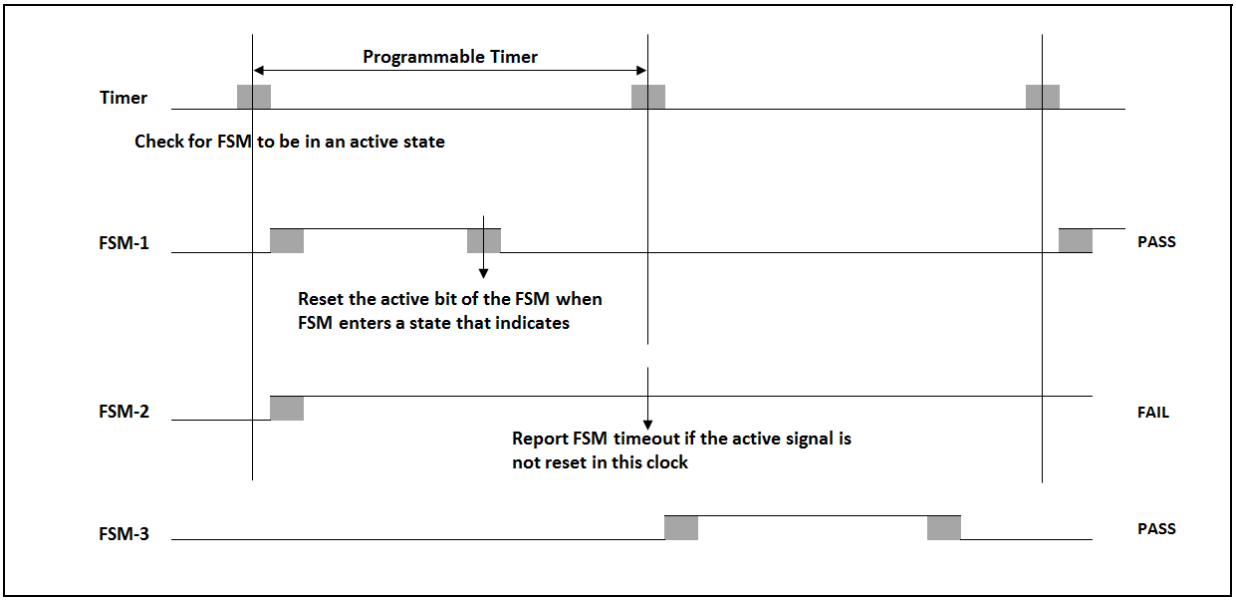
When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control register.

The FSM Parity error is classified as non-recoverable error and software intervention (IP reset) is required to recover from the error state.



50.3.18.3.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of APB cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1µs, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on

the programmable bits NTMRMD and LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

Figure 1320. FSM Timeout Timing diagram

In *Figure 1320*, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains.

The module does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting the module).

50.3.18.4 AHB Master Interface Timeout Protection

This feature provides timeout protection to the AHB Master Interface request. The timeout is triggered when AHB master interface initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register.

The hardware does not attempt to recover from AHB Master Interface hangs and relies on software to take appropriate corrective action.

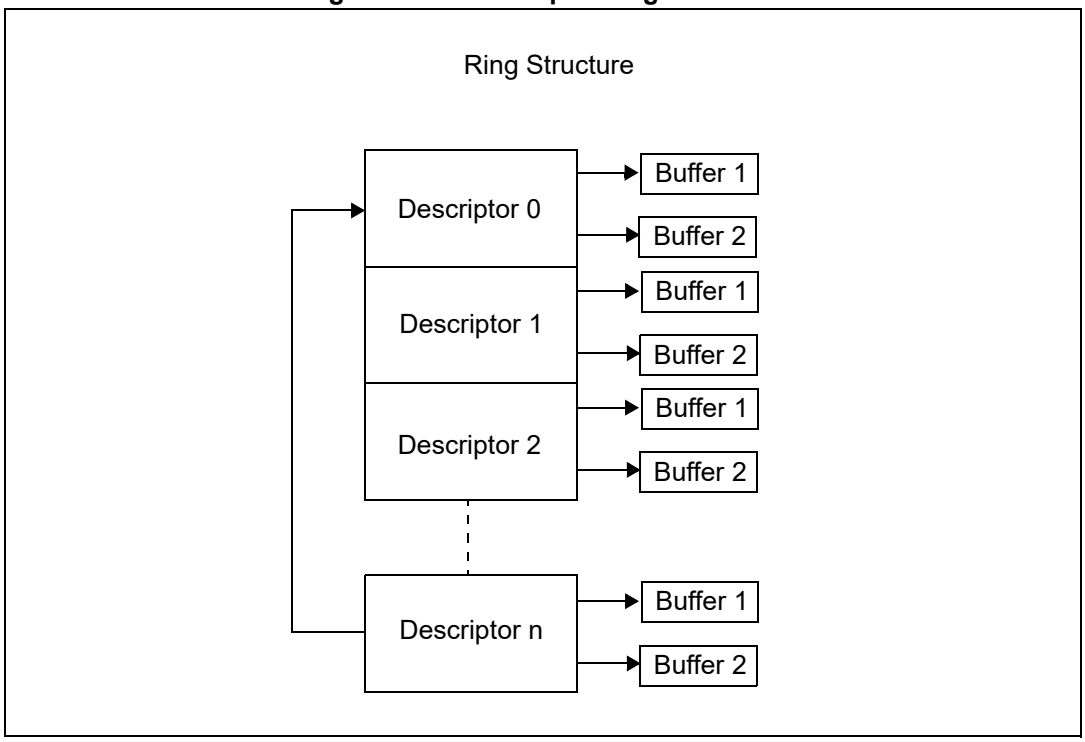
The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when AHB Master Interface timeout status is set.

50.4 Descriptors

50.4.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The Ethernet module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted



Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for number of descriptors that can be used for a single packet.

50.4.2 Descriptor structure

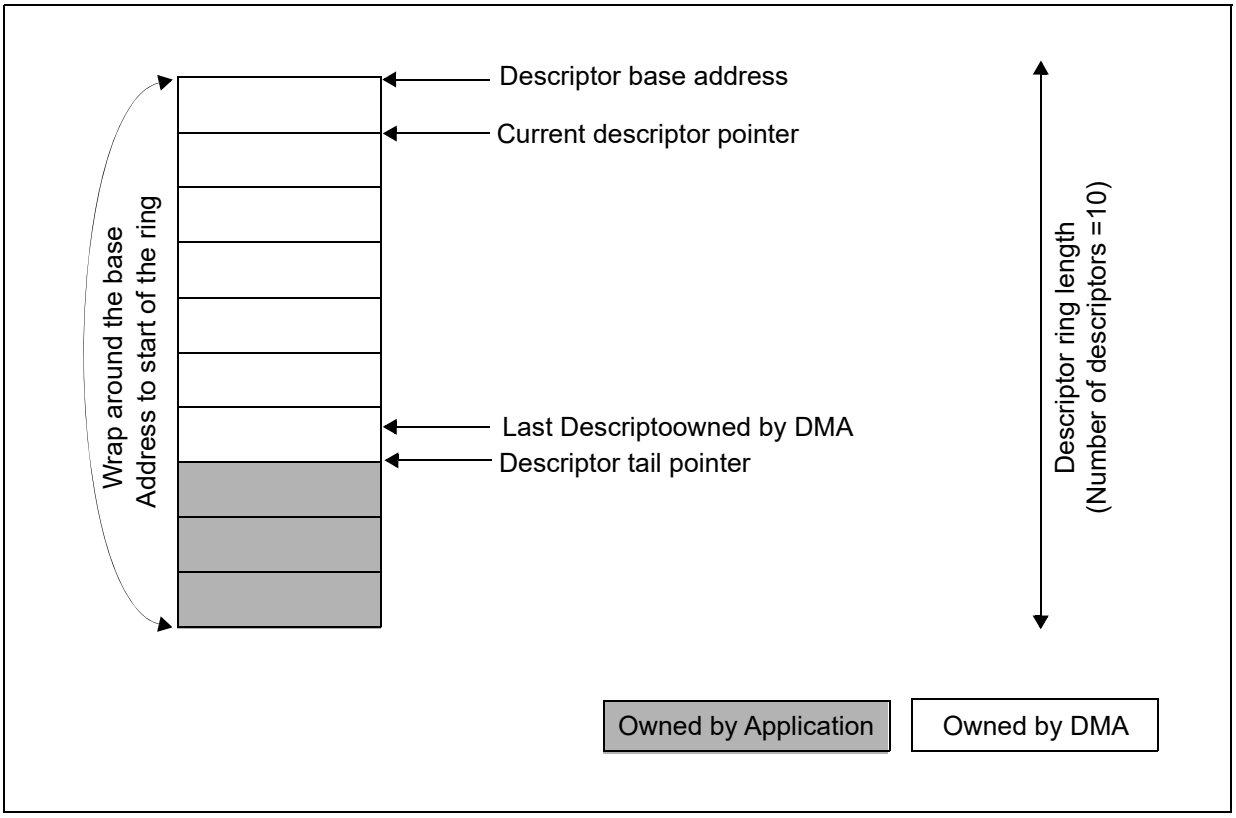
The Ethernet module supports the ring structure for DMA descriptor.

