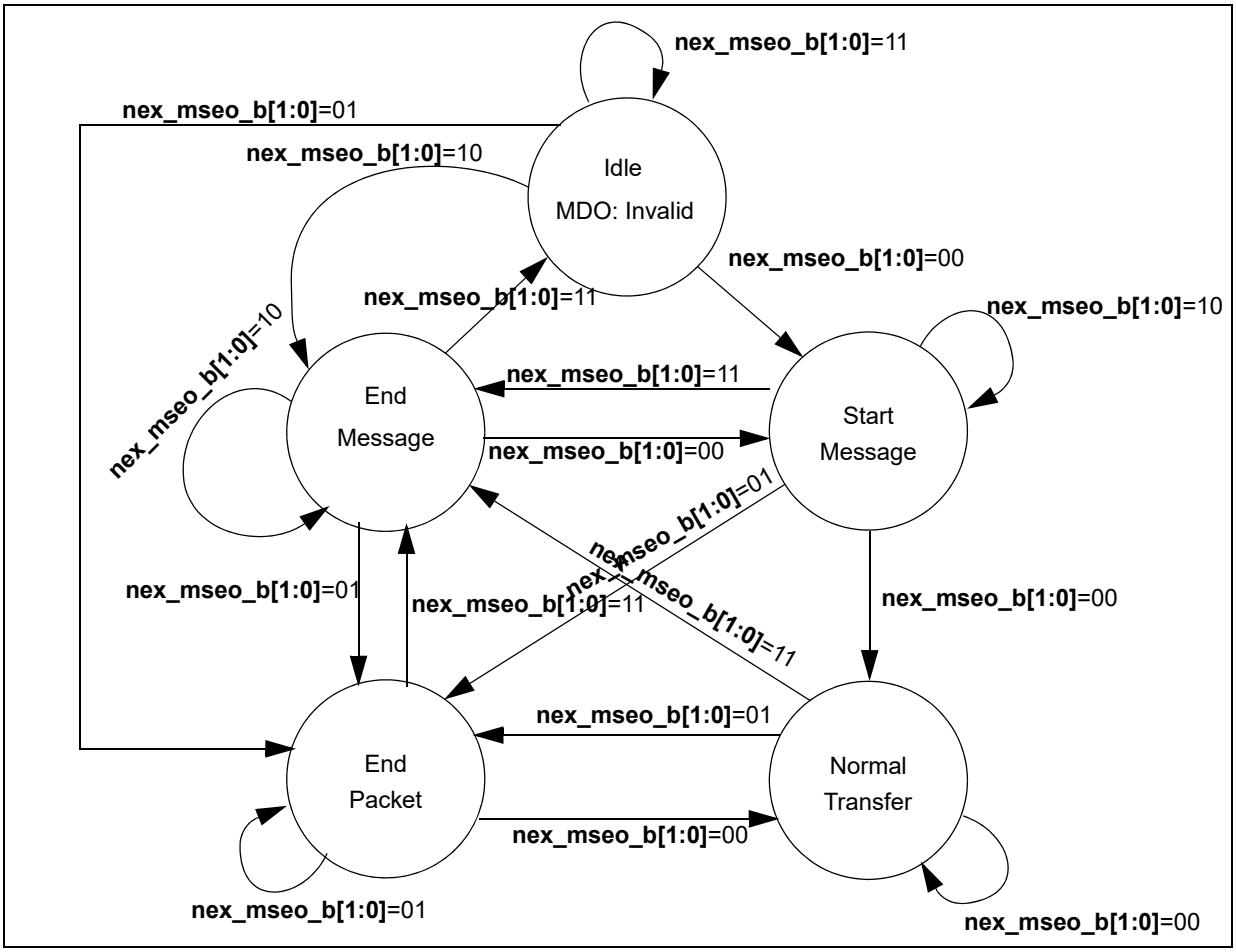


Figure 2284. Single pin MSEO transfers

Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 2285 illustrates the state diagram for dual pin MSEO transfers.

Figure 2285. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

75.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is

impossible to know which bit is from the last packet and which bit is from the next packet.)

- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2-bit wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

75.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 2218 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 2219* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 2218. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet

Table 2218. Indirect branch message example (2 MDO / 1 MSEO) (continued)

Clock	nex_mdo[1:0]		nex_mseo_b	State
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 2219. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 2220 and *Table 2221* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 2220. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 2221. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)

2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

75.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, refer to the SPC58xHx Data Sheet.

75.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

75.22.1 JTAG sequence for accessing internal Nexus registers

Table 2224. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

75.22.2 JTAG sequence for read access of memory-mapped resources

Table 2225. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

75.22.3 JTAG sequence for write access of memory-mapped resources

Table 2226. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

76 Nexus Crossbar Multi-Master Client (NXMC)

76.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA AHB, and CPU Data Bus AHB start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools. This also provides the capability of sending user defined messages for the peripherals attached to it.

76.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads or writes, or both, to (selected) internal memory resources
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

76.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 2228*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (refer to *Section 76.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 2227* describes the JTAG pins.

Table 2227. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 2228. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (refer to *Section 76.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

76.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number or size of the packets, or both, to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 2229*. The SRC

and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 2229. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2230*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2230*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (refer to *Table 2231*)
	14	14	ECODE	fixed	Error code (refer to *Table 2232*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message with Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2230*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2229. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message with Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (refer to *Table 2230*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (refer to *Table 2244*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 2230. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 2231. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved

Table 2231. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 2232. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved
000000	XX1XXXXX	Reserved
000000	X1XXXXXX	Reserved
000000	1XXXXXXX	Reserved
Source (SRC) n = peripheral index		
CKSRCn	XXXXXXX1	Reserved
CKSRCn	XXXXXX1X	Reserved
CKSRCn	XXXXX1XX	Reserved
CKSRCn	XXXX1XXX	Reserved
CKSRCn	XXX1XXXX	Reserved
CKSRCn	XX1XXXXX	Reserved
CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

76.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. Refer to *Section 76.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 2233*.

Table 2233. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	0x2	R/W	0x04	0x05
Development Control 2 (DC2)	0x3	R/W	0x06	0x07
Watchpoint Trigger (WT)	0xB	R/W	0x16	0x17
Data Trace Control (DTC)	0xD	R/W	0x1A	0x1B
Data Trace Start Address1 (DTSA1)	0xE	R/W	0x1C	0x1D
Data Trace Start Address2 (DTSA2)	0xF	R/W	0x1E	0x1F
Data Trace End Address1 (DTEA1)	0x12	R/W	0x24	0x25
Data Trace End Address2 (DTEA2)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register1 (BWC1)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register2 (BWC2)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register1 (BWA1)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register2 (BWA2)	0x1F	R/W	0x3E	0x3F

76.4.1 Register definitions

Detailed register definitions for the current NXMC implementation are described in the following sections.

76.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. *Figure 2286* shows the format of the DC1.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0(1)	0(1)	0(1)	EOC		0	0	WEN	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	EIC		TM		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 2286. Development control register 1 (DC1)

The DC1 is described in *Table 2234*.

Table 2234. DC1 register field description

Field	Description
3:4 EOC	$\overline{\text{EVTO}}$ Control. 00 $\overline{\text{EVTO}}$ upon occurrence of watchpoint (internal or external) 01 $\overline{\text{EVTO}}$ upon entry into system-level Debug Mode 1x Reserved
7 WEN	Watchpoint Trace Enable. 0 Watchpoint Messaging disabled 1 Watchpoint Messaging enabled
27:28 EIC	$\overline{\text{EVTI}}$ Control 00 $\overline{\text{EVTI}}$ for synchronization (Data Trace) 01 Reserved 10 $\overline{\text{EVTI}}$ disabled 11 Reserved
29:31 TM	Trace Mode 000 No Trace 1xx Reserved x1x Data Trace enabled xx1 Reserved

76.4.1.2 Development control register 2 (DC2)

The Development Control Registers control the basic development features of the NXMC module. *Figure 2287* shows the format of the DC2.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EWC								0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PME0(1)
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not implemented and its value has no impact on the system.

Figure 2287. Development control register 2 (DC2)

The DC2 is described in *Table 2235*.

Table 2235. DC2 register field description

Field	Description
0:7 EWC	$\overline{\text{EVTO}}$ Watchpoint Configuration(1). 00000000 No Watchpoints trigger $\overline{\text{EVTO}}$ 1XXXXXXX External Watchpoint #1 triggers $\overline{\text{EVTO}}$ X1XXXXXX External Watchpoint #2 triggers $\overline{\text{EVTO}}$ XX1XXXXX Reserved(2) XXX1XXXX Reserved(2) XXXX1XXX Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$ XXXXX1XX Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$ XXXXXX1X Reserved(2) XXXXXXX1 Reserved(2)
31 PME0	Peripheral Messaging Enable for the In-Circuit Trace (ICT) feature.(3) 0 Peripheral Interface disabled 1 Peripheral Interface enabled

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. Writing bits 2,3,6,7 has no impact and read value will be 0 for these bits.
3. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

76.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 2288* shows the format of the WT register.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	DTS			DTE			0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2288. Watchpoint trigger register (WT)

The WT register is described in *Table 2236*.

Table 2236. WT register field description

Field	Description(1)
6;8 DTS	Data Trace Start Control. 000 Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved
9;11 DTE	Data Trace End Control. 000Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

76.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. *Figure 2289* shows the format of the DTC register.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2289. Data trace control (DTC) register

The DTC register is described in *Table 2237*.

Table 2237. DTC field description

Field	Description
0:1 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
2:3 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
7 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
12:15 MID	ID of the system bus Master to be traced(1)
24 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
25 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

76.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 2290* shows the format of the DTSA1 and DTSA2 registers.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE START ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2290. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

76.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. *Figure 2291* shows the format of the DTEA1 and DTEA2 registers.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA TRACE END ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2291. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 2238 illustrates the ranges that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 2238. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range – no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

76.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. *Figure 2292* shows the format of the BWC1 register.

Address: refer to *Table 2233* Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2294. Breakpoint /watchpoint address registers 1 and 2 (BWA1 and BWA2)

76.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 2233*. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

76.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of TRST and system reset de-assertion, after the JTAG ID register has been read by the tool after negation of TRST and should be programmed before deassertion of system reset.

76.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 76.5.4: NXMC register access via JTAG*.

76.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the TRST pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

76.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the TRST pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set.

76.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 2233*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to *Table 2233*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 2295* and *Table 2241*.

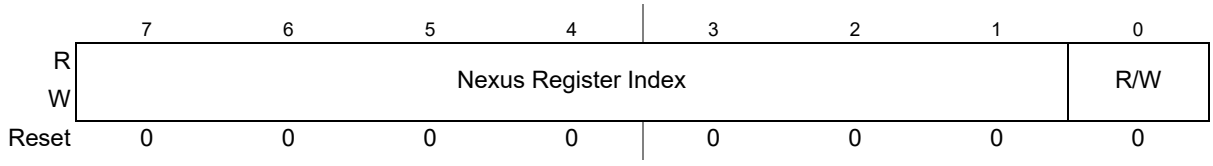

Figure 2295. JTAG DR for Nexus register access

Table 2241. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 2233*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

76.6 Functional description

76.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

76.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

76.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

76.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in *Figure 2296*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

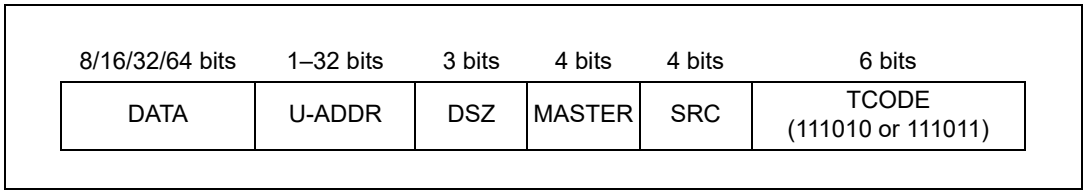

Figure 2296. DTM message format for DATA width = 64 bits

TSTAMP is another optional field which is inserted based on the controls received from the NAR, refer to *Section 76.6.4: Timestamping feature*.

76.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

76.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 2297*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

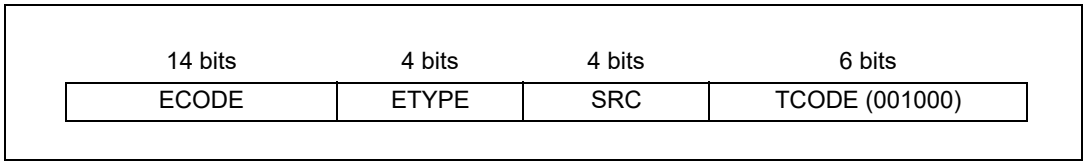

Figure 2297. DTM error message format (fixed length = 48 bits)

76.6.1.2.3.1 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to *Table 2242*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message
- Upon returning from a low power state, the first data trace message is a synchronization message
- Upon returning from debug mode, the first data trace message is a synchronization message
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message. This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 2298*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Figure 2298. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 2242*.

Table 2242. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table 2242. Data trace exception summary (continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

76.6.1.3 DTM operation

76.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

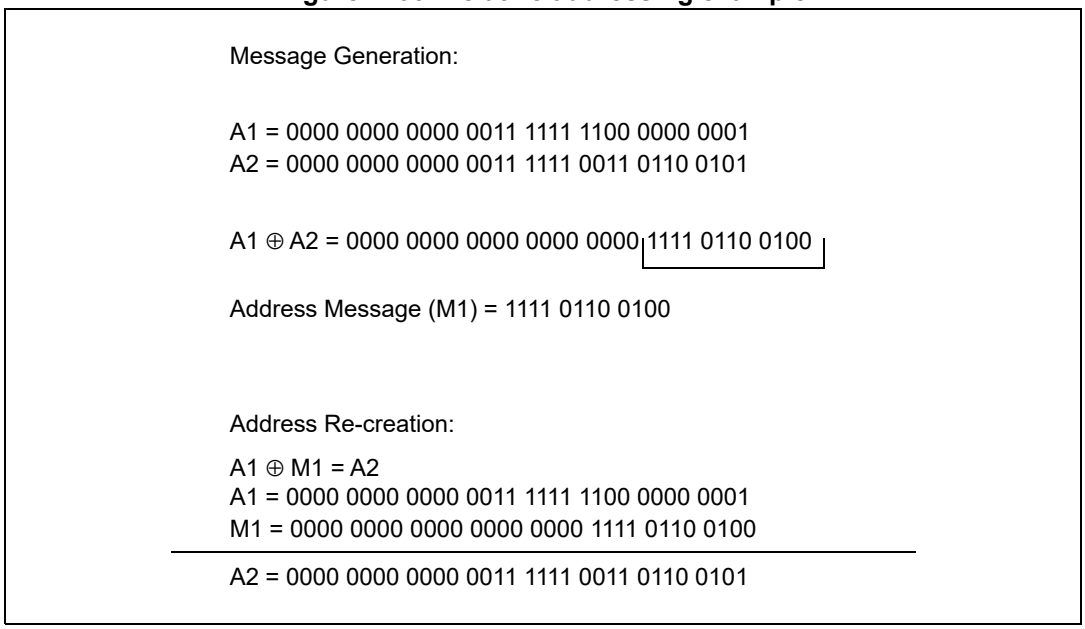
- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (that is DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure the correct DTM functionality.

76.6.1.3.2 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).



76.6.1.3.3 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address

transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 2299*.

Figure 2299. Relative addressing example

76.6.1.3.4 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

76.6.1.3.5 System bus cycle special cases

The system bus cycle special cases are shown in *Table 2243*.

Table 2243. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

76.6.1.3.6 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (refer to figure in *Section 76.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

76.6.1.3.7 HSM master filtering

For security reasons certain HSM masters need to be disabled or filtered from data tracing operations.

76.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

76.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (that are BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints: Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 76.6.1.3.6: System bus multi-master tracing*).
- External watchpoints: The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (that is on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 2300* and *Table 2244*.

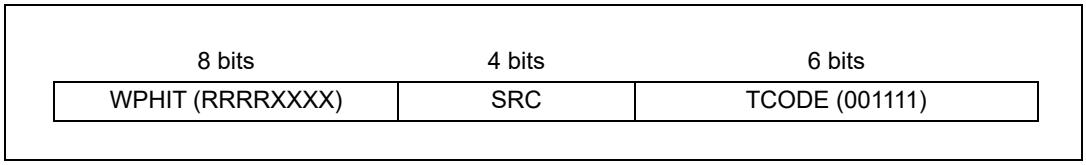


Figure 2300. Watchpoint message format (fixed length = 18 bits)

Table 2244. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

76.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 2301*.

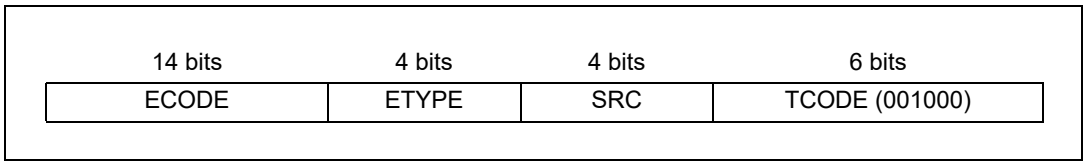

Figure 2301. Error message format (fixed length = 28 bits)

76.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

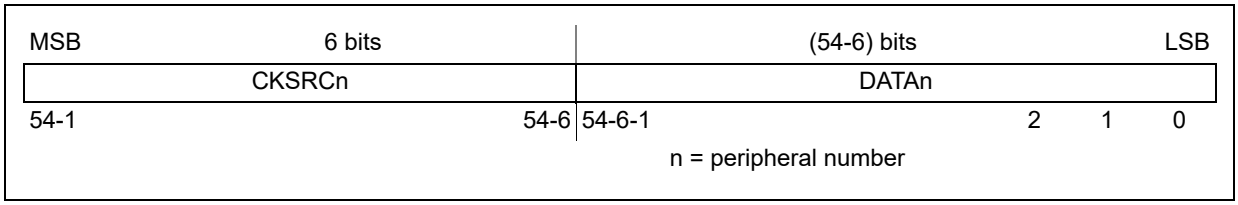

Figure 2302. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

76.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in *Figure 2303*. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

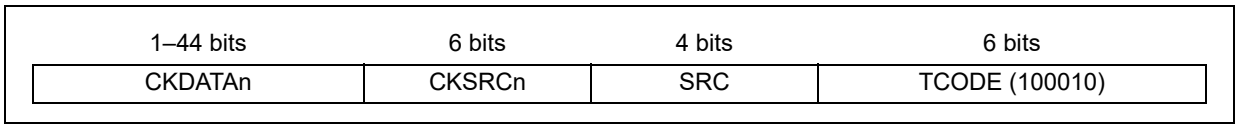

Figure 2303. Peripheral message format (max length = 60 bits, min length = 17 bits)

76.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in *Figure 2304*.

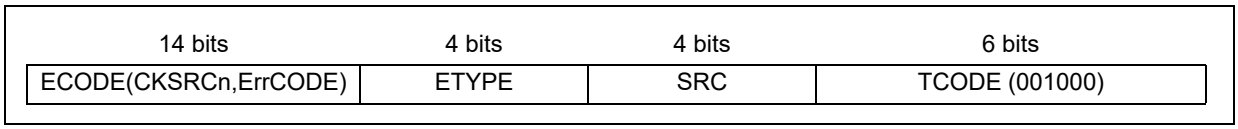

Figure 2304. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in *Table 2231* and *Table 2232*.

76.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. *Figure 2305* shows an example of ICTM message with a TSTAMP field.

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 2305. Message with TSTAMP field example

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via such as TM, PME0 control bits)

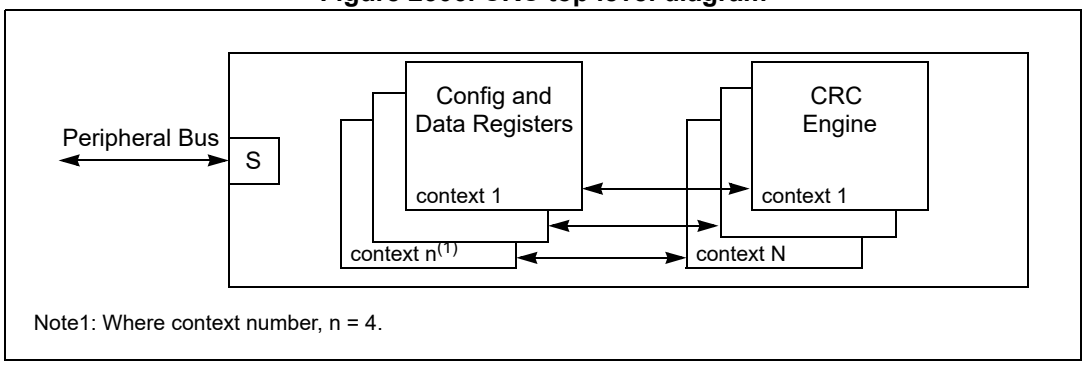
77 Cyclic Redundancy Check (CRC) Unit

77.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of four hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

77.2 Main features

- 4 contexts for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 4 hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
  - Support for byte, halfword, or word width of the input data stream



77.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

77.3 Block diagram

The top level diagram of the CRC module is given in *Figure 2306*.

Figure 2306. CRC top level diagram

77.4 Signal description

The CRC module does not generate any external signals.

77.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

77.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

77.5.1 Register description

Table 2245 shows the memory map for the CRC registers.

Table 2245. CRC unit memory map

Table 2248. CRC_CSTATn field descriptions

Field	Description
0:31 CSTAT	Status of the CRC signature The CSTAT register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be read and written by software. **Note:** This register can be written only during the configuration phase.

77.5.1.4 CRC Output Register *n* (CRC_OUTP*n*)

Figure 2310. CRC Output Register *n* (CRC_OUTP*n*)

Table 2249. CRC_OUTP*n* field descriptions

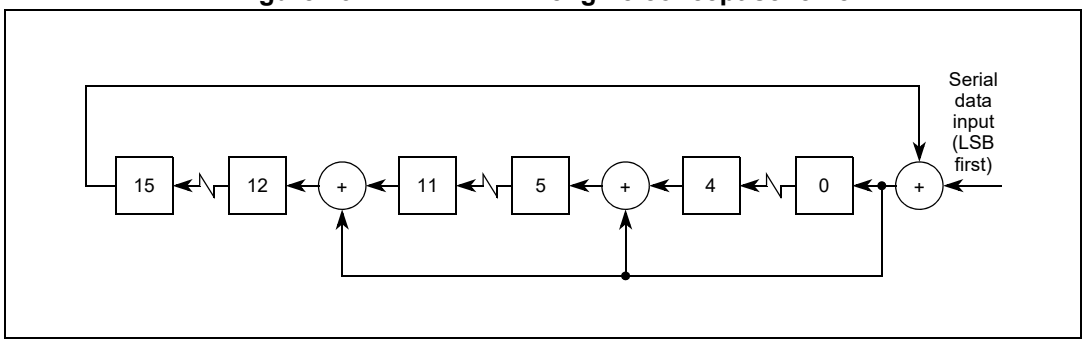
Field	Description
0:31 OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

77.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 87*, *Equation 88* and *Equation 89* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.



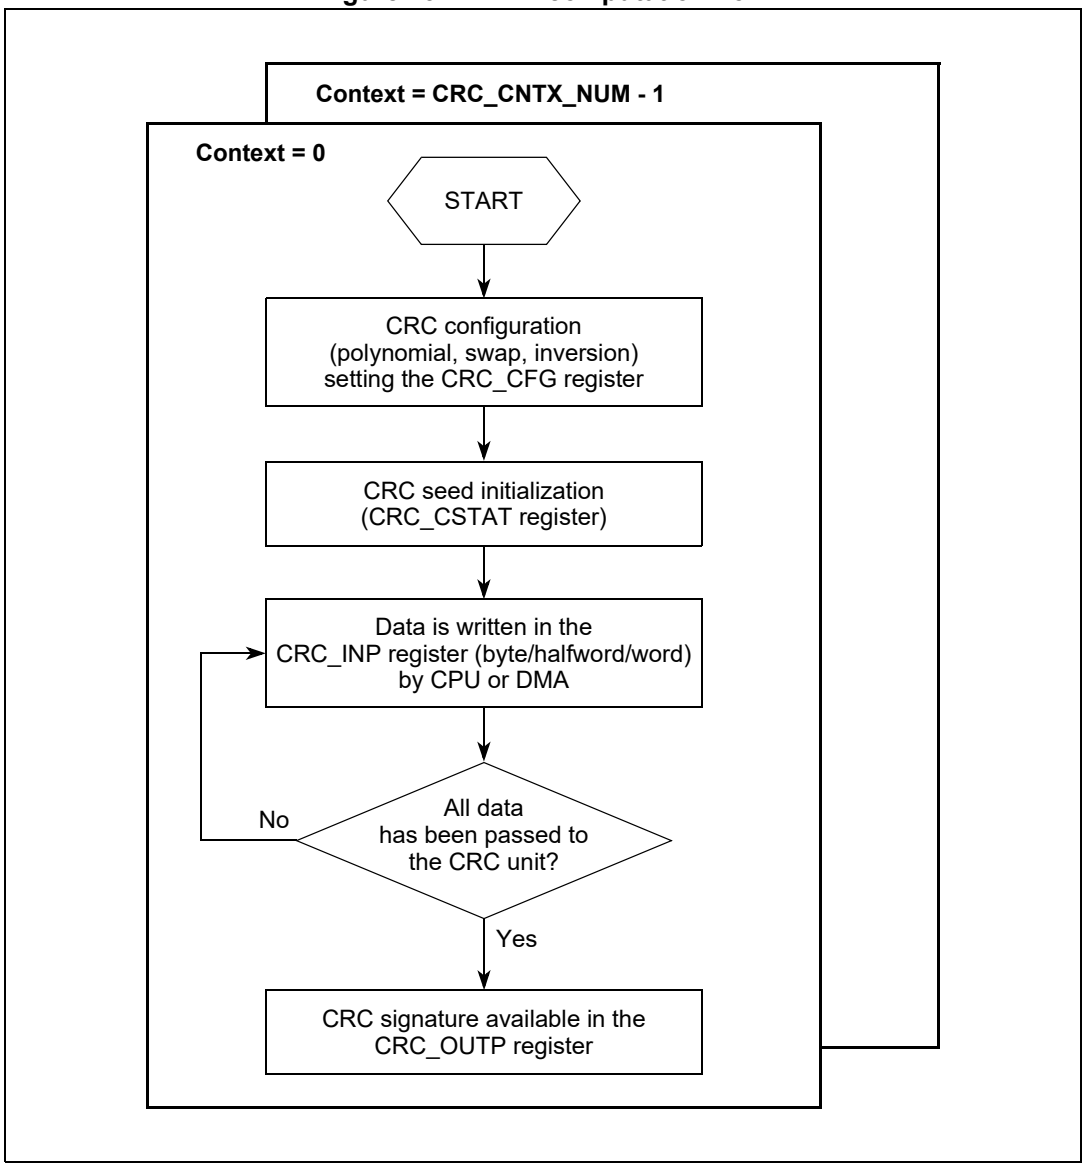
Equation 87 CRC8 VDA CAN:
$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 88 CRC-CCITT (x.25 protocol):
$$x^{16} + x^{12} + x^5 + 1$$

Equation 89 CRC-32 (Ethernet protocol):
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 90 CRC-8-H2F (Autosar 4.0 protocol):
$$x^8 + x^5 + x^3 + x^2 + x + 1$$

Figure 2311. CRC-CCITT engine concept scheme



The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 2311* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (such as SPI), a bit swap (MSB → LSB, LSB → MSB) or bit inversion of the final CRC signature, or both can be applied (CRC_OUTP register) before transmitting the CRC.

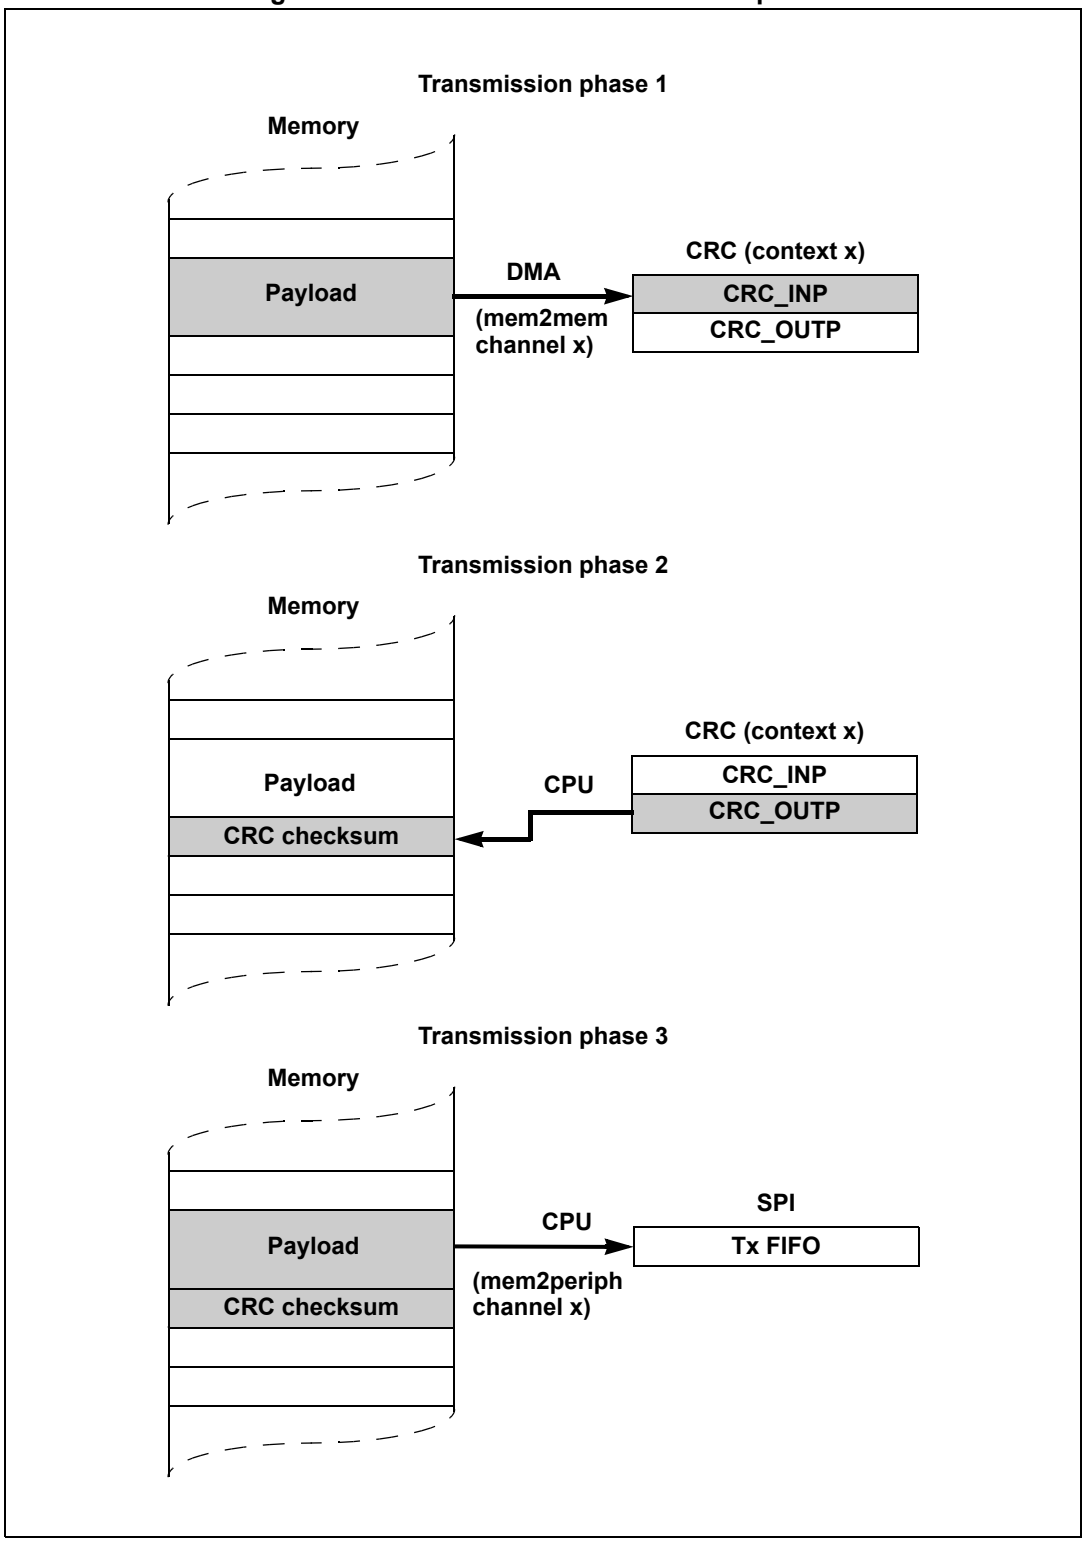
Use of the CRC module is summarized in the flow chart given in *Figure 2312*.

Figure 2312. CRC computation flow

77.7 Use cases

77.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:



- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer: mem2mem, periph2mem, mem2periph; then this sequence, as shown in *Figure 2313*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 2313. DMA-CRC transmission sequence

77.7.2 Register programming

- INV or SWAP, or both (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

78 Memory Error Management Unit (MEMU)

78.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- SRAM
- Peripheral RAM
- Flash memory.

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single/Double bit error in the data part that is detected via ECC for flash memory. Reporting of single/double bit error as correctable error depends on CTRL.FLASH_ERR_SELECT configuration.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Double/Multiple (more than two) bit error that is detected via ECC for Flash Memory. Reporting of double bit error as uncorrectable error depends on CTRL.FLASH_ERR_SELECTION configuration.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

When multiple errors are indicated from various sources at the same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

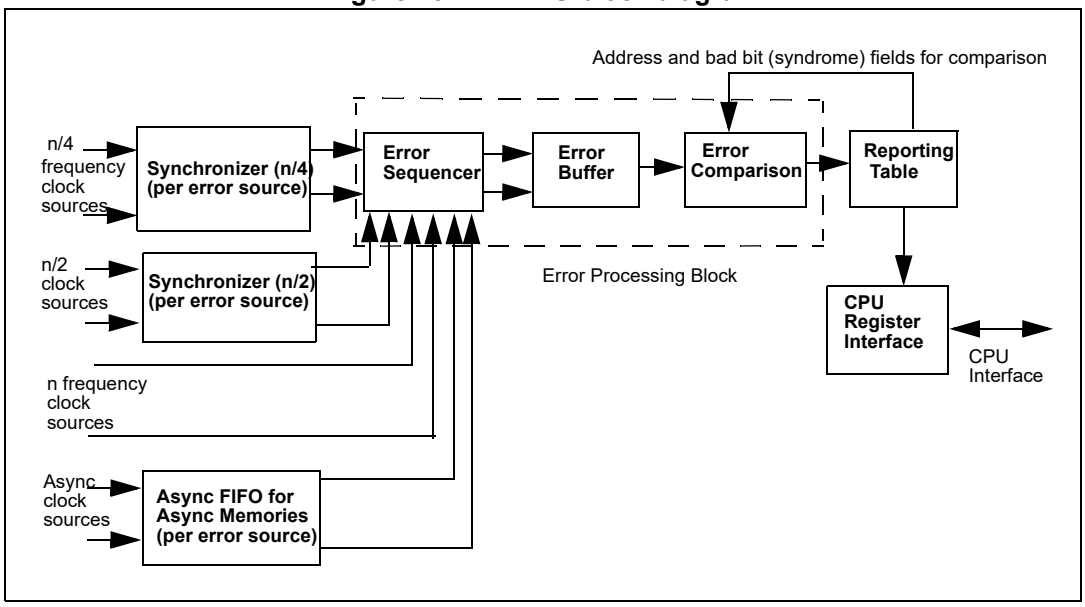
MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral SRAM ECC
- Flash memory ECC.

Each instance has two reporting tables–Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 78.4: Design overview* for the reporting block details.



78.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral SRAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

78.3 Block diagram

Figure 2314. MEMU block diagram

78.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 78.7.3: Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set, else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error (Correctable Error: CE or Uncorrectable Error: UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with

the error buffer, if the type of errors (CE and UCE) differ they are treated as unique.

– Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable).
– Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (*System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see *Chapter 7: Device configuration* that describes how modules are configured and connected.