Figure 1321. Descriptor ring structure

In Ring structure, descriptors are separated by the DWord number programmed in the DSL field of the DMA_CH*n*_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH*n*_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH*n*_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (*N*). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (*N* – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:



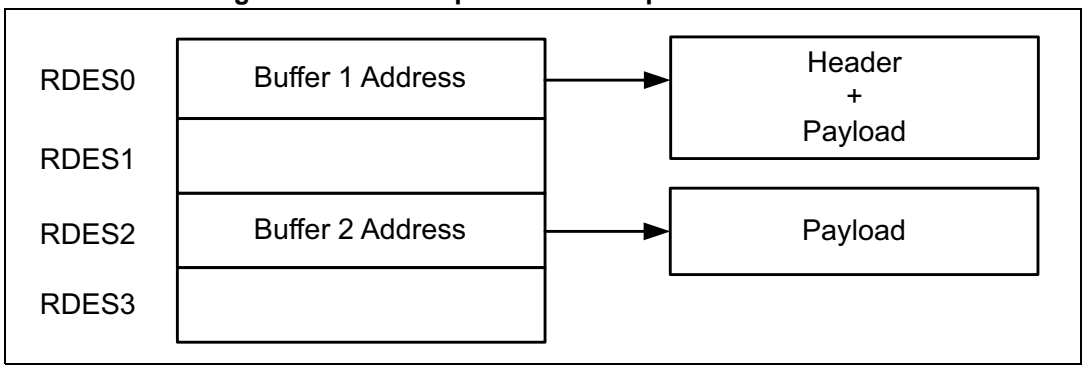
```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in *Figure 1322*.

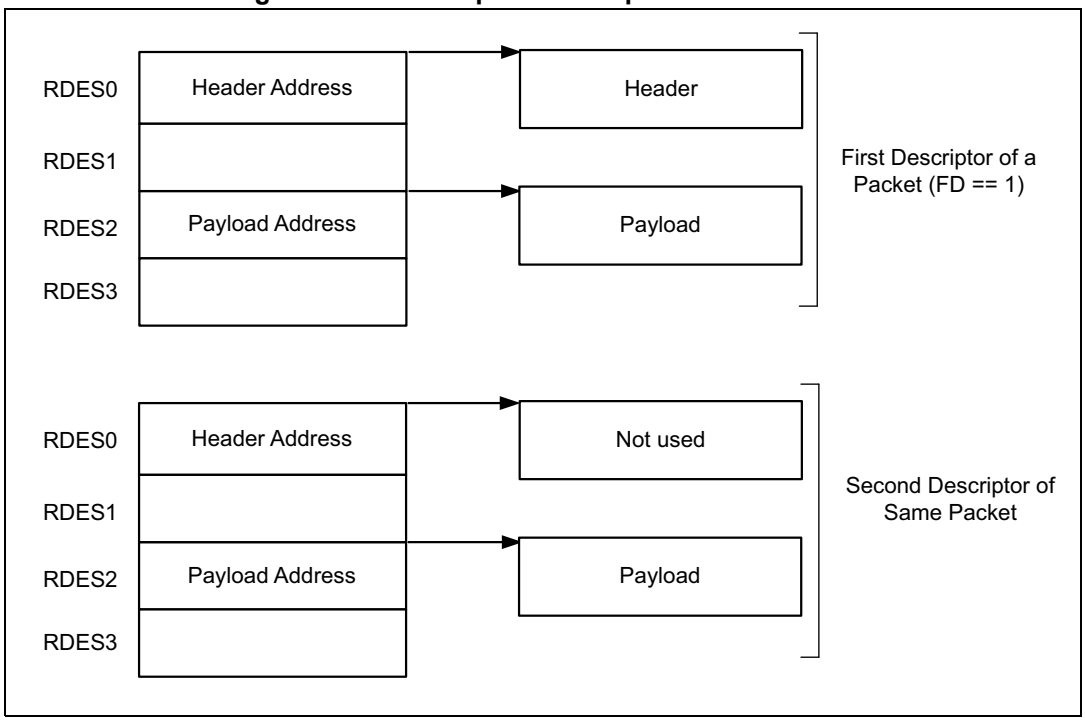
Figure 1322. DMA descriptor ring



For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

50.4.2.1 Descriptor structure for split header support

Ethernet module supports splitting the incoming receive packet header such that the header and the payload are stored in different buffers in the system memory. For more details about splitting header on receive packets, refer to *Section 50.3.10.2.2.1: Splitting header on receive*.



The figure below shows the descriptor structure without the Split Header feature.

Figure 1323. Descriptors without split header feature

The figure below shows the descriptor structure with the Split Header feature.

Figure 1324. Descriptors with split header feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[2] (FD Bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[3] (LD Bit) set). The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA Channel Register 2 (Receive Control Register). The DMA fills receive buffers fully in all except the last descriptor.

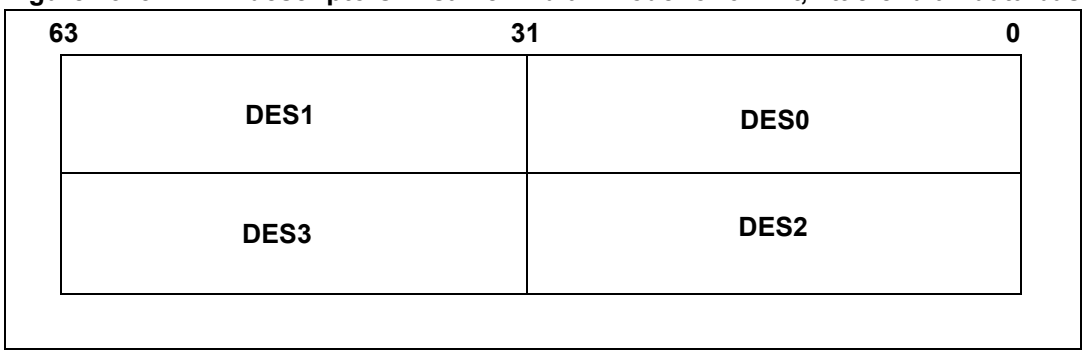
The header length is taken to be the value based on the bits programmed in the MAC Extended Configuration Register HDSMS field (Bits [9:11]).

50.4.2.2 Descriptor endianness

The descriptor addresses must be aligned to configured bus width (DWord for 64-bit bus). The data bus can be configured for either little-endian or big-endian format.

Figure 1325 shows the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is little-endian or big-endian and the endian mode of descriptors is reverse-endian.

Figure 1325. Rx/Tx descriptors in same-Endian mode for 64-Bit, little-endian data bus



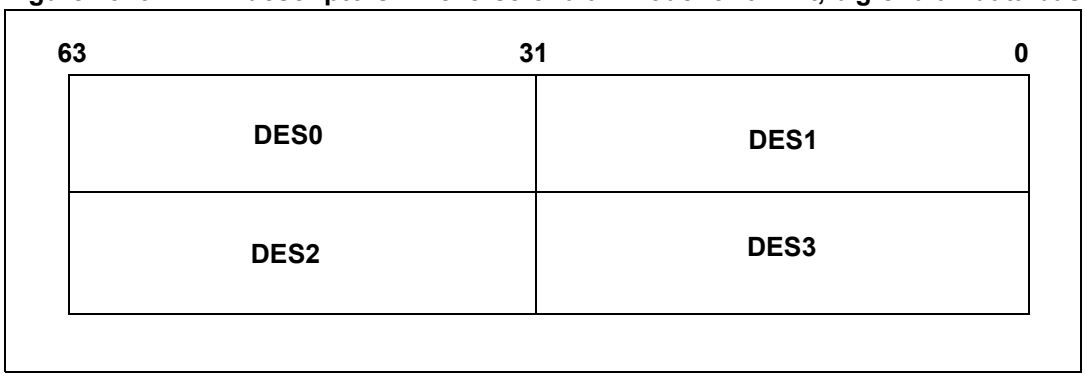


Figure 1325 and *Figure 1326* show the normal Receive and Transmit descriptors for 64-bit data bus when the endian mode of data bus is big-endian and the endian mode of descriptors is reverse-endian. In 64-bit big-endian data bus systems, when the descriptors are configured for reverse endianness, the order of the descriptor subset is reversed from the default (7-3 Rx/Tx Descriptors in Same-Endian Mode for 64-Bit, Little-Endian Data Bus). For example, Bits[63:32] are DES0 while Bits[31:0] are DES1.

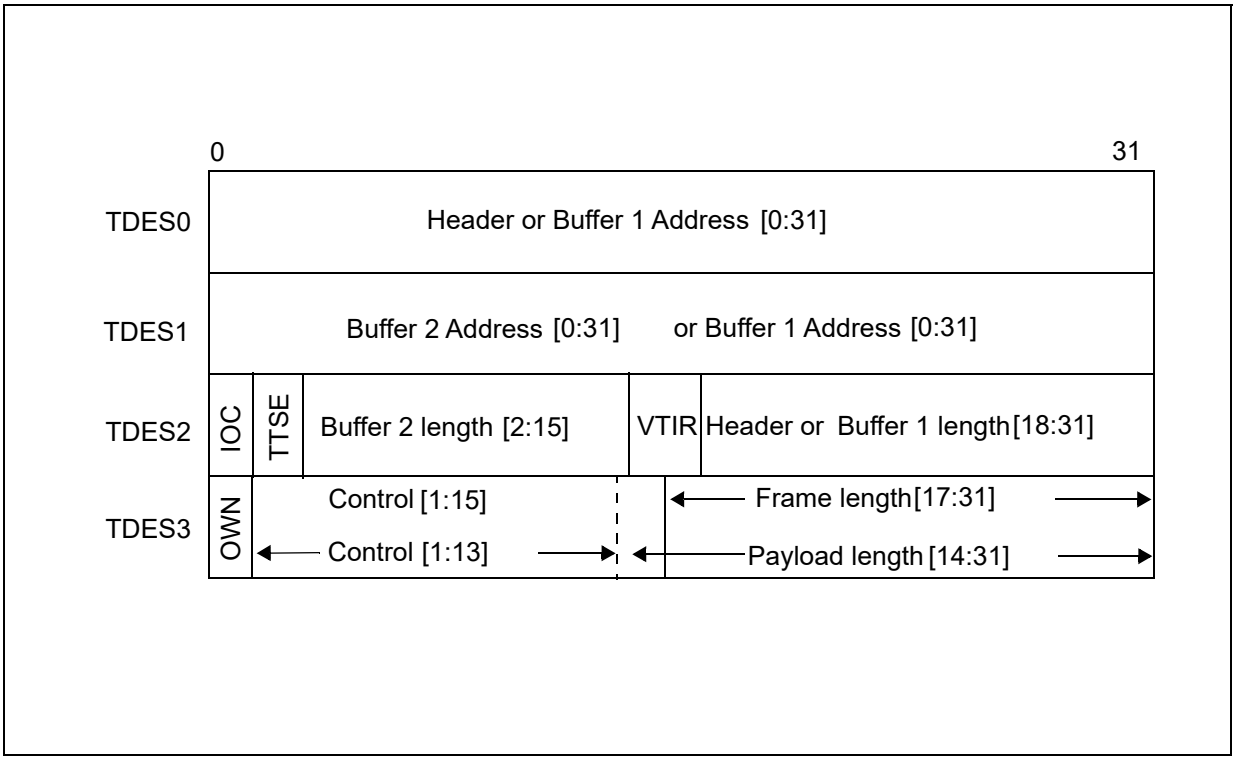
Figure 1326. Rx/Tx descriptors in reverse-endian mode for 64-Bit, big-endian data bus



50.4.3 Transmit descriptor

The DMA in the Ethernet module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has the following two formats: Read format and Write-Back format.

50.4.3.1 Transmit normal descriptor (Read format)

Figure 1327 shows the Read format for a Transmit normal descriptor.

Figure 1327. Transmit descriptor Read format

50.4.3.1.1 TDES0 normal descriptor (Read format)

Table 1423. TDES0 normal descriptor (Read format)

Field	Description
0:31 BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: – TSE bit of TDES3 – FD bit of TDES3

50.4.3.1.2 TDES1 normal descriptor (Read format)

Table 1424. TDES1 normal descriptor (Read format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.

50.4.3.1.3 TDES2 normal descriptor (Read format)

Figure 1328. TDES2 normal descriptor (Read format)

0	1	2:15	16:17	18:31
IOC	TTSE	B2L	VTIR	HL or B1L

Table 1425. TDES2 normal descriptor (Read format)

Field	Description
0 IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CHn_STATUS register after the present packet has been transmitted.
1 TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor.
2:15 B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
16:17 VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: 00 Do not add a VLAN tag. 01 Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. 10 Insert a VLAN tag with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. 11 Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. This option should be used only with the VLAN packets.
18:31 HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

50.4.3.1.4 TDES3 normal descriptor (Read format)

Figure 1329. TDES3 normal descriptor (Read format)

0	1	2	3	4:5	6:8	9:12	13	14:15	16	17:31
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM/THL	TSE	CIC/TPL	TPL	FL/TPL

Table 1426. TDES3 normal descriptor (Read format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
1 CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
2 FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
4:5 CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[2]) is set. The following list describes the values of Bits[4:5]: 00 CRC and Pad Insertion - The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. 01 CRC Insertion (Disable Pad Insertion) - The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. 10 Disable CRC Insertion - The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. 11 CRC Replacement - The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. *Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.*

Table 1426. TDES3 normal descriptor (Read format) (continued)

Field	Description
6:8 SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 6 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[7:8]: 00 Do not include the source address 01 Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 10 Replace the source address. For reliable transmission, the application must provide frames with source addresses. 11 Reserved This field is valid only for the first descriptor and when the First Segment control bit (TDES3 [29]) is set.
9:12 SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH*n*_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
13 TSE	TCP Segmentation Enable When this bit is set, the DMA performs the TCP/UDP segmentation or UDP fragmentation for a packet depending on the TSE_MODE[1:0] bit of the DMA_CH*n*_Tx_Control Register. This bit is valid only if the FD bit is set.
14:15 CIC or TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: 00 Checksum Insertion Disabled. 01 Only IP header checksum calculation and insertion are enabled. 10 IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. 11 IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload. This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.

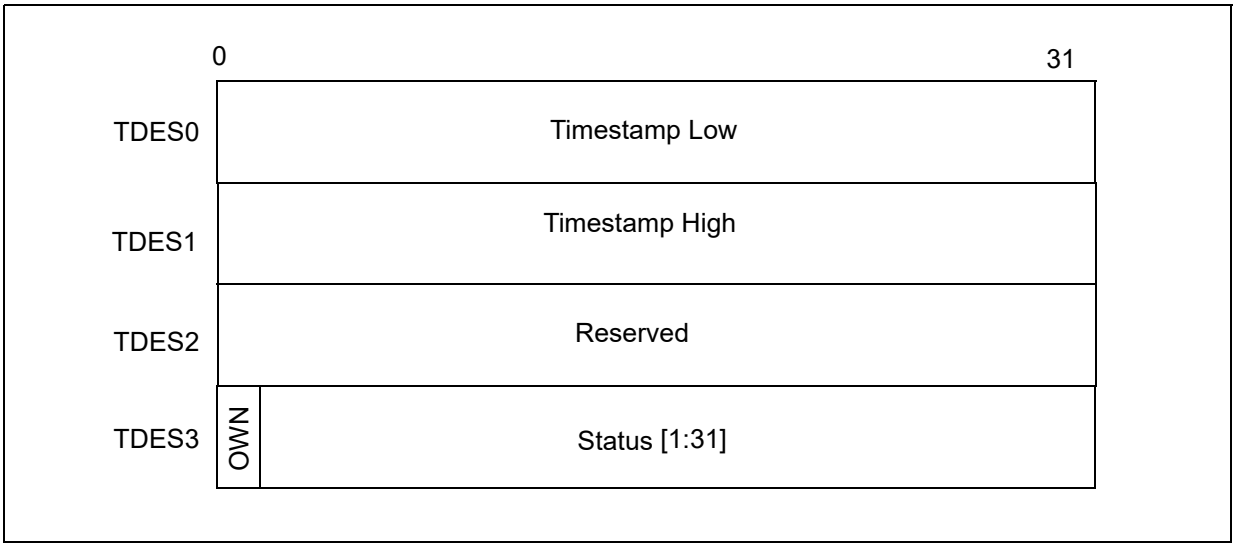


Table 1426. TDES3 normal descriptor (Read format) (continued)

Field	Description
16 TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0].
17:31 FL or TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length.

50.4.3.1.5 Transmit normal descriptor (Write-Back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[3]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 1330. Transmit descriptor Write-Back format

50.4.3.1.6 TDES0 normal descriptor (Write-Back format)

This format is only applicable to the last descriptor of a packet.

Table 1427. TDES0 normal descriptor (Write-Back format)

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

50.4.3.1.7 TDES1 normal descriptor (Write-Back format)

This format is only applicable to the last descriptor of a packet.

Table 1428. TDES1 normal descriptor (Write-Back format)

Field	Description
0:31 TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding Receive packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

50.4.3.1.8 TDES2 normal descriptor (Write-Back format)

This format is applicable only to the last descriptor of a packet.

Table 1429. TDES2 normal descriptor (Write-Back format)