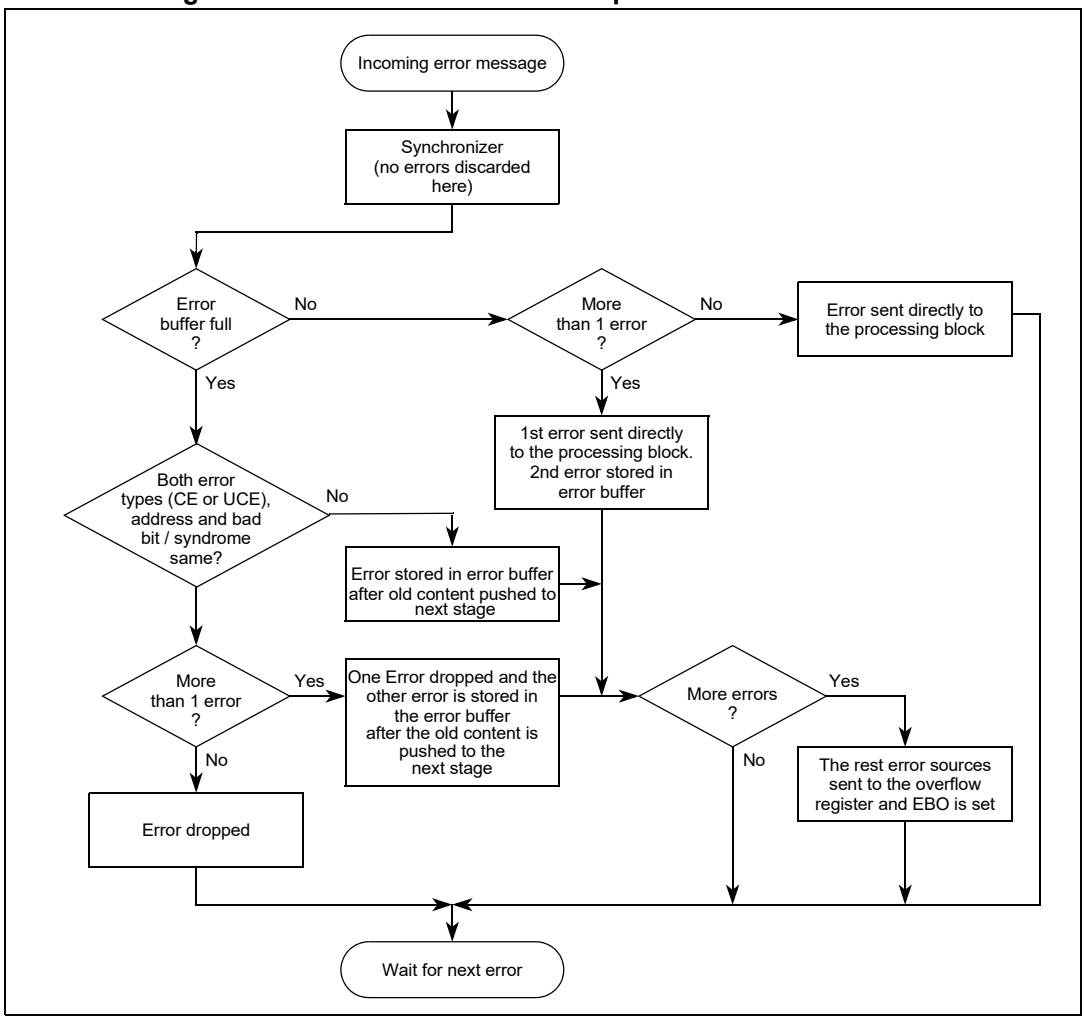
4. Register block

The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 2315. MEMU error buffer uniqueness check flow chart



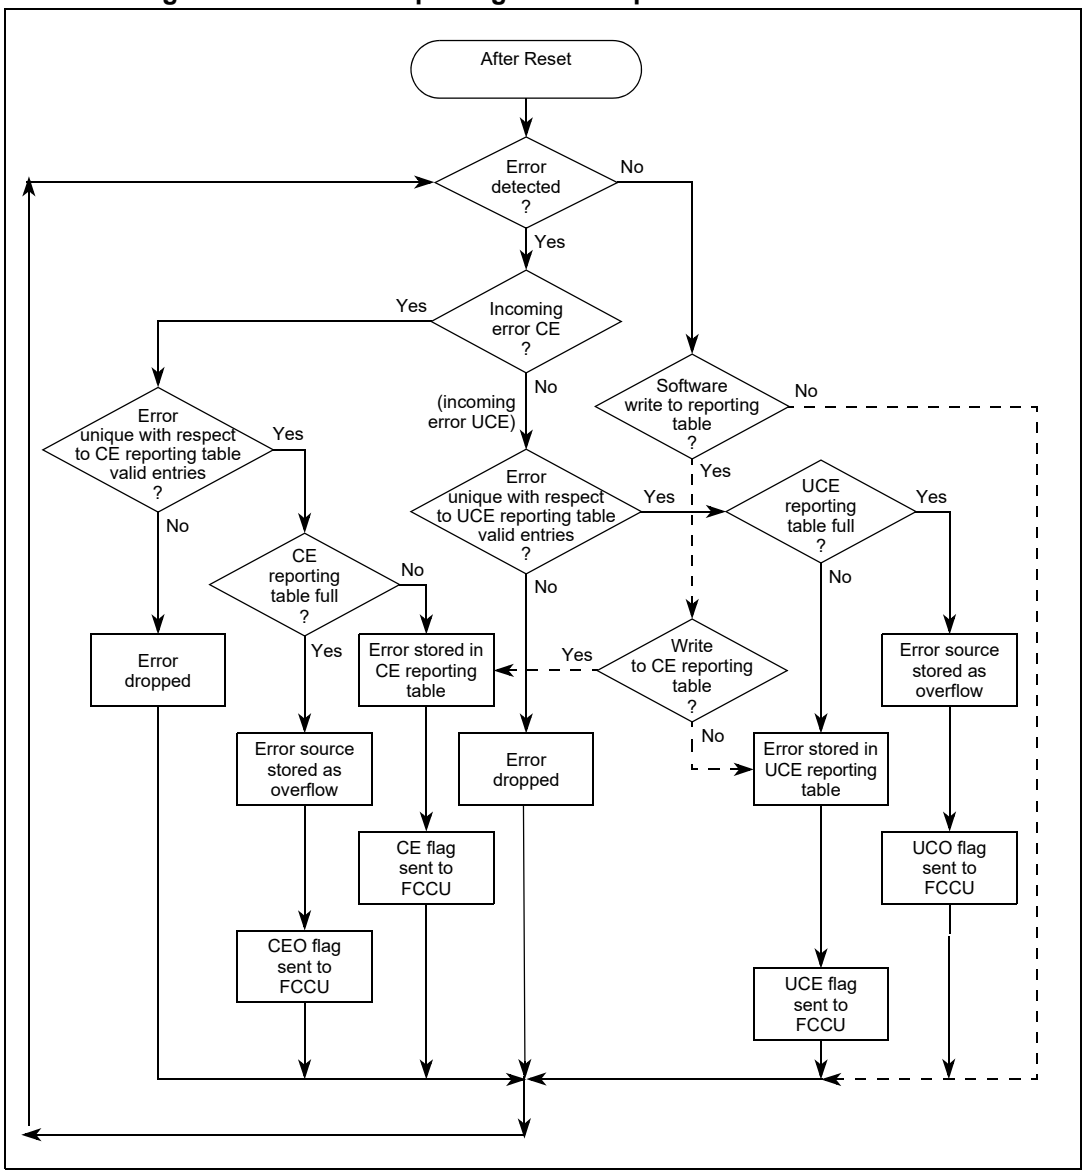


Figure 2316. MEMU reporting table uniqueness check flow chart

78.5 External signal description

MEMU has no external signals.

78.6 Memory map and register definition

78.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see Chapter 7: Device configuration that describes how modules are configured and connected.

Table 2251. CTRL field descriptions

Field	Description
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
30:31 FLASH_ERR_SELECT	FLASH_ERR_SELECT[1:0] 00 Store 20xDEC (Default). Flash Double-bit error corrections only are stored as correctable errors. 01 Store 20xDEC or SEC. Flash Single-bit or Double-bit error corrections, both are stored as correctable errors. 10 Store 20xSEC. Flash Single-bit error corrections only are stored as correctable errors 11 Reserved

78.6.2.2 Error Flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a ‘1’. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 2318. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 2252. ERR_FLAG field descriptions

Field	Description
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table 2252. ERR_FLAG field descriptions (continued)

Field	Description
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to ‘1’ if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.

Table 2252. ERR_FLAG field descriptions (continued)

Field	Description
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to '1' if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

78.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Field	Description
0:31 OFLW	Overflow Bit Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 78.7.3: Handling overflows (Multiple error reporting)* occurs.

78.7 Functional description

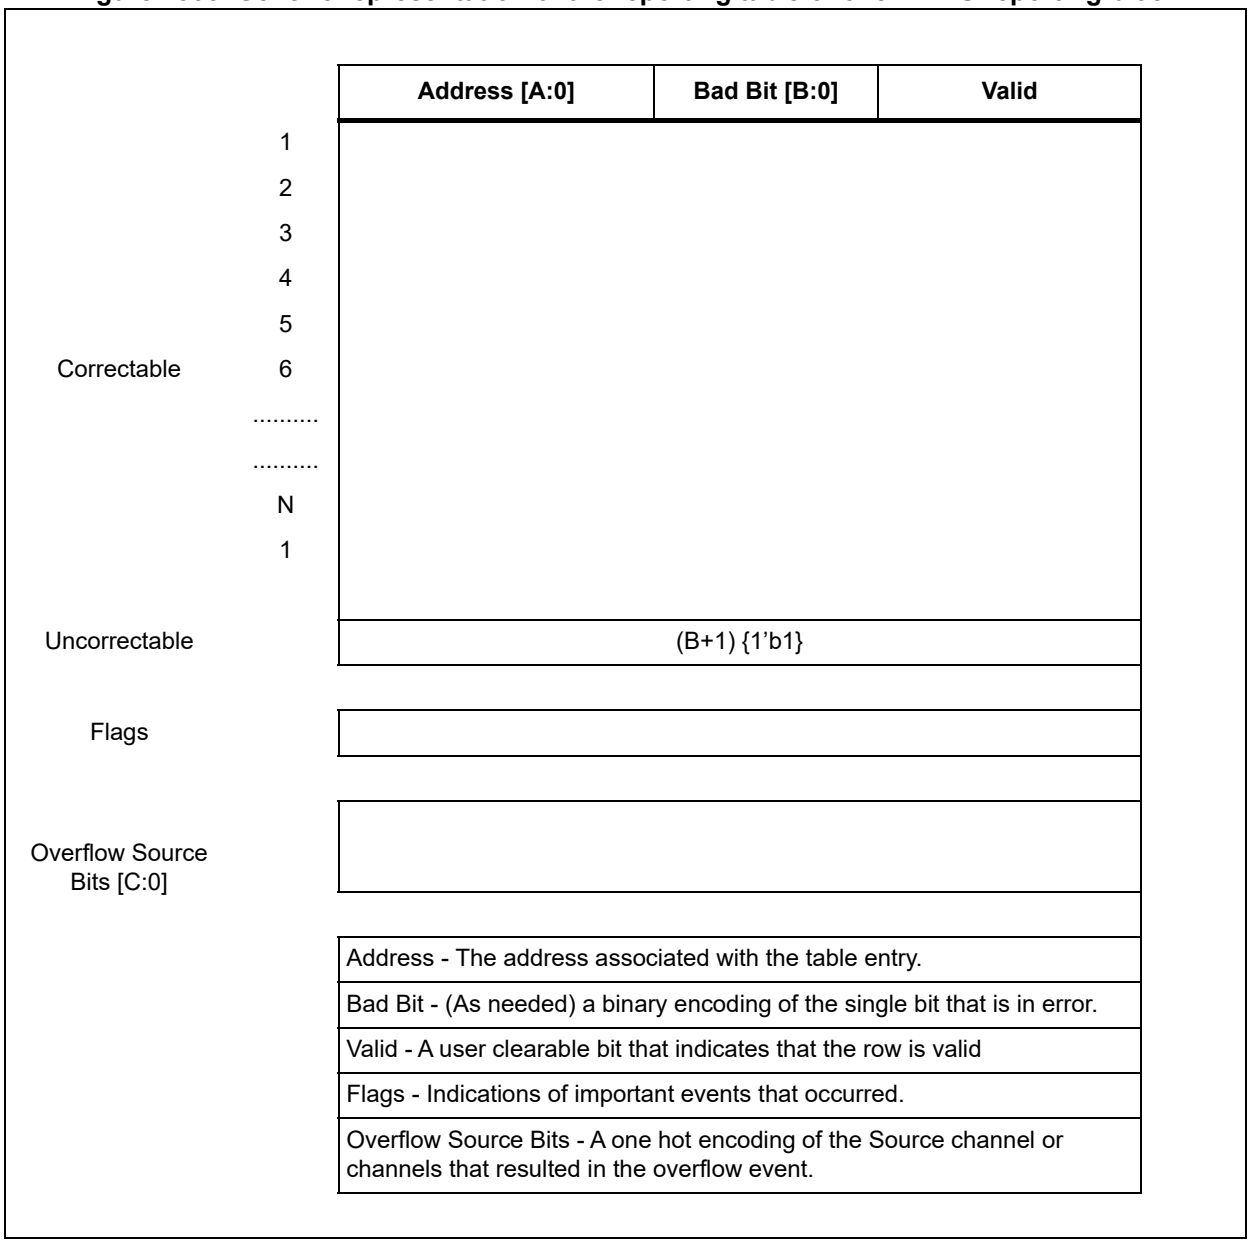
In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

78.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:



1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (duplicate entries).

78.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 2335. Generic representation of the reporting table of one MEMU reporting block

78.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
   - More than 2 errors detected at the same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
   - An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order which means that if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

79 Indirect Memory Access (IMA)

79.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading or modifying data, or both, including ECC check bits. This capability is useful for test activities, for example, verifying ECC functionality.

The SPC58xHx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays.
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. Refer to the Device Configuration chapter for details.

79.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no backdoors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed: I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

79.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control register (CDACNTL)
- Cache Debug Access Data register (CDADATA)

These registers are summarized in the following sections.

79.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

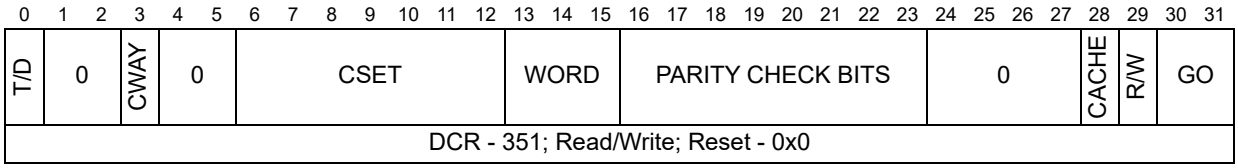


Figure 2336. Cache Debug Access Control register (CDACNTL)

The CDACNTL bits are described in *Table 2269*.

Table 2269. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1:2	—	Reserved - read as zeros.
3	CWAY	Cache Way: Specifies the cache way to be selected.
4:5	—	Reserved - read as zeros.
6:12	CSET	Cache Set: Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13:15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set.
16:23	PARITY CHECK BITS	Parity check bits (I or D-cache): D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24:27	—	Reserved - read as zeros.
28	CACHE	Cache Select: Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30:31	GO	GO command bits: 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

79.2.1.2 Cache Debug Access Data register (CDADATA)

The Cache Debug Access Data register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR - 350; Read/Write; Reset - Undefined/Unaffected																															

Figure 2337. Cache Debug Access Data register (CDADATA)

The CDADATA bits are described in *Table 2270*.

Table 2270. CDADATA field descriptions

Bits	Name	Description
0:31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1- Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23 byte 2 24–31 byte 3

79.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

79.2.2.1 e2eECC Error Control/Status register 0 (E2EECSR0)

The e2eECC Error Control/Status register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31
0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
DCR - 511; Read/Write; Reset - 0x0; Privileged						

Figure 2338. e2eECC Error Control/Status register 0 (E2EECSR0)

The E2EECSR0 bits are described in *Table 2271*.

Table 2271. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros.
4:11	RCHKBIT	Read Checkbits: This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12:15	—	Reserved - read as zeros.
16:17	WRC	Write Control: 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control: 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection

Table 2271. E2EECSR0 field descriptions (continued)

Bits	Name	Description
20:23	—	Reserved - read as zeros.
24:31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask: This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

79.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Note the following restrictions on memory access via IMA:

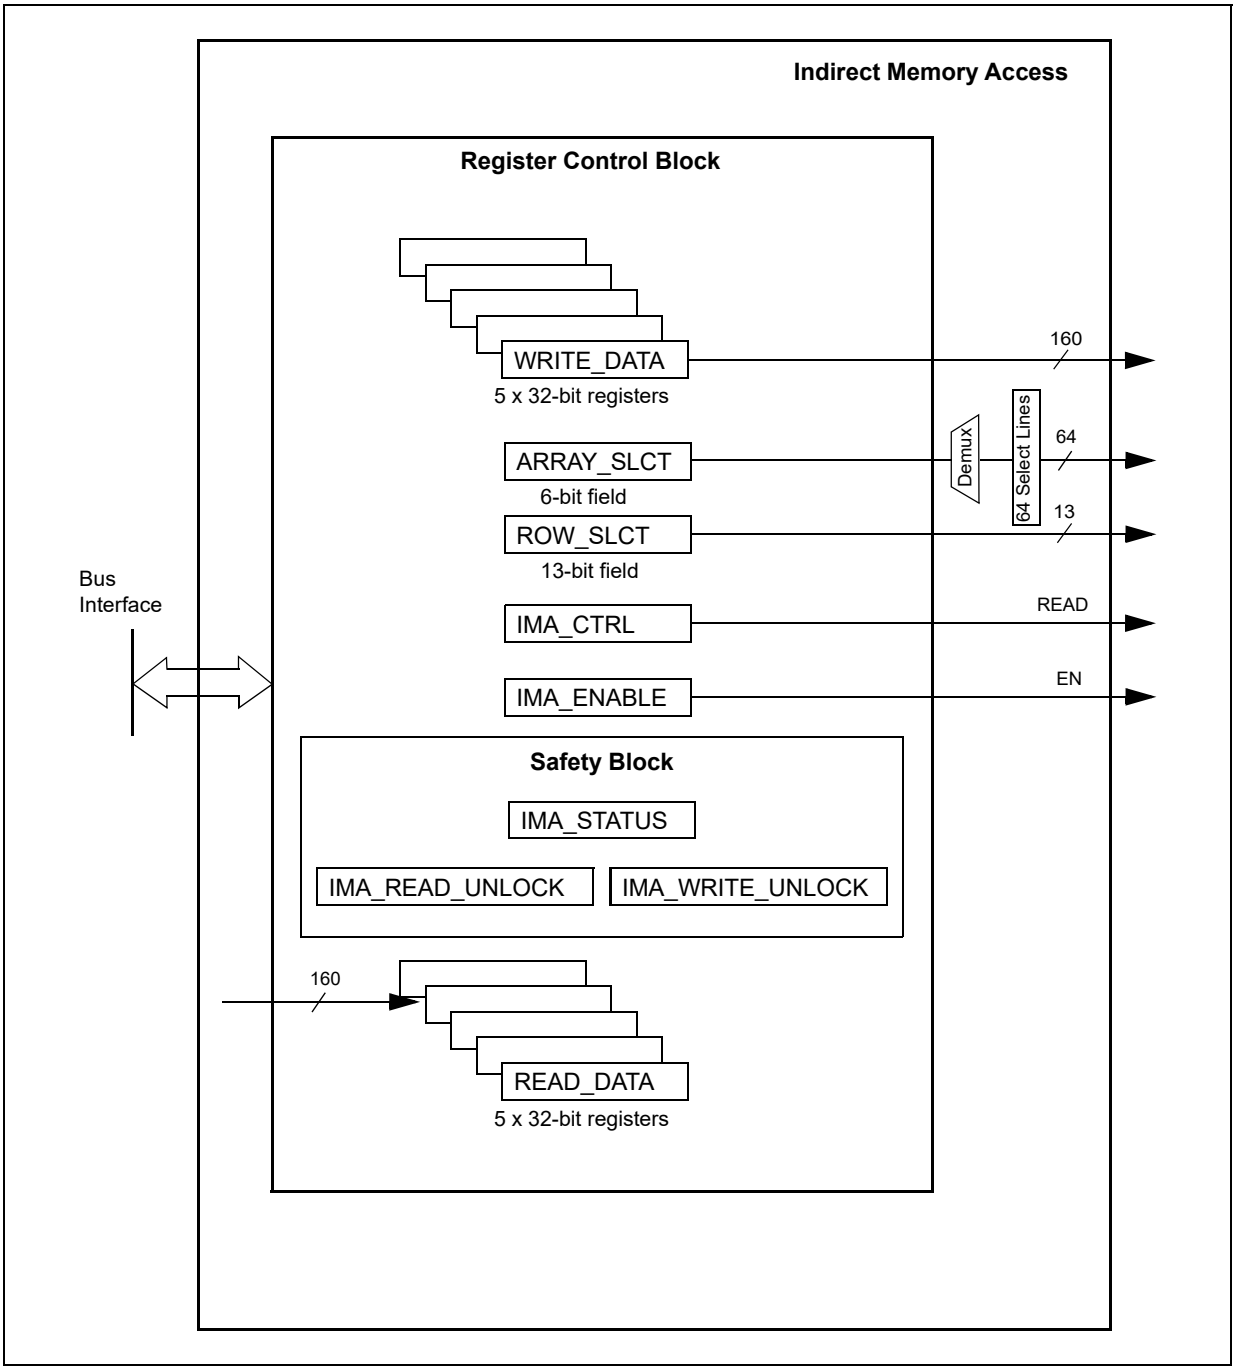
- When a bus master performs an IMA access, no other bus master shall perform an access to the same memory.
- Before any IMA access, the user shall disable the FCCU fault related to the IMA. If not, the FCCU triggers a fault.
- The IMA must be unlocked for reads.

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

79.3.1 Features



The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads.
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data
  - Writes have no effect
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

79.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it too.

Figure 2339. IMA block diagram

79.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 2272. IMA memory map

79.3.3.1 IMA Control register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Offset: 0x00 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 2273. IMA_CTRL field descriptions

Field	Description
31 READ	IMA Read This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

79.3.3.2 IMA Enable Access register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: Back to back writes to the enable bit is not valid. It will still generate a two-clock enable pulse and will be considered as a single access initiation.

Offset: 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2342. IMA Status register (IMA_STATUS)

Table 2275. IMA_STATUS field descriptions

Field	Description
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed. 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

79.3.3.4 IMA RAM Select register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, such as accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. Refer to the Device Configuration chapter for details.

Offset: 0x0C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2343. IMA RAM SELECT register (IMA_SLCT)

Table 2276. IMA_SLCT field descriptions

Field	Description
3:15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is 32 KB RAM.
26:31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

79.3.3.5 IMA Write Unlock register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

Offset: 0x10 Access: User read/write

Field	Description
0:31 WRITE_KEY	Key to unlock the IMA. – 0x04A43F95 is the first key that has to be written to start the unlock process. – 0xE4A9EBF7 is the second key that has to be written to unlock the IMA.

79.3.3.6 IMA Read Unlock register (IMA_READ_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The READ_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for reads.

Offset: 0x14 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

79.3.3.7 IMA RAM Write Data register n (IMA_WRITE_DATA_*n*)

The IMA_WRITE_DATA_*n* registers hold the data values to be written to the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

0x2C (WRITE_DATA_4)
0x30 (WRITE_DATA_3)

Field	Description
0:31 WRITE	Contains data to be written to RAM. – WRITE_DATA_4[WRITE] contains write data bits[159:128] – WRITE_DATA_3[WRITE] contains write data bits[127:96] – WRITE_DATA_2[WRITE] contains write data bits[95:64] – WRITE_DATA_1[WRITE] contains write data bits[63:32] – WRITE_DATA_0[WRITE] contains write data bits[31:0]

79.3.3.8 IMA RAM Read Data register n (IMA_READ_DATA_*n*)

The IMA_READ_DATA_*n* registers hold the data values read from the RAM. The number of active data bits depends on the number of bits for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_*n* registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Offset: 0x4C (READ_DATA_4), 0x50 (READ_DATA_3), 0x54 (READ_DATA_2), 0x58 (READ_DATA_1), 0x5C (READ_DATA_0)

Field	Description
0:31 READ	Contains data to be written to RAM. – READ_DATA_4[READ] contains read data bits[159:128] – READ_DATA_3[READ] contains read data bits[127:96] – READ_DATA_2[READ] contains read data bits[95:64] – READ_DATA_1[READ] contains read data bits[63:32] – READ_DATA_0[READ] contains read data bits[31:0]

79.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

79.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

79.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

79.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Refer to the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

79.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

79.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY.
2. Write 0x14081B56 to READ_KEY.

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY.

79.3.4.3.3 Unlocking writes

The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY.
2. Write 0xE4A9EBF7 to WRITE_KEY.

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY.
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

79.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

79.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections show the different accesses that are available depending on the options.

79.3.4.5.1 Read access

Read Accesses are expected to follow the sequence below:

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register.
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

79.3.4.5.2 Write access

Write Accesses are expected to follow the sequence below:

1. Unlock Write Access by performing appropriate consecutive writes to WRITE_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

79.3.5 Application information

Caution: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

80 Fault Collection and Control Unit (FCCU)

80.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a systematic approach to fault detection and control. The FCCU provides a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

80.2 Features

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

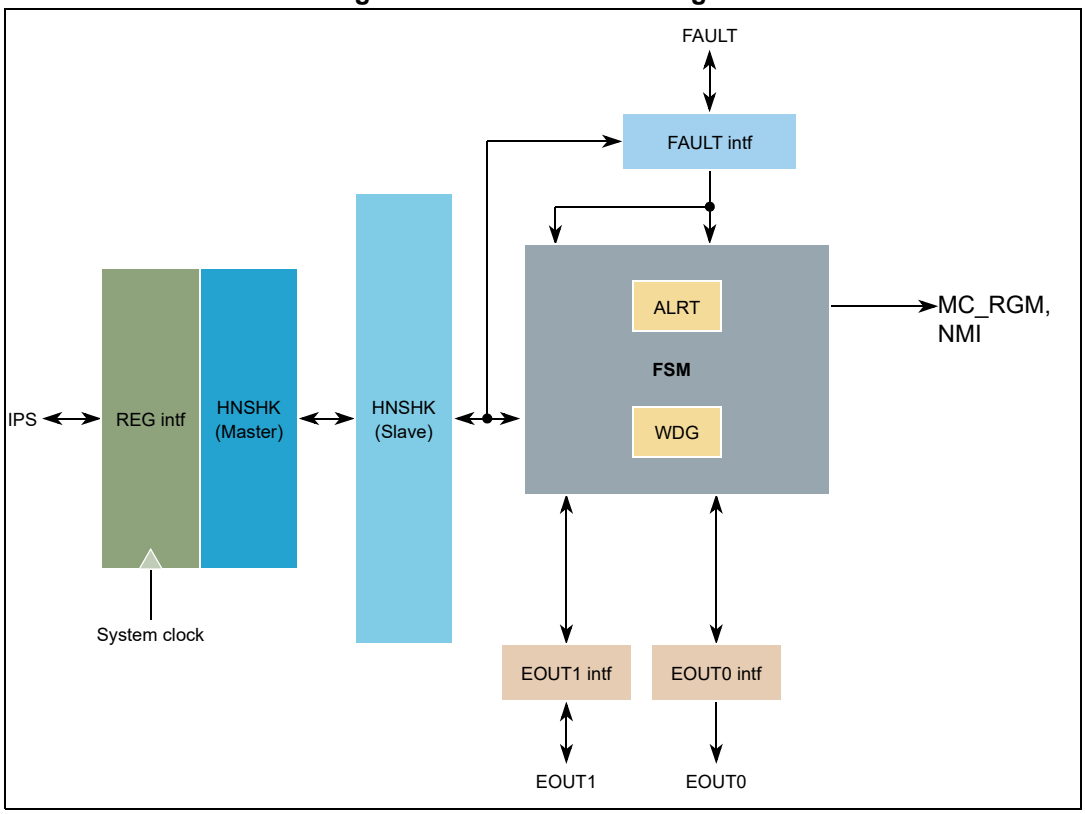
- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; refer to the implementation-specific details)
- Bi-stable, Dual Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Redundant collection of hardware checker (for example RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal (SoC) reactions
  - ALARM state: interrupt request
  - FAULT state: long functional reset request pulse, short functional reset request pulse, NMI
- Internal reactions (independently configurable for each RF)
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU
- Configuration lock: The FCCU’s configuration is lockable in two ways
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into

FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register

- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol that is dual rail and time switching
- After power-on the error out pins have high impedance[aa]. FCCU goes to operational state only on software request
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms
- The overall error detection, processing and indication time is less than 10 ms
- The actual maximum time is five safe (IRCOSC) clock cycles

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster than the IRC clock.

80.2.1 Standard features



- IPS (slave bus signals) bus interface

80.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 2348*.

aa. Actual value depends on the SoC settings at pad level.

Figure 2348. FCCU block diagram

The FCCU module includes the submodules listed in *Table 2281*.

Table 2281. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of two asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: Watchdog timer (WDG) Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

80.4 Signal description

80.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 80.5.9: EOUT interface*.

For the availability of these signals on a chip, refer to the device configuration chapter.

80.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers.
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers.
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0] data write/read operations to any registers.
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (for example FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2290: FCCU memory map*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode.

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

80.5 Functional description

80.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization.
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization.
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

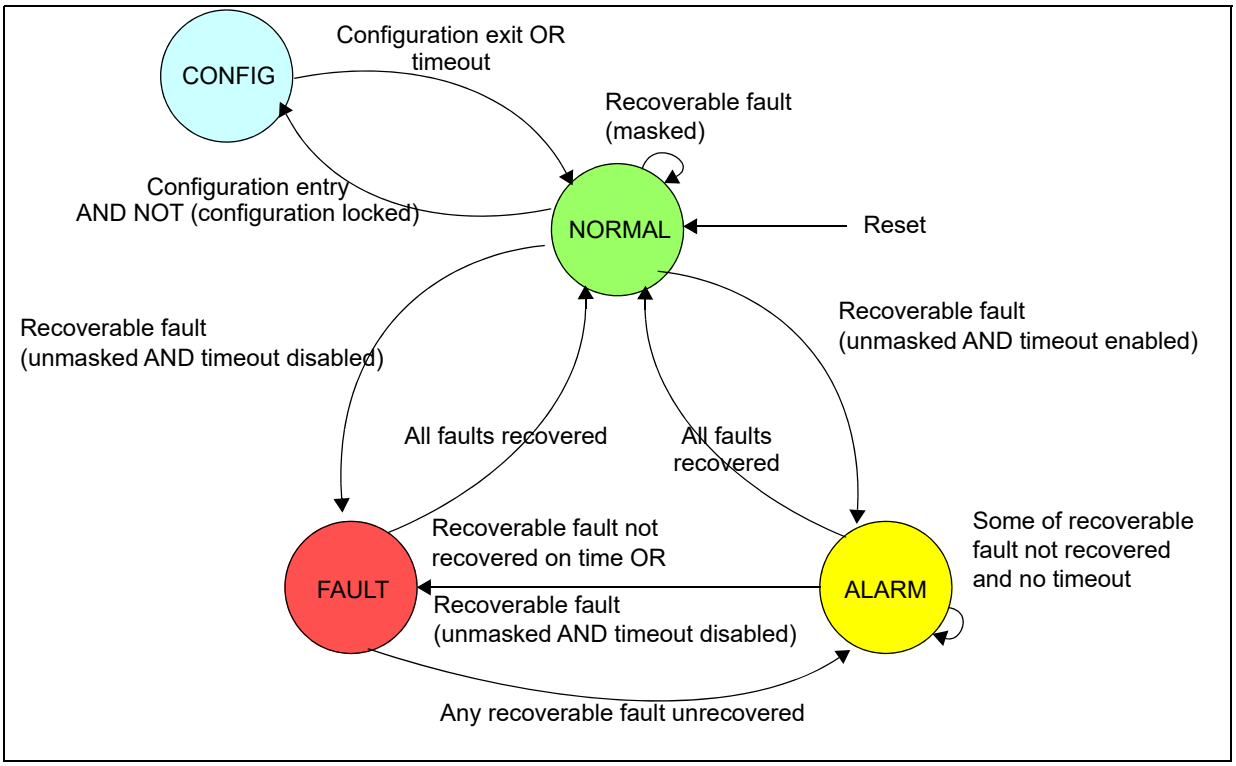
80.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 2349*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (a value different from 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Succeeding one of the following events:
  - unmasked recoverable faults with the timeout disabled → the FCCU moves to the FAULT state.
  - unmasked recoverable faults with the timeout enabled → the FCCU moves to the ALARM state.
  - masked recoverable faults → the FCCU stays in NORMAL state.
- ALARM: the FCCU moves into the ALARM state when an unmasked recoverable fault occurs and the timeout is enabled. The transition to the ALARM state goes along with an interrupt request (ALARM state), if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the

FAULT state. The timeout is re-initialized if the FCCU state moves to the NORMAL state. The timeout restarts following the recovery from the FAULT state.



- FAULT: the FCCU moves into the FAULT state when one of the following conditions occurs:
  - timeout related to a recoverable fault when the FCCU is in the ALARM state.
  - unmasked recoverable faults with the timeout disabled.

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional).
- EOUT signaling (optional).
- SW option: Soft reaction (Short functional reset request pulse if configured).
- SW option: Hard reaction (Long functional reset request pulse if configured).

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 2349. FCCU state diagram

80.5.3 Reset interface

The FCCU has two input resets, as described in *Table 2282* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 2283* for each type of fault reaction (hard, soft or self-checking), the respective output reset (Long functional reset, Short functional reset) is activated. In *Table 2284* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit generates the corresponding input reset as described in *Table 2282*.

Table 2282. Input reset

Input reset	Description
System reset	Global reset of the FCCU synchronous to the system clock.
System reset (RC oscillator)	Global reset of the FCCU synchronous to the IRCOSC.

Table 2283 and *Table 2284* describe a typical reset strategy at system level.

Table 2283. Reset reactions

FAULT reaction	Active reset	System reset signal
Hard	Long functional reset	disabled
Soft	Short functional reset	disabled

Table 2284 shows the Reset sources.

Table 2284. Reset sources

Reset source	System reset signal
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 2285 summarizes the MC actions corresponding to each reset generated by FCCU.

Table 2285. MC actions

Active reset	MC action
Long functional reset	Reset Flash and digital modules excluded FCCU, STCU
Short functional reset	Reset digital modules excluded FCCU, STCU

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for two IRCOSC clock periods.

80.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (possible for RFs only) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a RF (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the RF (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any RF is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the RF that causes an ALARM to FAULT state transition. In this case the alarm timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

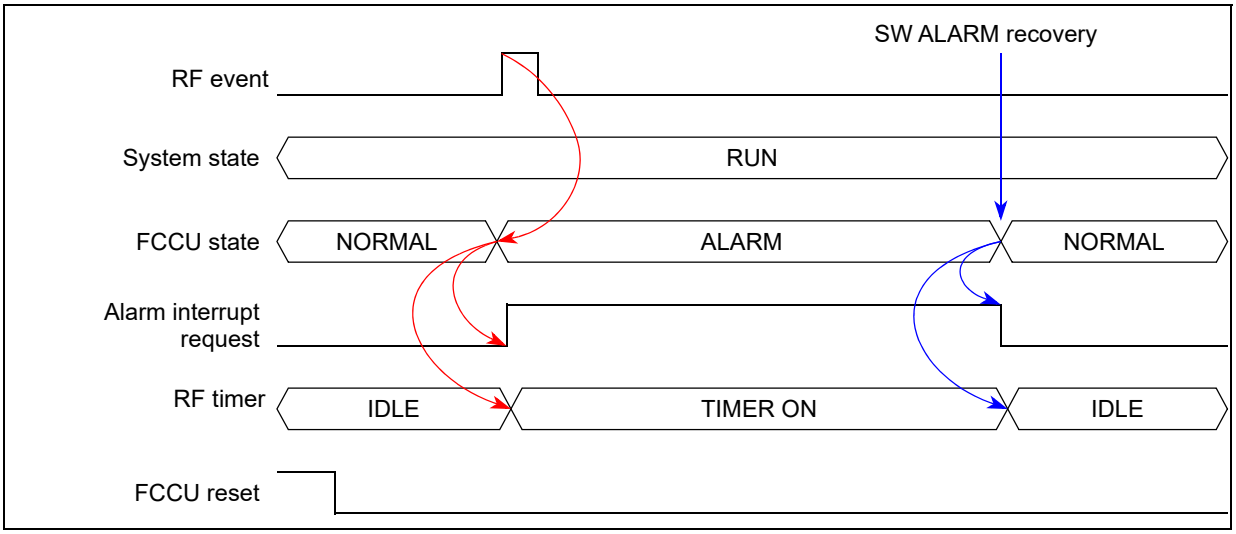
80.5.5 Fault recovery

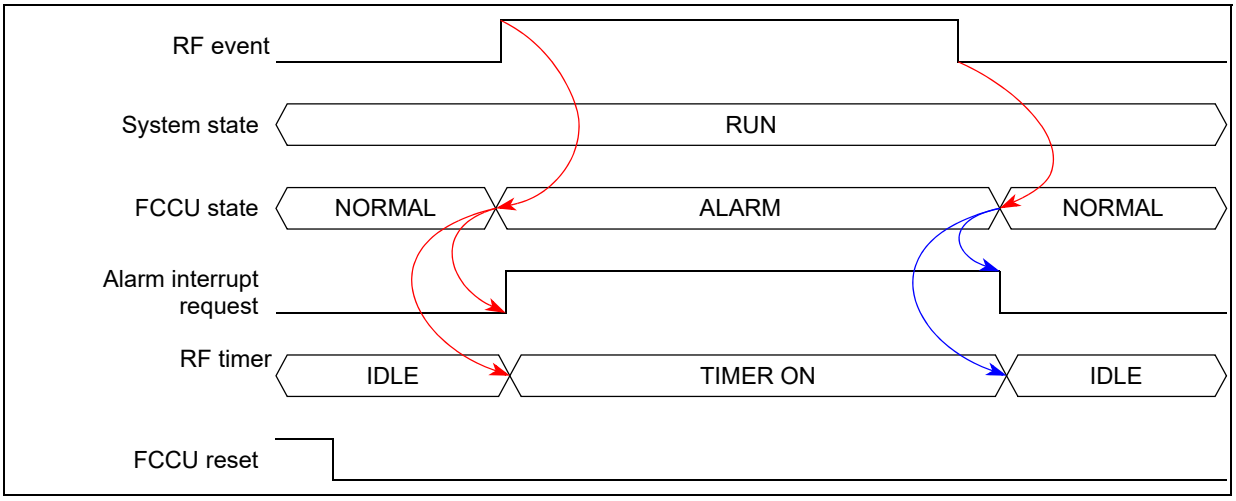
The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a RF management (ALARM state), refer to *Figure 2350* and *Figure 2351*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if configured)
  - Timeout running
- System state: RUN
- Alarm interrupt management: FAULT recovery (by SW): FCCU state transition ALARM → NORMAL

Figure 2350. RF (ALARM state) recovery (a)





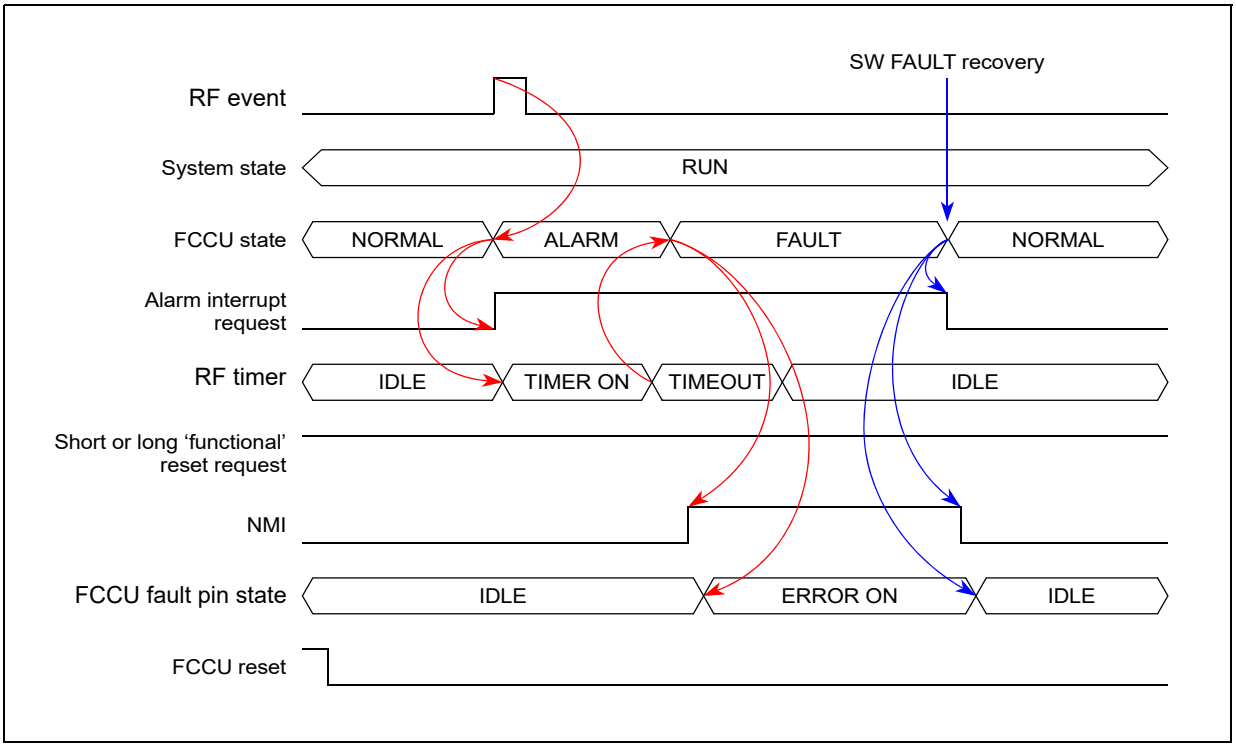


Figure 2351. RF (ALARM state) recovery (b)

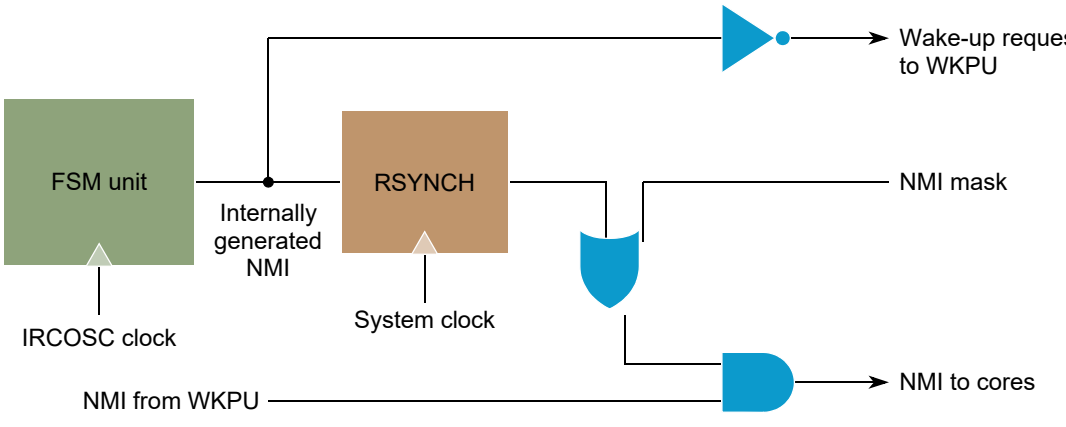
A typical sequence related to a RF management (ALARM → FAULT state), refer to *Figure 2352*, is as follows:

- RF assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - Alarm interrupt request (if enabled)
  - Timeout running
- FCCU state transition (following the timeout trigger): ALARM → FAULT: NMI assertion (if enabled)
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL

Figure 2352. RF(ALARM -> FAULT state) recovery

80.5.6 NMI/WKPU interface



The wake-up interface includes non-maskable interrupt: NMI interrupt source generated by the WKPU. It is synchronous with the system clock and active low. A logical AND interconnects the NMI sources (internally generated by FCCU and by WKPU) in order to provide a single NMI output.

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (MC state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (MC mode SW change request = 1).

Figure 2353. NMI/WKUP scheme

Note: All NMI signals are shown active-low.

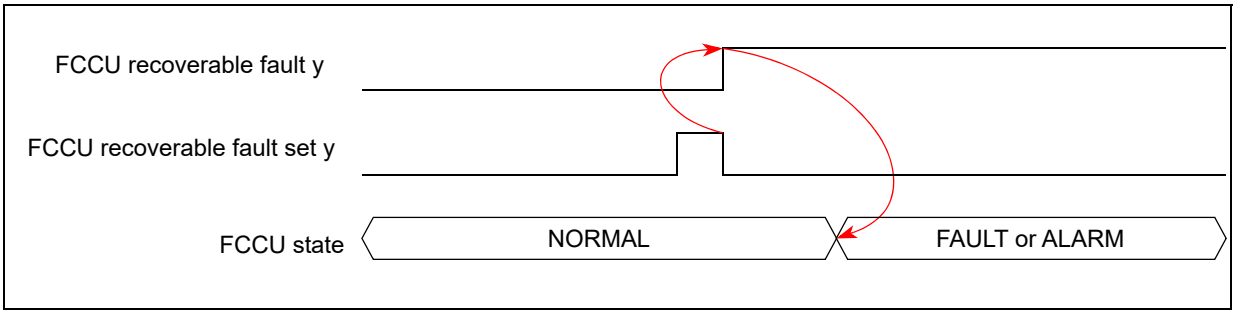
80.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple, programmable edge-sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2354*. The fault injection is executed by a write operation in the FCCU_RFF register. The reaction following a fake RF cannot be masked. The fault injection mechanism is optional; refer to the implementation-specific details. Refer to “FCCU failure inputs” table in Functional Safety chapter, for more details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (FCCU recoverable faults clear) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 2355*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_S*n*. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 2354. FAULT injection



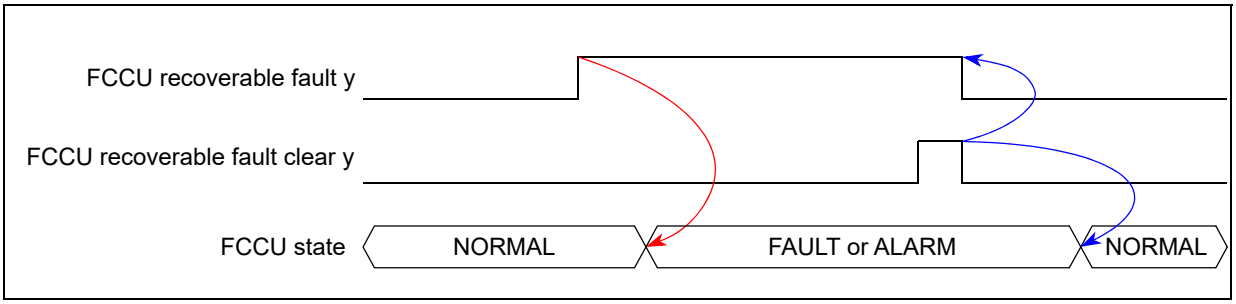


Figure 2355. FAULT clearing

80.5.8 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the following FCCU fault:
  - Recoverable
- The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- A mask (EOUT mask[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible for providing a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible for providing the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 2356. STCU-FCCU (case a)

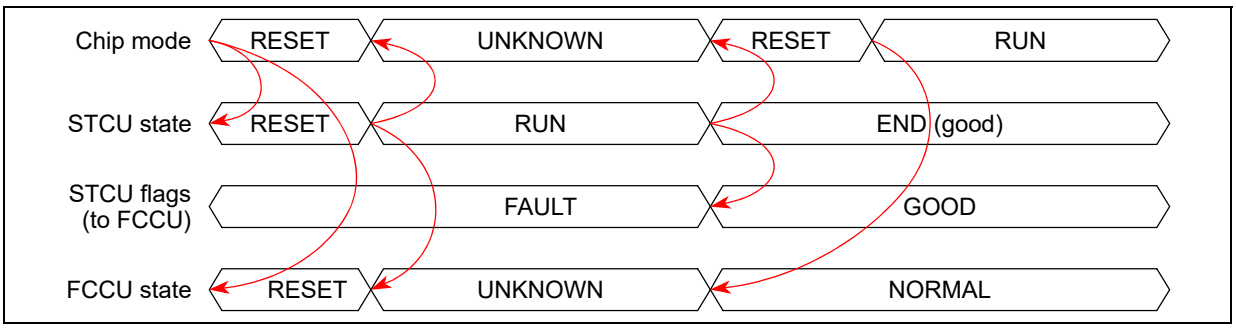

Figure 2357. STCU-FCCU (case b)

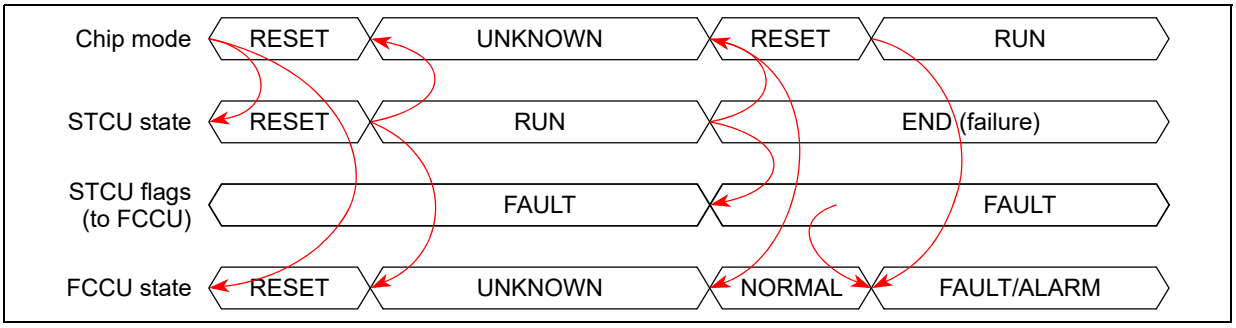

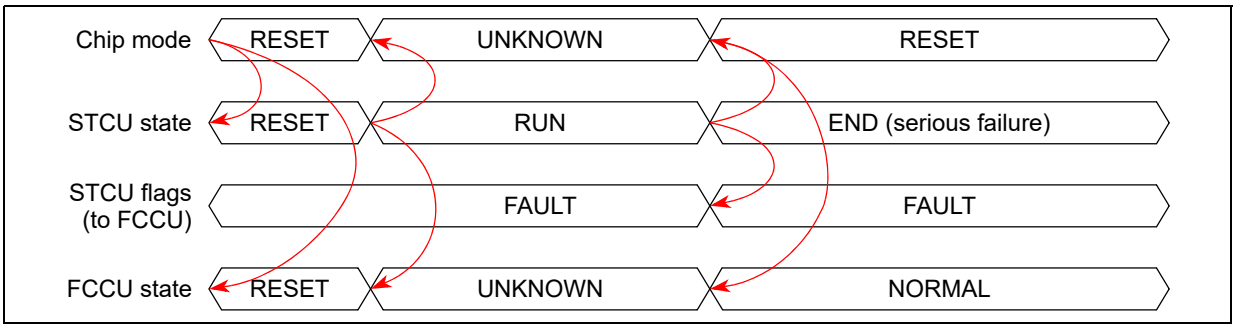

Figure 2358. STCU-FCCU (case c)

80.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (refer to table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS field in the FCCU_CFG register. For example, for PS = 0, FCCU Error output[0] = 0 and FCCU Error output[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual rail or time switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL). The EOUT protocol

transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.

- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or vice-versa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occur in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18}. With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual rail or time switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, that is an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset, and software bit FCCU_RST in RGM_PRST5) should not influence the state of the failure indication, pins.

Note: The transition from FAULT to CONFIG state is not possible but is shown to display the behavior in all four states: RESET, NORMAL, FAULT and CONFIG.

Table 2286. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written FCCU_SET_AFTER_RESET bit to 1.

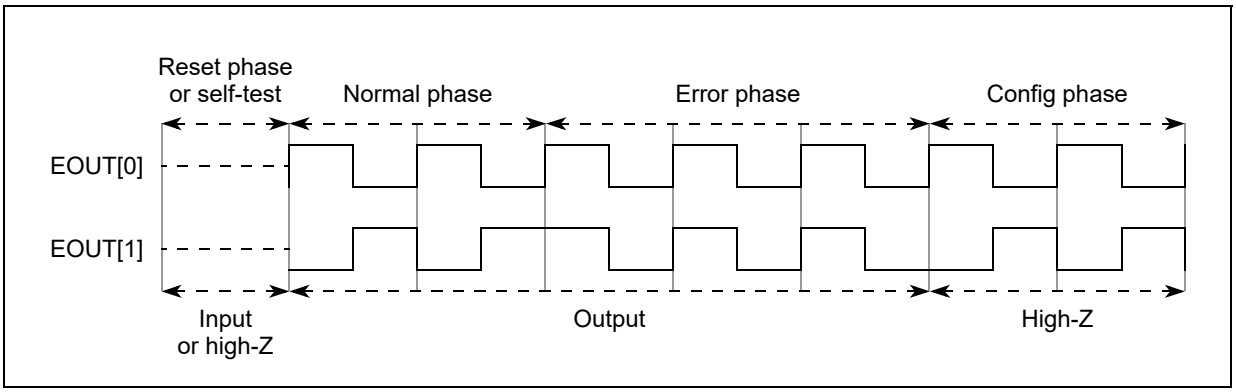
Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

80.5.9.1 Dual rail protocol

Dual rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual rail encoded circuits use two wires to carry each bit. The encoding scheme is given in *Table 2287* and the related timing diagram is given in *Figure 2359* and *Figure 2360*.

Table 2287. Dual rail encoding

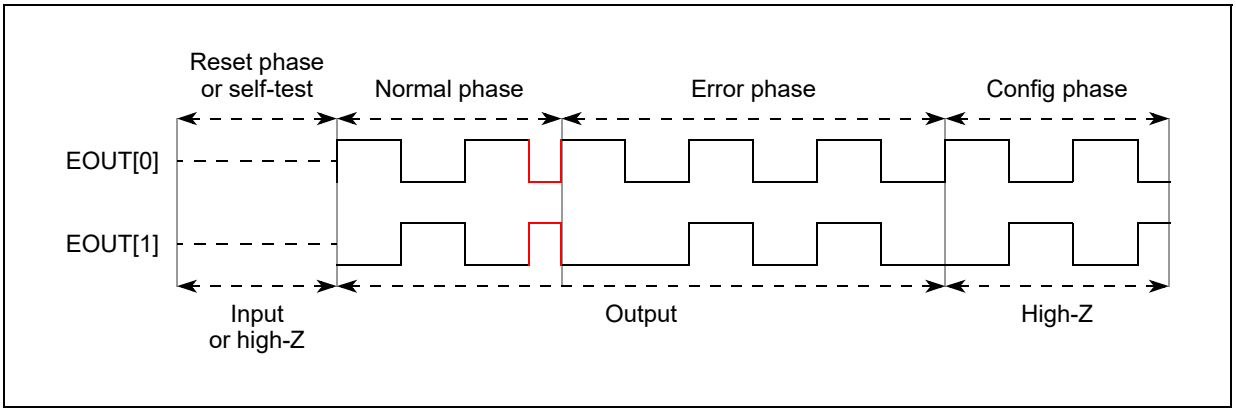
Logical state	Dual rail encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	00	toggling
faulty	11	
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling



1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the RESET phase the output pins are set as “high impedance”[ab].



Note: Figure 2359 and Figure 2360 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 2359. Dual rail protocol (slow switching mode)

ab. Actual value depends on the SOC settings at pad level.

Figure 2360. Dual rail protocol (fast switching mode)

80.5.9.2 Time switching protocol

The encoding scheme is given in *Table 2288* and the related timing diagram is given in *Figure 2361*.

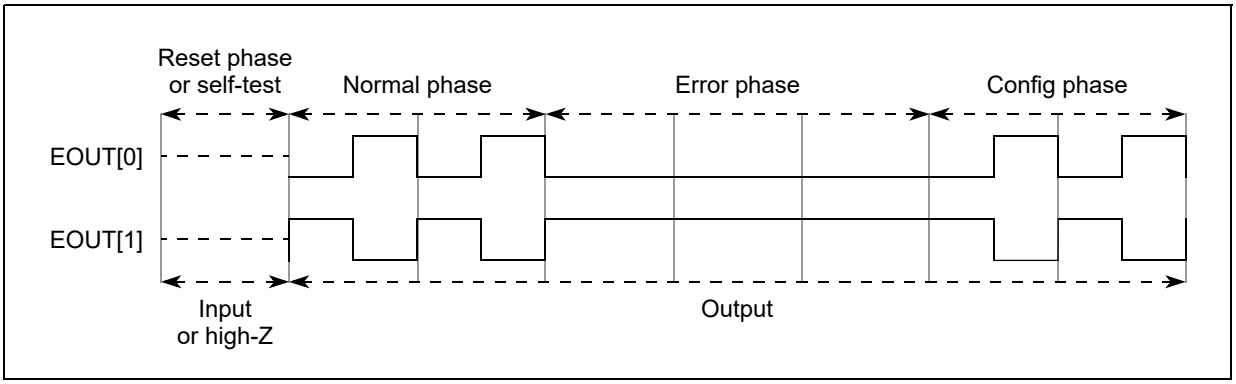
Table 2288. Time switching encoding

Logical state	Time switching encoding (FCCU Error output pins [1:0])	Note
nonfaulty	10	toggling
nonfaulty	01	
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “nonfaulty” signal. Output pins #0, #1 will toggle between 01 and 10.

In the FAULT state, the output pin FCCU Error output pin[0] is set as low.



In Time Switching mode the second output (FCCU Error output pin[1]) is the inverted signal of first output (FCCU Error output pin[0]).

In the RESET phase the output pins are set as “high impedance”(ac).

Note: Figure 2361 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

ac. Actual value depends on the SOC settings at pad level.

Figure 2361. Time switching protocol

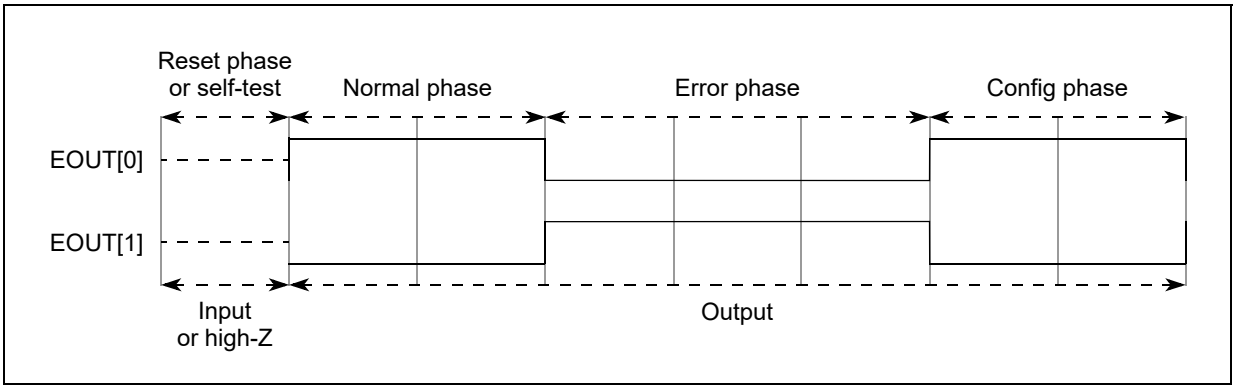
80.5.9.3 Bi-stable protocol

The encoding scheme is given in *Table 2289* and the related timing diagram is given in *Figure 2362*.

Table 2289. Bi-stable encoding

Logical state	Bi-stable encoding (FCCU Error output pins [1:0])	Note
nonfaulty	01	no toggling
faulty	10	no toggling
reset	high-Z(1)	no toggling
configuration	same as NORMAL(2)	no toggling

1. Final value depends on the SoC settings at pad level.
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.



In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (FCCU Error output[1]) is the inverted signal of first output (FCCU Error output[0]).

In the RESET phase the output pins are set as “high impedance”(ad).

Note: Figure 2362 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

ad. Actual value depends on the SOC settings at pad level.

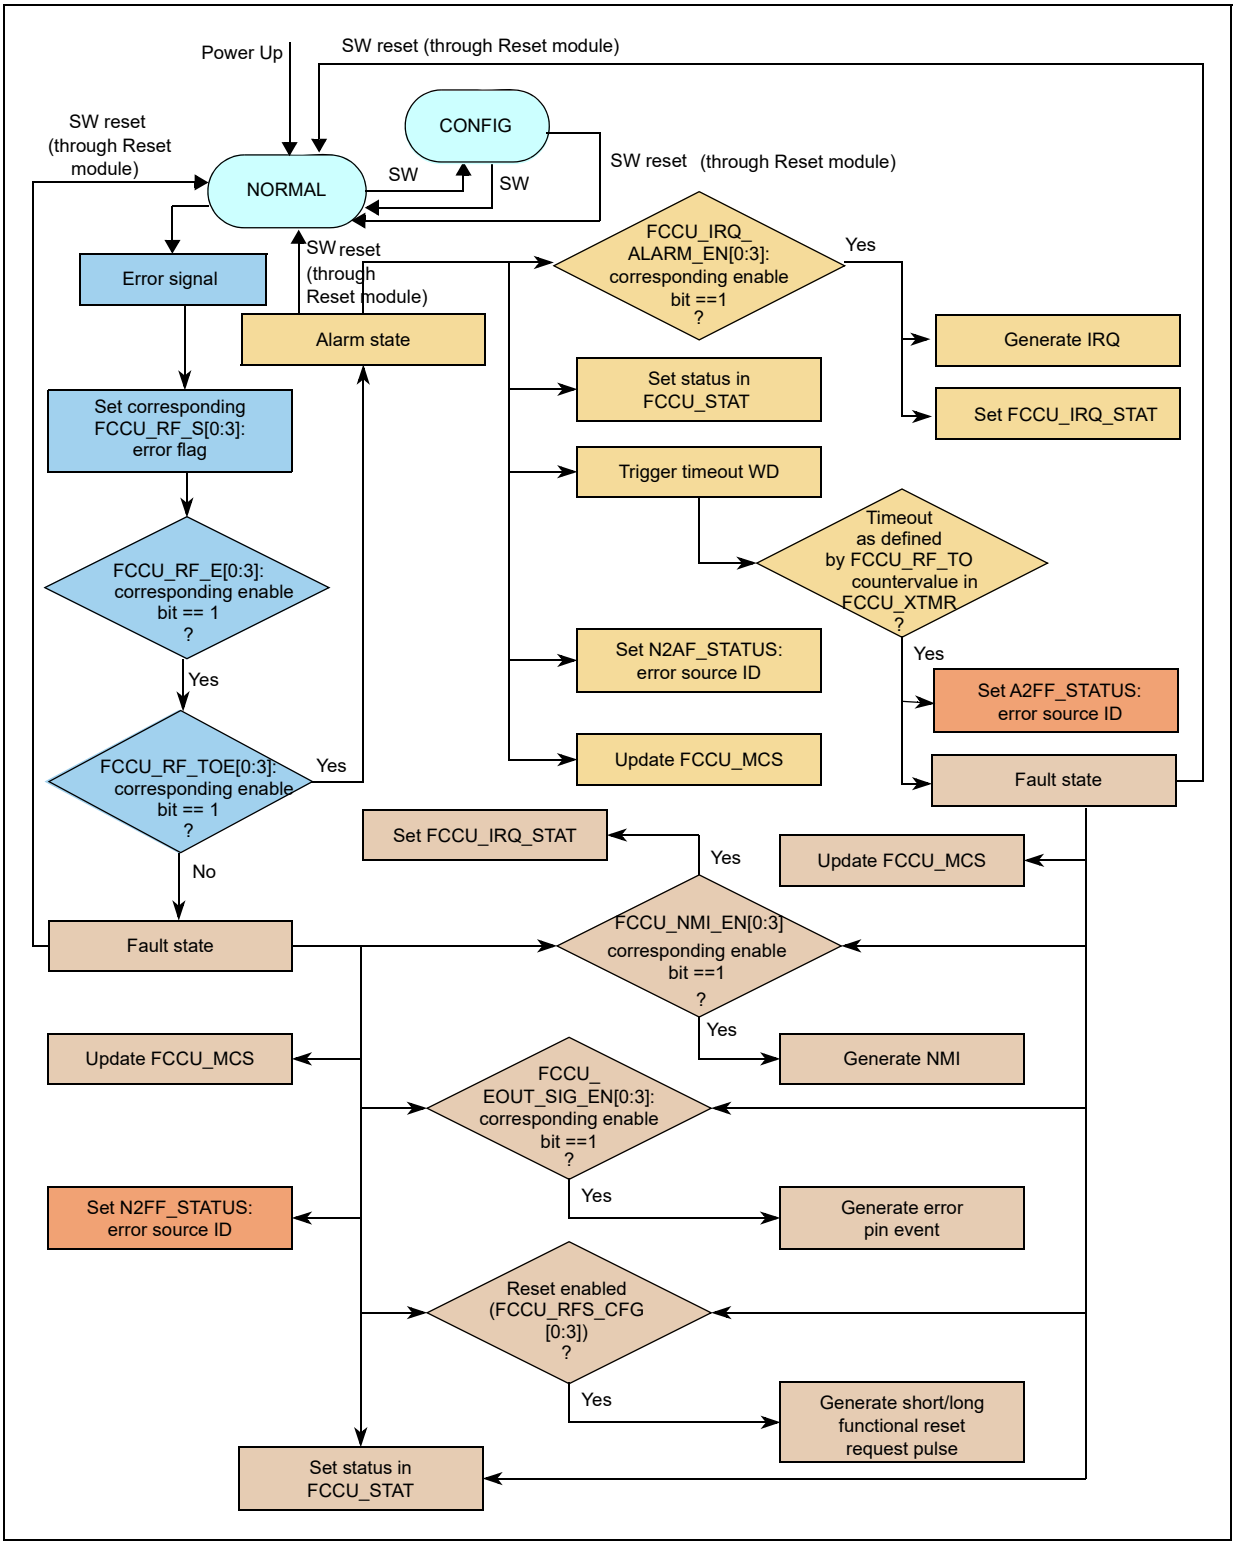


Figure 2362. Bi-stable protocol

80.5.10 Error signal flow for RF case

On Power up, FCCU moves to NORMAL state. SW can configure it by moving it to CONFIG and back again. SW reset leads to movement back to NORMAL. On reaching ALARM state, depending on ALARM being enabled, FCCU generates IRQ (alarm) and the FCCU_IRQ_STAT's alarm status is also set. FSM status is set in FCCU_STAT along with N2AF_STATUS. If Error is enabled (FCCU_RF_E) and timeout disabled (FCCU_RF_TOE), FCCU moves straight to FAULT state and depending on FCCU_NMI_EN or FCCU_SIG_EN, or both, being set, it generates a NMI or signals error, or both, out to the external world. FCCU FSM status is also captured in FCCU_STAT.

Figure 2363. Error signal flow

80.6 Register description

The FCCU registers are listed in *Table 2290*. Any address offset not explicitly mentioned in *Table 2290* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 2290*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

Table 2290. FCCU memory map

Address offset	Register	Access(1)	Location
0x000	FCCU Control Register (FCCU_CTRL)	R/W always	*Section 80.6.1*
0x004	FCCU CTRL Key Register (FCCU_CTRLK)	W always	*Section 80.6.2*
0x008	FCCU Configuration Register (FCCU_CFG)	R always; W in CONFIG state only	*Section 80.6.3*

80.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state.
- moving the FCCU state from the CONFIG state into the NORMAL state.
- reading or to clear the RF status register.
- reading the FCCU FSM status register.
- reading or to clear the FCCU freeze registers.
- reading the ALARM timer.
- reading the Watchdog timer.
- configure the glitch filter present on EIN0 input (FCCU failure input #94).

Some critical operations require a key as defined in the FCCU_CTRLK register.

The Glitch filter, filters out pulses of widths up to 50/75/100 µs, as governed by FCCU_CTRL[FILTER_WIDTH]. It becomes active as soon as FCCU_CTRL[FILTER_BYPASS] is de-asserted (default value).

The implementation is as follows:

1. Fault line assertion - If a Fault is asserted, then the output of the filter is asserted after the delay, equal to the programmed glitch width time. If the fault is de-asserted before

the programmed glitch width time, then the output of the filter is not asserted and stays at the deactivated level (after having rejected the spurious glitch).

2. Fault line de-assertion - If a Fault, which was kept asserted for a time greater than the programmed pulse width is de-asserted (and glitch filter output is at asserted level now), then the output of the filter is de-asserted only after the delay equal to the programmed glitch width time. If the fault is again asserted before the programmed glitch width time, then the output of the filter is not de-asserted and stays at the active level (after having rejected the spurious glitch).

The output of the filter becomes the effective fault input fed to the FCCU error management engine. Since there is an inherent latency involved, SW must either wait for the programmed delay value before trying to clear the fault status flag, FCCU failure input #94 or first set FCCU_CTRL[FILTER_BYPASS] to one and then try to clear the fault status flag. This bit should not be made '1' again, till the filter width time elapses, else fault status will be latched again.

1:2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs for 20 MHz IRC clock 11 filters glitches up to 100 µs for 20 MHz IRC clock Make sure that the filter width does not cross the FOSU timeout value else unintended reset may occur.

Table 2291. FCCU_CTRL field descriptions (continued)

Field	Description
22 DEBUG	Debug mode entry 0 Normal operation 1 Put FCCU into debug mode When Debug pin signal is asserted and this bit is set, FCCU moves into debug state and suspend the transition of the FSM by suspending timer elapse time effect.
24:25 OPS	Operation status 00 Idle 01 In progress 10 Aborted 11 Successful These bits can be read and cleared (via OP15 operation) by the software.

Table 2291. FCCU_CTRL field descriptions (continued)

Field	Description
27:31 OPR	Operation run 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (refer to the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (refer to the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (refer to the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (refer to the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (refer to the F2A_STATUS register) [OP7] 01000 Reserved 01001 Reserved 01010 Read the RF status register (refer to the FCCU_RF_S register) [OP10] 01011 Reserved 01100 RF status clear operation in progress (refer to the FCCU_RF_S register) [OP12] 01101 Clear the freeze status registers (refer to the freeze registers) [OP13] 01110 CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111 Clear the operation status (OPS=Idle) [OP15] 10000 Reserved 10001 Read the ALARM timer (refer to the FCCU_XTMR register) [OP17] 10010 RESERVED 10011 Read the CFG timer (refer to the FCCU_XTMR register) [OP19] 10100 Read the Error Pin low counter value (refer to *Section 80.6.21: FCCU XTMR Register (FCCU_XTMR)*) [OP20] 10101 Reserved ... 11111 Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution The max timing needed for ABORT/SUCCESS response is 15 IRC cycles

80.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There shall not be any other operation in between the above steps and the 32 bits need to be written in one cycle. So, store FCCU_CTRLK, merge with OP1 or OP2 then send it.

The FCCU_CTRLK register is not readable, a 0x0000_0000 value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0(2)	0	0	0

1. Writable only in the CONFIG state.
2. After powerup, reset value will be 0. If configuration timeout occurs then default value will be changed to 1.

Figure 2366. FCCU Configuration Register (FCCU_CFG)

Table 2293. FCCU_CFG field descriptions

Field	Description
7 FCCU_SET_AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0 FCCU's Error indication stops functioning and error pins are in HI-Z state(1). 1 write to start FCCU functioning. After power-on the error out pins shall be in high impedance(1). They will go to normal state only on software request, this bit is set to 1. It is Software responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
8:9 FCCU_SET_CLEAR	Error pin state can be controlled by these bits 01 Error Pin driven to logic 0. 11 Error Pin driven to logic 1 (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault). 00 FCCU acts independent of above SW control. 10 FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z(1). Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state. This bit feature may not work with toggling protocols for example say EOUT pins are set high by SW using this bit followed by switching to a toggling protocol after returning control to FCCU FSM via setting this bit to 00 or 10, the user may find that EOUT pins do not toggle as was being expected.

Table 2293. FCCU_CFG field descriptions (continued)

Field	Description
19 OD	Open Drain Mechanism to select between Push-pull and Open drain (OD) mode for the error indicating pin(s). 0 push-pull 1 OD
21 SM	Switching mode 0 EOUT protocol (dual rail, time switching) slow switching mode. 1 EOUT protocol (dual rail, time switching) fast switching mode. SM has no effect on the bi-stable protocol.
22 PS	Polarity selection 0 FCCU Error output[1] active high, FCCU Error output[0] active low. 1 FCCU Error output[1] active low, FCCU Error output[0] active high. This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non toggling in Error phase.
23:25 FOM	Fault Output Mode selection 000 Dual Rail (default state) [FCCU Error output[1:0]= outputs] 001 Time Switching [FCCU Error output[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [FCCU Error output[0]= input, FCCU Error output[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [FCCU Error output[0]= output, FCCU Error output[1]= input] **Note:** In Test mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.

1. Actual value depends on the SOC settings at pad level.

80.6.4 FCCU RF Configuration Register *n* (FCCU_RF_CFG*n*)

The FCCU_RF_CFG*n* registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

Offset: 0x01C + *n**0x4 (*n* = 0 to 3) Access: User read/write(1)

80.6.6 FCCU RF Status register *n* (FCCU_RF_S*n*)

The FCCU_RF_S*n* register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_E*n* register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_S*n* register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field
3. Wait for the completion of the operation (FCCU_CTRL.OPS field)
4. Read the FCCU_RF_S*n* register in order to verify the effective deletion and in case of failure to repeat the sequence

As a result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (refer to *Section 80.5.7: FAULT interface*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_S*n* read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_RF_S*n* register

In case of reconfiguration of the FCCU (CONFIG state), before returning in NORMAL state the pending status bits into the FCCU_RF_S*n* must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

0x08C	FCCU_RF_S3	RFS[127:96]

80.6.7 FCCU RF Key register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_S*n* register.

The status bits of the FCCU_RF_S*n* register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register
2. Clear the status (flag) bit RFSx

The key must be written for each FCCU_RF_S*n* clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0x0000_0000 value is always returned in case of read operation.

80.6.8 FCCU RF Enable Register *n* (FCCU_RF_E*n*)

The FCCU_RF_E*n* registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_S*n* register is anyway set, only the reaction is masked.

These registers are writable only in the CONFIG state.

80.6.9 FCCU RF Timeout Enable Register *n* (FCCU_RF_TOE*n*)

The FCCU_RF_TOE*n* registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective timeout is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

80.6.10 FCCU RF Timeout Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state. The alarm timeouts value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU timeout.

This register is writable only in the CONFIG state.

Field	Description
0:31 TO	Recoverable fault timeout Timeout = (TO) x $T_{RC16MHz}$

80.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Refer to *Table 2290: FCCU memory map*. The watchdog timeout is clocked with the RC oscillator clock (16 MHz). The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

80.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the FCCU Error output pin[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the FCCU Error output pin[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the FCCU Error inputs level

Table 2307: Bi-stable encoding shows Bi-stable encoding.

Table 2307. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

1. FCCU Error input x depends on the PAD configuration, that is, internal pull-up enabled as default or pull-down and therefore EINx bit is 1 or 0 upon reset.
2. Refer to the Device Configuration chapter for chip-specific reset value.

Figure 2375. FCCU IO Control Register (FCCU_EINOUT)

Table 2308. FCCU_EINOUT field descriptions

Field	Description
26 EIN1	Error input 1 0 when FCCU Error input[1] = 0 1 when FCCU Error input[1] = 1 The EIN1 captures the respective FCCU Error input[1] signal.
27 EIN0	Error input 0 0 when FCCU Error input[0] = 0 1 when FCCU Error input[0] = 1 The EIN0 captures the FCCU Error input[0] signal.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => FCCU Error output[1] configured in output mode). 0 force FCCU Error output[1] = 0 1 force FCCU Error output[1] = 1 The EOUT1 set/clear the respective FCCU Error output[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a “do not care” value.
31 EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => FCCU Error output[0] configured in output mode) 0 force FCCU Error output[0] = 0 1 force FCCU Error output[0] = 1 The EOUT0 set/clear the respective FCCU Error output[0] signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a “do not care” value.

80.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status. The FCCU finite state machine (FSM) operates by the RC oscillator clock asynchronous with the System clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization

sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Figure 2376. FCCU Status Register (FCCU_STAT)

Table 2309. FCCU_STAT field descriptions

Field	Description
26:27 PhysicErrorPin	Physical Error Pin state PhysicErrorPin[26] corresponds to error pin 0, PhysicErrorPin[27] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0 Error Pin is at logical 0 1 Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. **Note:** This field indicates the real time status of the Error pin as driven by FCCU (at FCCU boundary) to the pad and not what is seen at/from the pad, which is based on different IPs (such as SIUL2) configurations of the SoC.
28 ESTAT	Current Error Pin Status SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in nonfaulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state. This state is taken from the FCCU Eout logic (That is, as late as possible).
29:31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state Other: UNKNOWN state

80.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the recoverable source (FCCU recoverable fault x) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

80.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

80.6.16 FCCU NF Freeze Status Register (N2FF_STATUS)

The N2FF_STATUS register contains a unique code to identify the recoverable fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

80.6.17 FCCU FA Freeze Status Register (F2A_STATUS)

The F2A_STATUS register contains a unique code to identify the recoverable fault source (recoverable fault x) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified.