Field	Description
0:31	Reserved

50.4.3.1.9 TDES3 normal descriptor (Write-Back format)

This format is applicable only to the last descriptor of a packet.

Figure 1331. TDES3 normal descriptor (Write-Back format)

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
OWN	CTXT	FD	LD	Reserved				DE	Reserved					TTSS	Reserved

ES	JT	FF	PCE	LoC	NC	LC	EC	CC				ED	UF	DB	IHE

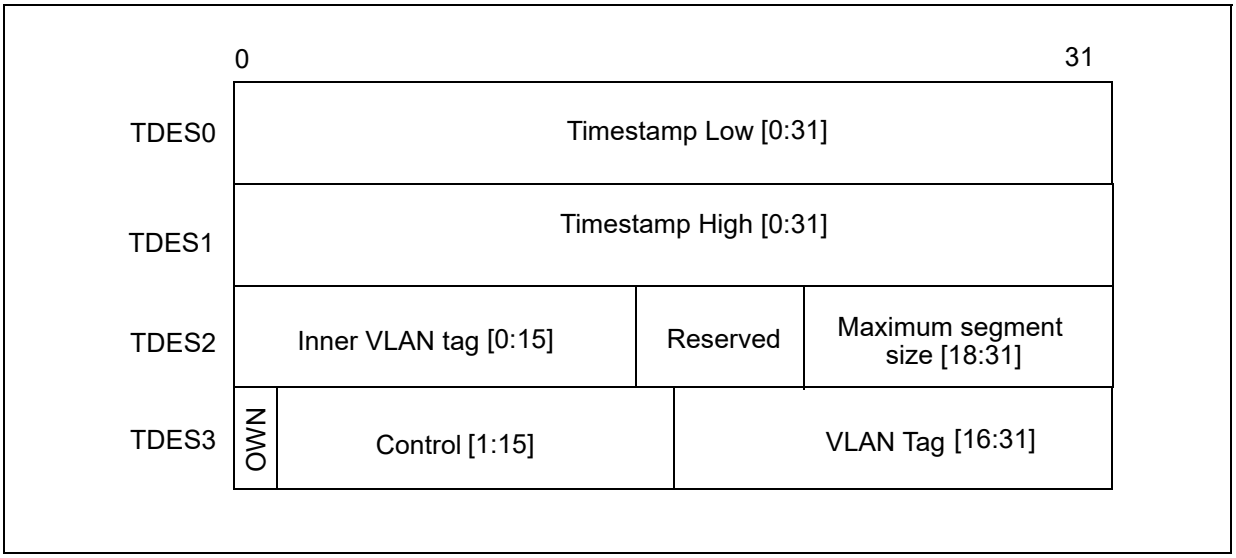
Table 1430. TDES3 normal descriptor (Write-Back format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
1 CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
2 FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
3 LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
8 DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: – Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. – All 1s – CTXT, LD, and FD bits set to 1 **Note:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register **Note:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
14 TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [3]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16 ES	Error Summary This bit indicates the logical OR of the following bits: TDES3[31]: IP Header Error TDES3[17]: Jabber Timeout TDES3[18]: Packet Flush TDES3[19]: Payload Checksum Error TDES3[20]: Loss of Carrier TDES3[21]: No Carrier TDES3[22]: Late Collision TDES3[23]: Excessive Collision TDES3[28]: Excessive Deferral TDES3[29]: Underflow Error

Table 1430. TDES3 normal descriptor (Write-Back format) (continued)

Field	Description
17 JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
18 FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
19 PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
20 LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the MII_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
21 NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
22 LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode). This bit is not valid if Underflow Error is set.
23 EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
24:27 CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
28 ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24288 bit times (155680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.

Table 1430. TDES3 normal descriptor (Write-Back format) (continued)



Field	Description
29 UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: The DMA encountered an empty Transmit Buffer while transmitting the packet The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_INTERRUPT_STATUS register.
30 DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
31 IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

50.4.3.1.10 Transmit context descriptor

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.
When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.
The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 1332. Transmit context descriptor format

50.4.3.1.11 TDES0 context descriptor

Table 1431. TDES0 context descriptor

Field	Description
0:31 TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

50.4.3.1.12 TDES1 context descriptor

Table 1432. TDES1 context descriptor

Field	Description
0:31 TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

50.4.3.1.13 TDES2 context descriptor

Table 1433. TDES2 context descriptor

Field	Description
0:15 IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[0:15] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
16:17	Reserved
18:31 MSS	Maximum Segment Size When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

50.4.3.1.14 TDES3 context descriptor

Figure 1333. TDES3 context descriptor

0	1	2:3	4	5	6:7	8	9:13	14	15	16:31
OWN	CTXT	Reserved	OSTC	TCMSSV	Reserved	DE	Reserved	IVLTV	VLTV	VT

Table 1434. TDES3 context descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
2:3	Reserved
4 OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
5 TCMSSV	One-Step Timestamp Correction Input When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.

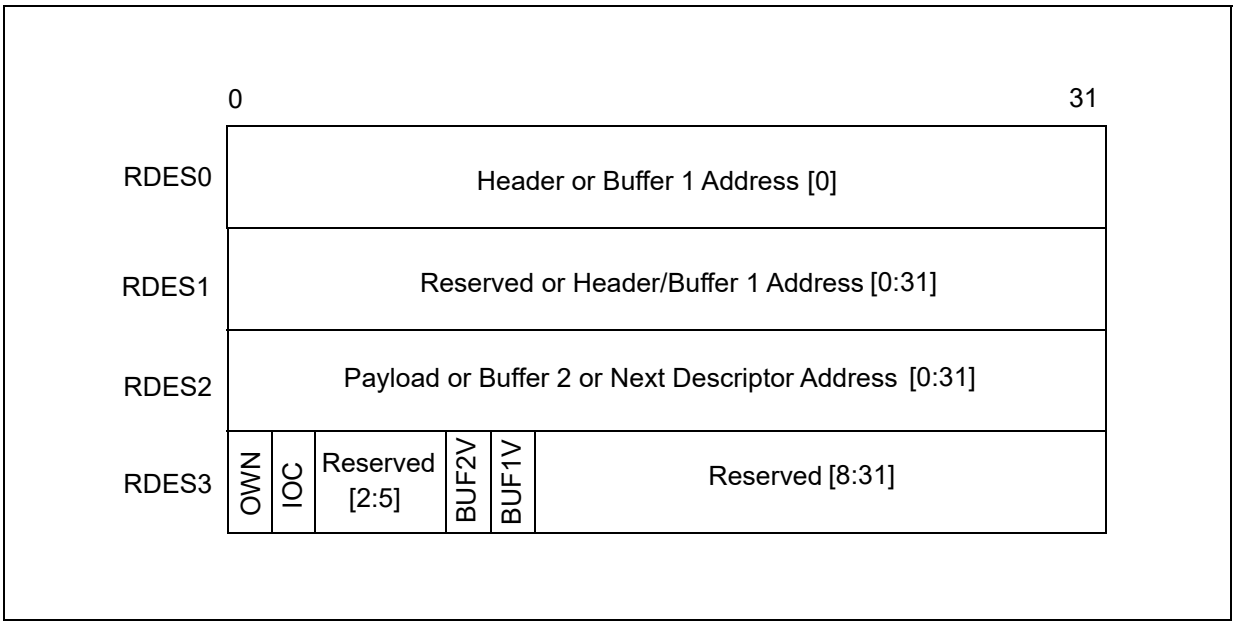
Table 1434. TDES3 context descriptor (continued)

Field	Description
6:7	Reserved
8 DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: – Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. – All 1s. – CD, LD, and FD bits set to 1. **Note:** When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CHn_STATUS register **Note:** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
9:11	Reserved
12:13 IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: 00 Do not add the inner VLAN tag. 01 Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. 10 Insert an inner VLAN tag with the tag value programmed in the MAC_VLAN_INCL register or context descriptor. 11 Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames.
14 IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
15 VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
16:13 VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_INCL register is reset.

50.4.4 Receive descriptor

The DMA in the Ethernet module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive descriptors are present:



- Normal
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as “Normal” Descriptors with the content as shown in *Section 50.4.4.1: Receive normal descriptor (Read format)*. The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the *Section 50.4.4.2: Receive normal descriptor (Write-Back format)*.

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA will write the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in *Section 50.4.4.3: Receive context descriptor*.

50.4.4.1 Receive normal descriptor (Read format)

Figure 1334. Receive normal descriptor (Read format)

Note: In the Receive Descriptor (Read format), if the Buffer Address field is all 0s, the Ethernet module does not transfer data to that buffer and skips to the next buffer or next descriptor.

50.4.4.1.1 RDES0 normal descriptor (Read format)

Table 1435. RDES0 normal descriptor (Read format)

Field	Description
0:31 BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[30:31] (or RDES0[29:31]/[28:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

50.4.4.1.2 RDES1 normal descriptor (Read format)

Table 1436. RDES1 normal descriptor (Read format)

Field	Description
0:31	This field is reserved.

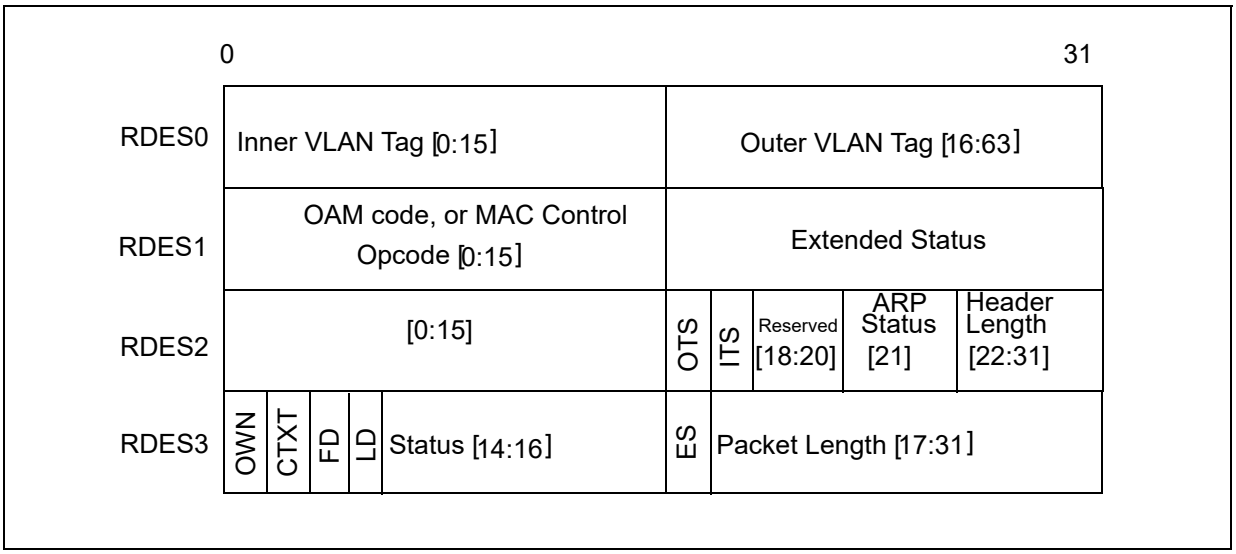
50.4.4.1.3 RDES2 normal descriptor (Read format)

Table 1437. RDES2 normal descriptor (Read format)

Field	Description
0:31 BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[28:31, 29:31, or 30:31] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[28:31, 29:31, or 30:31] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

50.4.4.1.4 RDES3 normal descriptor (Read format)

Figure 1335. RDES3 normal descriptor (Read format)



0	1	2:5	6	7	8:31
OWN	IOC	Reserved	BUF2V	BUF1V	Reserved

Table 1438. RDES3 normal descriptor (Read format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception The buffers associated with the descriptor are full
1 IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
2:5	Reserved
6 BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is Valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
7 BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
8:31	Reserved

50.4.4.2 Receive normal descriptor (Write-Back format)

Figure 1336. Receive normal descriptor (Write-Back format)

Figure 1337. RDES0 normal descriptor (Write-Back format)

0:15	16:31
IVT	OVT

Table 1439. RDES0 normal descriptor (Write-Back format)

Field	Description
0:15 IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
16:31 OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

50.4.4.2.2 RDES1 normal descriptor (Write-Back format)

The status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

Figure 1338. RDES1 normal descriptor (Write-Back format)

0:15	16	17	18	19	20:23	24	25	26	27	28	29:31