The SW application executes the F2A_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the N2FF_STATUS register

The SW application executes the F2A_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

80.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recoverable fault in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 80.5.7: FAULT interface*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

80.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The external interrupt line (Interrupt request) is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

80.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The external interrupt line “Interrupt request (miscellaneous conditions)” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

Field	Description
31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled. 1 Configuration timeout interrupt enabled.

80.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

EOUTMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it loads (a value corresponding to T_min = 250 µs + value programmed in FCCU_DELTA_T register) and then starts down-counting and becomes 0 on the expiry of T_min window. It reloads on occurrence of another fault event which has EOUT signaling enabled. T_min feature is available only in Bi-Stable

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   a) OP17
   b) OP19
   c) OP20
2. Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

Table 2318: Timer state/value shows Timer state/value.

80.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

1. Refer to *Table 2328* for register offset to channel number relationship.

Figure 2391. FCCU EOUT Signaling Enable register *n* (FCCU_EOUT_SIG_EN*n*)

Table 2327. FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0:31 EOUTEN[31:0]	EOUT signaling enable 0 EOUT signaling is disabled for error (RF) source x for bistable protocol. Error pins are as if in nonfaulty state.(1) 1 EOUT signaling is enabled for error (RF) source x.

1. In case of time switching and dual rail protocols, the error out signaling remains active even if the EOUT flag is 0b.

Table 2328: FCCU EOUT signaling enable register channels shows FCCU EOUT signaling enable register channels.

Table 2328. FCCU EOUT signaling enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
0x11C	FCCU_EOUT_SIG_EN0	EOUTEN[31:0]
0x120	FCCU_EOUT_SIG_EN1	EOUTEN[63:32]
0x124	FCCU_EOUT_SIG_EN2	EOUTEN[95:64]
0x128	FCCU_EOUT_SIG_EN3	EOUTEN[127:96]

80.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (that is FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a “static” input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

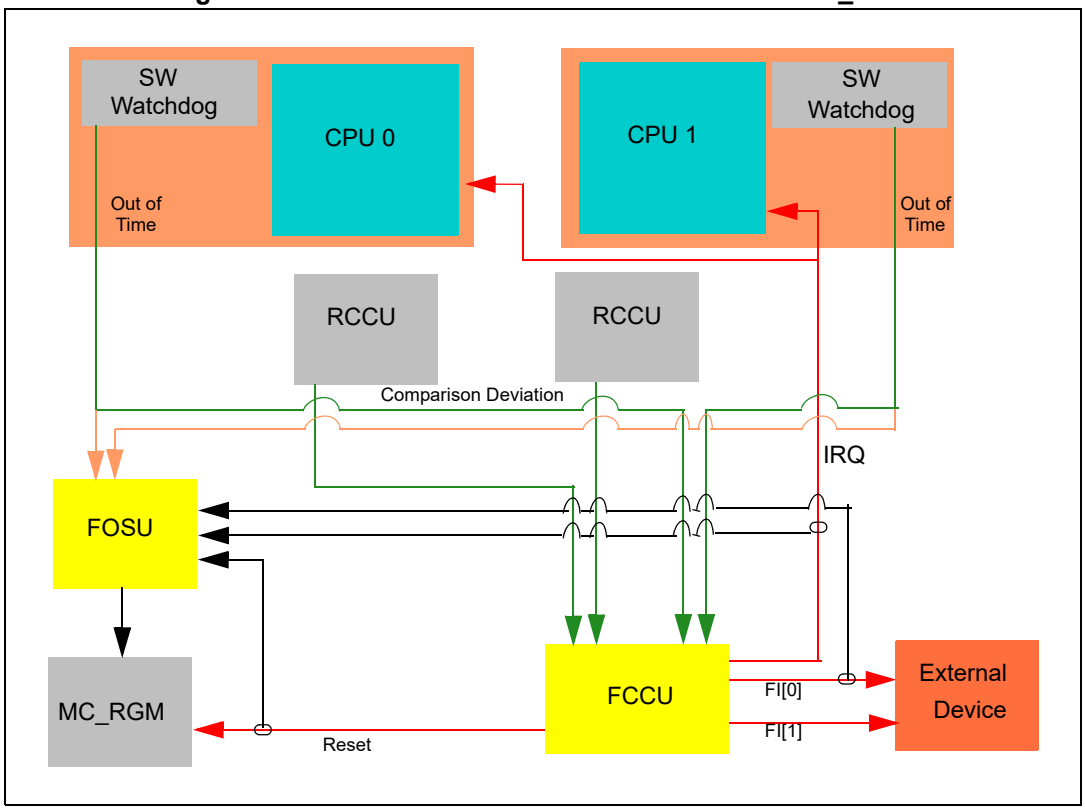
The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset.
- IRQ: NMI or Alarm.
- Error out triggered (by FCCU or by SW).

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is de-asserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as it is used by the FCCU (System reset), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is de-asserted.

The following conditions show a use case of the FOSU:



1. The user configures the channel x of the FCCU to react with a functional reset, either long or short.
2. The user sets the EOUTEN[x] flag of EOUT_SIG_EN register to 0.
3. The software does not clear the FCCU status flag related to the fault x after its first occurrence.
4. The fault x triggers again after the functional reset. Under these circumstances, the FOSU triggers a destructive reset after the FOSU timeout.

The rationale behind is that the functional reset is not able to clear the source of the fault. If the software can't react to the second occurrence of the fault before the FOSU timeout expires, the FOSU triggers a destructive reset.

If the users want to increase the availability of the system by avoiding the destructive reset, they can set the EOUTEN[x] flag of EOUT_SIG_EN register to 1. In such a case, the FOSU does not trigger the destructive reset.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 2392. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

80.8 Use cases and limitations

80.8.1 Mis-configurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.

Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.

4. Software reset is optional.
5. The user must program the FCCU for a higher timeout value than the value hard-coded for FOSU. In this way FCCU reacts later than FOSU expects and as a result, FOSU generates a destructive reset request on its timeout, if a fault occurred when the FCCU was in CONFIG state.

80.8.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, the following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status.
   b) Verify FCCU is in NORMAL state, else repeat step (a) above.
   c) Configure FCCU.
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire.
   b) Check and clear fault status.
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires.
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state.
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU.
   f) Check and clear any new pending fault status until FCCU is in NORMAL state.
   g) Reconfigure FCCU.

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

81 Self-Test Control Unit (STCU2)

81.1 Introduction

The self-test control unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the offline or online, or both, conditions. The hardware can manage the logic built-in self-test (LBIST) and the Memory (SRAM or ROM) built-in self-test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the self-test parameters (LBIST or MBIST scheduling activity, LBIST setup, unrecoverable faults (UF) or recoverable faults (RF) management, CRC and MISR expected values, PLL management, and so on) from Flash memory during the offline self-test phase. This interface is only able to write the configuration parameters and start the self-test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the offline self-test and to load or check the execution of the online self-test.

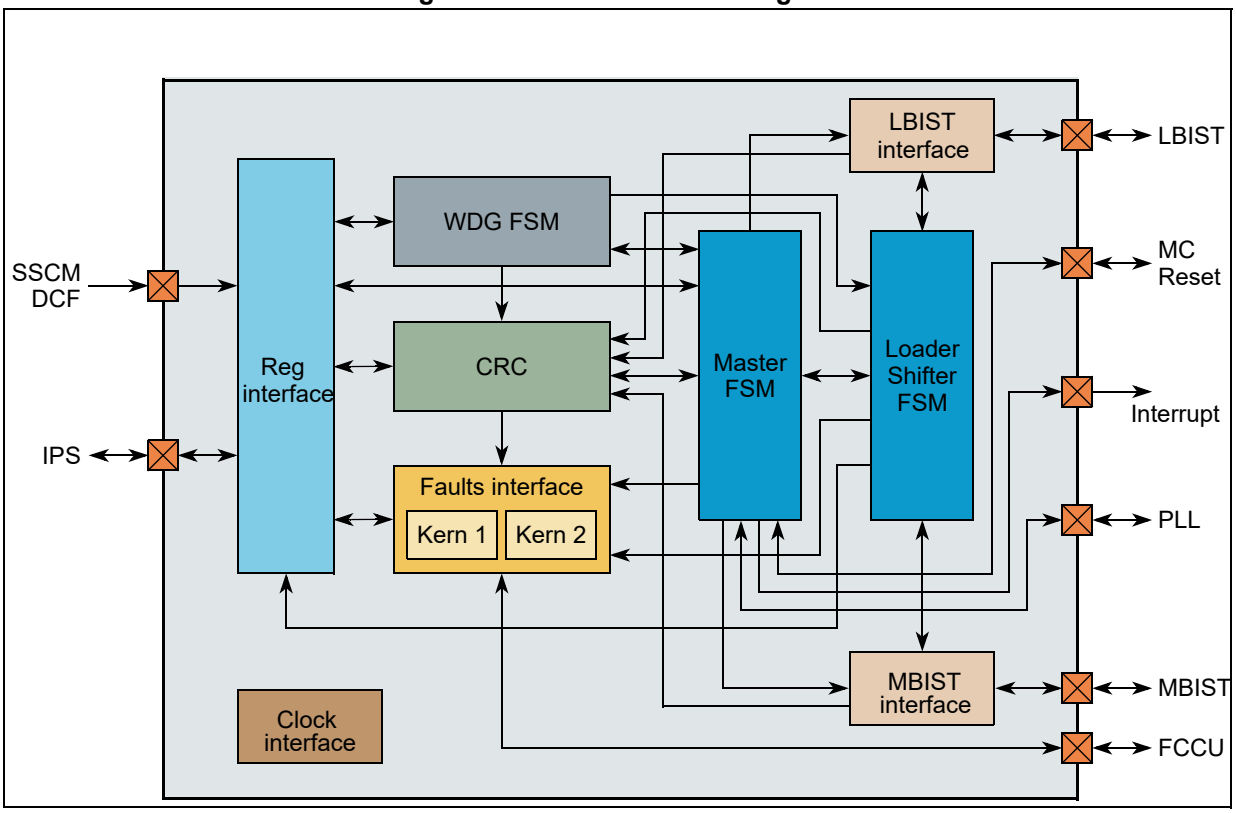
The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the self-test run to increase the STCU2's self-checking capability.
- A programmable watchdog timer (WDG) to check the LBIST and MBIST self-test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before watchdog timeout.
- Direct PLL control during the offline self-test sequence.
- Two interrupt lines enabled only during the online self-test to simplify the software handling of self-test execution end.
- Two sets of registers to separately collect the LBIST or MBIST results during offline and online self-test.

To increase the security of this module, a different security key sequence is also required during offline and online self-test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after self-test sequence is completed.
- The register ITF clock when the WDG timeout is detected after a double security key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

81.2 Main features



- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG[WRP] bit) register interface.
- Programmable scheduler for LBIST or MBIST execution.
- LBIST concurrent/sequential execution.
- MBIST concurrent/sequential execution.
- Programmable LBIST delayed concurrent start.

- 32-bit CRC for STCU2 self-checking capability (enabled by STCU_CFG[CRCEN] bit).
- Online hardware self-test sequence abort capability.
- Programmable internal clock prescaler to reduce internal and MBIST or LBIST TCK clocks.
- Programmable PLL direct control during offline self-test sequence.
- PLL lock signal monitoring during offline and online self-test.
- MBIST dedicated online interrupt source generation.
- Programmable WDG timer for self-check MBIST or LBIST time execution.
- Hard-coded WDG timeout to flag offline initialization errors.
- Hard-coded WDG timeout to auto-lock STCU2 write access after double key sequence.
- LBIST and SRAM or ROM MBIST offline status flags.
- STCU2 internal errors offline status flag.
- LBIST and SRAM or ROM MBIST online status flags.
- STCU2 internal errors online status flag.
- Online hardware abort status flag.
- LBIST and SRAM or ROM MBIST offline or online programmable failure severity (UF/RF).
- STCU2 internal errors offline or online programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software.
- LBIST MISRE registers access to perform redundant software checks.
- Self-test bypass capability.
- Protection mechanism of the global write register based on double security key.
- STCU2 global auto power-saving when:
  - Self-test is completed.
  - bypass mode is selected.
  - WDG timeout is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).
- STCU2 ITF/WDG auto power-saving when hard-coded WDG timeout is detected after software application writes double security key sequence (available when STCU_CFG[WRP] bit is active).

81.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 2393*.

Figure 2393. STCU2 block diagram

The STCU2 module includes the following submodules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface.
- **CRC**: This module is the core of the self-checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface:** This module collects the error conditions respective to LBIST or MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the set or clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- **Clock Block:** This module manages the internal and the LBIST or MBIST TCK clock prescaler, the internal clock gating power saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different watchdogs:
  - A hard-coded Watchdog used to auto-lock the STCU2 access, forcing a reset condition on the double security key registers.
  - A dual function watchdog:

    - After a reset event initializes the STCU2, it is used as a hard-coded watchdog timeout.

    - During LBIST or MBIST runs, it is used as a programmable watchdog timer to check the LBIST or MBIST have completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the self-test sequence.

- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the LBIST or MBIST registers and read back the data to be checked at the end of each self-test operation.
- **LBIST interface**: This module includes the interface between the LBIST engines and the STCU2 controllers of the device.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

81.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The self-test sequence parameters are loaded before offline self-test is executed.
- The IPS access on some specific registers (see *Section 81.5: Register description*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following R/W bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register.
- Any write operation on double security key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the double security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed offline on registers where writes are only allowed during the online self-test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on read only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 81.5: Register description*.

81.4 Functional description

81.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the self-test operations and the other state machines.
- Loader/Shifter State Machine: used to program the MBIST and the LBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the master state machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and LBIST and the timeouts in case of incorrect STCU2 programming.

81.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the offline self-test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the self-test execution phase depends on the self-test conditions and on the content of the STCU_LBRMSW register reported in the following subsections.

In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the associated MC_RGM module.

81.4.2.1 Offline reset generation

At the end of the offline self-test execution, the STCU2 raises the global functional reset. In case of unrecoverable fault during offline self-test execution, the STCU2 generates a request of destructive reset to the MC_RGM module.

81.4.2.2 Online reset generation (only MBIST)

The online execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences respective to the write operations performed by the MBIST execution other than prevent any read/write operation during the self-test execution. If necessary, the software must also restore the memory content (only for RAM) at the end of the self-test execution.

81.4.2.3 Online Reset generation (LBIST enabled)

At the end of the execution, the online execution of the LBIST generates two possible types of reset depending on the status of the STCU_LBRMSW register. See *Section 81.5.16: STCU2 Online LBIST Reset Management (STCU_LBRMSW)*.

If all the selected LBISTs do not require the global functional reset, only the partitions subjected to LBIST are cleaned up applying a pulse on the dedicated reset line. If at least one of the selected LBISTs requires the global functional reset, the global functional reset is raised at the end of the online self-test execution.

Note: If an ABORT condition is detected by STCU2 during the online self-test execution, regardless of the value of the STCU_LBRMSW register, only the respective reset line is pulsed to prevent any potential dangerous system level operations

81.4.3 LBIST and MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST or LBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 81.6.4: Design implementation information*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first LBIST is mapped on 0x00, the second on 0x01, and so on. The first MBIST is mapped at the address 0x10, the second on 0x11 and so on. The additional pointers are in the bitfield STCU_LB_CTRL*x*[PTR] for LBIST*x* (where *x* is the selected LBIST) and STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_LB_CTRL[CSM] and STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the LBIST or MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 81.5.38: STCU2 LBIST Control n Register (STCU_LB_CTRLn)* and *Section 81.5.50: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*.

81.4.4 ABORT management

The STCU2 module provides online self-test execution abort. When the abort is detected, the online self-test operation stops running and the status of the currently running MBIST or LBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run. For an LBIST run, see *Section 81.4.2: Reset management*, regarding reset specific management when abort is detected.

81.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a functional reset that requires the self-test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the online self-test execution run.

81.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the offline self-test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 81.5.2: STCU2 Run Software Register (STCU_RUNSW)*.

When STCU_RUN[RUN] is set to start the offline self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configuration parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end of the MBIST run, the clock source reverts to the original one.

The same behavior applies when STCU_RUN[LBPLLEN] is active and LBIST is currently selected.

81.4.6 Interrupt interface

There are two interrupt sources:

- One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1).
- One triggered by LBIST (enabled by programming STCU_RUNSW[LBIE] = 1).

As described in *Section 81.5.2: STCU2 Run Software Register (STCU_RUNSW)*, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential runs in the same session, the number of interrupts generated is equivalent to the number of sequential sessions, thus providing fine granularity with respect to the completed run.

The MBIFLG bit in the *STCU2 Interrupt Flag Register (STCU_INT_FLG)* registers flag interrupt condition and allows the clearing of interrupt requests. Interrupt bit to be cleared by writing the respective bit to 1 to enable the next interrupt request.

81.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an unrecoverable failure (UF) or a recoverable failure (RF) during the self-test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

81.4.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished on time.

81.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the self-test sequence (safety mode).
- Bypass the self-test sequence by setting the STCU_RUN[BYP] bit. If Bypass bit is configured/set by DCF it cannot be anymore changed on the device even though STCU_RUN register itself is not Write once.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded watchdog timeout flags the incorrect behavior. See *Section 81.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* for more details.

81.4.8.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time is configured as described in *Chapter 81.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* to account for the overall execution time of the self-test sequence. If the selected LBISTs or MBISTs are not yet completed:

- During an offline self-test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBE1/2/3/4 or STCU_LBE registers.
- During an online self-test, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBE1SW/2SW/3SW/4SW or STCU_LBESW.

In case of multiple sequential runs in the same online or offline session and the timeout occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 81.4.2: Reset management*.

81.4.8.3 Write access timeout

The access on the STCU2 registers during the self-test configuration phase (both online or offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software self-test configuration as the software application may enable write access to the STCU2 registers.

81.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomy to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the self-test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

81.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

81.5 Register description

The STCU2 registers are listed in *Table 2329*.

Note: n and k are variables representing the repeated register blocks of the multiple LBISTs and MBISTs: n is 0, k ranges from 0 up to 104.

Table 2329. STCU2 memory map

Address offset	Register Name	Location

81.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the offline self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is still active.

Offset: 0x0000 Access: User read/write

Figure 2394. STCU2 Run Register (STCU_RUN)

Table 2330. STCU_RUN field descriptions

Field	Description
21 BYP	Bypass mode 0 Offline self-test is active. If the STCU_RUN[RUN] bit is not set before the hard-coded WDG timeout, the WDTO error is generated in the STCU_ERR_STAT register. 1 Offline self-test is bypassed and access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
22 MBPLLEN	Offline MBIST with PLL0 Enabled 0 Offline MBIST is executed without using the on-chip PLL0. 1 Offline MBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
23 LBPLLEN	Offline LBIST with PLL0 Enabled 0 Offline LBIST is executed without using the on-chip PLL0. 1 Offline LBIST is executed enabling the on-chip PLL0 control interface selecting the parameters defined in STCU_PLL_CFG register.
31 RUN	RUN The RUN bit is automatically cleared by the STCU2 when the offline self-test procedure has been completed. 0 Idle 1 Offline self-test procedure is running

81.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the online self-test procedure if some configuration bits are required *only* during this self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- Online self-test phase is active. The online condition starts when the offline condition finishes. In this condition, the system is alive and the SW can program the STCU.

Figure 2395. STCU2 Run Software Register (STCU_RUNSW)

Table 2331. STCU_RUNSW field descriptions

Field	Description
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories, the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are concluded. If there is a sequence of concurrent runs in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[MBIFG] bit in between.
21 LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST, the STCU2 forces an interrupt request to notify LBIST of the concurrent selected partitions are concluded. If there is a sequence of concurrent run in the same self-test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[LBIFG] bit in between.
22 MBSWPLLEN	Online MBIST with PLL1 Enabled 0 Online MBIST is executed without waiting for PLL1 lock. 1 Online MBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.

Table 2331. STCU_RUNSW field descriptions (continued)

Field	Description
23 LBSWPLLEN	Online LBIST with PLL1 Enabled 0 Online LBIST is executed without waiting for PLL1 lock. 1 Online LBIST is executed once PLL1 is locked. PLL1 configuration used is the one specified in the PLLDIG PLL1DV register. STCU2 does not take the PLL1 control but monitors the PLL1 lock signal to check if PLL1 is working correctly.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the online self-test procedure has been completed. 0 Idle. 1 Online self-test procedure is running.

81.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2 asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the offline or online test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: Note that after the self-test sequence has been completed or the bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.

In case of invalid access or sequence (Keys1 and 2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG timeout, STCU2 write access is locked and the WDG and register ITF clocks are switched off. Also in this case the correct sequence must be applied in order to re-enable write access to the STCU2 and the WDG and register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG timeout expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 0x00000000.

81.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the offline and online test steps.

Access to this register is described in *Figure 2397*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the online self-test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Offset: 0x000C Access: User read/write

1. You can always read this field. In the offline self-test phase, you can always write to this field. In the online self-test phase, you can write to this field only when WRP = 0.

Figure 2397. STCU2 Configuration Register (STCU_CFG)

Table 2333. STCU_CFG field descriptions

Field	Description
0:7 PTR	LBIST or MBIST pointer. PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0, then the LBIST0 is initially scheduled. (0x00 to LBIST - 1) – pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution.
8:15 LB_DELAY	Delay LBIST run. LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. 0x00 No delay 0x01 1 × 16 STCU2 Core clock cycles 0x02 2 × 16 STCU2 Core clock cycles 0x03 3 × 16 STCU2 Core clock cycles … 0xFD 253 × 16 STCU2 Core clock cycles 0xFE 254 × 16 STCU2 Core clock cycles 0xFF 255 × 16 STCU2 Core clock cycles **Note:** STCU2 is being clocked from PBRIDGE Clock. Refer to Clocking chapter for PBRIDGE clock frequency value.
23 WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after offline self-test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after offline self-test sequence has completed, thus preventing any user application write operation.

Table 2333. STCU_CFG field descriptions (continued)

Field	Description
26 CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values. 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS test is not enabled 1 MBIST PMOS test is enabled
28 MBU	MBIST MBU Test Enabled. 0 MBIST full algorithm or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified multi-bit upset algorithm is used to check the RAM. If a ROM is selected, the applied algorithm will be standard one without PMOS test. ***This bit overwrites the PMOSEN feature***.
29:31 CLK_CFG	Logic, memory BIST and STCU2 core clock configuration. CLK_CFG defines the ratio between the STCU2 core clock and the TCK used to program the LBIST, the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 PBRIDGE_CLK 001 PBRIDGE_CLK/2 010 PBRIDGE_CLK/3 011 PBRIDGE_CLK/4 100 PBRIDGE_CLK/5 101 PBRIDGE_CLK/6 110 PBRIDGE_CLK/7 111 PBRIDGE_CLK/8 **Note:** refer to Clocking chapter for PBRIDGE_CLK clock frequency value.

81.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the offline LBISTs or MBISTs are performed and STCU_RUN[MBPLLEN] = 1 or STCU_RUN[LBPLLEN] = 1.

In the online state, these bits are not effective. It is also possible to set the PLL during active online mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when offline self-test phase is active.

Figure 2398. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Note: f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.

Table 2334. STCU_PLL_CFG field descriptions

Field	Description
2:7 PLLODF	PLL Output Division Factor. The value of this field drives the output division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the respective PLL's output division factor.
13:15 PLLIDF	PLL Input Division Factor. The value of this field drives the input division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the respective PLL's input division factor.
25:31 PLLLDF	PLL Loop Division Factor. The value of this field drives the loop division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the respective PLL's loop division factor.

81.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for LBIST and MBIST execution, providing protection against dead-locks or infinite loop conditions during the self-test procedure. When the offline self-test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15 to 0 define the timeout before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the offline or online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active
- Online self-test phase is active and STCU_CFG[WRP] = 0

Offset: 0x0014 Access: User read/write

Figure 2399. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 2335. STCU_WDG field descriptions

Field	Description
0:31 WDGEOC	Watchdog End of Count Timer. This value must be set in order to define the time budget respective to the offline and online self-test execution and check that everything is working correctly in this timeslot. The allowed time delays are: 0x00000000 1*k*STCU2 core clock cycles 0x00000001 2*k*STCU2 core clock cycles 0x00000002 3*k*STCU2 core clock cycles … 0xFFFFFFFD 4294967294*k*STCU2 core clock cycles 0xFFFFFFFE 4294967295*k*STCU2 core clock cycles 0xFFFFFFFF 4294967296*k*16 STCU2 core clock cycles where k is: – ‘1’ for offline self-test – ‘16’ for online self-test **Note:** STCU2 core clock is specified through STCU_CFG[CLK_CFG] field.

81.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST and LBIST interrupt pending bits. These bits are effective only during the online self-test phase and managed only when the respective control bit in the STCU_RUNSW register (MBIE and LBIE) enabled.

Offset: 0x0018 Access: User read/write

Field	Description
30 MBIFLG	MBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled MBIST is completed is pending. Write 1 to clear the bit.
31 LBIFLG	LBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the online execution of the concurrent scheduled LBIST is completed is pending. Write 1 to clear the bit.

81.5.8 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the self check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

CRC-32 (ethernet protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Note: The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.

81.5.9 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the offline and online self-test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Field	Description
0:31 CRCR	Read CRC signature

81.5.10 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the online and offline self-test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 81.6.4: Design implementation information*.

Access to this register is described in *Figure 2403* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

1. You can always read this field. The content of this field is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Figure 2403. STCU2 Error Register (STCU_ERR_STAT)

Table 2339. STCU_ERR_STAT field descriptions

Field	Description
6 ABORTHW	Online hardware abort flag. 0 No hardware abort was requested during the online self-test sequence 1 A hardware abort was detected during the online self-test sequence
11 LOCKESW	Online LOCK Error. 0 If PLL is enabled, it is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the online self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW[LBSWPLLEN] is set or during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1, or during both.
12 WDTOSW	Online Watchdog timeout. 0 LBIST and MBIST time slots have completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not completed in the assigned watchdog time or there are internal mismatches in the end of execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 CRCSSW	Online CRC Status. This flag is activated *only* when online self-test is performed and STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to 0) 1 Failed CRC comparison
14 ENGESW	Online Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	Online Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the unrecoverable faults condition 1 There are errors that trigger the unrecoverable faults condition

Table 2339. STCU_ERR_STAT field descriptions (continued)

Field	Description
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the recoverable faults condition 1 There are errors that trigger the recoverable faults condition
27 LOCKE	Offline LOCK Error 0 The PLL is correctly locked during the self-test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the offline self-test sequence execution. The online self-test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLLEN] = 1 or during the MBIST run when STCU_RUN[MBPLLEN] = 1, or during both.
28 WDTO	Offline Watchdog timeout. 0 LBIST and MBIST time slots have been completed within the assigned watchdog time. 1 LBIST and MBIST time slots have not been completed within the assigned watchdog time or there are internal mismatches among end of execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the watchdog reach the end of count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Offline CRC status. This flag is activated *only* when offline self-test is performed STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
30 ENGE	Offline Engine Error. 0 Valid engine execution 1 Invalid engine execution. The following conditions set this bit: – STCU2 state machines (watchdog, master and loader/shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Offline Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)

81.5.11 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of Unrecoverable or recoverable faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

81.5.12 STCU2 Offline LBIST Status Register (STCU_LBS)

The STCU_LBS register includes the results corresponding to the execution of the selected offline LBIST. The size of the register depends on the number of LBISTs.

Note: On this device, the LBIST is 1.

Offset: 0x002C Access: User read

81.5.16 STCU2 Online LBIST Reset Management (STCU_LBRMSW)

The STCU_LBRMSW register defines the online reset mapping for each LBIST. Global or specific functional resets can be programmed depending on the online Self Test requirements and top level integration architecture.

The size of the register depends on the number of LBISTs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Offset: 0x003C Access: User read/write

81.5.17 STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)

The STCU_LBUFM register defines the fault mapping of each LBIST in terms of unrecoverable or recoverable fault. The size of the register depends on the number of LBISTs.

Note: On this device, the LBISTs are 1.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Figure 2425. STCU2 Online MBIST 3 End Flag Register (STCU_MBE3SW)

1. The availability of this field is based on the number of NMCUT available in this device. For details, refer to *Table 120: MBIST registers in STCU2 with available fields* in Device configuration chapter.

Table 2361. STCU_MBE3SW field descriptions

Field	Description
0:31 MBESW[95:64]	MBESW*x*: online End status (64 to 95) of the selected MBIST 0 MBIST execution still ongoing 1 MBIST execution finished

81.5.33 STCU2 Online MBIST 4 End Flag Register (STCU_MBE4SW)

The STCU_MBE4SW register includes the end flag respective to the execution of the selected online MBIST in the range NMCUT = 96 to 127. The size of the register depends on the amount of RAM or ROM subject to BIST. The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Note: On this device, the selected offline MBIST is in the range 96 to 104.

Note: Refer to Section 7.10.6: STCU2 configuration in Device configuration chapter for the number of NMCUT available in this device.

Figure 2431. STCU2 LBIST Control *n* Register (STCU_LB_CTRL*n*)

Table 2367. STCU_LB_CTRL*n* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer, the CSM bit has to be set Sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current LBIST has been completed. (0x0 to NLBIST - 1) pointer to LBIST (0x10 to 0x10 + MBIST - 1) pointer to MBIST 0xFF pointer to NIL. No BIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
13:15 SHS	Shift Speed 000 Shift at full rate (STCU core clock) 001 Shift at 1/2 rate (STCU core clock) 010 Shift at 1/3 rate (STCU core clock) 011 Shift at 1/4 rate (STCU core clock) 100 Shift at 1/5 rate (STCU core clock) 101 Shift at 1/6 rate (STCU core clock) 110 Shift at 1/7 rate (STCU core clock) 111 Shift at 1/8 rate (STCU core clock)

Table 2367. STCU_LB_CTRL*n* field descriptions (continued)

Field	Description
16:19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
20:23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles … 1111 15 delay cycles
26 PFT	Past Flush Test The LBIST controller, by default apply 32 flush test patterns. This bit allows to skip/apply the flush test pattern sequence. 0 Apply flush test patterns 1 Skip flush test patterns
27:31 CWS	Capture window size 00000 Controller waits 16 shift cycle for capture to finish. 00001 Controller waits 1 shift cycle for capture to finish. 00010 Controller waits 2 shift cycles for capture to finish. … 00111 Controller waits 7 shift cycles for capture to finish.

81.5.39 STCU2 LBIST PC Stop *n* Register (STCU_LB_PCS*n*)

The STCU_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self-test phase is active.
- Online self-test phase is active and STCU_CFG[WRP] = 0.

Figure 2443. STCU2 MBIST Control *k* Register (STCU_MB_CTRL*k*)

Table 2379. STCU_MB_CTRL*k* field descriptions

Field	Description
0:7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set sequential (0) to define this is the end of the list. The self-test procedure is stopped when the current MBIST has been completed. (0x00 to LBIST - 1) — pointer to LBIST PTR = 0x10 + $MBIST_i$ (Pointer to MBIST) for i = 0 to XX: please refer to the MBIST partitions table for the $MBIST_i$ code. PTR = 0xFF: Pointer to NIL. No additional MBIST execution. Any other value is considered as invalid pointer and an error is set in the STCU_ERR register.
8 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode

81.6 Use cases and limitations

The STCU2 module is designed to give high flexibility during the online and offline self-test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Offline self-test sequence after a reset trigger event
- Bypass mode of the self-test sequence after a reset trigger event
- Online self-test sequence

The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.

81.6.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and LBIST or MBIST execution parameters stored in the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the system RAM or ROM according to the system specifications. The sequence is the following:

- Unlock the offline STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFM1/2/3/4 registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, the STCU_LB_PRPGL/H can also be programmed to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the offline self-test sequence in the STCU_CRCE register.
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.
- Program the RUN bit in the STCU_RUN register to enable the offline self-test execution and the LM/BPLLEN bits to enable the PLL during LBIST or MBIST execution according to STCU_PLL_CFG register content.
- Start the offline self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the self-test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application read the STCU_LBS flag register to check the failed LBIST when UF or RF conditions are detected.

- The software application read the STCU_LBE flag register to check the LBIST still on-going when UF or RF are detected.
- The software application read the STCU_MBS1/2/3/4 flag registers, depending on the number of memories, to check the failed RAM or ROM memory BIST when UF or RF are detected.
- The software application read the STCU_MBE1/2/3/4 flag registers, depending on the number of memories, to check the RAM or ROM memory BIST still running when UF or RF are detected.
- The software application read the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- For each LBIST, the software application reads the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after offline self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

81.6.2 Online self-test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the LBIST or MBIST execution. Since the online operations clean up the content of the respective digital logic (LBIST) or RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the online STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 online self-test registers.
- The LBIST, MBIST and STCU2 internal fault reaction should already be programmed during the offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_LBUFM, STCU_MBUFM1/2/3/4 and STCU_ERR_FM.
- Program the Reset management during online LBIST execution setting the STCU_LBRMSW register.
- The STCU_LB_CTRL, STCU_LB_PCS should already be programmed during offline self-test sequence. If they have not been programmed or there is a need to change them, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.

- Overwrite/Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBISTs are running simultaneously to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the online self-test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the online self-test execution, the L/MBIE to enable the Interrupt requests, and the L/MBSWPLLEN bits to enable the PLL lock signal monitor during LBIST or MBIST execution.
- Start the online self-test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- If the L/MBIE are enabled, an interrupt is generated at the end of all the LBIST or MBIST runs. The software application has to manage these interrupt signals and clean up the respective flags (L/MBIFLG) in the STCU_INT_FLG register.
- The STCU2 switches off the core clock at the end of the self-test run.
- The activated functional reset is managed by the STCU_LBRMSW.
- If at least one of the selected LBISTs enables the global functional reset, the STCU2 requests a functional reset which restarts the system. If all the selected LBISTs enable their own dedicated functional reset, only these local reset lines are applied and only the respective LBIST partitions are cleaned up.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBESW flag register to check the LBIST is still running when UFs or RFs are detected.
- The software application reads the STCU_MBS1SW/2SW/3S+W/4SW flag registers, depending on the number of memories, to check the failed RAM/ROM memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBE1SW/2SW/3SW/4SW flag registers, depending on the number of memories, to check the RAM/ROM memory BIST is still running when UFs or RFs are detected.
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.

- For each LBIST, the software application reads the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after online self-test execution has successfully completed are an additional safety layer added to improve the already implemented auto self-test feature included in STCU2.

81.6.3 Bypass USER Mode

In this mode, the user application parameters stored in Flash and read by SSCM are written to skip the self-test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the offline Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the self-test sequence is not applied and the system can wake up and start the user application.

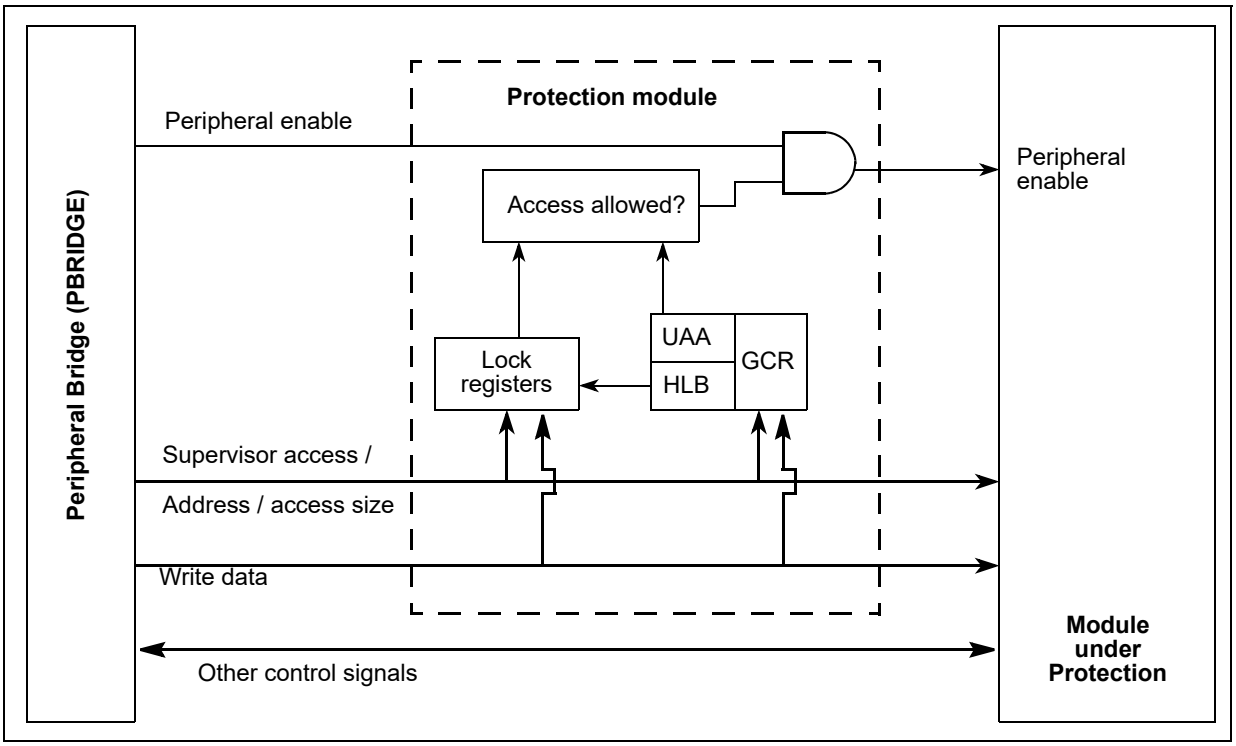
81.6.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the on/offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- As the software has full control of the system while applications are running during the online self-test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

82 Register Protection (REG_PROT)

82.1 Introduction



82.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Refer to Chapter 7: Device configuration for device-specific details of the protected registers and bytes.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 2444*.

Figure 2444. REG_PROT block diagram

82.1.2 Features

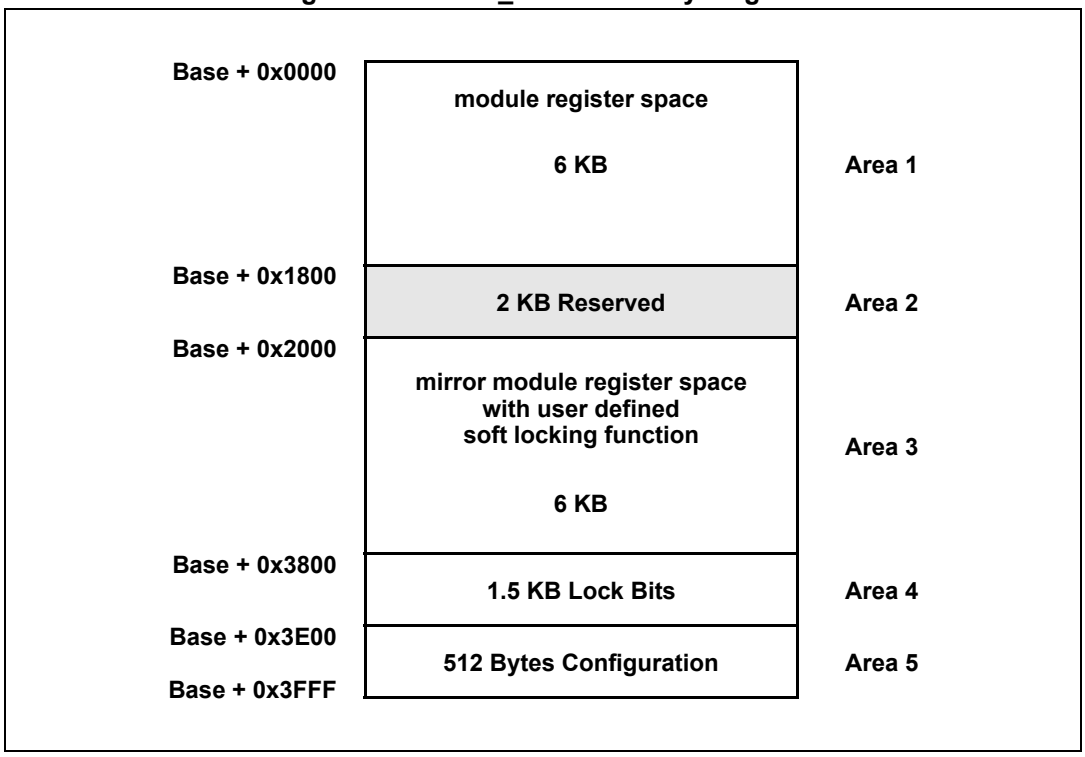
Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set.

82.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.



82.2 External signal description

There are no external signals.

82.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 2445*.

Figure 2445. REG_PROT memory diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

82.3.1 Memory map

Table 2380 shows the memory map for a module which is protected via a REG_PROT module.

Table 2380. REG_PROT memory map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*Section 82.3.2.1*

82.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

82.3.2.1 Module registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

82.3.2.2 Module register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 2382*.

82.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 2381. Soft lock bits vs. protected address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

Note: As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3800-0x3DFF

Access: Read always
Supervisor write

5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[*n* *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[*n* *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[*n* *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writable

82.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset: 0x3FFC

Access: Read Always

Figure 2447. Global Configuration Register (GCR)

Table 2383. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register cannot be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and cannot be modified 0 All SLB bits are accessible and can be modified.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

82.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

82.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size is device and module specific, please refer to *Chapter 7: Device configuration for details.*

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

82.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

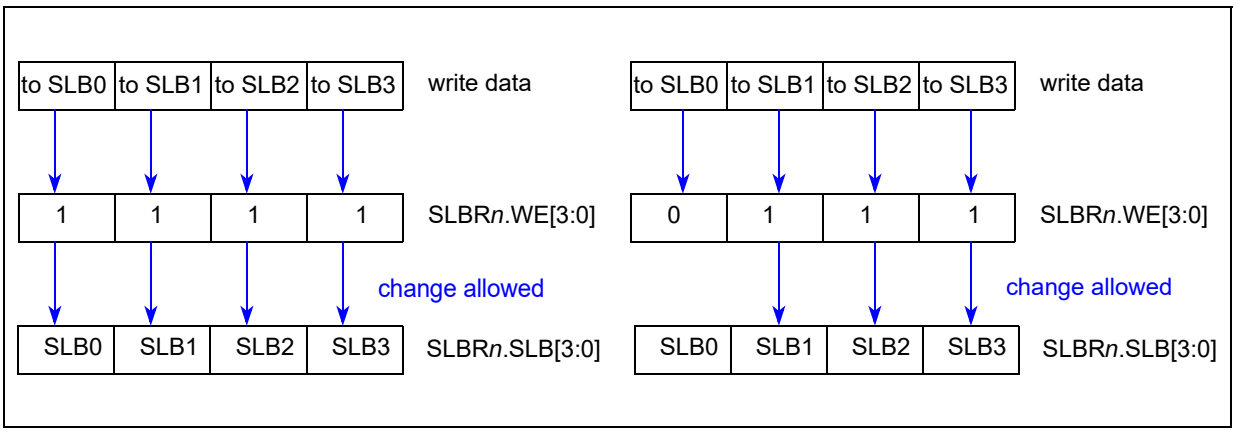
Both methods are explained in the following sections.

82.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 2448 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 2448. Change lock settings directly via Area #4



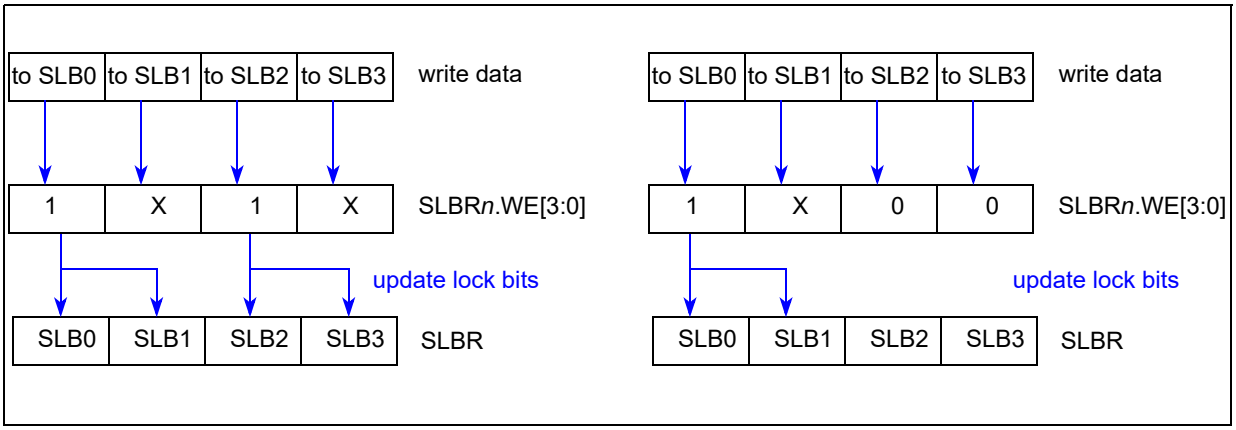


Figure 2448 shows four registers that can be protected 8-bit wise. In *Figure 2449* registers with 16-bit protection and in *Figure 2450* registers with 32-bit protection are shown:

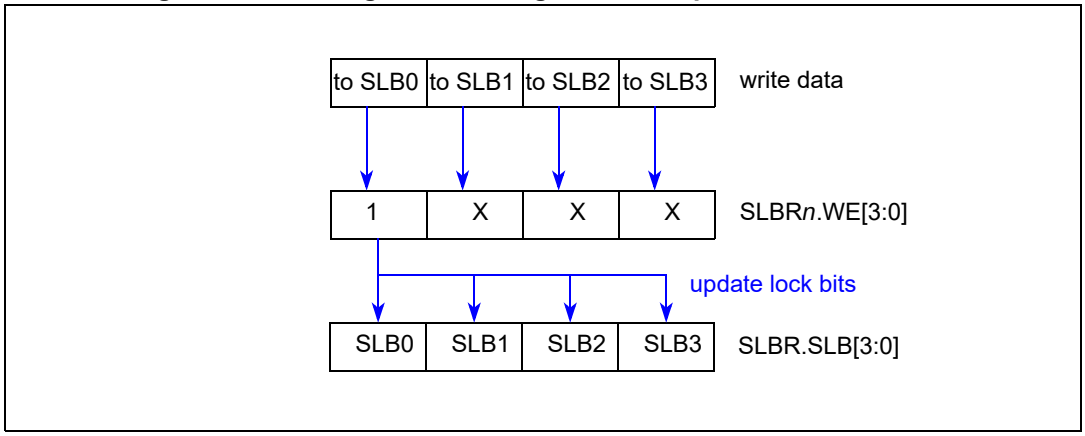
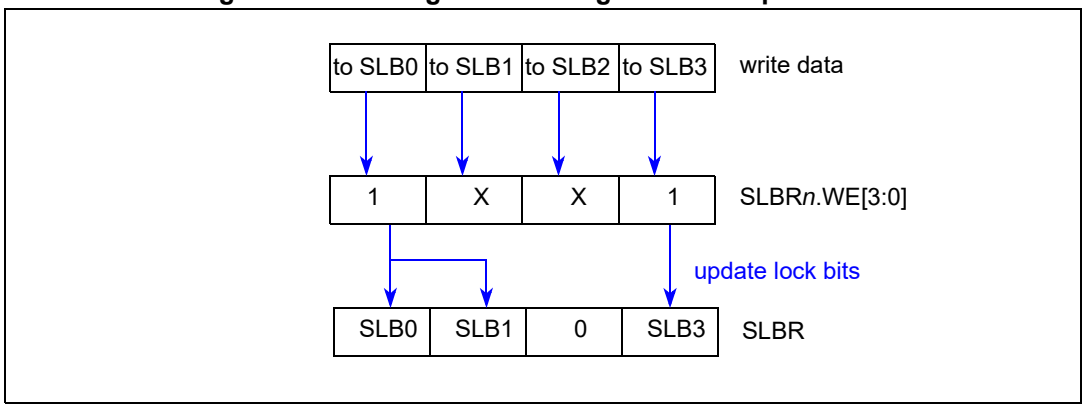
Figure 2449. Change lock settings for 16-bit protected addresses



On the right side of *Figure 2449* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 2449* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

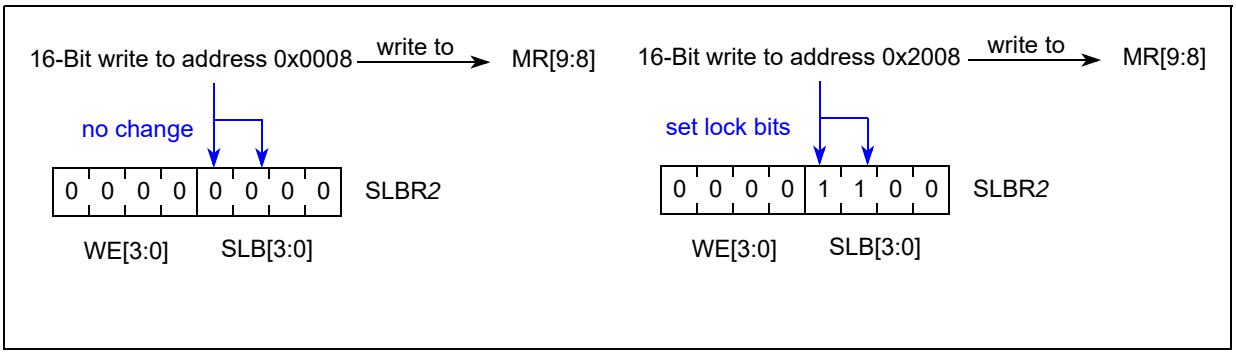


In *Figure 2450* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 2450. Change lock settings for 32-bit protected addresses

In *Figure 2451* an example is shown which has a mixed protection size configuration:

Figure 2451. Change lock settings for mixed protection

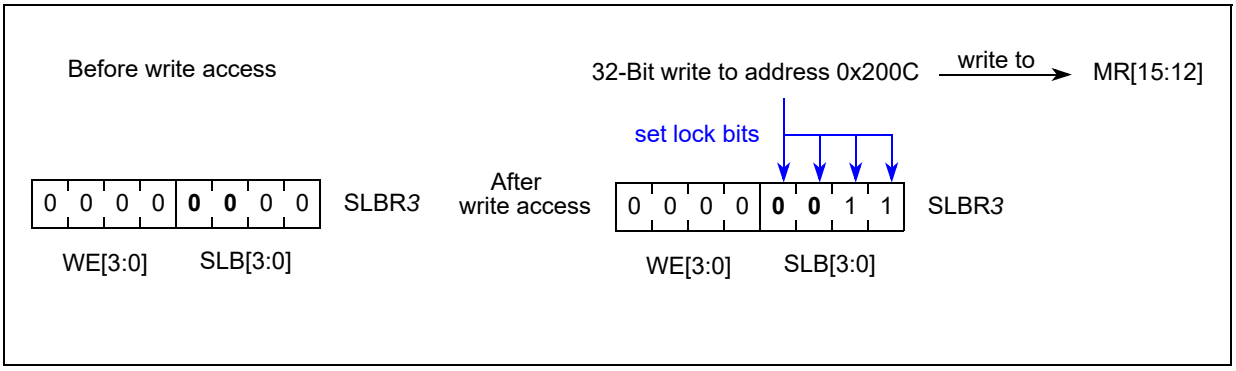


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

82.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 2452* shows one example:

Figure 2452. Enable Locking Via Mirror Module Space (Area #3)



When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 2449*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 2449*).

Figure 2453 shows an example where some addresses are protected and some are not:

Figure 2453. Enable locking for protected and unprotected addresses

In the example in *Figure 2453* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

82.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 82.4.2.1: Change lock settings directly via Area #4* and *Section 82.4.2.2: Enable locking via mirror module space (Area #3)* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

82.4.3 Access errors

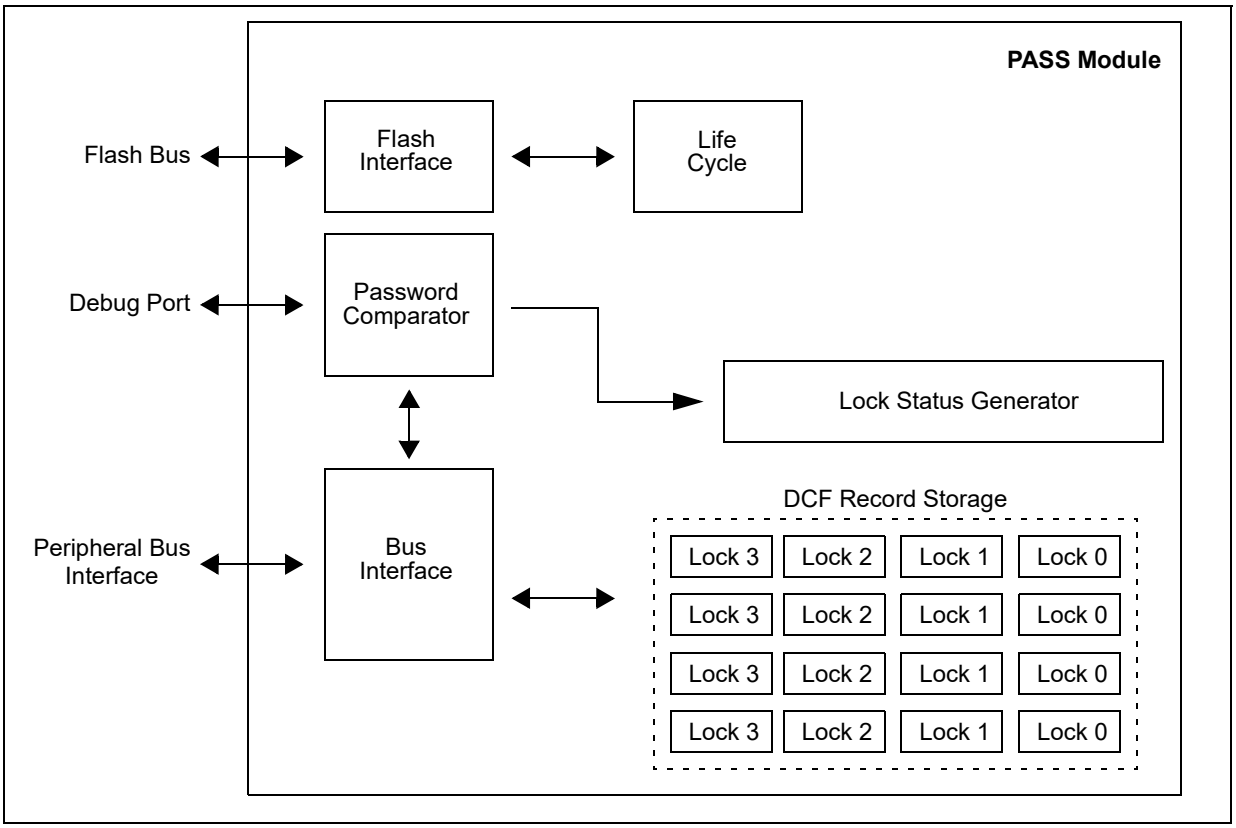
The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 2445*.

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set.

82.5 Initialization/application information

82.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 82.3.2*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.



83 Password and Device Security Module (PASS)

83.1 Introduction

83.1.1 Overview

The Password and Device Security (PASS) module shown in *Figure 2454* receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 2454. PASS module block diagram

83.1.2 Features

The PASS includes these distinctive features:

- Lifecycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Fuse Bypass Configuration and Password Comparison

83.1.3 Modes of operation

The PASS operates identically in all system modes.

83.2 External signal description

The PASS has 1 external pin that is used for Production Disable control (Refer to *Section 83.4.2: Production Disable*).

83.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 83.4: DCF clients*.)

Table 2384 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

Do not write to address 0x00D0 with bit value 0.

0x013C	Lock 3 Status Register (LOCK3_PG3)	R/W	0xXFXXXXXX[2]	0x013C	*Section 83.3.1.9*

1. DCF Client Address column shows what is the DCF used to preload the register value during reset. If the column value is “None”, it means that the register value at reset is fixed in hardware.
2. Reset value depends on password group lock state.

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

83.3.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

83.3.1.1 Lifecycle Status register (LCSTAT)

The Lifecycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device lifecycle forward), but never to revert the lifecycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external lifecycle management module (like SSCM). It is a 3-bit lifecycle. This register simply displays the lifecycle input from external blocks.

Offset: 0x0000 Access: Software Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

83.3.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.

The ID of the accessing master sets the CMST field of the Challenge Status register.

CIN register functions are as shown in *Table 2388*.

Table 2388. CIN*n* register field descriptions

Field	Description
0:31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

83.3.1.5 Clock Jitter Enable (CJE)

Software accessible one time writable register. This register stores the jitter enable status for the Pseudo Random Clock Divider Module (PRCD). The default value of this register if '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial communications modules includes large amounts of pseudo random clock edge jitter, making the serial communications modules unusable. For details about which serial communications modules are affected, refer to the clocking section of the Reference Manual.

For more information on Production disable, refer to *Section 83.5.5: Production Disable*

Debug access is blocked when Production disable bit[0] (Gated Debug Enable) is asserted, the Chip is *In Field* and Clock Jitter is not enabled.

Offset: 0x00D0 Access: Software Read/Write

Figure 2459. Clock Jitter Enable (CJE)

Table 2389. CJE field descriptions

Field	Description
31 CJE	Clock Jitter Enable 0 Clock Jitter is enabled. The baud rate clock to Serial communications modules includes large amounts of pseudo random clock edge jitter. 1 Clock Jitter is disabled. The baud rate clocks function normally.

83.3.1.6 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the lifecycle has matured to *OEM Production* or older.

Offset: 0x0100 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	TSLOCK	ATSL	LOWLOCK													
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MIDLOCK															
Reset	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)	x(1)

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 2460. Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

LOCK0_PG*n* register functions are as shown in *Table 2390*.

Table 2390. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTEST NVM Lock. This bit is used to lock the UTEST NVM block from programs on the alternate interface (erase protection not needed since UTEST NVM is OTP and not erasable).
2:15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16:31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, indicating that a block is locked.

Warning: **When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.**
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

When Production Disable register bit[1](BAF PLock Hardware Interlock enable) is asserted and lifecycle is *In Field*, then the external signal is ORed with BAF_plock(low_lock[0]) of LOCK0_PGx.

83.3.1.7 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x0104 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Figure 2461. Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

LOCK1_PG*n* register functions are as shown in *Table 2391*.

Table 2391. LOCK1_PG*n* register field descriptions

Field	Description
16:31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

83.3.1.8 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the lifecycle is matured to *OEM Production* or older.

Offset: 0x0108 + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

1. If no DCF records have been written to change the lock state, the bit resets to ‘1’.

Figure 2462. Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 2392*.

Table 2392. LOCK2_PG*n* register field descriptions

Field	Description
0:31 A256KLOCK	256K address space block lock A256KLOCK[31:0] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

83.3.1.9 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the lifecycle matures to *OEM Production* or older.

Offset: 0x010C + *n**0x10 (*n* = 0 to 3) Access: Software Read/Write & DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Not all devices include this field. Refer to the device reference manual's chip configuration chapter for details.
2. Reset value depends on lifecycle. If lifecycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Figure 2463. Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

LOCK3_PG*n* register functions are as shown in *Table 2393*.

Table 2393. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally (if lifecycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked).
1 DBL	Debug Interface Lock The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM). 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked.

Table 2393. LOCK3_PG*n* register field descriptions (continued)

Field	Description
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared. 1 Only the Master which unlocked the passgroup can change the passgroup settings.
4:7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
11 RL4	Read Lock Region 4 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 4 is not protected. 1 Region 4 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
12 RL3	Read Lock Region 3 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
13 RL2	Read Lock Region 2 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
14 RL1	Read Lock Region 1 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
15 RL0	Read Lock Region 0 lock bit The default value of this bit would be ‘1’ if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected. **Note:** The region lock plays an important role on protecting the flash from programming and reading operations.
16:31 A256KLOCK	256K address space block lock A256KLOCK[47:32] A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

Warning: When Password Slot Access bits are set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to In-Field renders the part unusable.
When Password Slot Access bits are not set, failure to program valid passwords or DCF records for all password groups before lifecycle matures to OEM Production renders the part unusable.
However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase are possible. However, unless the lifecycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to *Section 83.5.3: Flash Memory Read Protection*.

Once a censored device enters the *Failure Analysis* lifecycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash UTest region controlled by LOCK3[0]is read unlocked in Failure Analysis lifecycle.

83.4 DCF clients

Where a DCF client is listed, the reset value of that register may automatically be preloaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section.

83.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Censorship DCF client defines whether the MCU is censored or not (Refer to *Table 2384*).

DCF Client Address: 0x00B0 Censorship — Access: DCF Record Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 2464. Censorship register (not accessible)

Table 2394. Censorship register field descriptions

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored. If this value is anything other that 0x55AA, the MCU is censored.

83.4.2 Production Disable

Note: Production Disable is a DCF client that is not accessible by software. It is automatically preloaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable and Hardware Interlock aspects of the Production Disable feature (refer to Table 2384).

Note: The DCF client implements 2 bits with a default value of '0'. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, refer to *Section 83.5.5: Production Disable*

DCF Client Address: 0x00C0 Production Disable Access: DCF Record Write Once Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2465. Production Disable DCF client

Table 2395. Production Disable DCF Client field descriptions

Field	Description
HI	Hardware Interlock 0 BAF Flash block programming is controlled by PASS_LOCK0[BAF] bits. 1 BAF Flash block is locked for programming while external hardware pin is asserted '0'.
DD	Debug disable 0 Debug Interface is Enabled and Disabled using Censorship, JTAG password & PASS_LOCK3[DBL] bit as described elsewhere. 1 Debug Interface is disabled while Clock Jitter is NOT enabled .

83.4.2.1 Debug Disable (DD)

Note: Debug Disable is an optional feature that, once the Lifecycle is In Field or beyond, overrides all other debug controls and disables the debug interface (refer to Table 2398).

83.4.2.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the lifecycle is In Field or beyond, prevents programming of the BAF Flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

83.4.3 Fuse Bypass DCF Client

This DCF client is used to configure the password protected Fuse bypass feature. Refer to *Section 83.5.6: Fuse Bypass* for details.

The Fuse Bypass DCF Client is not directly readable in software, but the state of the Fuse Bypass bit can be read in the LCSTAT register (refer to *Lifecycle Status register (LCSTAT)*).

The DCF client is written during Destructive Reset Phase 3 and compared during Functional Reset Phase 3; if this compare does not match the data already written, the logic will decode No fuse bypass.

DCF Client Address: 0x00E0 Fuse Bypass — Access: DCF Record Write Once Only

1. This bit is not defined.
2. This value is loaded by DCF Record during reset.

Figure 2466. Fuse Bypass DCF Client

Table 2396. Fuse Bypass register field descriptions

Field	Description
31 FB	Fuse Bypass enable 0 The Fuse can NOT be Bypassed 1 Bypass of the fuse is possible with a password

83.4.4 Password Slot Access

Password Slot Access is a write-once DCF client. The DCF controls access for both read and write starting from Lifecycle = OEM Production. If the bit is 1, the slot is still accessible when Life Cycle = OEM Production (and blocked starting from Life Cycle = In Field). Otherwise if the bit is set to 0, the slot is blocked starting from Life Cycle = OEM Production.

DCF Client Address: : 0x00B4 Password Slot Access — Access: DCF Record Write Once

Figure 2467. Password Slot Access DCF Client

Table 2397. Password Slot Access DCF Client field descriptions

Field	Description
28:31	Password Slot Access per password group

83.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

83.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (refer to *Section 83.4.1: Censorship*).

83.5.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (refer to *83.3.1.9: Password Group n - Lock 3 status register (LOCK3_PGn)*). Both of these debug enabling options are further conditioned by lifecycle and Production Disable.

The following table describes all options for enabling/blocking Debug Interface access.

Table 2398. Debug Interface Enable Truth table

Input Conditions						Outcome
Lifecycle	**Production Disable mode**	**Clock Jitter Enable**	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
In Field	Disabled	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Disabled
	Enabled	Jitter enabled	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not matched	Disabled
		Jitter disabled		Don't Care	Don't Care	Disabled
Failure Analysis	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled

The HSM can also block Debug Interface Access, even if it enabled by PASS. This allows HSM to granted Debug Interface Access after an encrypted secure challenge/response protocol with an external tool (refer to the SPC58xHx Microcontroller Security Reference Manual).

83.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

83.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 2399: Flash Memory Read Protection truth table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The Flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (refer to *Chapter 7: Device configuration*, *Section 7.11.1: Password and Device Security Module (PASS) configuration*).

Table 2399. Flash Memory Read Protection truth table

INPUTS				OUTPUTS	
Lifecycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
STMicroelectronics Production / Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable

83.5.4 UTEST protection

During the *Customer Delivery* lifecycle, the user must program a valid password or a DCF record that writes LOCKm_PGn registers to unprotect the UTest for each password group in order to prevent permanent and irreversible locking of Flash blocks.

83.5.5 Production Disable

Production disable activation protocol and implementation is described in *Chapter 60: Boot Assist Flash (BAF)*, *Section 60.3.6: Production disable activation protocol and implementation*.

83.5.5.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

Note: Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (CAN and FlexRay). This jitter means those serial communications modules are not able to communicate on the network.
As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted (refer to Section 83.4.2: Production Disable for details).

83.5.5.2 Enabling

Note: The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. Bit 1 enables the Hardware Interlock pin.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

Note: If no DCF Record writes to this client, the default state of both features is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature cannot be Enabled accidentally.

83.5.5.3 Clock jitter activation

The BAF code copies the ‘Clock Jitter Activation’ constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (refer to *Section 83.3.1.5: Clock Jitter Enable (CJE)* for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF Flash is 0xFFFF_FFFF (erased state).

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF Flash should be programmed to make the most significant bit ‘0’. After the next reset, the BAF copies this updated value to the Clock Jitter Register and the feature is activated.

83.5.5.4 Clock Jitter Truth table

Table 2400 shows the relationship between Lifecycle, Production Disable & Clock Jitter enable input conditions versus the state of the Baud Rate Clock.

Table 2400. Clock Jitter Truth Table

Lifecycle	Production Disable [Debug Disable]	Clock Jitter Enable	Baud Rate Clock State
STMicroelectronics_ Production Customer_Delivery In_Field	Don’t Care	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
Failure_Analysis	Off[0]	0b1XXXXXXX_(24 more X)	Normal - No Jitter
		0b0XXXXXXX_(24 more X)	Jitter
	On[1]	Don’t Care	Jitter

83.5.6 Fuse Bypass

83.5.6.1 Fuse

Some devices include an additional security feature, whereby a silicon fuse is used to gate access to Flash Test Mode when the device is in Failure_Analysis lifecycle. The fuse must be blown, creating physical damage to the silicon, before access is granted to Flash Test Mode. The PASS implements a configurable feature to bypass the requirement to blow the fuse to enter flash test mode, by entering a password instead. This feature is called Fuse Bypass.

83.5.6.1.1 Use Case: No Fuse Bypass

Customers who want no alternative to the Fuse to enter Flash Test Mode in FA lifecycle:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 0.
- And as a back-up, during customer assembly, the customer could program the Fuse Bypass Password to a random value.

83.5.6.1.2 Use Case: Fuse Bypass Password

Customers who require a password to enter Flash Test Mode in FA lifecycle, but do not require the added sophistication of blowing a fuse:

- During customer assembly, customer programs DCF Record in UTEST to write this DCF client with 1.
- During customer assembly, the customer programs the Fuse Bypass Password into Flash.
- The customer maintains a system for retrieving these passwords for the life of the module.
- If the part is returned to STMicroelectronics for FA, the customer must provide the Fuse Bypass password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA can only be performed if the die is removed from the package and the fuse blown.

83.5.6.1.3 Use Case: No Fuse. No Password

Customers who are less concerned with security and will accept neither fuse nor password to enter Flash Test Mode in FA lifecycle:

- Customer need do nothing special for this mode in customer assembly.
- When the part is returned to STMicroelectronics for FA, The DCF Client is still in the default state of 1. This is Fuse Bypass.
- The Fuse Bypass password should still be in the erased state (all 1). The tester can enter all 1 as the password to gain access to Flash Test Mode.

83.5.6.2 Fuse Bypass Password

The Fuse Bypass Password is a password entered by the STMicroelectronics via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA lifecycle. Flash blocks that are assigned as sealed during production

are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

83.5.6.2.1 Fuse Bypass Password Generation

The Fuse Bypass password is created by the customer during their module assembly process. It must be programmed into UTest Flash while in CUSTOMER_DELIVERY lifecycle.

When an MCU is returned to STMicroelectronics for FA, the MCU must be in FA lifecycle and this password must also be provided to STMicroelectronics to allow access to Flash Test Mode without blowing the fuse. Therefore the customer should develop a process for managing Fuse Bypass passwords for the life of the module.

If the password is not available when a device is returned for FA, STMicroelectronics must remove the die from the package and blow the fuse before entry is possible to Flash Test Mode and Flash FA can be undertaken.

83.5.6.2.2 Fuse Bypass Password storage

The Fuse Bypass Password is 224 bits (28 bytes) wide and is to be stored in UTest Flash at a fixed location. Refer to the device reference manual for the address of the Fuse Bypass password.

The password region of UTest Flash is readable only when in CUSTOMER_DELIVERY lifecycle. In any lifecycle after this (including FA lifecycle), this region is read protected.

83.5.6.2.3 Fuse Bypass Password Challenge entry

The Fuse Bypass password challenge is entered by an external tool to the password register in JTAGC.

As the Fuse Bypass Password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

83.5.6.2.4 Fuse Bypass Password compare

The Fuse Bypass Password challenged, is compared against the password stored in UTest Flash. Only the least significant 224 bits are compared.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

83.6 Initialization/application information

83.6.1 Reset

The reset state of each individual bit is shown within *Section 83.3.1: Register descriptions*. However, many bits receive their values based on DCF records stored in the UTest Flash memory block.

83.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 2401. CS/ADDR values for Lock registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xXXXX0100(1)
Lock1	0xXXXX0104(1)
Lock2	0xXXXX0108(1)
Lock3	0xXXXX010C(1)
PW Group 1	
Lock0	0xXXXX0110(1)
Lock1	0xXXXX0114(1)
Lock2	0xXXXX0118(1)
Lock3	0xXXXX011C(1)
PW Group 2	
Lock0	0xXXXX0120(1)
Lock1	0xXXXX0124(1)
Lock2	0xXXXX0128(1)
Lock3	0xXXXX012C(1)
PW Group3	
Lock0	0xXXXX0130(1)
Lock1	0xXXXX0134(1)
Lock2	0xXXXX0138(1)
Lock3	0xXXXX013C(1)

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 2402*.

Table 2402. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA55AF	Start Record
0x04	0x00000000	
0x08	0x000000FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xXXXX0110(1)	

Table 2402. Setting some bits in the MIDLOCK field (continued)

ADDR offset	DATA	Description
0x10	0xFFFFFFFF	Stop Record
0x14	0xFFFFFFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device.

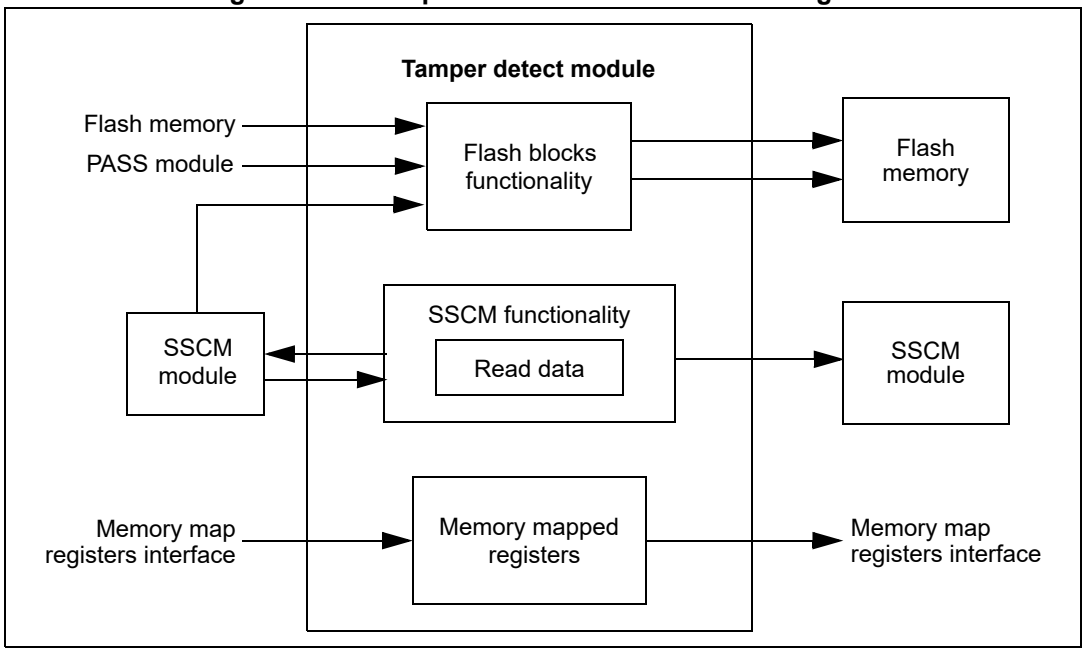
83.6.3 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTest Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS) and the address 0x00B0. Therefore 0xXXXX00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is censored.

84 Tamper Detection Module (TDM)



84.1 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR: it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

Figure 2468 shows the block diagram of the TDM and its interface to other system components.

Figure 2468. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One-Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information (via the DCF bus)
- Software tamper region override

The TDM module controls the flash blocks for erase operations and sets them as OTP

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

Note: The PASS module provides the control for erase operation for each flash block as well as for each region of the flash memory, and the PASS settings have priority over the settings of the TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

84.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 128-bit records
  - The diary block should be assigned as OTP region in flash
  - The diary area can store any type of relevant information
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled
- 32-bit Erase Lock DCF clients for each flash memory TDR defined
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[ae]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation
- Memory Map Registers Interface for reading via software of specific registers

84.3 External signal description

There are no external signals driving or being driven by the TDM.

84.4 DCF client

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

ae. The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 2403. DCF client address map

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write-once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR – "*n*" specifies a TDR – "*m*" specifies the flash blocks as per the LOCK registers of the flash memory	write 0 to 1 only

84.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. *Figure 2469* shows the diagram for this register.

Caution: This DCF client is implemented as Write Once and is writable from 1 to 0 only. After one DCF record has written to this client, all subsequent writes are ignored.

The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

84.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0)

This DCF client holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF client however holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. Therefore, the diagram of this register mirrors the LOCK0 register in the flash memory. *Figure 2475* depicts the TDR*n*_LOCK0 DCF client.

Caution: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

84.5 Memory Map and Registers

Note: The Tamper Detection Module's memory-mapped registers are read-only. Any attempted write generates a transfer error.

Table 2414. TDM memory map

Address offset (hex)	Register name	Location
0x00	TDR Status Register (TDM_TDRSR)	*Section 84.5.1*
0x04	Last Flash Programmed Address Register (TDM_LFPAR)	*Section 84.5.2*
0x08	Diary Base Address (TDM_DBA)	*Section 84.5.3*
0x10–0x24	Software Tamper Override Key Region (TDM_STO_KEY0–TDM_STO_KEY5)	*Section 84.5.4*

84.5.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, such as locked or unlocked, of each tamper region, such as TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

Note: TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.

If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Table 2415. TDM_TDRSR field descriptions

Field	Description
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

Table 2415. TDM_TDRSR field descriptions (continued)

Field	Description
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

84.5.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Offset: 0x04 Access: User read

Figure 2482. Software Tamper Override Key Region (TDM_STO_KEY*n*)

Table 2418. TDM_STO_KEY*n* field descriptions

Field	Description
0:31 STO_KEY	Software Tamper Override Key Diary *n* This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Note:** The STO_KEYn registers can only be written once. **Note:** Refer to the section *Section 60.3.7: TDM Diary Operation* for programming details.