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 1440. RDES1 normal descriptor (Write-Back format)

Field	Description
0:15 OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If bits[13:15] of RDES3 are set to 111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If bits[13:15] of RDES3 are set to 110, this field contains the MAC Control packet opcode field.
16 TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table 1440. RDES1 normal descriptor (Write-Back format) (continued)

Field	Description
17 TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [3]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
18 PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
19 PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
20:23 PMT	PTP Message Type These bits are encoded to give the type of the message received: 0000 No PTP message received 0001 SYNC (all clock types) 0010 Follow_Up (all clock types) 0011 Delay_Req (all clock types) 0100 Delay_Resp (all clock types) 0101 Pdelay_Req (in peer-to-peer transparent clock) 0110 Pdelay_Resp (in peer-to-peer transparent clock) 0111 Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) 1000 Announce 1001 Management 1010 Signaling 1011–1110 Reserved 1111 PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
24 IPCE	IP Payload Error When this bit is set, it indicates either of the following: The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 16 (ES) of RDES3 is not set when this bit is set.
25 IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed.
26 IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected.
27 IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected.

Table 1440. RDES1 normal descriptor (Write-Back format) (continued)

Field	Description
28 IPHE	IP Header Error When this bit is set, it indicates either of the following: The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. The IP datagram version is not consistent with the Ethernet Type value. Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 26 or bit 27 is set.
29:31 PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): 000 Unknown type or IP/AV payload not processed 001 UDP 010 TCP 011 ICMP 110 AV Tagged Data Packet 111 AV Tagged Control Packet 101 AV Untagged Control Packet 100 IGMP if IPV4 Header Present bit is set else data center bridging (DCB) link layer discovery protocol (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 000.

50.4.4.2.3 RDES2 normal descriptor (Write-Back format)

Figure 1339. RDES2 normal descriptor (Write-Back format)

Table 1441. RDES2 normal descriptor (Write-Back format)

Field	Description
0:2 L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: 000 Filter 0 This field is valid only when Bit 3 or Bit 4 is set high. When more than one filter matches, these bits give the number of lowest filter. **Note:** This status is not available when Flexible RX Parser is enabled.
3 L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: Layer 3 fields are not enabled and all enabled Layer 4 fields match All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[0:2]. **Note:** This status is not available when Flexible RX Parser is enabled.
4 L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. All enabled filter fields match. When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[0:2]. **Note:** This status is not available when Flexible RX Parser is enabled.
5:12 MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. **Note:** This status is not available when Flexible RX Parser is enabled.
13 HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[5:12] indicate the hash value. **Note:** This status is not available when Flexible RX Parser is enabled.
14 DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. **Note:** When this bit is set, ES bit of RDES3 is also set.

Table 1441. RDES2 normal descriptor (Write-Back format) (continued)

Field	Description
15 SAF	SA Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. **Note:** When this bit is set, ES bit of RDES3 is also set.
16 OTS	Outer VLAN Tag Filter Status (OTS) This bit is valid for both Single and Double VLAN Tagged frames.
17 ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames.
18:20	Reserved
21 ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).
22:31HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header.

50.4.4.2.4 RDES3 normal descriptor (Write-Back format)

Figure 1340. RDES3 normal descriptor (Write-Back format)

Table 1442. RDES3 normal descriptor (Write-Back format)

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} 00 Intermediate Descriptor 01 First Descriptor 10 Reserved 11 Descriptor Error (due to all 1s) **Note:** When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
2 FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.
3 LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
4 RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
5 RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
6 RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
7 CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
8 GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). **Note:** Giant packet indicates only the packet length. It does not cause any packet truncation.

Table 1442. RDES3 normal descriptor (Write-Back format) (continued)

Field	Description
9 RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
10 OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. **Note:** This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
11 RE	Receive Error When this bit is set, it indicates that the MII_RXER signal is asserted while the MII_RX_DV signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
12 DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
13:15 LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: 000 The packet is a length packet 001 The packet is a type packet. 011 The packet is a ARP Request packet type 100 The packet is a type packet with VLAN Tag 101 The packet is a type packet with Double VLAN Tag 110 The packet is a MAC Control packet type 111 The packet is a OAM packet type 010 Reserved

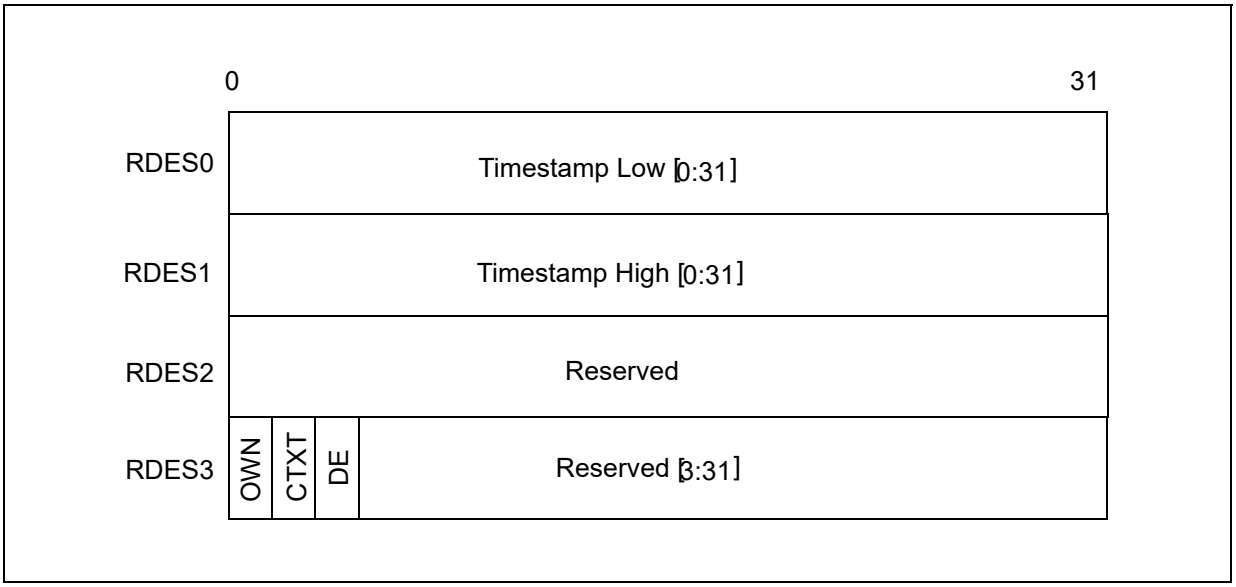

Table 1442. RDES3 normal descriptor (Write-Back format) (continued)

Field	Description
16 ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: RDES3[7]: CRC Error RDES3[12]: Dribble Error RDES3[11]: Receive Error RDES3[9]: Watchdog Timeout RDES3[10]: Overflow Error RDES3[8]: Giant Packet RDES2[14]: Destination Address Filter Fail, when Flexible RX Parser is enabled. RDES2[15]: SA Address Filter Fail, when Flexible RX Parser is enabled. This field is valid only when the LD bit of RDES3 is set.
17:31 PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

50.4.4.3 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 1 of RDES3 indicates the context type descriptor.

Figure 1341. Receive context descriptor

50.4.4.3.1 RDES0 context descriptor

Table 1443. RDES0 context descriptor

Field	Description
0:31 RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

50.4.4.3.2 RDES1 context descriptor

Table 1444. RDES1 context descriptor

Field	Description
0:31 RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

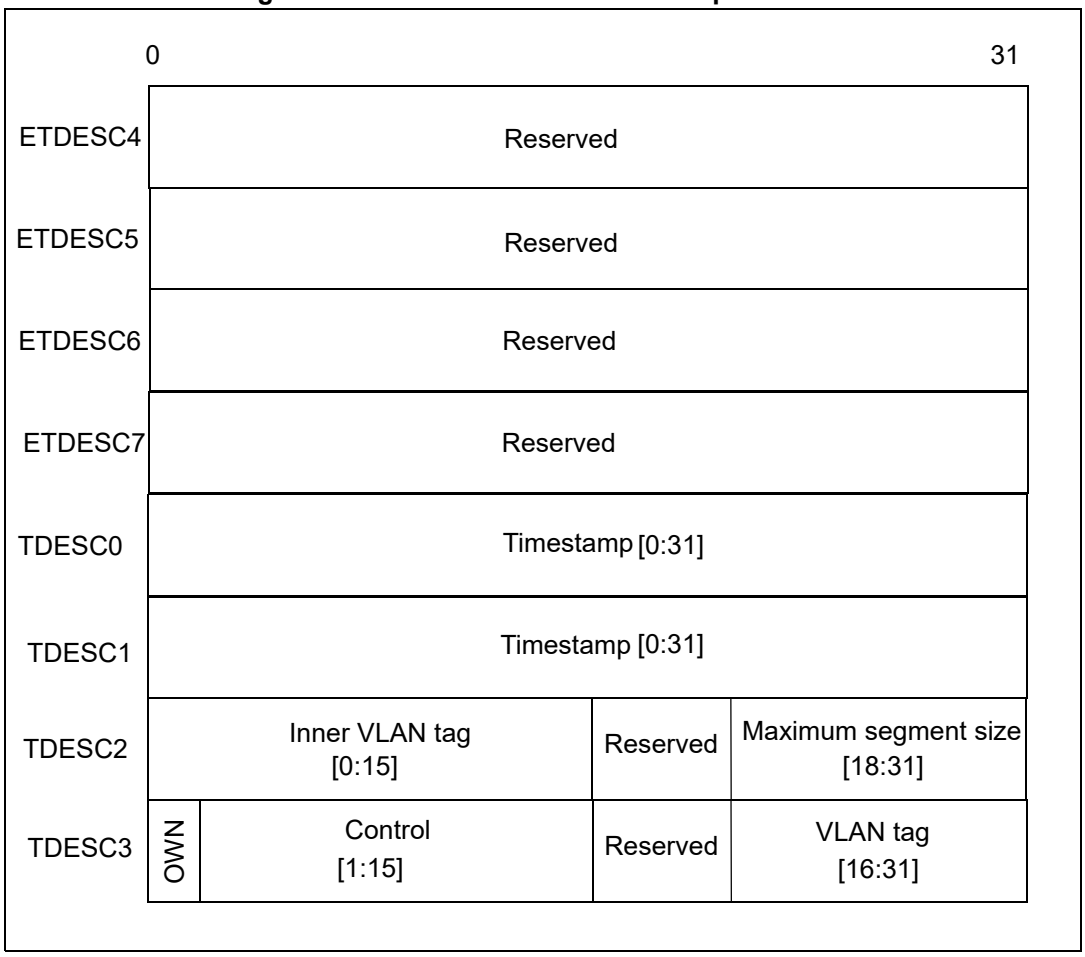
Table 1446. RDES3 context descriptor

Field	Description
0 OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: The DMA completes the packet reception. The buffers associated with the descriptor are full.
1 CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor. DMA writes 2fb11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} 00 Reserved 01 Reserved 10 Context Descriptor 11 Descriptor Error **Note:** When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
2 DE	Descriptor Error Refer to the CTXT bit description for details of using the DE bit along with CTXT bit.
3:31	Reserved

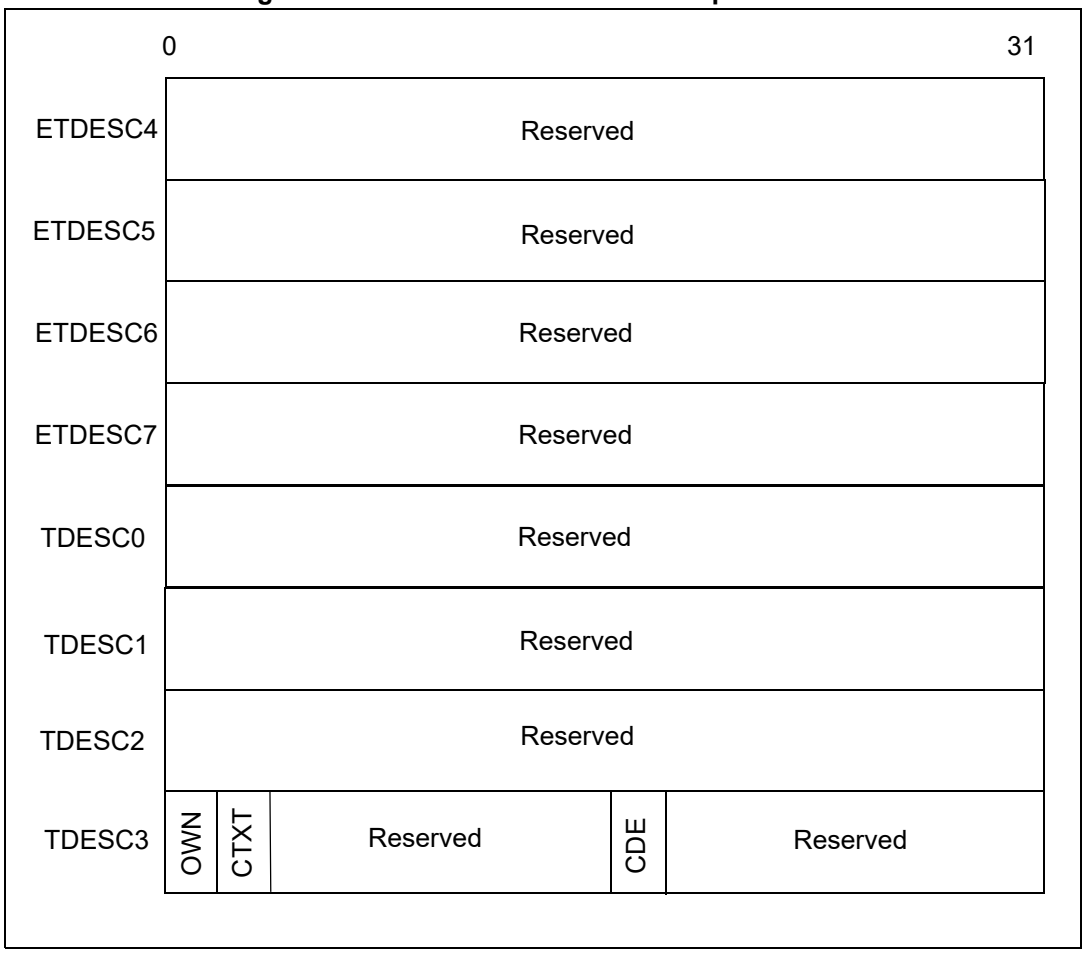
50.4.5 Enhanced descriptor for time-based scheduling