84.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

84.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Dairy is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256 × 128-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

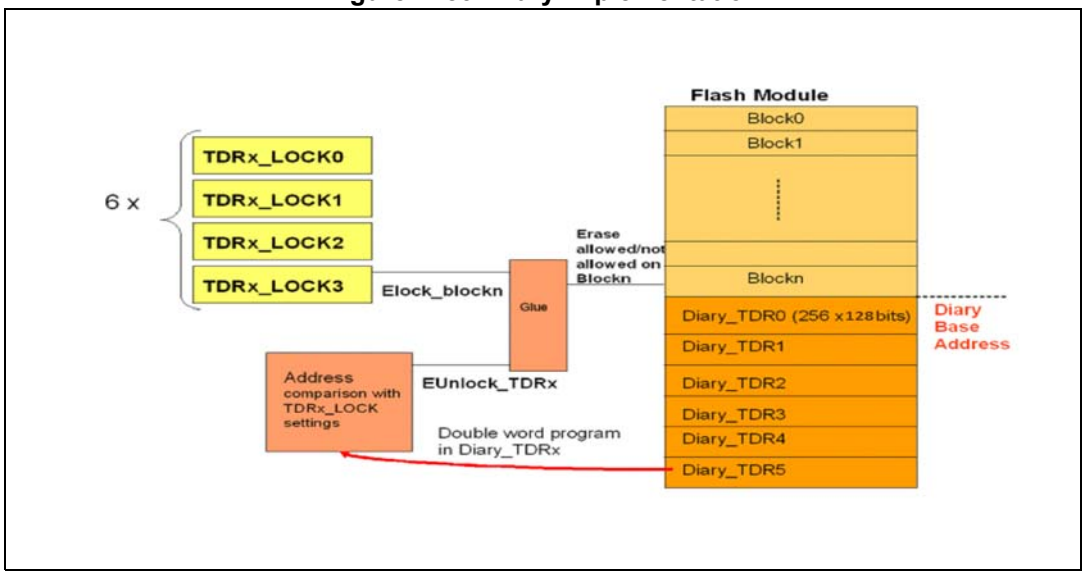
Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR Diary Location and then unlocks the blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the next program operation on any block, other than Diary, is performed with program completion interrupt enabled or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programmed in the diary. If diary is detected to be full, TDM provides a means to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programmed in the diary location is flexible, and may include count information or other important customer information.



Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from “override tamper region lock” DCF record (refer to *Section 84.6.3: Diary*) has priority over the settings in the TDRn_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDRn_LOCK*m* settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in *Figure 2483*.

Figure 2483. Diary implementation

Note: The settings in the Tamper Region Override Register have priority over the TDRn_LOCKm Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programmed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

84.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 × 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK

registers bits from the flash module. Hence, the block assignment registers are named as TDRn_LOCKm where n is the number of a tamper region, that is, 0-5 and m varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They cannot be read nor written. They can only be initialized by DCF record within the UTEST flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

Note: No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

84.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 4 KB, and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector to honor OTP restrictions. Therefore, each diary can hold a maximum of two-hundred and fifty-six 128-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients cannot be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

84.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records are defined by the customer. The only hardware constraints are that each diary has a maximum size of 4 KB and the minimum size of any programming operation depends on the Flash sector, which is 8 bytes for Data sector and 16 bytes for the remaining sector.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is ‘0’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 4 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

84.6.5 Diary Base Address Verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as “TDR Erase Blocked”. Refer to *Section 84.5.1: TDR Status Register (TDM_TDRSR)* for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning “TDR Erase Enabled”.

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. Refer to *Section 84.5.1: TDR Status Register (TDM_TDRSR)*. The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. Refer to *Section 84.5.2: Last Flash Programmed Address Register (TDM_LFPAR)*.

84.6.5.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each record within the 4 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. Refer to the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

84.6.6 One Time Programmable (OTP)

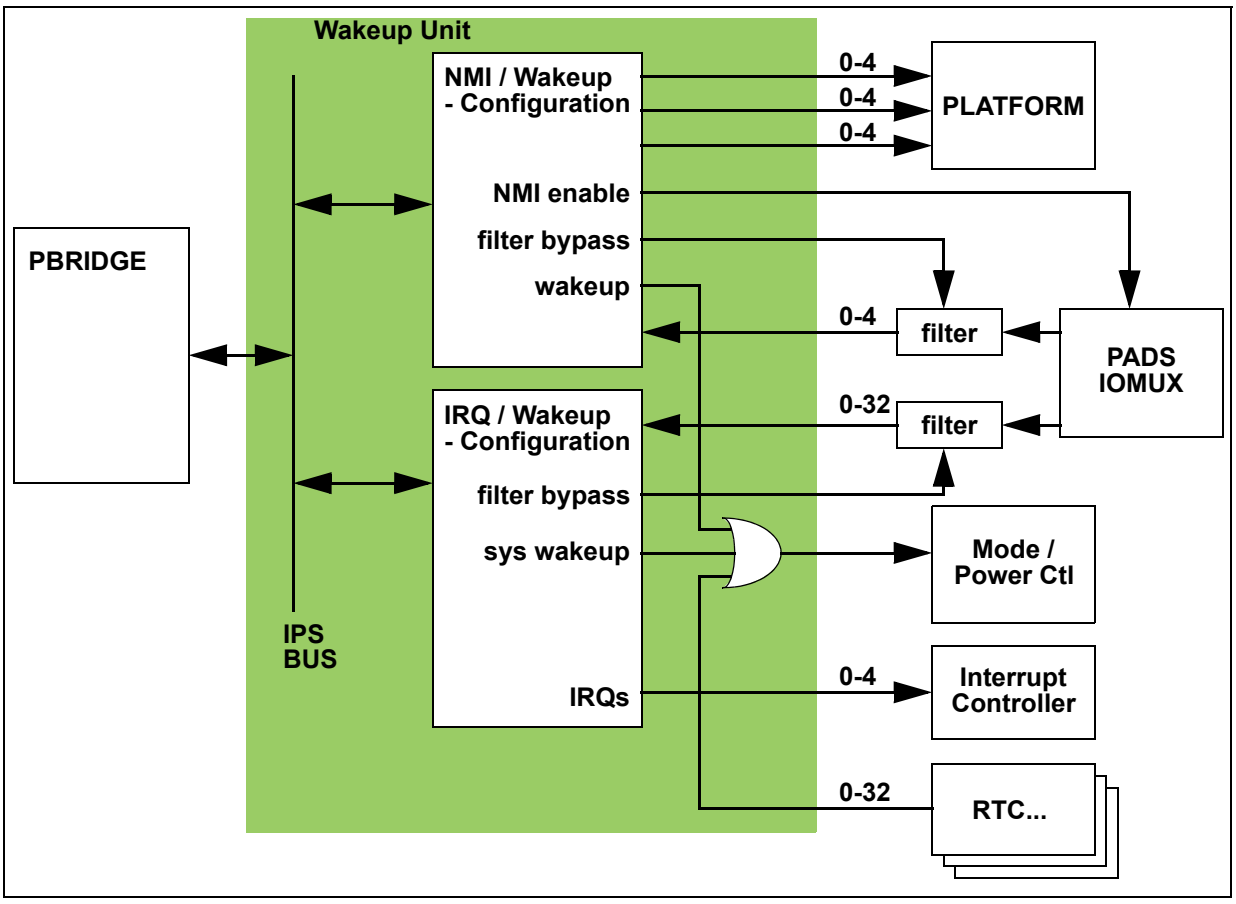
84.6.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

85 Wakeup unit (WKPU)



85.1 Introduction

85.1.1 Overview

The Wakeup unit supports up to 32 external sources that can generate CPU exceptions or wakeup events and up to 3 external sources that can cause non-maskable interrupt requests or wakeup events. In addition, it combines its wakeup events with those generated from up to 32 other wakeup sources to supply a single wakeup to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 2484* is a block diagram of the Wakeup unit and its interfaces to other system components.

Note: For the chip-specific implementation details of this module refer to the Device Configuration chapter.

Figure 2484. Wakeup unit block diagram

85.1.2 Features

The Wakeup unit supports these distinctive features:

- Non-maskable interrupt support with:
  - Up to 4 NMI sources
  - Up to 4 analog glitch filters
  - Independent CPU exceptions destination: non-maskable interrupt, critical interrupt, or machine check request
  - Edge detection
  - Configurable system wakeup triggering from all NMI sources
- External wakeup/interrupt support with:
  - Up to 4 system interrupt vectors for up to 32 interrupt sources
  - Up to 32 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable padkeeper functionality
- On-chip wakeup support with:
  - Up to 32 wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status

Note: For the chip-specific feature details of this module refer to the Device Configuration chapter.

85.2 External signal description

The Wakeup unit has 0 to 32 signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

The module has 0 to 4 signal inputs that can be used as non-maskable interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

85.3 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

85.3.1 Memory map

Table 2419 gives an overview on the WKPU registers implemented.

Table 2419. WKPU memory map

Address offset	Registers	Supported access sizes	Location
0x0000	NMI Status Flag Register (NSR)	32/16/8	*Section 85.3.2.1*

0x0034	Wakeup Padkeeper Disable Register (WPDR)	32	*Section 85.3.2.9*
0x0038–0x3FFF	Reserved		

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

85.3.2 Register descriptions

This section describes in address order all the Wakeup unit registers.

85.3.2.1 NMI Status Flag Register (NSR)

This register holds the non-maskable interrupt status flags.

Offset: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NIF0	NOVF0	0	0	0	0	0	0	NIF1	NOVF1	0	0	0	0	0	0	NIF2	NOVF2	0	0	0	0	0	0	RIF	ROVF	0	0	0	0	0	0

Figure 2485. NMI Status Flag Register (NSR)

Table 2420. NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE0 and NFEE0 has occurred. 0 No event has occurred on the pad.
1 NOVF0	NMI Overrun Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 1 An overrun has occurred on NMI input 0. 0 No overrun has occurred on NMI input 0.
8 NIF1	NMI Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE1 and NFEE1 has occurred. 0 No event has occurred on the pad.
9 NOVF1	NMI Overrun Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 1 An overrun has occurred on NMI input 1. 0 No overrun has occurred on NMI input 1.
16 NIF2	NMI Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an exception to the associated CPU, as configured within the NDSS bit of the NCR register. In addition this event can also be configured to trigger a system wakeup. 1 An event as defined by NREE2 and NFEE2 has occurred. 0 No event has occurred on the pad.
17 NOVF2	NMI Overrun Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 1 An overrun has occurred on NMI input 2. 0 No overrun has occurred on NMI input 2.

Table 2420. NSR field descriptions (continued)

Field	Description
24 RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (that is if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An event as defined by RREE and RFEE has occurred. 0 No event has occurred on the pad.
25 ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the F_WAKEUP reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1 An overrun has occurred on NMI input. 0 No overrun has occurred on NMI input.

Note: Refer to the Device Configuration chapter to see how the NMI Status Flag Register (NSR) is used in the device.

85.3.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Offset: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 2486. NMI Configuration Register (NCR)

1. Writing this bit has no functional impact.

Table 2421. NCR field descriptions

Field	Description
0 NLOCK0	NMI Configuration Lock Register 0 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
1:2 NDSS0	NMI Destination Source Select 0 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request

Table 2421. NCR field descriptions (continued)

Field	Description
3 NWRE0	NMI Wakeup Request Enable 0 1 NMI0 wakeup is enabled. A set NIF0 bit or set NOVF0 bit causes a system wakeup request. 0 NMI0 wakeup is disabled. System wakeup requests from the corresponding NIF0 bit are disabled.
5 NREE0	NMI Rising-edge Events Enable 0 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
6 NFEE0	NMI Falling-edge Events Enable 0 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
7 NFE0	NMI Filter Enable 0 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
8 NLOCK1	NMI Configuration Lock Register 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
9:10 NDSS1	NMI Destination Source Select 1 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request
11 NWRE1	NMI Wakeup Request Enable 1 1 NMI1 wakeup is enabled. A set NIF1 bit or set NOVF1 bit causes a system wakeup request 0 NMI1 wakeup is disabled. System wakeup requests from the corresponding NIF1 bit are disabled
13 NREE1	NMI Rising-edge Events Enable 1 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
14 NFEE1	NMI Falling-edge Events Enable 1 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
15 NFE1	NMI Filter Enable 1 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
16 NLOCK2	NMI Configuration Lock Register 2 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.

Table 2421. NCR field descriptions (continued)

Field	Description
17:18 NDSS2	NMI Destination Source Select 2 This value is reset on system reset. 00 Non-maskable interrupt 01 Critical interrupt 10 Machine check request 11 Reset request
19 NWRE2	NMI Wakeup Request Enable 2 1 NMI2 wakeup is enabled. A set NIF2 bit or set NOVF2 bit causes a system wakeup request. 0 NMI2 wakeup is disabled. System wakeup requests from the corresponding NIF2 bit are disabled.
21 NREE2	NMI Rising-edge Events Enable 2 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.
22 NFEE2	NMI Falling-edge Events Enable 2 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
23 NFE2	NMI Filter Enable 2 Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.
24 RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
25:26 RDSS	Reset Destination Source Select This value is reset on system reset. 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request. 0 System wakeup requests from the corresponding RIF bit are disabled. **Note:** To wake up the system from standby by this way, ESR1 option has to be disable in MC_RGM. To disable the MC_RGM ESR1 function, the bit 30 of RGM_FERD and RGM_FEAR registers have to be set.
29 RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled. 0 Rising-edge event is disabled.

Table 2421. NCR field descriptions (continued)

Field	Description
30 RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled. 0 Falling-edge event is disabled.
31 RFE	Reset Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled. 0 Filter is disabled.

Note: Refer to the Device configuration chapter to see how the NMI Configuration Register (NCR) is used in the device.

Note: Writing a '0' to both NREEx and NFEEx disables the NMI functionality completely (no system wakeup or interrupt will be generated on any pad activity).

85.3.2.3 Wakeup/Interrupt Status Flag Register (WISR)

This register holds the wakeup/interrupt flags.

Offset: 0x0014 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 2487. Wakeup/Interrupt Status Flag Register (WISR)

Table 2422. WISR field descriptions

Field	Description
0 EIF31	External Wakeup/Interrupt Status Flag 31 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER31), EIF31 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
1 EIF30	External Wakeup/Interrupt Status Flag 30 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER30), EIF30 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
2 EIF29	External Wakeup/Interrupt Status Flag 29 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER29), EIF29 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2422. WISR field descriptions (continued)

Field	Description
3 EIF28	External Wakeup/Interrupt Status Flag 28 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER28), EIF28 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
4 EIF27	External Wakeup/Interrupt Status Flag 27 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER27), EIF27 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
5 EIF26	External Wakeup/Interrupt Status Flag 26 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER26), EIF26 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
6 EIF25	External Wakeup/Interrupt Status Flag 25 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER25), EIF25 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
7 EIF24	External Wakeup/Interrupt Status Flag 24 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER24), EIF24 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
8 EIF23	External Wakeup/Interrupt Status Flag 23 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER23), EIF23 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
9 EIF22	External Wakeup/Interrupt Status Flag 22 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER22), EIF22 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
10 EIF21	External Wakeup/Interrupt Status Flag 21 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER21), EIF21 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
11 EIF20	External Wakeup/Interrupt Status Flag 20 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER20), EIF20 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2422. WISR field descriptions (continued)

Field	Description
12 EIF19	External Wakeup/Interrupt Status Flag 19 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER19), EIF19 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
13 EIF18	External Wakeup/Interrupt Status Flag 18 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER18), EIF18 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
14 EIF17	External Wakeup/Interrupt Status Flag 17 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER17), EIF17 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
15 EIF16	External Wakeup/Interrupt Status Flag 16 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER16), EIF16 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
16 EIF15	External Wakeup/Interrupt Status Flag 15 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER15), EIF15 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
17 EIF14	External Wakeup/Interrupt Status Flag 14 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER14), EIF14 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
18 EIF13	External Wakeup/Interrupt Status Flag 13 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER13), EIF13 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
19 EIF12	External Wakeup/Interrupt Status Flag 12 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER12), EIF12 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
20 EIF11	External Wakeup/Interrupt Status Flag 11 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER11), EIF11 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2422. WISR field descriptions (continued)

Field	Description
21 EIF10	External Wakeup/Interrupt Status Flag 10 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER10), EIF10 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
22 EIF9	External Wakeup/Interrupt Status Flag 9 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER9), EIF9 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
23 EIF8	External Wakeup/Interrupt Status Flag 8 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER8), EIF8 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
24 EIF7	External Wakeup/Interrupt Status Flag 7 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER7), EIF7 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
25 EIF6	External Wakeup/Interrupt Status Flag 6 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER6), EIF6 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
26 EIF5	External Wakeup/Interrupt Status Flag 5 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER5), EIF5 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
27 EIF4	External Wakeup/Interrupt Status Flag 4 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER4), EIF4 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
28 EIF3	External Wakeup/Interrupt Status Flag 3 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER3), EIF3 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
29 EIF2	External Wakeup/Interrupt Status Flag 2 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER2), EIF2 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Table 2422. WISR field descriptions (continued)

Field	Description
30 EIF1	External Wakeup/Interrupt Status Flag 1 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER1), EIF1 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.
31 EIF0	External Wakeup/Interrupt Status Flag 0 This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER0), EIF0 causes an interrupt request. 1 An event as defined by WIREER and WIFEER has occurred. 0 No event has occurred on the pad.

Note: Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

85.3.2.4 Interrupt Request Enable Register (IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

Offset: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 2423. IRER field descriptions (continued)

Field	Description
18 EIRE13	External Interrupt Request Enable 13 1 A set EIF13 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF13 bit are disabled.
19 EIRE12	External Interrupt Request Enable 12 1 A set EIF12 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF12 bit are disabled.
20 EIRE11	External Interrupt Request Enable 11 1 A set EIF11 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF11 bit are disabled.
21 EIRE10	External Interrupt Request Enable 10 1 A set EIF10 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF10 bit are disabled.
22 EIRE9	External Interrupt Request Enable 9 1 A set EIF9 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF9 bit are disabled.
23 EIRE8	External Interrupt Request Enable 8 1 A set EIF8 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF8 bit are disabled.
24 EIRE7	External Interrupt Request Enable 7 1 A set EIF7 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF7 bit are disabled.
25 EIRE6	External Interrupt Request Enable 6 1 A set EIF6 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF6 bit are disabled.
26 EIRE5	External Interrupt Request Enable 5 1 A set EIF5 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF5 bit are disabled.
27 EIRE4	External Interrupt Request Enable 4 1 A set EIF4 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF4 bit are disabled.
28 EIRE3	External Interrupt Request Enable 3 1 A set EIF3 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF3 bit are disabled.
29 EIRE2	External Interrupt Request Enable 2 1 A set EIF2 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF2 bit are disabled.
30 EIRE1	External Interrupt Request Enable 1 1 A set EIF1 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF1 bit are disabled.
31 EIRE0	External Interrupt Request Enable 0 1 A set EIF0 bit causes an interrupt request. 0 Interrupt requests from the corresponding EIF0 bit are disabled.

85.3.2.5 Wakeup Request Enable Register (WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

Note: Any wakeup pad must be properly driven either externally or internally (enabling weak pull-up/pull-down) before enabling its corresponding WREx bit.

Offset: 0x001C Access: User read/write

85.3.2.8 Wakeup/Interrupt Filter Enable Register (WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

Note: Glitch filter must be enabled in case the wake-up sources are used to exit from Standby.

Offset: 0x0030 Access: User read/write

85.4 Functional description

85.4.1 General

This section provides a complete functional description of the Wakeup unit.

85.4.2 Non-maskable interrupts

The Wakeup unit supports up to 4 non-maskable interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports the generation of 3 types of interrupts per NMI input to the SoC. The Wakeup unit supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a by-passable analog glitch filter.

Note: Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

85.4.2.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 2486*). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note: After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 2421* for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see *Figure 2485*). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (it has not yet been cleared).

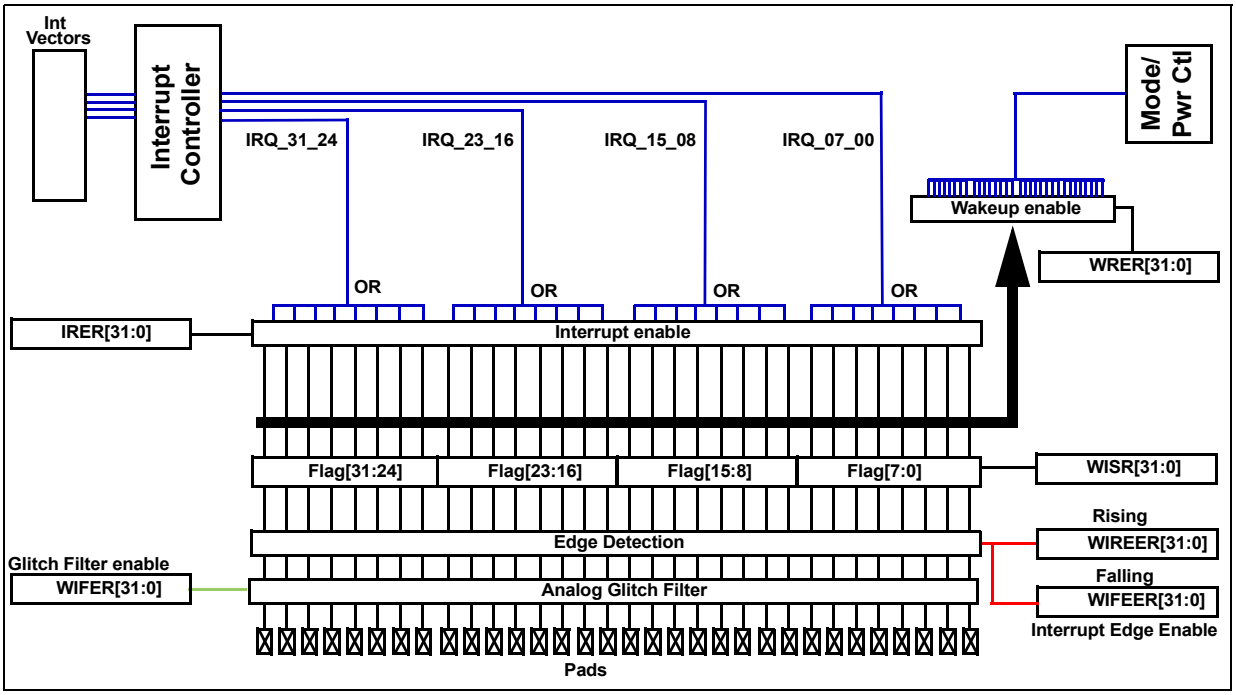
Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

85.4.3 External wakeups/interrupts

The Wakeup unit supports up to 32 external wakeup/interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The Wakeup unit supports up to 4 interrupt vectors to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N - 1, the next is for N through N + M - 1, and so forth.

The parameter IRQ_VEC defines the number of interrupt vectors (the ipi_int_pins output size).



The parameter EIRQ_PER_VEC defines the number of external interrupt sources assigned to each interrupt vector. It is split up into four 6-bit fields, one for each possible interrupt vector, with the lowest field corresponding to ipi_int_pins[0], the second field to ipi_int_pins[1], and so forth.

For example, for EIRQS = 17, IRQ_VEC = 3 and EIRQ_PER_VEC = {6'd0, 6'd5, 6'd3, 6'd9}, ipp_ind_int[8:0] are assigned to ipi_int_pins[0], ipp_ind_int[11:9] are assigned to ipi_int_pins[1], and ipp_ind_int[16:12] are assigned to ipi_int_pins[2]. The signals ipp_ind_int[31:17] and ipi_int_pins[3] do not exist.

Note: If EIRQS = 0, the unused ipp_ind_int[0] input has no effect on the sys_wakeup output.

Refer to *Figure 2494* for an overview of the external interrupt implementation for the example of four interrupt vectors with eight external interrupt sources each.

Figure 2494. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

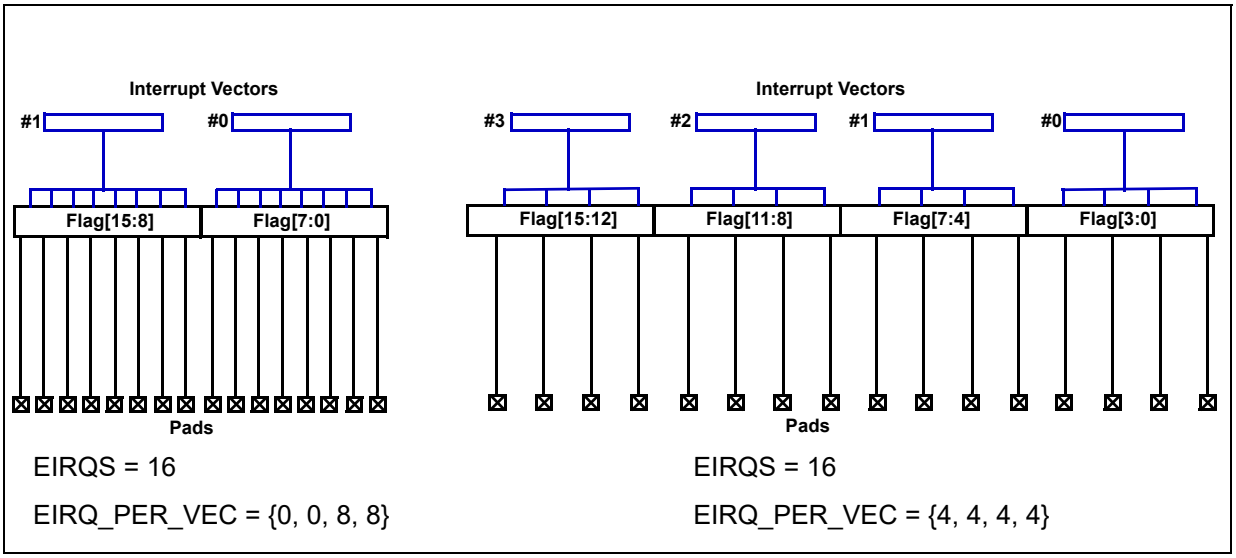
The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

An SoC specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 0 to 32.

Note: Glitch filter control and pad configuration should be done while the external interrupt line is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

85.4.3.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (*Figure 2488*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.



Note: Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (no system wakeup or interrupt will be generated on any activity on that pad)!

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

For devices with less than the maximum number of interrupt sources, it is possible for the SoC to implement either all four interrupt vectors with fewer sources or to reduce the number of vectors as the number of sources are reduced. *Figure 2495* shows two examples of how this could be supported.

Figure 2495. Example of different interrupt to vector mapping at SOC level

85.4.4 On-Chip wakeups

The Wakeup unit supports up to 32 on-chip wakeup sources. It combines the on-chip wakeups with the external ones to generate a single wakeup to the system.

Note: If WUPS = 0, the unused wakeup_in input has no effect on the sys_wakeup output.

85.4.4.1 On-Chip wakeup management

In order to allow software to determine the wakeup source at one location, on-chip wakeups are reported along with external wakeups in the WISR register (see *Figure 2487* for details). Enabling and clearing of these wakeups are done via the on-chip wakeup source's own registers.

86 Real Time Clock / Autonomous Periodic Interrupt (RTC/API)

86.1 Overview

The RTC is a free running counter used for time keeping applications. The RTC may be configured to generate an interrupt at a predefined interval independent of the mode of operation (run mode or low power mode). When the RTC interval is reached, the RTC will generate a wakeup request to the wakeup unit. The RTC can be configured to generate an interrupt on the RTC interval timeout.

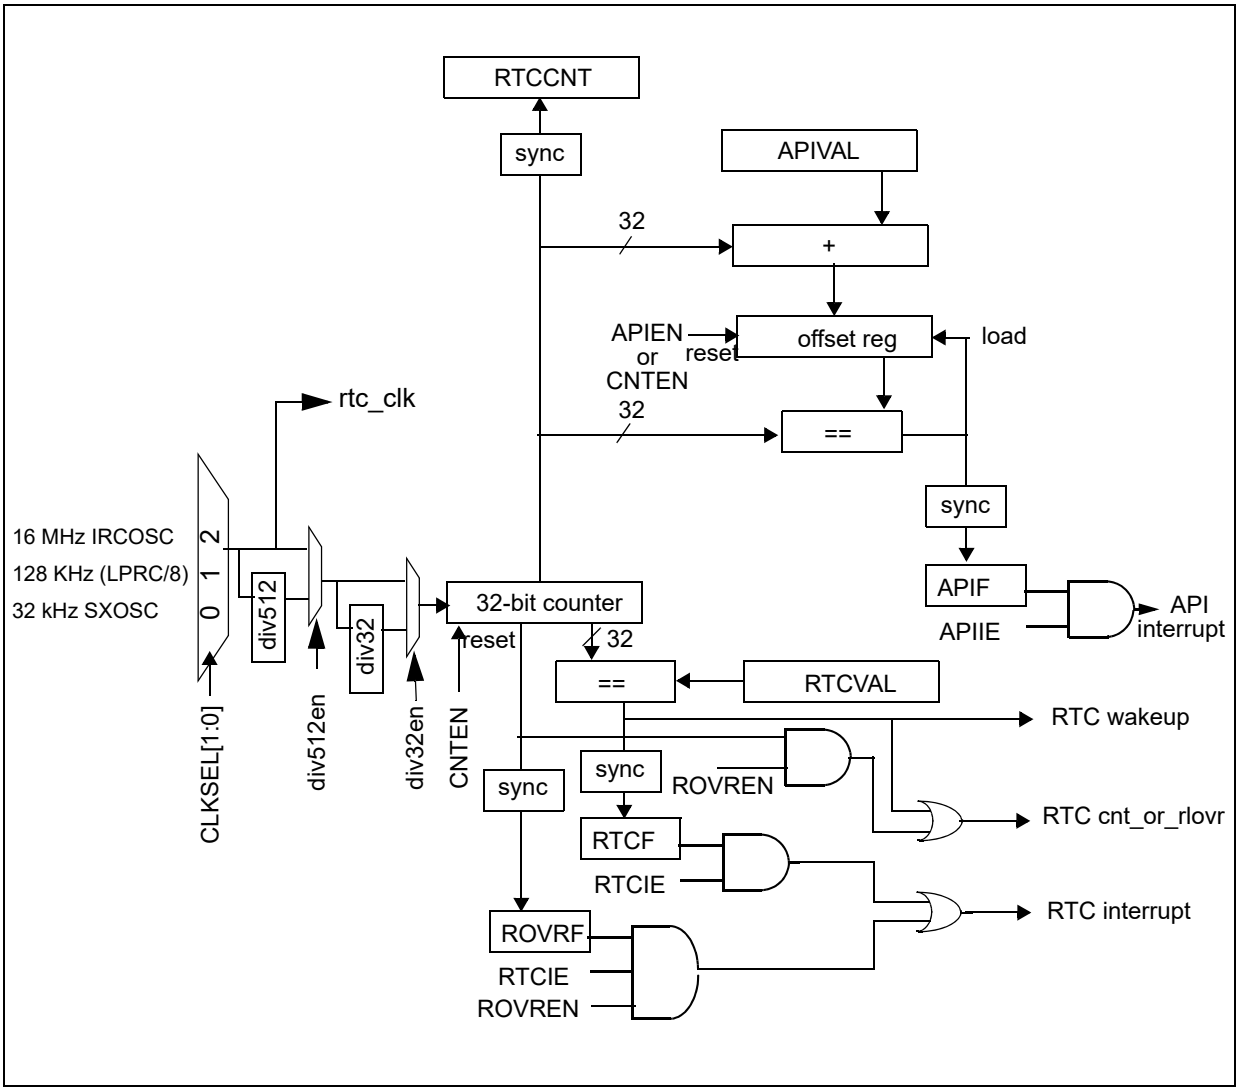
The RTC also supports an autonomous periodic interrupt (API) function which can be used to generate a periodic event to the wakeup unit or an interrupt request.

86.2 Features

Features of the RTC/API include:

- 3 selectable counter clock sources:
  - LPRC prescaled by 8 (128 kHz)
  - SXOSC (32 kHz)
  - IRCOSC (16 MHz)
- Clock sources can optionally be prescaled by 512 or 32
- 32-bit counter
  - Supports times up to 1.5 months with 1 ms resolution
  - Runs in all modes of operation, including normal RESET
  - Reset when disabled by software and by POR
- 12-bit compare value to support an extended range of interrupt intervals
- RTC compare value changeable while counter is running
- RTC status and control register are reset only by POR
- Autonomous periodic interrupt (API) to support an extended range of interrupt intervals
- Configurable interrupt for RTC match, API match, and RTC rollover
- Configurable wakeup event for RTC match, API match, and RTC rollover

Figure 2496. RTC/API block diagram



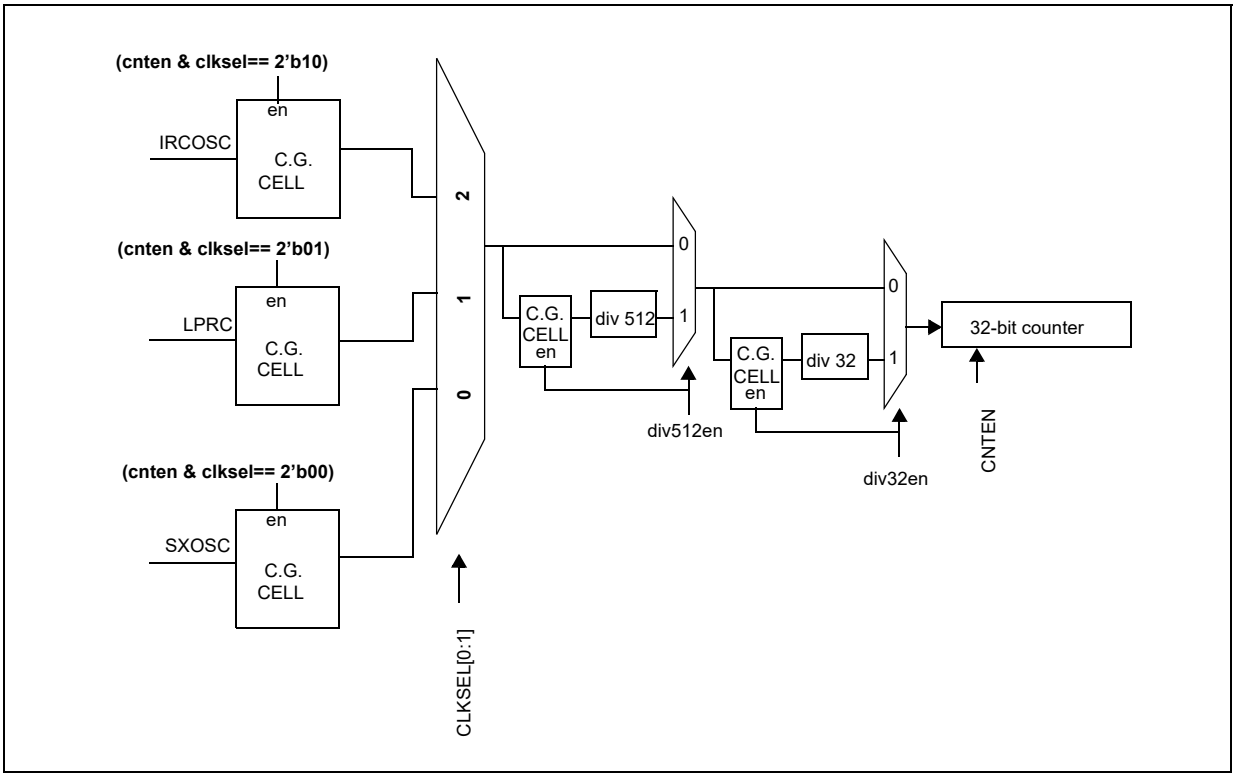


Figure 2497. Clock gating for RTC clocks

86.3 Modes of operation

86.3.1 Functional mode

There are two functional modes of operation for the RTC: normal operation and low power mode. In normal operation, all RTC registers can be read or written. The RTC/API and associated interrupts are optionally enabled. In low power mode, the bus interface is disabled and no configuration changes are permitted. The RTC/API is enabled if enabled prior to entry into low power mode.

86.3.2 Debug mode

If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. If RTCC[FRZEN] is clear, the counter will continue counting (and set flags accordingly) when the device is in debug mode.

86.4 Register descriptions

The registers listed in *Table 2429* are described in the following sections.

Table 2429. RTC/API register map

Address offset	Register	Location
0x0000	RTC Supervisor Control Register (RTCSUPV)	*Section 86.4.1*
0x0004	RTC Control Register (RTCC)	*Section 86.4.2*
0x0008	RTC Status Register (RTCS)	*Section 86.4.3*
0x000C	RTC Counter Register (RTCCNT)	*Section 86.4.4*
0x0010	API Compare Value Register (RTC_APIVAL)	*Section 86.4.5*
0x0014	RTC Compare Value Register (RTC_RTCVAL)	*Section 86.4.6*

86.4.1 RTC Supervisor Control Register (RTCSUPV)

The RTCSUPV register contains the SUPV bit which determines whether other registers are accessible in supervisor mode or user mode.

Note: RTCSUPV register is accessible only in supervisor mode.

Offset: 0x0000 Access: Supervisor R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SUPV	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 2430. RTCSUPV register field descriptions

Field	Description
0 SUPV	RTC Supervisor Bit 0 All registers are accessible in both user as well as supervisor mode. 1 All other registers are accessible in supervisor mode only.