The time-based scheduling feature needs Enhanced Descriptors (that are 32 Bytes) to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH*n*_TX_Control register).

The structure of 32-byte descriptor for the context and the normal descriptor in Read and Write formats are described in the following sections.

50.4.5.1 Enhanced context descriptor (Read, 32-bit mode)



The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

Figure 1343. Enhanced context descriptor - Read

50.4.5.2 Enhanced context descriptor (Write, 32-bit mode)

Figure 1344. Enhanced context descriptor - Write

50.4.5.3 Enhanced Normal descriptor - Read (32-bit mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid.

  The LTV must be set only if the FD bit of the descriptor is not.
- GSN

  This field indicates the GCL slot number associated with the packet.
- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

Figure 1345. Enhanced normal descriptor - Read (32-bit mode)

50.4.5.4 Enhanced normal descriptor (Write, 32-bit mode)

Figure 1346. Enhanced normal descriptor Write (32-bit mode)

Note: All the enhanced descriptor examples, assumes a 32-bit data width configuration. However, the same definitions are valid in 64- and 128-bit configurations.

In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.

Fetch time when enabled overrides the AV slot function.

When TSO is enabled, the Launch and Fetch times are applicable to first segment that is transferred, all subsequent segments do not have any time restrictions.

When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed.

50.5 Programming guidelines

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

50.5.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit 31 of *DMA mode register (DMA_MODE)*).
2. Wait for the completion of the reset process (poll bit 31 of the *DMA mode register (DMA_MODE)*, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the *DMA system bus mode register (DMA_SYSBUS_MODE)*:
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values for AHB bus interface
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 0 of descriptor TDES3/RDES3).

Note: Descriptor address from start to end of the ring should not cross the 4 GB boundary.

5. Program the Transmit and Receive Ring length registers (DMA_CH*n*_TxDesc_Ring_Length and DMA_CH*n*_RxDesc_Ring_Length). The ring length programmed must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH*n*_TxDesc_List_Address, DMA_CH*n*_RxDesc_List_Address). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH*n*_TxDesc_Tail_Pointer and DMA_CH*n*_RxDesc_Tail_Pointer).
7. Program the settings of the following registers for the parameters such as maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   a) DMA_CH*n*_TX_Control
   b) DMA_CH*n*_TX_Control
   c) DMA_CH*n*_TX_Control
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register.
9. Start the Receive and Transmit DMAs by setting SR (bit 31) of the DMA_CH*n*_RX_Control and ST (bit 31) of the DMA_CH*n*_TX_Control register.
10. Repeat steps *4* to *9* for all the Tx DMA and Rx DMA channels selected in the hardware.

50.5.2 Initializing MTL registers

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation for multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in the MTL_RxQ_DMA_Map0 register.

3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode.
   b) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0.
   c) Transmit Queue Size (TQS).
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a) Receive Store and Forward (RSF) or RTC in case of Threshold mode.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d) Receive Queue Size (RQS).
5. Repeat previous two steps for the second MTL Tx and Rx queue.

50.5.3 Initializing MAC

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. For more than one MAC address program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   a) Receive All
   b) Promiscuous mode
   c) Hash or Perfect Filter
   d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a) Pause time and other Pause frame control bits
   b) Transmit Flow control bits
   c) Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required.
5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 31 and 30 in MAC_Configuration registers to start the MAC transmitter and receiver.

50.5.3.1 For normal operation

Complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register.
   a) DMA_CH*n*_TxDesc_Tail_Pointer
   b) DMA_CH*n*_RxDesc_Tail_Pointer
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process.
   a) DMA_CH*n*_Current_App_TxDesc
   b) DMA_CH*n*_Current_App_RxDesc
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process.
   a) DMA_CH*n*_Current_App_TxBuffer
   b) DMA_CH*n*_Current_App_RxBuffer

50.5.3.2 For stopping and starting transmission

Complete the following steps to pause the transmission for some time.

Note: The steps are provided for Channel 0.

1. Disable the transmit DMA (if applicable) by clearing Bit 31 (ST) of the DMA_CH*n*_TX_Control register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of the MTL_TxQ0_Debug register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit 31 (RE) and Bit 30(TE) of the MAC_Configuration register.
4. Disable the receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of the MTL_RxQ0_Debug register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register).
6. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver.

Note: Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. The Software should change these parameters only when the MAC transmitter and receiver are not active.
Similarly the DMA related configuration should not be changed when Transmit and Receive DMA are in active.

50.5.3.3 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

50.5.4 Programming guidelines for multi-channel multi-queuing

Following are the steps for Transmit:

1. Program the Transmit queue size in the TQS field of MTL_TxQ*n*_Operation_Mode register. Based on the value programmed in TQS field, the size of the queue is determined. In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel to Queue mapping is fixed.
2. Enable ST bit of DMA_CH*n*_TX_Control register and corresponding TXQEN in MTL_TxQ*n*_Operation_Mode register.
3. The scheduling method need to be programmed in SCHALG of the MTL_Operation_Mode register.
4. In case of CBS algorithm in AVB queues, the following registers also needs to be programmed as required:
   a) MTL_TxQ*n*_ETS_Control
   b) MTL_TxQ*n*_SendSlopeCredit
   c) MTL_TxQ*n*_HiCredit
   d) MTL_TxQ*n*_LoCredit

Following are the steps for Receive:

1. Program the Receive queue size in the RQS field of MTL_RxQ*n*_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 1 in the fields RXQ0EN to RXQ1EN in MAC_RxQ_Ctrl0 Register for AV. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH*n*_RX_Control Register and corresponding RXQ*n*_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a) AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
   b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 register.
   c) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ1-0 of the MAC_RxQ_Ctrl2 register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 1.
   d) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 register.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b) Program the MTL_RxQ*n*_Control to decide the weights and the packet arbitration for each RxQ.
   c) If static mapping is programmed in MTL_RxQ_DMA_Map0 register (RXQ*n*DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d) Set RXQ*n*DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue.
   e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

Note: The priorities set in PSRQ1-0 should be unique.

50.5.4.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

50.5.4.1.1 Recovering from the receive DMA channel failure

Follow these steps if you get bus error in the Receive DMA channel:

1. Set the RPF bit to 1. This flushes all the packets one after the other.
   This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.
2. Re-program the specific Registers of the DMA channel.
3. Start the DMA channel.

50.5.4.1.2 Recovering from the transmit DMA channel failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Re-program the specific Registers of the DMA channel.
4. Start the DMA channel.

50.5.5 Programming guidelines for MII link state transitions

The following steps are to be performed when the link is down but the Transmit and Receive clocks are running:

Note: The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 31 (ST) of DMA_CH*n*_TX_Control register.
2. Disable the MAC receiver by clearing Bit 29 (RE) of the MAC_Configuration register
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug register (TRCSTS is not 01).
   -or-
   Flush the Tx FIFO for faster empty operation.
4. Disable the MAC transmitter by clearing Bit 30 (TE) of the MAC_Configuration register.

5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in the MTL_TxQ0_Debug register and RXQSTS is 0 in the MTL_RxQ0_Debug register).
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers.
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver.

You do not need to disable the Rx DMA. As the Receiver is disabled, the FIFO does not get any data in the Rx FIFO.

Do the following steps when the link is down and the Transmit and Receive clocks are stopped:

Note: The steps are provided for Channel 0.

1. Disable the MAC Transmitter and Receiver by clearing bits RE and TE of MAC_Configuration register. This will not take effect immediately as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait for the completion of the transfer of any partial frame if any at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug Register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

50.5.6 Programming guidelines for IEEE 1588 timestamping

50.5.6.1 Initialization guideline for system time generation

The timestamp feature is enabled by setting Bit 31 of the MAC_Timestamp_Control register. However, it is essential that the timestamp counter should be initialized after this bit is set. Complete the following steps during for initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 15 of MAC_INTERRUPT_ENABLE register.
2. Set Bit 31 of MAC_Timestamp_Control register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 26 of MAC_Timestamp_Control register.
5. Poll the MAC_Timestamp_Control register until Bit 26 is cleared.
6. Program Bit 30 of MAC_Timestamp_Control register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value.
8. Set Bit 29 in MAC_Timestamp_Control register.
   The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers.

If one-step timestamping is enabled:

a) To enable one-step timestamping, program Bit 4 of the TDES Context Descriptor.

b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.

9. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing Bit 31 of MAC_Timestamp_Control Register, you need to repeat all these steps to restart the timestamp operation.

50.5.6.2 System time correction

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 28 (TSUPDT) of the MAC_Timestamp_Control Register.
   The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in System Time Register Module, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_Timestamp_Addend with the new value and set Bit 26 of the MAC_Timestamp_Control register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in the MAC_PPS0_Target_Time_Seconds register and the MAC_PPS0_Target_Time_Nanoseconds register.
5. Enable the Timestamp interrupt in bit 19 of MAC_INTERRUPT_ENABLE register.
6. Set bit 27 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS register.
8. Reprogram MAC_Timestamp_Addend register with the old value and set bit 26 again.

50.5.7 Programming guidelines for AV feature

Complete the following steps to initialize the DMA for AV feature:

1. Provide a software reset to reset all QOS internal registers and logic (bit 31 in DMA_Mode register).
2. Wait for the completion of the reset process. Poll bit 31 of the DMA_Mode register, which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers. The ring length programmed must be at least 4. Then initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor. Finally program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors:
   a) DMA_CH*n*_TxDesc_Ring_Length
   b) DMA_CH*n*_RxDesc_Ring_Length
   c) DMA_CH*n*_TxDesc_List_Address
   d) DMA_CH*n*_RxDesc_List_Address
   e) DMA_CH*n*_TxDesc_Tail_Pointer
   f) DMA_CHn_RxDesc_Tail_Pointer
7. Program the following fields to initialize the mode of operation in the MTL_TxQ1_Operation_Mode register:
   a) Transmit Store And Forward (TSF)
   b) Transmit Threshold Control (TTC)
   c) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d) Transmit Queue Size (TQS)
8. Enable the interrupts by programming the DMA_CH*n*_Interrupt_Enable register.
9. Repeat steps *4* through *9* for all additional channels of AV feature.
10. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
11. Start the Receive and Transmit DMA by setting bit 31 of the DMA_CH*n*_TX_Control register and bit 31 of the DMA_CH*n*_RX_Control register.

50.5.7.1 Enabling slot number checking

The slot number check feature is used to specify the intervals at which the DMA Channels mapped to AV Queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable time-stamping and program the MAC_Sub_Second_Increment register. Complete the following steps to enable the slot number checking:

Note: These steps should be completed after Step 10 and before Step 11 of Section 50.5.7: Programming guidelines for AV feature.

1. Enable time-stamping by following the steps described in *Section 50.5.6.1: Initialization guideline for system time generation*.
2. Make sure that the SLOTNUM field (bits 9:12) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH*n*_Slot_Function_Control_Status.
3. Set Bit 31 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

50.5.7.2 Enabling average bits per slot reporting

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this

register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. Enable time-stamping by following the steps described in *Section 50.5.6.1: Initialization guideline for system time generation*.
2. Program Bits [25:27], SLC, of the MTL_TxQ*n*_ETS_Control register of a channel with number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 22 (ABPSSIE) of the MTL_Q*n*_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.
4. Read Bits [15:31], ABS, from the MTL_TxQ*n*_ETS_Status register of a channel on each interrupt.

Note: The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 30 (ABPSIS) of the MTL_TxQn_ETS_Status register indicates that a new value is updated in the ABS field.

The frequency of this interrupt depends on the value programmed in the Step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
When not required, you can disable this interrupt to stop the interrupt flooding.

50.5.8 Programming guidelines for energy efficient ethernet

50.5.8.1 Entering and exiting the Tx LPI mode

For entering and exiting the Tx LPI Mode, complete the following steps:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode).
3. Program Bits[6:15] and Bits[16:31] in MAC_LPI_Timers_Control register.
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 14 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPIET and LPITXA (bit[11:12]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Set Bit 15 of MAC_LPI_Control_Status register to make the MAC Transmitter enter the LPI state.
   The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[31]) after entry to LPI state.
9. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits

LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

10. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
11. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set Bit 12 in MAC_LPI_Control_Status register.
To switch off the MII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.
To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.

50.5.8.2 Gating off the CSR clock in the LPI mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.

50.5.8.3 Gating off the CSR clock in the Rx LPI mode

The following operations are performed when the MAC receives the LPI pattern from the PHY.

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN] interrupt of MAC_LPI_Control_Status register is set.
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register.

After the interrupt is asserted and the MAC Tx is also in the LPI mode, you can gate-off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status register is read.

50.5.8.4 Gating off the CSR clock in the Tx LPI mode

The following operations are performed when Bit 15 (LPIEN) of MAC_LPI_Control_Status register is set:

1. The Transmit LPI Entry interrupt (TLPIEN bit of MAC_LPI_Control_Status register) is set.
2. The interrupt pin is asserted. The interrupt is cleared when the host reads the MAC_LPI_Control_Status register.

After the interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR.

For restoring the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. After the CSR clock is resumed, reset Bit 15 (LPIEN) of MAC_LPI_Control_Status register to bring the MAC out of the LPI mode.

50.5.9 Programming guidelines for flexible Pulse-Per-Second (PPS) output

50.5.9.1 Generating single pulse on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the width of the PPS signal output in MAC_PPS0_Width Register.
4. Program Bits [28:31], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS0_Width.
3. Program Bits [28:3], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

50.5.9.2 Generating a pulse train on PPS

1. Program 11 or 10 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of the PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS0_Interval Register.
4. Program the width of the PPS signal output in MAC_PPS0_Width Register.
5. Program Bits[28:3], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands

6. Program the stop value in the Target Time registers. Ensure that Bit 0 (TSTRBUSY) of MAC_PPS0_Target_Time_Nanoseconds Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit [28:31]) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step *6* elapses.

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

50.5.9.3 Generating an Interrupt without affecting the PPS

The Bits [25:26], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) to do any one of the following:

- Generate only interrupts
- Generate interrupts and the PPS start and stop time
- Generate only PPS start and stop time

To program the Target Time registers to generate only interrupt event:

1. Program 00 (for interrupt) in Bits [25:26], TRGTMODSEL, of MAC_PPS_Control register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.
   If Bits [25:26], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programmed Target Time register value.

50.5.10 Programming guidelines for TSO

The TCP Segmentation Offload (TSO) engine is used to offload the TCP segmentation functions to the hardware. To program the TSO, set the TSE bit to enable TCP packet segmentation, and program descriptor fields to enable TSO for the current packet.

Complete the following steps to program TSO:

1. Program the TSE bit of corresponding DMA_CH[n]_Tx_Control register to enable TCP packet segmentation in that DMA.
2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a) Enable TSE in Bit 18 of TDES3.
   b) Program the length of the un-segmented TCP/IP packet payload in bits [17:0] of TDES3 and the TCP header in bits [22:19] of TDES3.
   c) Program the maximum size of the segment in MSS of DMA_CH[n]_Control register or MSS in the context descriptor.

If MSS field is programmed in both DMA_CH[n]_Control register and in the context descriptor, the latest software programmed sequence is considered.

3. The header of the unsegmented TCP/IP packet should be in Buffer 1 of the first descriptor and this buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

Note: If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.

50.5.11 Programming guidelines for split header on Receive

Split Header support is an optional feature that you can enable by selecting the Enable Split Header Feature option and by setting the SPH bit in the DMA_CH#_Control register. The DMA can process the header and payload of received packets separately.

When split header support is enabled, the buffer 1 (RDES0) of the descriptors is used only for the header. Therefore the DMA writes the header of the received packet in buffer 1 when FD bit of RDES3 is set. The payload of the received packet is directed to the buffer2 (RDES2).

For subsequent descriptors (FD is set to 0), buffer1 is not used and the payload is written only to buffer 2. When the host enables split header structure by setting the SPH Bit[24] of register DMA_CH[n]_Control_register, the host must ensure that Buffer1 is always valid in all descriptors by creating Buffer1 and indicating this by setting Bit[24] (BUF1V) of RDES3 for all descriptors.

50.5.12 Programming guidelines for VLAN filtering on Receive

1. Program MAC_VLAN_Tag Register for the following bit to select the filtering method:
   a) ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison. VTHM: VLAN Tag Hash Table Match Enable.
   b) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP).
   c) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL).
   d) DOVLTC: Ignores VLAN Type for Tag Match.
   e) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching.
2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table Register. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

50.5.13 Programming guidelines for extended VLAN filtering and routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps:

- Write
  - Write the required data into the MAC VLAN Tag Data register.
  - Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
  - Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  - Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  - Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

50.5.14 Programming sequence for queue/channel based VLAN inclusion register

To program the queue/channel-based VLAN inclusion register, complete the following steps:

Note: Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCLn register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCLn register.
3. The BUSY bit of MAC_VLAN_INCL register is set by ethernet module to indicate the progress of access to indirect access MAC_VLAN_INCLn register. On completion of the access, the BUSY bit is cleared.
   The application must not attempt subsequent access to MAC_VLAN_INCL *n* register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

50.5.15 Programming guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in *Section 50.2: Memory map and registers description* to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

50.5.15.1 Programming the GCL and GCL linked registers

Follow these steps to program the Gate Control List (GCL) and the four other registers implemented per GCL.

1. The GCL and the four other GCL-linked registers should be accessed via indirect addressing using the MTL_EST_GCL_Control and MTL_EST_GCL_Data registers. The SWOL bit of the MTL_EST_Status register indicates if GCL0 or GCL1 is owned by software.
2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_Data register. Then program TL_EST_GCL_Control register to write the write address and other control information.
3. In the MTL_EST_GCL_Data register, Write Data consists of up to 8 bits (configurable) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.