86.4.2 RTC Control Register (RTCC)

The RTCC register contains:

- RTC counter enable
- RTC interrupt enable
- RTC clock source select
- RTC compare value
- API enable
- API interrupt enable
- API compare value

Offset: 0x0004 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2499. RTC Control Register (RTCC)

Table 2431. RTCC register field descriptions

Field	Description
0 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Clearing CNTEN has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic as well as resetting the 32-bit counter. This allows for the RTC configuration and clock source selection to be updated without causing synchronization issues. 0 Counter disabled and reset 1 Counter enabled
1 RTCIE	RTC Interrupt Enable The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0 RTC interrupts disabled 1 RTC interrupts enabled
2 FRZEN	Freeze Enable Bit If RTCC[FRZEN] is set, the counter will stop on the last valid count when the device enters debug mode. On debug mode exit, the counter will resume counting from the frozen value. 0 Counter running in debug mode 1 Counter stops (freezes) in debug mode
3 ROVREN	Counter Roll Over Interrupt Enable The ROVREN enables interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0 RTC rollover interrupt disabled 1 RTC rollover interrupt enabled
16 APIEN	Autonomous Periodic Interrupt Enable The APIEN bit enables the autonomous periodic interrupt function. 0 API disabled 1 API enabled

Table 2431. RTCC register field descriptions (continued)

Field	Description
17 APIIE	API Interrupt Enable The APIIE bit enables interrupts requests to the system if APIF is asserted. 0 API interrupts disabled 1 API interrupts enabled
18:19 CLKSEL	Clock Select The CLKSEL[0:1] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. 00 SXOSC 01 LPRC prescaled by 8 10 IRCOSC 11 Reserved
20 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0 Divide by 512 is disabled. 1 Divide by 512 is enabled.
21 DIV32EN	Divide by 32 enable The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0 Divide by 32 is disabled. 1 Divide by 32 is enabled.
31 TRIG_EN	Trigger enable Used for self clearing of WKPU API event. This bit is required in case API event is being used to trigger SSWU eCTU commands. 0 Trigger enable is disabled. 1 Trigger enable is enabled.

86.4.3 RTC Status Register (RTCS)

The RTCS register contains:

- RTC interrupt flag
- API interrupt flag
- ROLLOVR Flag

Offset: 0x0008 Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	RTCF	0	0	0	0	0	0	0	0	0	0	INV_RTC	INV_API	INV_ANL
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	APIF	0	0	ROVRF	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2500. RTC Status Register (RTCS)

Table 2432. RTCS register field descriptions

Field	Description
2 RTCF	RTC Interrupt Flag The RTCF bit indicates that the RTC counter has reached the counter value matching RTCVAL. RTCF is cleared by writing a 1 to RTCF. Writing a 0 to RTCF has no effect. 0 RTC counter is not equal to RTCVAL. 1 RTC counter matches RTCVAL.
13 INV_RTC	Invalid RTC write This bit becomes value 1 after a value has been written to the RTCVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the RTCVAL register again will be ignored.
14 INV_API	Invalid APIVAL write This bit becomes value 1 after a value has been written to the APIVAL register and the synchronization process is continuing. During this synchronization period, any attempt to write to the APIVAL register again will be ignored.
15 INV_ANL	Invalid ANLCMP write This bit becomes value 1 after a value has been written to the ANLCMP_CNT register and the synchronization process is continuing. During this synchronization period, any attempt to write to the ANLCMP_CNT register again will be ignored.
18 APIF	API Interrupt Flag The APIF bit indicates that the RTC counter has reached the counter value matching API offset value. APIF is cleared by writing a 1 to APIF. Writing a 0 to APIF has no effect. 0 No API interrupt 1 API interrupt
21 ROVRF	Counter Roll Over Interrupt Flag The ROVRF bit indicates that the RTC has rolled over from 0xffff_ffff to 0x0000_0000. ROVRF is cleared by writing a 1 to ROVRF. 0 RTC has not rolled over. 1 RTC has rolled over.

86.4.4 RTC Counter Register (RTCCNT)

The RTCCNT register contains the current value of the RTC counter.

Offset: 0x000C Access: User read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2501. RTC Counter Register (RTCCNT)

Table 2433. RTCCNT register field descriptions

Field	Description
0:31 RTCCNT	RTC Counter Value Due to the clock synchronization, the RTCCNT value may actually represent a previous counter value.

86.4.5 API Compare Value Register (RTC_APIVAL)

The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted.

Offset: 0x0010 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	APIVAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	APIVAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2502. API Compare Value Register (RTC_APIVAL)

Table 2434. RTC_APIVAL register field descriptions

Field	Description
0:31 APIVAL	API Compare Value The APIVAL bits are compared to the RTC counter bits and if a match occurs, an interrupt/wakeup request is asserted. **Note:** API functionality is active only when APIVAL is non zero. The first API interrupt takes two more cycles because of synchronization of APIVAL to rtc clock. After that, interrupts are periodic in nature and it takes APIVAL+1 cycles. Minimum supported value of APIVAL is 4. This is due to synchronization issues.

86.4.6 RTC Compare Value Register (RTC_RTCVAL)

The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set.

Note: If RTC interrupt is enabled (RTCIE), it is required after each RTC counter match to reload the RTCVAL via software, to enable the interrupt again.

With RTCC[CTNEN] = 1 (RTC running) the user needs to wait the RTCS[RTC_INV] goes to zero (completed the synchronization process) before updating the RTCVAL counter. Otherwise the latter update will have no effect.

Offset: 0x0014 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	RTCVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2503. RTC Compare Value Register (RTC_RTCVAL)

Table 2435. RTC_RTCVAL register field descriptions

Field	Description
0:31 RTCVAL	RTC Compare Value The RTCVAL bits are compared to the RTC counter bits and if a match occurs, RTCF is set. **Note:** Minimum supported value of RTCVAL is 4. This is due to synchronization issues.

86.5 RTC functional description

The RTC consists in a 32-bit free running counter enabled with the RTCC[CNTEN] bit. (When CNTEN is cleared, the counter is asynchronously reset.) The value of the counter may be read via the RTCCNT register. Note that due to the clock synchronization, the RTCCNT value may actually represent a previous counter value. The difference between

the counter and the read value depends on ratio of counter clock and main clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the RTCC[CLKSEL] field, which gives four options for clocking the RTC/API. The three clock sources are:

- LPRC prescaled by 8 (128 kHz)
- SXOSC (32 kHz)
- IRCOSC (16 MHz)

The output of the clock mux can be optionally divided by combination of 512 and 32 to give a 1 ms RTC/API count period for different clock sources. Note that the RTCC[CNTEN] bit must be disabled when the RTC/API clock source is switched.

When the counter value matches the 32-bit value in the RTCC[RTCVAL] field, then the RTCS[RTCF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[RTCIE] interrupt enable bit is set, then the RTC interrupt request is generated. If there is a match while in low power mode then the RTC will first generate a wakeup request to force a wakeup to run mode, then the RTCF flag will be set.

A rollover interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. Rollover events are enabled by setting the RTCC[ROVEN] bit. If this bit is set, an RTC rollover will cause a request. To enable interrupts on a rollover request, the RTCC[RTCIE] bit also needs to be set.

All the flags and counter values are synchronized with ipg_clk the main clock. It is assumed that ipg_clk the main clock frequency is always more than or equal to the rtc_clk RTC clock used to run the counter.

86.6 API functional description

Setting the RTCC[APIEN] bit enables the autonomous interrupt function. The 32-bit RTCC[APIVAL] field selects the time interval for triggering an interrupt and/or wakeup event. Since the RTC is a free running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, a interrupt and/or wakeup request is generated. Then the offset value is recalculated and re-triggers a new request when the new value is reached. APIVAL may only be updated when APIEN is disabled. When a compare is reached, the RTCS[APIF] interrupt flag bit is set (after proper clock synchronization). If the RTCC[APIIE] interrupt enable bit is set, then the API interrupt request is generated. If there is a match while in low power mode, then the API will first generate a wakeup request to force a wakeup into normal operation, then the APIF flag will be set.

Appendix A Acronyms and abbreviations

Table 2436 lists acronyms and abbreviations used in this document.

Table 2436. Acronyms and abbreviations

Term	Meaning
AHB	Advanced high-performance bus
AIC	PBRIDGE (AIPS) integrity checker
AMBA	Advanced microcontroller bus architecture
APFC	Auxiliary pin function control
APU	– Advanced protocol unit – Auxiliary processing unit
ASILB	Automotive SIL B
AUTOSAR	Automotive open system architecture
AVB	Audio video bridging
BAF	Boot assist flash
BCU	Buffer control unit
BIST	Built-in self test
BIU	Bus interface unit
BMIF	Bus master interface
CAN	Controller area network
CC	Communication controller
CDC	Clock domain crosser
CF	Critical fault
CGM	– Clock generation module – Conditional group member
CGMC	Conditional group membership count
CHI	Controller host interface
CID	Controller ID
CJTAG	Compact JTAG
CLTAPC	Chip-level TAPC
CP	Check packet
CPA	Check process active
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check

Table 2436. Acronyms and abbreviations (continued)

Term	Meaning
CSI	Combined serial interface. DSPI configuration that alternates DSI and SPI frames.
CTU	Cross triggering unit
DCF	Device configuration format
DCU	Data channel unit
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DSI	Deserial serial interface. DSPI configuration that serializes and deserializes registers or signals to allow for pin reduction.
EBI	External bus interface
ECC	Error correction code
ECSM	Error correction status module
EIM	Error injection module
EMI	Electromagnetic interference
EOT	End of transfer
EOUT	Error out
EPU	Extended protocol unit
ESD	Electromagnetic static discharge
FCCU	Fault collection and control unit
FMPLL	Frequency-modulated phase-locked loop
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
FSS	Frame start sequence
FTTI	Fault tolerant time interval
GPIO	General-purpose I/O
HIF	Host interface
HVD	High voltage detector
HW	Hardware
ID	LIN identifier field
IEEE	Institute of electrical and electronics engineers
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety

Table 2436. Acronyms and abbreviations (continued)

Term	Meaning
IPS	– Internal peripheral system – IPI slave bus
IRQ	Interrupt request
ISR	Interrupt service routine
JDC	JTAG data communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
Jscan	JTAG scan
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LRAM	Look up table RAM
LUT	Look up table
LVD	Low voltage detector
LWB	Late-write buffer
MB	Message buffer
MBIDX	Message buffer index
MBIST	Memory built-in self test
MBM	Message buffer management
MBNum	Message buffer number
MC	MC_CGM, MC_ME, MC_PCU, and MC_RGM modules
MCU	Microcontroller unit
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit
MFD	Multiplication factor divider
Mscan	Maximum-flexibility scan
MT	Macrotick
MTS	Media access test symbol
Mux	Multiplex
NCF	Non-critical fault
NIT	Network idle time
NMI	Non-maskable interrupts
nTRST	Active low test reset
NVM	Non-volatile memory
OPP	Over-program protection
OSC	Oscillator

Table 2436. Acronyms and abbreviations (continued)

Term	Meaning
Oscan	Optimized scan
OTP	One time programmable
PASS	Password and device security module
PBRIDGE	Peripheral bridge
PCM	– Platform configuration module – Peripheral control module
PCU	Power control unit
PE	Protocol engine
PFLASH	Platform flash controller
PIT	Periodic interrupt timer
PLL	Phase-locked loop
PMC	Power management controller
POC	Protocol operation control
PRAM	Platform RAM controller
PSS	Pause selection state
PWD	Password
RC	– Resistance-capacitance – Resistor-capacitor
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RSU	Reset and selection unit
RTL	Register transfer language
RWW	Read-while-write
RX	Receive
SAG	Safety application guide
SAR ADC	Successive approximation register analog-to-digital converter
SECDED	Single-bit error correction, double-bit error detection
SEQ	Sequencer engine
SIL	Safety integrity level
SIUL	System integration unit lite

Table 2436. Acronyms and abbreviations (continued)

Term	Meaning
SMPU	System memory protection unit
SoC	System-on-chip
SOR	Sphere of redundancy
SP	Scan packet
SPA	Scan packet active
SPI	Serial peripheral interface
Sscan	Segmented scan
SSCM	System status and configuration module
SSD	Scan selection directive
SSM	Scan state machine
STCU	Self-test control unit
STL	System test logic
STM	System timer module
SW	Software
SWT	Software watchdog timer
TAP	Test access point
TAP.1	An IEEE 1149.1 test access port
TAP.7	An IEEE 1149.7 test access port
TBD	To be defined
TCA	Tap controller access
TCD	Transfer control descriptor
TCK	Test clock
TCKC	Test clock compact
TCU	Time control unit
TDI	Test data input
TDIC	Test data input compact
TDO	Test data output
TDOC	Test data output compact
TMS	Test mode select
TMSC	Test mode select compact
TS	Target System
TSENS	Temperature sensor
TX	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault

Table 2436. Acronyms and abbreviations (continued)

Term	Meaning
VCO	Voltage controlled oscillator
VREG	Voltage regulator
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar
XBIC	XBAR integrity checker
ZBS	Zero bit scan
µT	Microtick

Revision history

Table 2437. Document revision history

Date	Revision	Changes
26-Mar-2018	1	Initial release
28-Jun-2019	2	Throughout document: Formatting and editorial changes; Replaced eMMC by SDMMC Removed references to USB, LFAST, SIPI, I2S *Chapter 2: Introduction* *Section 2.1.5: Features*: – Updated all bullets referring to both Ethernet 0 features and Ethernet 1 features. – Flexible Power Supply options: sentence “Single internal SMPS regulator (FPBGA302 and FPBGA386)” removed. – Changed “eMMC 4.51 interface” by “SD3.01/SDIO3.0/MMC4.51” – Eleven DSPI modules, one working even in low power mode. – Sixteen MCAN. – Removed RevMII. – Added Turbo MII (“TMII” , overclocked MII @200 Mbps) – Removed Half-duplex operation details. – Removed Standard IEEE 802.3az-2010 and 64-bit data transfer interface. – Removed (64-bit timestamps...). – Removed bullets about VLAN tags. – Changed “Flexible...” to “Fixed address filtering modes:”. – Removed some details of MAC Rx features bullet. – Removed Transaction layer Tx/Rx features bullets. – Removed some details of DMA block features bullet. – Removed some details of Audio and video features bullet. – Removed some Generic queuing features bullet. – Added SDMMC feature details. – Added OctalSPI feature details. – Reworked Low power supply options – Updated bullet “182 KB HSM...32 KB data)” to “224 KB HSM...32 KB data)” – Updated “RGMII PHY...on TX clock” in bullet One ethernet controller 10/100/1000 Mbps *Table 3: Features list*: – Other - SMPS deleted. – Changed MCAN, I2C, OctalSPI description. – Removed SIPI/LFAST, USB, HyperBus and SMPS features. – Updated row headed User Flash. – Updated row headed Security Flash. – Updated row headed DSPI. – Removed I2S feature. Updated *Figure 2: Block diagram* Updated *Figure 3: Periphery allocation*

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 3: Embedded memories*: Updated *Section 3.2.1: System SRAM* Updated *Figure 5: Flash memory segmentation and Read While Write partitioning* *Chapter 5: Memory Map* *Table 5: Overview Memory Map*: – changed OctalSPI start and end addresses to 0x60000000–0x80000200B. – removed USB mapping. *Table 6: Flash memory map*: updated Security Code Flash block3 and block5 addresses and descriptions. *Table 7: System and stand-by RAM memory map*: – Updated HSM end offset. – Updated start offset of a reserved field *Table 8: Processor local RAM memory map*: Updated I-MEM CPU_0 end offset Updated *Table 9: OctalSPI memory map* *Table 10: SDMMC register map*: Added footnote on Reserved *Table 11: Peripheral memory map (PBRIDGE 2)* – Removed CCCU_0 – Changed SEM42 by SEMA42 – removed XBIC_Concentrator_1 at start address 0xF4010000. – added IIC_2 at start address 0xF7E6C000. – added PLL_DIG_ETH at start address 0xF7FB0140. – removed LFAST_0 at start address 0xF7FD8000. *Table 12: Peripheral memory map (PBRIDGE 1)*: – added IIC_1 at start address 0xFBE68000. – added IIC_3 at start address 0xFBE6C000. – added CMU_18 at start address 0xFBFB0600. – removed SIPI_1 at start address 0xFBFD0000. – removed LFAST_1 at start address 0xFBFD8000. *Table 13: Peripheral memory map (PBRIDGE 0)*: – removed I2S_0 at start address 0xFFE68000. – removed I2S_1 at start address 0xFFE6C000. – added DSPI_LP at start address 0xFFE70000. – added PCM_1 at start address 0xFFE74000. – added CAN_SUB_3_MESSAGE_RAM at start address 0xFFED8000. – added CAN_SUB_3_M_CAN_1/2/3/4 respectively at start address 0xFFEF4000/0xFFEF8000/0xFFEFC000/0xFFF00000. – removed SIPI_0 at start address 0xFFFD0000. Removed Section: Security module memory *Table 14: UTest memory map*: Added a footnote, “Factory could program.....find it” to the “UTest DCF records” for Start offset of 0x0370.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 6: Functional safety* *Table 16: Module classification*: ViMos classification: – changed Module description for all cores. – removed concentrator DMA, MC_PMC and PIT modules. – added MC_PCU, PMC_DIG, GST, PBRIDGEn, IAHBG, PLLDIG_ETH, and IRCOSC modules. – Added “Concentrator HSM” PeMos classification: – removed XBAR_1, SD ADC and PBRIDGEn modules. – added BCTU and eMIOS modules. – removed M_TTCAN and LFAST NoSaMos classification: – added DSPI_LP, RTC, SSWU, LPRC, OSC32K, DCI, PASS and TDM modules. – removed external memory interface (LFAST and SIPI) and Concentrator HSM – Changed SEMA4 by SEMA42. SuMos classification: – removed IRCOSC module. – added STCU2, XBIC and SMPU modules. Updated *Figure 6: Simplified view of E2E ECC* *Table 17: FCCU failure inputs*: Updated source names for FCCU channels 54 & 55 *Table 18: ECC RAM implementations*: Replaced all JTAG occurences by ITAG *Section 6.4.4.4: Memory Error Management Unit (MEMU)*: – Rephrased the first paragraph. – removed MEMU connections figure. *Chapter 7: Device configuration* Extensive changes throughout the chapter *Chapter 8: Reset and Boot* Updated *Section 8.1: Introduction* Updated *Section 8.3.1: Power-on and the Reset Generation Module* Updated *Figure 45: Reset Generation Module Reset Sequence* Updated *Table 125: Module status during reset phases* *Section 8.3.2: Power-up phase: power stabilization*: – removed ESR0 from the fifth bullet. – changed Peripheral supplies VDD_HV_IO_JTAG to VDD_HV_IO_ETH*, and VDD_HV_IO_FLEX to VDD_HV_IO_EMMC. *Section 8.3.6: PHASE3[DEST] Phase: device configuration*: removed “either” and “or ESR0” from the note. Updated *Section 8.3.8: PHASE1[FUNC] Phase: temporization and monitoring setup* *Section 8.3.10: PHASE3[FUNC] Phase: device configuration monitoring*: removed “ESR0” pin from the second bullet (second set).

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 10: Power management* Updated *Figure 60: Device power management framework* *Table 143: Device power management controller external signals*: Updated rows-headed VDD_HV_IO_ETH0 and VDD_HV_IO_ETH1; added row-headed VDD_HV_IO_EMMC Updated *Section 10.1.3: Power management controller overview* Updated *Figure 62: Voltage Monitor Coverage*(1)(2) *Table 144: Voltage monitors description*: Updated rows-headed LVD290_EMMC, LVD290_ETH1, LVD290_ETH0, HVD400_ETH0, HVD400_ETH1, LVD400_EMMC, LVD400_ETH0, LVD400_ETH1, UVD600_ETH0 and UVD600_ETH1 Updated *Figure 64: Voltage monitors functionality* Updated *Figure 68: VDD_HV monitored voltages during power-up* *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* *Section 11.3: Architecture* – Updated 1st bullet list with DSPI_LP and PCM1. – Updated last bullet list with sentences for DSPI_LP and PCM1. Updated *Figure 71: Smart Wake-up Architecture* Updated *Figure 72: SSWU clock architecture* *Figure 83: Commands list register 1–64 (CLR1–CLR64)*: changed Channel bit field to [18:23] *Table 159: CLR1–CLR64 field descriptions*: changed Channel bit field to [18:23] Added *Section 11.5.11.5: Commands list register 1–64 (CLR1–CLR64) - DSPI client* *Table 166: CTUCR field descriptions*: – Updated description of bitfield GRE – updated note for bit field 24. *Section 11.5.15: Double buffered registers*: Updated definitions of GRE and FGRE *Section 11.6.2: CD (Command Dispatcher)* – *Table 169: OPC Command*: updated description for [2:0] value 010-111. – *Table 170: PDC Commands*: updated description for [6:5] value 11. Added *Section 11.6.6.2: DSPI frame* *Chapter 13: Debug and Trace* Updated *Section 13.2.1: Debug and Calibration Interface (DCI)*: Removed Section: JTAG Master (JTAGM) *Section 13.2.6: JTAG Master (JTAGM)*: Updated the paragraph “The JTAG Master (JTAGM)...JTAG-mapped resources.” Removed Section: Development Trigger Semaphore (DTS) *Section 13.3: Debug over CAN*: Updated paragraph “As well as supporting...JTAG interface.” *Table 179: DCI_PINCR register field descriptions*: changed PINCR1 and PINCR3 bit field value 10 to “No client is selected”. Updated *Section 13.4.1: Nexus Port Controller (NPC)* Updated *Figure 105: NXMC integration block diagram* Updated *Table 191: NXMC source and master client IDs*

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 15: Core (z4256n3) description* Updated *Figure 107: Core (z4256n3) Supervisor Mode Programmer's Model SPRs* Updated *Table 200: Exceptions and conditions* *Figure 130: DMEM Configuration Register 0 (DMEMCFG0)*: updated DMSIZE. *Chapter 16: System Integration Unit Lite2 (SIUL2)* *Section 16.2.2: Register descriptions*: – *Table 234: SIUL2_MIDR1 field descriptions*: changed default value in the description of bit field 0:15. *Section 16.2.2.11: Soc Configuration Register 0 (SIUL2_SCR0)*: – updated Note. – *Figure 149: Soc Configuration Register 0 (SIUL2_SCR0)*: updated. – *Table 244: SIUL2_SCR0 field descriptions*: updated. *Section 16.2.2.12: I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IOn)*: changed the latest sentence by referring to the device I/O_Definition document. *Table 246: SIUL2_MSCR_IOn field description* : – Changed WPDE and WPUE field descriptions. – Updated description of ILS bitfield – 101 changed to Reserved for ODC bit field *Chapter 17: Crossbar switch (XBAR)* *Table 255: XBAR memory map*: added MASTER channel n (n = 0 to 7) title and XBAR_MGPCRn registers at 0x0800 +n*0x100 address offsets. *Table 257: XBAR_CRSn field descriptions*: Updated the note of PARK field from " Only select master.....behavior may occur." to "Only select master.....parking configuration." *Section 17.3.3: Master General Purpose Control Register (XBAR_MGPCRn)*: added this section. *Chapter 22: Semaphores2 (SEMA42)* *Table 288: Memory map/register definition*: – Updated register name for 0x0040 – Deleted line for 0x0042 – Updated Address offset for Reserved line Updated *Section 22.2.2: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: – *Figure 189: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT)*: added RSTGSM and RSTGMS. – *Table 290: SEMA4_RSTGT field descriptions*: added RSTGSM and RSTGMS. Removed Section: Semaphores2 (Secure) Reset Gate (SEMA4_RSTGT_R) *Chapter 26: Clocking* Updated *Figure 252: Clock generation (part 1 of 2)* *Table 353: MC_CGM relationship to clocks*: – STM and SWT moved from CGM_SC_DC3 to CGM_SC_DC1. – Output clock for LIN_CLK0 and LIN_CLK1: updated.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	– changed CGM_AC2_DC1 register description. – removed PD LFAST PLL output clock from CGM_AC1_SC register. – addedCGM_AC10_DC0/SC registers description. – SEM4 replaced by SEMA42. – updated CGM_AC2_DC1 with PLL0_PHI_DIV. – updated CGM_AC10_SC with ETH_PLL_REF_CLK. – updated CMU_OCTSPI_CLK by CMU_16_OCTSPI_CLK – updated CMU_PER_CLK1 by CMU_17_PER_CLK1 – updated Note with CMU_18 *Table 354: Maximum system level clock frequencies*: updated value to 160 MHz in PFBRIDGE_CLK Note. *Table 355: Maximum auxiliary level clock frequencies*: – row “FRAY_CLK”: updated ‘40’ by ‘80’. – changed Aux Clock 1 Selector at divider 1 to CAN_CLK3 at 25 MHz. – set frequency of Aux Clock 8 Selector to 80 MHz. – added footnote to OCTSPI_CLK – updated Aux Clock 2 Selector with PLL0_PHI_DIV. – updated Aux Clock 10 Selector with PLL_ETH. Updated *Figure 254: Clock distribution in Stand-by Domain* updated. *Section 26.5: Clock sources*: added clock source bullet ETHPLL. Added *Section 26.5.1.3: PLL_ETH* Updated *Section 26.5.1.4: PLL register interface* Updated *Figure 256: Clock distribution* Updated *Figure 26.6.3.1: Reference Clock for PTP Timestamp Logic* Deleted Ethernet 100 Mbps interfaces Updated *Figure 26.6.3.1: Reference Clock for PTP Timestamp Logic* Deleted Ethernet 1000 Mbps interfaces *Section 26.5.1.8: PLLDIG initialization information*: added, at the end of the section, Note “PLL_ETH is not controlled...”. *Section 26.6.3.1: Reference Clock for PTP Timestamp Logic*: replaced PER_CLK0 by PER_CLK1. *Table 363: Clock input sources*: added CMU_18_ETH. *Chapter 27: Dual PLL digital interface (PLLDIG)* *Section 27.1: Introduction*: Added note with a cross-reference to Clocking chapter for chip-specific implementation details *Figure 260: Dual PLL digital interface block diagram*: updated this figure by adding a divider by 2 in PLL0 block. *Section 27.4: Modes of operation*: – Changed “the operating modes” by “the operating mode” – Changed “The various modes of operation for the PLL are” by “The mode of operation for the PLL is defined below” *Figure 261: PLL0 control register (PLL0CR)*: added sentence “Exception is CLKCFG bits control the PD for PLL_DIG_ETH.” to note *3.*

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 28: Clock Monitor Unit (CMU)* *Section 28.4.1.1: CMU Control Status Register (CMU_CSR)*: Updated the description of RCDIV from, “Ensure clock.....CMU_CSR[RCDIV].” to “ Ensure clock.....otherwise the operation can lead to a spurious OLR event.” *Chapter 29: Clock Generation Module (MC_CGM)* Changed LFAST_PLL by CAN_CLK3 in the chapter. Fixed offsets for registers: – CGM_AC13_SC/SS/DC0 – CGM_AC14_SC/SS/DC0/DC1 – CGM_AC15_SC/SS/DC0. *Section 29.3: Memory map and register definition*: *Table 383: MC_CGM memory map*: added CGM_AC10_SC and CGM_AC10_SS. *Table 421: CGM_AC1_SC field descriptions*: changed 0101 to Reserved. *Table 422: CGM_AC1_SS field descriptions*: changed 0101 to Reserved. *Section 29.3.1.40: Auxiliary Clock 1 Divider 0 Configuration Register (CGM_AC1_DC0)*: changed DIV size to [10:15]. Updated *Section 29.3.1.42: Auxiliary Clock 2 Divider 1 Configuration Register (CGM_AC2_DC1)* – *Figure 318: Auxiliary Clock 2 Divider 1 Configuration Register (CGM_AC2_DC1)*: changed DIV bit field to [11:15] and changed [30:31] to Reserved. – *Table 425: CGM_AC2_DC1 field descriptions*: changed DIV bit field to [11:15], changed I2S_CLK by PLL0_PHI_DIV and removed line for [30:31]. Added *Section 29.3.1.59: Auxiliary Clock 10 Select Control Register (CGM_AC10_SC)* Added *Section 29.3.1.60: Auxiliary Clock 10 Select Status Register (CGM_AC10_SS)*: *Section 29.4.2: Auxiliary clock generation*: added link to CGM_AC10_SC. *Chapter 30: OSC digital interface (XOSC)* Added *Section 30.2.4.1: Automatic Level Control (ALC)* *Chapter 35: Flash memory controller* Updated *Section 35.5.13.1.1: e2eECC and Flash accesses* Updated *Section 35.5.14: e2eECC on data Flash accesses* *Chapter 36: Embedded Flash Memory* *Table 488: Flash memory partition 4 memory map*: corrected B2F4 addresses from 0x012C_0000 to 0x012F_FFFF. *Section 36.3.2.1: Module Configuration Register (MCR)*: – updated description of bitfield EEE – updated PEEE field description. Updated size of customer OTP area in *Table 494: UTEST block memory map* Updated bitfields EEE and DWEE in *Table 497: MCR field descriptions* Updated bitfields N64KL and N16KL in *Table 500: MCRE field descriptions*

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	Updated bitfield PDWEE in *Table 511: MCR2 field descriptions* Updated bitfield ADDR in *Table 513: ADR field descriptions* Updated bitfield PADR in *Table 550: ADR2 field descriptions* Updated *Section 36.4.4.2: Error correction code* Added *Section 36.4.4.2.1: Multi-bits error management (more than 3 bits error >=4)* Added SEL3 in the text description of *Table 555: Flash Modify operations* Updated *Section 36.4.1: Reset* *Chapter 37: Flash Memory Programming and Configuration* Updated *Section 37.4: Secure read protection* *Chapter 39: Analog-to-Digital Converters (ADC) Configuration* *Section 39.2.1.1.1: 12-bit Fast SAR ADC*: updated “analog input channel for each SARADC instances. Updated *Section 39.2.1.1.3: 10-bit Fast SAR ADC STDBY* Updated *Figure 450: SAR ADC integration diagram*(1)(2) *Chapter 40: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Section 40.4.4.1: Conversion timings*: Changed SAMPSEL by CTSEL field name. *Section 40.4.6: Test channel connection with internal analog channel*: removed temperature sensor and bandgap from the first sentence of the first paragraph. Updated *Table 567: SARADC digital interface register map* *Table 568: MCR field descriptions*: – Added note to NSTART, JSTART and PWDN field descriptions. – Updated the note for NSTART *Table 587: PDEDR field descriptions*: added latest paragraph in PDED field description. *Table 588: ICDRn field descriptions*: Updated CDATA field description. Added *Table 589: Valid data bit organization* *Chapter 45: Periodic Interrupt Timer (PIT)* *Section 45.5: Example Configuration for the Lifetime Timer*: Updated *Equation 29:* From, “current_uptime = PIT_LTMR64H << 64” to “current_uptime = PIT_LTMR64H << 32” *Chapter 46: Enhanced Modular IO Subsystem (eMIOS)* Updated *Section 46.1.2: Features of the eMIOS module* *Figure 534: Channel configuration*: updated this figure with eMIOS_2 that is similar to eMIOS_1. *Figure 541: eMIOS bus counters*: added figure footnote *Note:* for eMIOS_2. *Chapter 47: Global System Timer (GST)* Extensive changes throughout the chapter

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 48: CAN Subsystem* *Section 48.1: Introduction*: add bullet for CAN subsystem 3. *Table 735: IP user manual versions*: changed MCAN IP version to Revision 3.2.3. Updated *Table 736: M_CAN memory map* *Table 739: DBTP field descriptions*: updated DBRP field description. *Table 744: TSCC field descriptions*: – TCP: Removed the note, “With CAN FD...(TSS = ‘10’).” – TSS: Added a note, “In case of CAN FD mode...timestamp generation.” Removed Section: Clock Calibration on CAN Unit (CCCU) *Table 743: NBTP field descriptions*: updated range of NTSEG2 field description. *Table 793: Shared memory map versus CAN transmit, receive and filters elements*: added CAN Subsystem_3 - PBRIDGE_0 details. *Chapter 49: Ethernet 10 Mbps/100 Mbps* Extensive changes throughout the chapter *Chapter 50: Ethernet 10 Mbps/100 Mbps/1000M bps* Extensive changes throughout the chapter *Chapter 51: FlexRay communication controller (FlexRay)* *Table 1448: FlexRay memory map*: Added Strobe Port Control Register (FR_STBPCR) at 0x000A offset. Added *Section 51.5.2.7: Strobe Port Control Register (FR_STBPCR)* *Figure 1444: Stop Watch Count High Register (FR_STPWHR)* and *Figure 1445: Stop Watch Count Low Register (FR_STPWLR)*: Changed register and STPW field accesses to Read-only (was Read-write). *Chapter 53: Peripheral Sensor Interface (PSI5)* Updated *Table 1613: PSI5 memory map* *Figure 1539: PSI5 Channel Control Register (PSI5_CH0_PCCR)*: Updated the access of bit 16 from “Read only” to “RW” and added a note “This is a redundant bit and RW will not have any effect”. *Chapter 54: Peripheral Sensor Interface-Support module (PSI5-S)* *Section 54.1.2: Features*: – Removed “(big endian)” from the first bullet. – Removed GTM from the seventh bullet. *Figure 1629: PSI5-S global control register (PS_GLCR)* and *Figure 1630: PSI5-S global status register (PS_GLSR)*: removed GTM from TRIG_SEL field name and descriptions. *Table 1701: PS_WD_CFGR_CHn field descriptions*: removed GTM from WDCS field description. *Table 1704: PS_E2SCR_CHn field descriptions*: removed GTM from DDSR_SHIFT_SEL and DDSR_CLK_SEL field descriptions. *Figure 1663: DDSR internal shift trigger generator*: updated this picture. *Section 54.4.4: Timestamp*: removed GTM from trigger in the first paragraph. *Figure 1672: Clock distribution in PSI5-S*: updated this picture.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 55: Deserial Serial Peripheral Interface (DSPI)* *Table 1713: DSPI_MCR field descriptions*: added Note to field 24 description *Chapter 56: LINFlexD* *Section 56.2.2: UART mode features*: updated the 3 latest bullets. *Table 1778: TCD setting: UART - Tx mode*: removed note at DADDR[31:0]. *Table 1779: TCD setting: UART - Rx mode*: removed note at SADDR[31:0]. *Table 1780: LINFlexD memory map*: Removed “Register classification” column. *Chapter 58: OctoSPI interface (OCTOSPI)* *Section 58.3: OCTOSPI functional description*: replaced ‘12’ by ‘11’, removed nCLK line *Figure 1887: OCTOSPI block diagram for octal communication*: removed OCTOSPI_NCLK *Section 58.3.2.6: DTR mode*: added Note. *Section 58.3.3: HyperBusTM mode*: removed ‘to 12’, ‘depending on the operating voltage’ and nCLK line *Section 58.5.2: OCTOSPI device configuration*: – added bullet and sentence related to CKCSHT. – removed ‘CKCSHT’ bullet. *Table 1869: OCTOSPI memory map* updated with 5 new registers. *Section 58.7.2.2: Device configuration register 1 (OCTOSPI_DCR1)*: – added field CKCSHT. – fixed “RESRVED” by “RESERVED” *Table 1872: OCTOSPI_DCR2 field descriptions*, bitfield WRAPSIZE: added sentence “For memories... the OCTOSPI_WPIR register”. *Section 58.7.2.5: Device configuration register 4 (OCTOSPI_DCR4)* added. *Section 58.7.2.14: Communication configuration register (OCTOSPI_CCR)* and *Section 58.7.2.23: Write communication configuration register (OCTOSPI_WCCR)*: – updated fields DDTR with ‘data’ instead of ‘alternate bytes’ – removed duplicated lines for fields ABMODE – fixed “height” by “eight” – updated ADDTR access to RW. *Section 58.7.2.19: Wrap communication configuration register (OCTOSPI_WPCCR)* to *Section 58.7.2.22: Wrap alternate bytes register (OCTOSPI_WPABR)* added. *Table 1901: OCTOSPI_DELAY_CTRL field descriptions* and *Table 1902: OCTOSPI_DELAY_CFG field descriptions*: updated field descriptions. Updated *Section 58.7.2.3: Device configuration register 2 (OCTOSPI_DCR2)* and *Section 58.7.2.29: Version register (OCTOSPI_VER)* *Chapter 59: Reset Generation Module (MC_RGM)* Updated *Section 59.3.1.12: Peripheral Reset Register 0 (RGM_PRST0)* – *Figure 1951: Peripheral Reset Register 0 (RGM_PRST0)*: Removed bitfields 20: SIPI_0_RST and 22: LFAST_0_RST – *Table 1915: RGM_PRST0 register field descriptions*: Removed row-headed SIPI_0_RST and LFAST_0_RST

Date	Revision	Changes
28-Jun-2019	2 (contd.)	Updated *Section 59.3.1.13: Peripheral Reset Register 1 (RGM_PRST1)* – *Figure 1952: Peripheral Reset Register 1 (RGM_PRST1)*: Added bitfield 0: M_CAN_4_SUB_3_RST and removed bitfield 1:CCCU_RST – *Table 1916: RGM_PRST1 register field descriptions*: Added row headed M_CAN_4_SUB_3_RST and removed row-headed CCCU_RST Updated *Section 59.3.1.14: Peripheral Reset Register 2 (RGM_PRST2)* – *Figure 1953: Peripheral Reset Register 2 (RGM_PRST2)*: Added bitfield 22: CAN_RAM_SUB_3_CTR_RST, 29: M_CAN_1_SUB_3_RST, 30: M_CAN_2_SUB _3_RST and 31: M_CAN_3_SUB_3_RST; and removed bitfield 20: USB_RST – *Table 1917: RGM_PRST2 register field descriptions*: Updated description for row headed eMMC_RST; added row headed CAN_RAM_SUB_3_CTR_RST, M_CAN_1_SUB_3_RST, M_CAN_2_SUB_3_RST and M_CAN_3_SUB_3_RST; and removed row-headed USB_RST Updated *Section 59.3.1.15: Peripheral Reset Register 3 (RGM_PRST3)* – *Figure 1954: Peripheral Reset Register 3 (RGM_PRST3)*: Added bitfield 23: DSPI_LP_RST and 24: PCM_1_RST; updated 27: IIC_2_RST; and removed bitfield 25: I2S_0_RST – *Table 1918: RGM_PRST3 register field descriptions*: Updated row headed IIC_2_RST; added row headed DSPI_LP_RST and PCM_1_RST; and removed row-headed I2S_0_RST Updated *Section 59.3.1.17: Peripheral Reset Register 5 (RGM_PRST5)* – *Figure 1956: Peripheral Reset Register 5 (RGM_PRST5)*: Added bitfield 3: M_CAN_1_SUB_2_RST, 4: M_CAN_2_SUB_2_RST, 5: M_CAN_3_SUB_2_RST, and 6: M_CAN_4_SUB_2_RST – *Table 1920: RGM_PRST5 register field descriptions*: Added row headed M_CAN_1_SUB_2_RST, M_CAN_2_SUB_2_RST, M_CAN_3_SUB_2_RST, and M_CAN_4_SUB_2_RST Updated *Section 59.3.1.18: Peripheral Reset Register 6 (RGM_PRST6)* – *Figure 1957: Peripheral Reset Register 6 (RGM_PRST6)*: Added bitfield 31: CAN_RAM_SUB_2_CTR_RST – *Table 1921: RGM_PRST6 register field descriptions*: Added row headed CAN_RAM_SUB_2_CTR_RST Updated *Section 59.3.1.19: Peripheral Reset Register 7 (RGM_PRST7)* – *Figure 1958: Peripheral Reset Register 7 (RGM_PRST7)*: Added bitfield 26: IIC_1_RST and 27: IIC_3_RST – *Table 1922: RGM_PRST7 register field descriptions*: Added row headed IIC_1_RST and IIC_3_RST Updated *Section 59.3.1.20: Peripheral Reset Status Register 0 (RGM_PSTAT0)* – *Figure 1959: Peripheral Reset Status Register 0 (RGM_PSTAT0)*: Removed bitfields 20: SIPI_0_STAT and 22: LFAST_0_STAT – *Table 1923: RGM_PSTAT0 register field descriptions*: Removed row-headed SIPI_0_STAT and LFAST_0_STAT Updated *Section 59.3.1.21: Peripheral Reset Status Register 1 (RGM_PSTAT1)* – *Figure 1960: Peripheral Reset Status Register 1 (RGM_PSTAT1)*: Added bitfield 0: M_CAN_4_SUB_3 _STAT and removed bitfield 1: CCCU_STAT – *Table 1924: RGM_PSTAT1 register field descriptions*: Added row headed M_CAN_4_SUB_3_STAT and removed row-headed CCCU_STAT

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	Updated *Section 59.3.1.22: Peripheral Reset Status Register 2 (RGM_PSTAT2)* – *Figure 1961: Peripheral Reset Status Register 2 (RGM_PSTAT2)*: Added bitfield 22: CAN_RAM_SUB_3_CTR_STAT, 29: M_CAN_1_SUB_3_STAT, 30: M_CAN_2_SUB_3_STAT and 31: M_CAN_3_SUB_3_STAT; and removed bitfield 20: USB_STAT – *Table 1925: RGM_PSTAT2 register field descriptions*: Updated description for row headed eMMC_STAT; added row headed CAN_RAM_SUB_3_CTR_STAT, M_CAN_1_SUB_3_STAT, M_CAN_2_SUB_3_STAT and M_CAN_3_SUB_3_STAT; and removed row-headed USB_STAT Updated *Section 59.3.1.23: Peripheral Reset Status Register 3 (RGM_PSTAT3)* – *Figure 1962: Peripheral Reset Status Register 3 (RGM_PSTAT3)*: Added bitfield 23: DSPI_LP_STAT and 24: PCM_1_STAT; updated 27: IIC_2_STAT; and removed bitfield 25: I2S_0_STAT – *Table 1926: RGM_PSTAT3 register field descriptions*: Updated row headed IIC_2_STAT; added row headed DSPI_LP_STAT and PCM_1_STAT; and removed row-headed I2S_0_STAT Updated *Section 59.3.1.25: Peripheral Reset Status Register 5 (RGM_PSTAT5)* – *Figure 1964: Peripheral Reset Status Register 5 (RGM_PSTAT5)*: Added bitfield 3: M_CAN_1_SUB_2_STAT, 4: M_CAN_2_SUB_2_STAT, 5: M_CAN_3_SUB_2_STAT, and 6: M_CAN_4_SUB_2_STAT – *Table 1928: RGM_PSTAT5 register field descriptions*: Added row headed M_CAN_1_SUB_2_STAT, M_CAN_2_SUB_2_STAT, M_CAN_3_SUB_2_STAT, and M_CAN_4_SUB_2_STAT Updated *Section 59.3.1.26: Peripheral Reset Status Register 6 (RGM_PSTAT6)* – *Figure 1965: Peripheral Reset Status Register 6 (RGM_PSTAT6)*: Added bitfield 31: CAN_RAM_SUB_2_CTR_STAT – *Table 1929: RGM_PSTAT6 register field descriptions*: Added row headed CAN_RAM_SUB_2_CTR_STAT Updated *Section 59.3.1.27: Peripheral Reset Status Register 7 (RGM_PSTAT7)* – *Figure 1966: Peripheral Reset Status Register 7 (RGM_PSTAT7)*: Added bitfield 26: IIC_1_STAT and 27: IIC_3_STAT – *Table 1930: RGM_PSTAT7 register field descriptions*: Added row headed IIC_1_STAT and IIC_3_STAT *Chapter 60: Boot Assist Flash (BAF)* Updated *Section 60.1: Introduction* *Chapter 61: System Status and Configuration Module (SSCM)* *Figure 1985: HSM and User Option Status Register (UOPS)*: – added fields FL_RUN, BAF_FA and FL_STDBY and their respective descriptions. – changed HSB bit field length to 3 bits and updated its description. *Section 61.2.1.3: Status register (SR)* – *Table 1952: SR field descriptions*: updated description. *Section 61.2.1.9: OTA Signature Address Location register (OSAL)*: updated sentence “When the OTA block is full...” and added Note. – *Table 1958: OSAL field descriptions*: updated description.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Section 61.2.1.10: Non Active Context Logical Address register (NACLA)* – *Table 1959: NACLA field descriptions*: updated description. *Section 61.3.3: Boot mode functionality*: updated Standby-Boot section. *Chapter 62: Power management controller digital interface (PMC_Dig)* *Table 1964: Power Management Controller Memory Map*: Updated row headed 0x0244 *Table 1966: VD number versus VD name table*: Updated VD meaning for row headed VD11 and VD14 *Table 1968: REE_LV0 field descriptions*: changed “REE” by “RES” in REE_XX field descriptions. *Table 1969: RES_LV0 field descriptions*: changed “RES” by “REE” in RES_XX field descriptions. *Table 1977: EPR_HV0 field descriptions*: Updated row headed LVD11_EMMC *Table 1978: REE_HV0 field descriptions*: Changed “REE” by “RES” in REE_XX field descriptions. Updated row headed REE11_EMMC *Table 1979: RES_HV0 field descriptions*: Updated row headed RES11_AD Changed “RES” by “REE” in RES_XX field descriptions. *Table 1980: IE_HV0 field descriptions*: Updated row headed LVD11IE_EMMC *Table 1981: FEE_HV0 field descriptions*: Updated row headed FEE11_EMMC *Table 1982: EPR_HV1 field descriptions*: Updated row headed LVD14_EMMC *Table 1984: RES_HV1 field descriptions*: Updated row headed RES14_EMMC *Table 1985: IE_HV1 field descriptions*: Updated row headed LVDIE14_EMMC *Table 1986: FEE_HV1 field descriptions*: Updated row headed FEE14_EMMC *Table 1987: GR_S field descriptions*: Updated row headed VD14_EMMC and VD11_EMMC *Figure 2022: Voltage selection of IO Register (VSIO)*: Updated reset value for bitfield 28: VSIO_EMMC *Table 1990: VSIO field description*: Updated row headed VSIO_EMMC *Section 62.5.26: HPREG SELECT STATUS (HPREG_SEL_S)*: – Changed HPRE to HPREG. – Updated bitfield 31 – *Table 1992: HPREG_SEL_S field descriptions*: changed “SMPS_HP_N_SEL” by “HPREG_SEL pad” in all field descriptions. *Section 62.5.27: Miscellaneous CTRL REG (MISC_CTRL_REG)*: – Changed Bit 31 to RESERVED with a footnote. – Updated bitfields 28 and 29 *Section 62.5.35: BIST Mask Status register (BIST_MASK_STATUS)*: Updated bitfield BIST_MASK *Section 62.5.39: User BIST Time1 and Time0 register (BIST_TIME10)*, *Section 62.5.40: User BIST Time3 and Time2 register (BIST_TIME32)* and *Section 62.5.41: User BIST Time6 and Time5 register (BIST_TIME65)*: added a cross-reference to Voltage monitor BIST programming section. *Table 2002: BIST_FLAGS_PHASE1 field descriptions* and *Table 2008: BIST_DEBUG field description*: Replaced “Status will be ignored” by “Status should be ignored”

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Section 62.9: Flash interface (DCF client usage)*: added 2 paragraphs relative to monitors reactions. Updated *Section 62.10: Voltage monitor BIST programming* *Chapter 64: Mode Entry Module (MC_ME)* *Table 2013: MC_ME register description*: – set ME_PCTL_9, ME_PCTL_11, ME_PCTL62, ME_PCTL75, ME_PCTL_77 and ME_PCTL102 registers to reserved. – added ME_PCTL_63, ME_PCTL_64, ME_PCTL_65, ME_PCTL_66, ME_PCTL_73, ME_PCTL_100, ME_PCTL_101, ME_PCTL103, ME_PCTL104, ME_PCTL_228 and ME_PCTL_229 registers. – changed ME_PCTL100 register to S_IIC_2 Control. – added S_CAN_SUB_2_* entries – restored ME_PCTL77, S_OctalSPI Control. *Section 64.4.1: Mode transition request*: Added a note, “If CMU reveals..... executed correctly. *Figure 2057: TEST Mode Configuration Register (ME_TEST_MC)*, *Figure 2058: SAFE Mode Configuration Register (ME_SAFE_MC)*, *Figure 2059: DRUN Mode Configuration Register (ME_DRUN_MC)* and *Figure 2060: RUN0–3 Mode Configuration Registers (ME_RUNn_MC)*: Removed the note “Only bit [3] has an effect...” *Figure 2064: Peripheral Status Register 0 (ME_PS0)* and *Table 2022: ME_PS0 register field descriptions*: removed S_SIPI_0 and S_LFAST_0 fields and their respective descriptions. *Figure 2065: Peripheral Status Register 1 (ME_PS1)* and *Table 2023: ME_PS1 register field descriptions*: – removed S_CCCU field and its description. – added S_CANSUBSYS3_MCAN_4 field and its description. *Figure 2066: Peripheral Status Register 2 (ME_PS2)* and *Table 2024: ME_PS2 register field descriptions*: – removed S_USB field and its respective description. – added S_CANSUBSYS3 _CAN_RAM_CTR, S_CANSUBSYS3 _MCAN_1/2/3 fields and their respective descriptions. *Figure 2067: Peripheral Status Register 3 (ME_PS3)* and *Table 2025: ME_PS3 register field descriptions*: – added S_DSPI_LP and S_PCM_1 fields and their respective descriptions. – changed field S_I2S_1 to S_IIC_2. – set S_I2S_0 field to reserved. *Figure 2069: Peripheral Status Register 5 (ME_PS5)* and *Table 2027: ME_PS5 register field descriptions*: – added S_CANSUBSYS2 _MCAN_1/2/3/4 fields and their respective descriptions. *Figure 2070: Peripheral Status Register 6 (ME_PS6)* and *Table 2028: ME_PS6 register field descriptions*: – added S_CANSUBSYS2_ CAN_RAM_CTR field and its descriptions. *Figure 2071: Peripheral Status Register 7 (ME_PS7)* and *Table 2029: ME_PS7 register field descriptions*: – added S_IIC_1 and S_IIC_3 field and their respective descriptions.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 66: Debug and Calibration Interface (DCI)* Extensive changes throughout the chapter *Chapter 69: JTAG Data Communication (JDC)* *Figure 2148: Module Status Register (JDC_MSR)*: corrected register access to read/write. *Chapter 71: JTAG Master (JTAGM)* Extensive changes throughout the chapter *Chapter 78: Memory Error Management Unit (MEMU)* *Table 2257: SYS_RAM_UNCERR_ADDR field descriptions*: Removed to “This register is not writable when the corresponding VLD bit is zero.” *Table 2264: FLASH_CERR_STSn register field descriptions*: Updated description of bitfield BAD_BIT to replace 0xFF by 0xFFFF *Table 2262: PERIPH_RAM_UNCERR_ADDR field descriptions* and *Table 2267: FLASH_UNCERR_ADDR field descriptions*: deleted the sentence “This register is not writable when the corresponding VLD bit is zero.)” *Chapter 79: Indirect Memory Access (IMA)* *Table 2271: E2EECSR0 field descriptions*: Corrected register name in title. *Chapter 80: Fault Collection and Control Unit (FCCU)* *Table 2290: FCCU memory map*: Removed “Register classification” column. *Table 2291: FCCU_CTRL field descriptions*: added field numbers *Figure 2364: FCCU Control Register (FCCU_CTRL)*, *Figure 2375: FCCU IO Control Register (FCCU_EINOUT)* and *Figure 2385: FCCU MCS Register (FCCU_MCS)*: Updated some reset bit values to “0/1” with a cross-reference to the Device configuration chapter. *Figure 2369: FCCU RF Status register n (FCCU_RF_Sn)*: Updated table footnote 1. *Section 80.6.8: FCCU RF Enable Register n (FCCU_RF_En)*: Deleted text “for debugging purposes”. *Section 80.6.13: FCCU Status Register (FCCU_STAT)*: Deleted text “for debugging purposes”. *Table 2309: FCCU_STAT field descriptions*: added a note to PhysicErrorPin field description. Deleted text “This register is for test/ debug purposes” from the following sections: – *Section 80.6.14: FCCU NA Freeze Status Register (N2AF_STATUS)* – *Section 80.6.15: FCCU AF Freeze Status Register (A2FF_STATUS)* – *Section 80.6.16: FCCU NF Freeze Status Register (N2FF_STATUS)* – *Section 80.6.17: FCCU FA Freeze Status Register (F2A_STATUS)* *Table 2313: F2A_STATUS field descriptions*: – Changed the table title from F2AF_STATUS to F2A_STATUS – Description of value 0xFF of bitfield FAFS: replaced word “critical” by word “recoverable” *Section 80.7: FCCU Output Supervision Unit*: updated this section.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 81: Self-Test Control Unit (STCU2)* *Section 81.4.2: Reset management*: added a third sentence. *Section 81.4.6: Interrupt interface*: added “there are two interrupt sources:” and a bullet “One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1)”. *Section 81.4.8.1: Initialization sequence*: updated second bullet *Table 2329: STCU2 memory map*: updated MBIST registers with k = 0 to 104. *Table 2330: STCU_RUN field descriptions*: updated MBSPLLEN and LBSPLLEN field descriptions. *Table 2331: STCU_RUNSW field descriptions*: Updated MBSWPLLEN and LBSWPLLEN field descriptions. *Table 2333: STCU_CFG field descriptions*: – Updated CLK_CFG field description. – Changed note in LB_DELAY field description. *Table 2335: STCU_WDG field descriptions*: updated WDGEOC field descriptions. *Table 2367: STCU_LB_CTRLn field descriptions*: – Updated CWS field description at enumerated value 0x0. – Updated SHS field description. *Table 2379: STCU_MB_CTRLk field descriptions*: updated PTR field description. *Figure 2443: STCU2 MBIST Control k Register (STCU_MB_CTRLk)*: updated offset values with k = 0 to 104. *Section 81.6: Use cases and limitations*: added paragraph: “The STCU setup has to be defined based on the application-specific safety, boot time and consumption requirements. Contact ST representative for support.” *Chapter 83: Password and Device Security Module (PASS)* *Table 2385: LCSTAT register field descriptions*: added note to all RLx field descriptions. Updated *Table 2399: Flash Memory Read Protection truth table* *Section 83.5.6.2.4: Fuse Bypass Password compare*: removed text “of the Flash page contain different data not related to Fuse Bypass” at the end of the first sentence. *Chapter 85: Wakeup unit (WKPU)* *Table 2419: WKPU memory map*: changed register WIPUER by WPDR at offset 0x0034. *Table 2420: NSR field descriptions*: added missing fields NIF2 and NOVF2. *Section 85.3.2.8: Wakeup/Interrupt Filter Enable Register (WIFER)*: Added a Note, “Glitch filter must be enabled in case the wake-up sources are used to exit from Standby.” *Section 85.3.2.9: Wakeup Padkeeper Disable Register (WPDR)*: – Updated the text from, “This register ..... value of 1” to “This register..... SIUL2_MSCR_IO_n.WPDE-WPUE bits.” – *Table 2428: WPDR field descriptions*: Replaced “Pullup” to “Pull” in the complete table. – Changed register WIPUER by WPDR with new definition.

Table 2437. Document revision history (continued)

Date	Revision	Changes
28-Jun-2019	2 (contd.)	*Chapter 86: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Section 86.4.6: RTC Compare Value Register (RTC_RTCVAL)*: Added a note “If RTC interrupt is enabled (RTCIE), it is required after each RTC counter match to reload the RTCVAL via software, to re-enable the interrupt again.”
22-Oct-2020	3	Throughout document: – Formatting and editorial changes; – Replaced System watchdog by SWT; – Removed section “Register classification for safety” Cover Page: Updated the sub-title Updated *Overview* *Chapter 2: Introduction* *Table 3: Features list*: updated CRC Channels from “2 x “4 to “3 x 4”. *Figure 2: Block diagram*: updated this figure. *Chapter 5: Memory Map* Added footnote *1.* in *Table 6: Flash memory map* Updated footnote *2.* in *Table 7: System and stand-by RAM memory map* *Table 9: OctalSPI memory map*: – Updated description for row-headed 0x60000000 and 0x70000000 – Added Note *2.* Added OCTALSPI_XBIC in *Table 11: Peripheral memory map (PBRIDGE 2)* Updated row-headed 0xFFC5C000 in *Table 13: Peripheral memory map (PBRIDGE 0)* *Chapter 6: Functional safety* Updated *Section 6.4.4.1: ECC for storage* for all devices *Table 17: FCCU failure inputs*: – Updated Failure Description for FCCU channel 15-18. – Updated failure description for FCCU channel 28 – Updated failure description for FCCU channel 66 – Updated failure description for FCCU channel 93 and added footnote – Updated FCCU channel 121 *Table 18: ECC RAM implementations*: – Added footnote for column-headed ECC in location Core0, Core1 and Core2 for all I-Dem and D-Mem – Updated MEMU Classification for Location HSM for devices – Updated column-head from memory classification to MEMU classification – Added footnote for column-headed ECC for System RAM for location Platform – Updated memory C3 to MPAES in row-headed HSM

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Chapter 7: Device configuration* Extensive changes throughout the chapter *Chapter 8: Reset and Boot* *Table 125: Module status during reset phases*: Updated row-headed SWT Updated *Section 8.3.5: PHASE2[DEST] Phase: flash initial configuration* *Section 8.3.10: PHASE3[FUNC] Phase: device configuration monitoring*: removed “ESR0” from sentence starting with “After all PHASE3[FUNC]...” Updated *Table 131: SSCM boot record search locations* *Chapter 9: Device Configuration Format (DCF) Records* *Table 135: DCF client list*: – Updated number of LBIST – Added row STCU_LBUFM – Added *2.* – Added row for ESR0_CONFIG – Updated row for PNREG_ENB Removed OPT_RGM_ESR0_HW in *Figure 54: UTEST Miscellaneous DCF Client* Removed row-headed OPT_RGM_ESR0_HW in *Table 137: UTEST Miscellaneous DCF Client field descriptions* *Chapter 11: Smart Stand-by Wake-up Unit (SSWU)* *Figure 100: Peripheral Control Module 1 register (PCM1)*, *Figure 101: Peripheral Control Module 2 register (PCM2)*, *Figure 102: Peripheral Control Module 3 register (PCM3)*: fixed offsets. Updated *Section 11.6.6.2: DSPI frame* Added *Table 172: IO mapping for DSPI_LP in SSWU mode* *Section 11.6.4: OPC*: added second and third bullets to the set of pads behavior. *Chapter 15: Core (z4256n3) description* Added note in *Section 15.10.1.1: End-to-End ECC Control Register 0 (E2ECTL0)* Updated *Figure 108: Core (z4256n3) Supervisor Mode Programmer's Model DCRs and PMRs* Updated *Section 15.9.2.1: DMEM Configuration Register 0 (DMEMCFG0)* Updated row-headed DMEM BASE ADDR *Table 225: DMEMCFG0 Field Descriptions* Updated *Section 15.9.2.4: IMEM Configuration Register 0 (IMEMCFG0)* Updated row-headed IMEM BASE ADDR *Table 228: IMEMCFG0 Field Descriptions* *Chapter 16: System Integration Unit Lite2 (SIUL2)* Updated bit 0 in *Figure 149: Soc Configuration Register 0 (SIUL2_SCR0)* Updated row-headed ETH1_RGMII_DOS, RGMII_TX_CLK_SEL and ETH1_REGPHY_IF_SELECT in *Table 244: SIUL2_SCR0 field descriptions* Updated row-headed ODC in *Table 246: SIUL2_MSCR_IOn field description*

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Chapter 17: Crossbar switch (XBAR)* *Table 256: XBAR_PRSn field descriptions*: added description of bitfield M3 *Chapter 18: Crossbar Integrity Checker (XBIC)* *Table 261: XBIC_EIR field descriptions*: In the second note, replaced “SMPU logical bus master assignments” with “AHB Master ID Assignments”. *Chapter 24: Enhanced Direct Memory Access (eDMA)* *Figure 206: Control Register (eDMA_CR)*: – changed GRP2PRI and GRP3PRI field access type to RW. – updated register reset value with a specific figure footnote. *Table 304: eDMA_CR field descriptions*: added note to GRP3PRI, GRP2PRI, GRP1PRI and GRP0PRI field descriptions. *Chapter 26: Clocking* Updated *Section 26.1: Introduction* *Section 26.8.1: Loss of PLL/XOSC clock*: Updated this section. Updated *Section 26.8.2: Loss of IRCOSC clock* *Table 355: Maximum auxiliary level clock frequencies*: – Added note to EMIOS_CLK. – Added note “DSPI_CLK frequency should always be greater than or equal to 1.25 times PBRIDGE_CLK” to DSPI_CLK. – Added note “80 MHz maximum frequency is at aux divider output. The maximum frequency of FRAY_CLK after the multiplexer is 40 MHz” to FRAY_CLK for Aux Clock 2 Selector. *Figure 26.6.3.1: Reference Clock for PTP Timestamp Logic* updated (text missing in Notes). *Section 26.5.1.7: Loss of clock detection*: deleted the last sentence “Software may enable or disable an optional backup clock in the PLL”. *Section 26.4: Default clock configuration*: Removed text about backup clock Updated *Figure 252: Clock generation (part 1 of 2)* Updated *Section 26.6.3: Ethernet clocking* Removed Ethernet 100 Mbps clocking Removed Ethernet 1000 Mbps clocking *Chapter 27: Dual PLL digital interface (PLLDIG)* *Figure 260: Dual PLL digital interface block diagram*: Backup Clock Selection” block is made blue and note added “Backup Clock Selection” block in blue is not implemented”. *Section 27.4.1: Normal mode with reference, PLL0 or both PLLs enabled*: added in Note cross-ref to *Section 27.7: Initialization information*. *Section 27.5.2.1: PLL0 control register (PLL0CR)*, *Section 27.5.2.4: PLL1 control register (PLL1CR)*: updated note for field LOLIE. *Chapter 28: Clock Monitor Unit (CMU)* Updated *Section 28.4.1.5: CMU Interrupt Status Register (CMU_ISR)*

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Chapter 30: OSC digital interface (XOSC)* Updated *Section 30.2.4.1: Automatic Level Control (ALC)* *Chapter 31: IRCOSC digital interface* *Table 471: IRCOSC_NT field descriptions*: updated description of bitfields FT_CODE and RCTRIM Updated chapter name *Chapter 34: Platform RAM controller AHB (PRAMC_AHB)* *Chapter 35: Flash memory controller* Updated *Section 35.5.16.1: Overview* *Chapter 36: Embedded Flash Memory* Added bit DDEF in *Section 36.3.2.17: User Test 0 register (UT0)* *Table 494: UTEST block memory map*: Added note to offset 0x140 Updated *Section 36.3.2.4: Lock 0 register (LOCK0)* Updated: – *Section 36.3.2.4: Lock 0 register (LOCK0)* – *Section 36.3.2.5: Lock 1 register (LOCK1)* – *Section 36.3.2.6: Lock 2 Register (LOCK2)* – *Section 36.3.2.7: Lock 3 Register (LOCK3)* – *Section 36.3.2.8: Alternate Lock 0 register (LOCK0A)* – *Section 36.3.2.9: Alternate Lock 1 register (LOCK1A)* – *Section 36.3.2.10: Select 0 register (SEL0)* – *Section 36.3.2.11: Select 1 register (SEL1)* – *Section 36.3.2.12: Select 2 register (SEL2)* – *Section 36.3.2.13: Select 3 register (SEL3)* *Chapter 37: Flash Memory Programming and Configuration* *Section 37.6.2: Creating the tamper detect diary*: – The maximum size of Diary updated from 2 KB to 4 KB. – Multiplied by 2 KB is updated to 4 KB. – Updated the *Example 7: Creating the tamper detect diary* *Example 4: Overriding secure write protection*: updated paragraph list 2. *Figure 436: Sample DCF record for secure write protection*: Updated the value of the figure. *Chapter 40: Successive Approximation Register Analog-to-Digital Converter (SARADC)* *Section 40.5.1.11: Watchdog Threshold Register n (WTHRHLRn)*: replaced in 1st note MSB=0 bits numbers by LSB=0 bit numbers. *Chapter 44: Software Watchdog Timer (SWT)* Removed section External signal description

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Chapter 46: Enhanced Modular IO Subsystem (eMIOS)* *Table 670: EMIOSMCR field descriptions*: Updated note in GTBE field description. *Chapter 47: Global System Timer (GST)* Removed register footnote and changed “word access” by “word write access” in the table description: – *Section 47.4.2.7: NSC lower word [31:0] reload register (NSC_LWORD_RELOAD)* – *Section 47.4.2.8: NSC higher word [63:32] reload register (NSC_HWORD_RELOAD)* – *Section 47.4.2.20: OTCn lower word [31:0] reload register (OTCn_LWORD_RELOAD)* – *Section 47.4.2.21: OTCn higher word [63:32] reload register (OTCn_HWORD_RELOAD)* Removed register footnote and added note to the table description: – *Section 47.4.2.28: ARCm reload config register (ARCm_RELOAD_VALUE)* – *Section 47.4.2.29: ARCm expiry config register (ARCm_EXPIRY_CFG)* – *Section 47.4.2.30: ARCm compare 1 config register (ARCm_COMPARE_1_CFG)* – *Section 47.4.2.31: ARCm compare 2 config register (ARCm_COMPARE_2_CFG)* – *Section 47.4.2.32: ARCm compare 3 config register (ARCm_COMPARE_3_CFG)* – *Section 47.4.2.33: ARCm compare 4 config register (ARCm_COMPARE_4_CFG)* *Table 730: TSk_BIT_SEL_CFG field descriptions*: updated description *Section 47.4: Memory map and register description*: added sub-sections titles and updated sections numbering. *Chapter 48: CAN Subsystem* *Section 48.3.5.2.3: Data Bit Timing and Prescaler Register (DBTP)*: corrected time quanta max number in the first sentence. *Table 757: XIDFC field descriptions*: corrected max enumerated value of LSE field to 0x7F. *Table 762: RXF0C field descriptions*: corrected max enumerated value of F0WM and FOS fields to 0x7F. *Table 793: Shared memory map versus CAN transmit, receive and filters elements*: changed to CAN_SUB_3_M_CAN_x in “CAN Subsystem_3 - PBRIDGE_0”. *Chapter 49: Ethernet 10 Mbps/100 Mbps* Extensive changes throughout the chapter *Chapter 50: Ethernet 10 Mbps/100 Mbps/1000M bps* Extensive changes throughout the chapter *Chapter 51: FlexRay communication controller (FlexRay)* *Table 1448: FlexRay memory map*: corrected not implemented and reserved spaces. *Figure 1422: Protocol Configuration Register 9 (FR_PCR9)*: corrected minislot_exists and symbol_window_exists field names.

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Figure 1423: Protocol Configuration Register 10 (FR_PCR10)*: corrected wakeup_channel field name. *Figure 1424: Protocol Configuration Register 11 (FR_PCR11)*: corrected key_slot_used_for_startup field name. *Section 51.5.2.67.23: Protocol Configuration Register 22 (FR_PCR22)*: updated bit field 'R' by 'Reserved'. *Chapter 52: Inter-Integrated Circuit (I2C)* Updated *Figure 1534: Flow-Chart of DMA mode master receive* *Section 52.4: Memory map and register definition*: added title *Section 52.4.2: Registers definition*: sub-section and updated registers sections numbering. *Chapter 55: Deserial Serial Peripheral Interface (DSPI)* Updated *Table 1713: DSPI_MCR field descriptions* *Section 55.4.6.3: Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)*: Added a second note. *Section 55.3.13: DSPI DSI Configuration Register 0 (DSPI_DSICR0)*: Added MTOE, MTOCNT, TRG, TPOL and TRRE fields with their descriptions. *Section 55.4.12.10: Receive FIFO Drain interrupt or DMA Request*: added 3 notes. *Chapter 56: LINFlexD* *Section 56.4: Memory map and register description*: added note that refer to the LinFlexD configuration of the Device Configuration chapter. *Table 1780: LINFlexD memory map*: removed note that refer to the Device Configuration chapter and all cross-references to this note. *Table 1805: DMATXE field descriptions*: field editorial changes to remove the table note. *Table 1806: DMARXE field descriptions*: field editorial changes to remove the table note. *Chapter 57: Secure Digital and MultiMediaCard controller (SDMMC)* Changed chapter title from "SD, SDIO and MMC card controller (SDMMC)" to "Secure Digital and Multi-Media Card controller (SDMMC)". *Section 57.1.2: Key features*: Removed "AMBA AHB" *Section 57.2.2.5: Clock generator*: updated. *Section 57.2.3: Clocks*: – Updated first sentence – Added note. *Figure 1839: Data port register (DATAPORT)*: Reset value is updated to 0000_0000. *Section 57.3.2.26: Capabilities[31:0] register (CAPABILITIES31_0)*: – Added fields "CORECFG_ASYNCHINTRSUPPORT" and "CORECFG_SUSPENDRESUME". – Updated the reset value. *Table 1841: CAPABILITIES31_0 field descriptions*: updated description for CORECFG_BASECLKFREQ.

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Figure 1857: Capabilities[63:32] register (CAPABILITIES63_32)*: Reset value is updated to 0000_0000. *Figure 1858: Maximum current capabilities[31:0] register (MAXCURRENTCAP31_0)*: Reset value is updated to 0000_0000. *Figure 1859: Maximum current capabilities[63:32] register (MAXCURRENTCAP63_32)*: Reset value is updated to 0000_0000. *Section 57.3.2.34: Force event for error interrupt status register (FORCEEVENTFORERRINTSTS)*: Removed “FORCETUNINGERR” field. *Section 57.2.2.2: Host controller register set*: Added paragraph “SDMMC IP does not provide....” *Figure 1840: Present state register (PRESENTSTATE)*: Updated the reset value of SDMMC_WP from 0 to 1. *Figure 1868: Core configuration register (CORE_CONFIG)*: Reset value of field “CORECFG_ASYNCHINTRSUPPORT” is changed from 0 to 1. *Section 57.3.2.30: Preset value n register (PRESETVALUEn)*: Updated the text from “shows a set of...device.” to “shows the offset...device”. *Section 57.3.2.16: Timeout control register (TIMEOUTCONTROL)*: added Note in TIMEOUT_CTRVALUE bit field. *Table 1821: PRESENTSTATE field descriptions*: Removed the notes from bits 18, 17, and 16. *Figure 1853: Error interrupt signal enable register (ERRORINTRSIGENA)*: Updated the “ERRORINTRSIG_ ENABLEREGBIT12” field from read only to read-write. *Figure 1855: Host control 2 register (HOSTCONTROL2)*: – Field “HOSTCTRL2_EXECUTETUNING” is updated to read-write. – Field “HOSTCTRL2_DRIVERSTRENGTH” is updated to Always read as 0 from read-write. *Chapter 58: OctoSPI interface (OCTOSPI)* Updated *Section 58.7: OCTOSPI memory map and registers*: added note. *Table 1896: OCTOSPI_HLCR field descriptions*: added Note to ‘LM’ bit field description. *Chapter 59: Reset Generation Module (MC_RGM)* *Table 1918: RGM_PRST3 register field descriptions*: In SAR_ADC_12BIT_B_RST field, added note “In case BCTU_0 is used to trigger SAR_ADC_12BIT_B....” *Section 59.4.7: ‘Destructive’ reset escalation*: added footnote to “each ‘destructive’ reset”. *Chapter 60: Boot Assist Flash (BAF)* *Section 60.3.8: Optionally perform a serial boot*: Deleted text “All Tx-channels have to be disabled during this phase” *Chapter 61: System Status and Configuration Module (SSCM)* *Table 1953: ERROR field descriptions*: Removed “This feature...application code.” for row-headed PAE and RAE Updated *Table 1962: Life Cycle Slots in Memory*

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	*Chapter 62: Power management controller digital interface (PMC_Dig)* Size of bitfields, TIME_x are updated to 12 bits from of 13 bits: – *Section 62.5.39: User BIST Time1 and Time0 register (BIST_TIME10)* – *Section 62.5.40: User BIST Time3 and Time2 register (BIST_TIME32)* – *Section 62.5.41: User BIST Time6 and Time5 register (BIST_TIME65)* Updated *Table 1964: Power Management Controller Memory Map* Removed footnote from *Figure 2021: Global Interrupt Enable Register (IE_G)* Added *Section 62.5.34: ESR0 Configuration Register (ESR0_CFG)* *Chapter 64: Mode Entry Module (MC_ME)* *Table 2021: ME_<mode>_MC Field Descriptions*: removed table footnote in XOSCON field description. *Chapter 66: Debug and Calibration Interface (DCI)* Updated *Section 66.1.3.3: SWT control* *Chapter 71: JTAG Master (JTAGM)* Updated row-headed IIE in *Table 2149: JTAGM_MCR register field descriptions* Updated *Table 2151: JTAGM_DOR0 register field descriptions* Updated *Table 2152: JTAGM_DOR1 register field descriptions* Updated *Table 2153: JTAGM_DOR2 register field descriptions* Updated *Table 2154: JTAGM_DOR3 register field descriptions* *Chapter 77: Cyclic Redundancy Check (CRC) Unit* *Figure 2307: CRC Configuration Register n (CRC_CFGn)*: swapped reset values versus function of n in the figure footnote of POLYG reset. *Chapter 80: Fault Collection and Control Unit (FCCU)* *Section 80.6.1: FCCU Control Register (FCCU_CTRL)*: Updated the bullet “configure the glitch filter present on location given by FILTER_POSITION parameter” to “configure the glitch filter present on EIN0 input (FCCU failure input #94)” and replaced text “(FCCU_RF_Sn[RFSx] where y = FILTER_POSTN)” to “FCCU failure input #94”. Updated *Figure 2348: FCCU block diagram* Updated row-headed “REG intf” for *Table 2281: FCCU submodules* Updated row-headed OPR for *Table 2291: FCCU_CTRL field descriptions* *Chapter 81: Self-Test Control Unit (STCU2)* For all available MBIST registers: – Added note, “Refer to..... number of NMCUT available in this device.” – Added note to all fields, “The availability of this field is based on.....Device configuration chapter” Updated *Section 81.4.9: CRC*

Table 2437. Document revision history (continued)

Date	Revision	Changes
22-Oct-2020	3 (contd.)	Updated *Section 81.5.6: STCU2 Watchdog Register Granularity (STCU_WDG)* *Section 81.5.8: STCU2 CRC Expected Status Register (STCU_CRCE)*: Added the note to “The expected value of the CRC depends on multiple internal critical signals and can differ among different samples.” *Section 81.5.5: STCU2 PLL Configuration Register (STCU_PLL_CFG)*: Added a note, “f_{RC} is the frequency if the internal RC oscillator (that is 16 MHz). f_{PLLin} must be higher than 8 MHz.” Updated row-headed LBIST registers in *Table 2329: STCU2 memory map* Updated Note in *Section 81.5: Register description* Updated Note in *Section 81.5.12: STCU2 Offline LBIST Status Register (STCU_LBS)* to *Section 81.5.15: STCU2 Online LBIST End Flag Register (STCU_LBESW)* Updated: *Section 81.5.38: STCU2 LBIST Control n Register (STCU_LB_CTRLn)* to *Section 81.5.49: STCU2 Online LBIST MISR Read High n Register (STCU_LB_MISRRHSWn)* *Chapter 83: Password and Device Security Module (PASS)* *Table 2398: Debug Interface Enable Truth table*: Updated the table. *Chapter 85: Wakeup unit (WKPU)* *Section 85.1.2: Features*: – Changed “configurable pullup” by “configurable padkeeper functionality”. – Added a note referring to the Device Configuration chapter. *Section 85.3.2.5: Wakeup Request Enable Register (WRER)*: added Note “Any wakeup pad...” *Chapter 86: Real Time Clock / Autonomous Periodic Interrupt (RTC/API)* *Section 86.4.6: RTC Compare Value Register (RTC_RTCVAL)*:updated note.
07-Jun-2021	4	Changed document classification from ST Restricted to Public.

IMPORTANT NOTICE – PLEASE READ CAREFULLY

STMicroelectronics NV and its subsidiaries (“ST”) reserve the right to make changes, corrections, enhancements, modifications, and improvements to ST products and/or to this document at any time without notice. Purchasers should obtain the latest relevant information on ST products before placing orders. ST products are sold pursuant to ST’s terms and conditions of sale in place at the time of order acknowledgement.

Product is not to be used following exposure greater than or equal to 50 KRAD silicon Total Ionizing Dose, for military applications, or for commercial space applications at altitudes above 50000 feet.

Purchasers are solely responsible for the choice, selection, and use of ST products and ST assumes no liability for application assistance or the design of Purchasers’ products.

No license, express or implied, to any intellectual property right is granted by ST herein.

Resale of ST products with provisions different from the information set forth herein shall void any warranty granted by ST for such product.