```
{8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
```

4. MTL_EST_GCL_Control register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the same indirect addressing method described above, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_Control register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_Control register to allow hardware to own and process the GCL.

When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

Note: The time unit in all the GCL related registers is Seconds and Nano-seconds. In cases where internally generated PTP System Time is used, the nano-seconds field must be programmed to use the Digital Rollover mode. (TSCTRLSSR field of MAC_Timestamp_Control must be set to value '1')

50.5.15.2 Programming the EST registers

After completing the steps mentioned in *Section 50.5.15.1: Programming the GCL and GCL linked registers*, program the MTL_EST_Control register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_Control register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.

Note: The CTOV recommendations for GMII for SPRAM configurations are:
96 xTx clock period, for 32- and 64-bit data width configurations.
128 xTx clock period for 128-bit data width configurations.

The CTOV recommendations for GMII for non-SPRAM configurations are:
30 xTx clock period, when SA/VLAN insertion is enabled.
22 xTx clock period, when SA/VLAN insertion is not enabled.

2. This will enable the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Appropriate action has to be taken by software to address any other interrupts (explained in the Interrupts section) received during the hardware execution of the GCL.

Set the SSWL (Switch to Software Owned List) bit in the MTL_EST_Control register to hand-off to hardware. Software is not allowed to write to the GCL and GCL linked registers when the SSWL bit is set, because the new GCL might be in use by the hardware.

The SSWL is reset/cleared by the hardware when it successfully switches to the new list. The hardware also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in *Section 50.5.15.1: Programming the GCL and GCL linked registers* and then program the MTL_EST_Control register as described above.

Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, in the DMA configurations, program the packet length in the first descriptor of every Tx frame.

Similarly, in the MTL configuration, provide the packet length in the control word.

Note: To avoid transmission overruns, the Packet Length provided in the Transmit Descriptor should account for the SA and VLAN insertion, if applicable, that is, Packet Length should represent the actual packet length on the Ethernet line.

50.5.16 Programming the launch time in time-based scheduling

The launch time is programmed in the Enhanced Normal Tx Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

50.5.17 Programming guidelines for ECC protection for memories

Programming guidelines for the ECC protection for memories:

- Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_Control register.
- A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_Interrupt_Status register.
- Debug mode is provided for each memory to specify errors.

Note: Enable the ECC feature before the traffic is online (or after the reset). Otherwise false interrupts might be triggered.

50.5.17.1 Programming guidelines for ECC hardware error injection (debug mode)

Follow these steps for ECC Hardware Error Injection:

- Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register. For more details about accessing memory in debug mode, refer to Accessing Memory In Slave/Debug Mode.
- Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_Control register.
- Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_ Indirect_Acc_Control_Status register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_Opeartion_Mode register to 0.
- Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

50.5.18 Programming guidelines for On-Chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Set the EDPP bit of MTL_DPP_Control register to enable the generation of parity and detection of parity Mismatch on datapath. An odd parity generation/detection can be enabled by setting the OPE bit of MTL_DPP_control register else by default even parity generation/detection will be active.
- An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated ti indicate to the application if any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_Safety_Interrupt_ status and MAC_DPP_FSM_Interrupt_Status register.
- Debug mode is supported for each parity generator, to insert error. For details of how to insert errors, refer to Parity Error Injection.

Note: To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

50.5.19 Programming guidelines for FSM parity and timeout

Follow these steps to program the FSM parity and timeout:

- Set the PRTYEN and TMOUTEN fields of MAC_FSM_Control register to enable the FSM parity and timeout feature respectively.
- For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_Interrupt_Status.
- For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_Control register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_Interrupt_Status.
- For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_Timer register.
- Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_Control Register.
- Set the TMR field of the MAC_ACT_Timer field with the appropriate number of CSR clock cycles used to generate 1us tic.
- Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_Interrupt_Status register.
- For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_Interrupt_Status.
- For application /CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_interrupt_ Status is set along with the safety interrupt.

51 FlexRay communication controller (FlexRay)

51.1 Introduction

51.1.1 Reference

The following documents are referenced in this chapter. They may be consulted for further information on the FlexRay communication controller's operation.

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A[u]
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0

51.1.2 Color coding

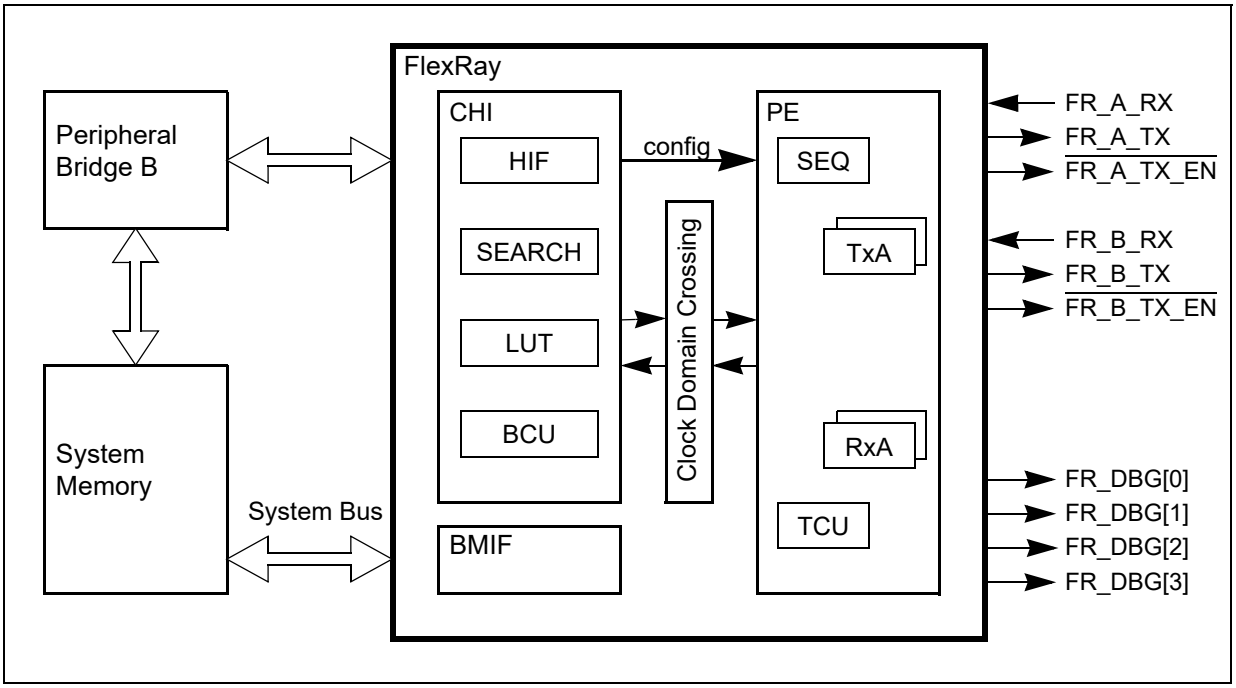
Throughout this chapter, some items are displayed in an italicized, colored font.

FlexRay protocol parameters, constants, and variables are highlighted with *blue italics*. An example is the parameter *gdActionPointOffset*.

FlexRay protocol states are highlighted in *green italics*. An example is the state *POC:normal active*.

51.1.3 Overview

The Communication Controller (CC) is a FlexRay communication controller that implements the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*



The CC has three main components:

- Controller Host Interface (CHI)
- Protocol Engine (PE)
- Clock Domain Crossing unit (CDC)

A block diagram of the CC with its surrounding modules is given in *Figure 1347*.

u. The FlexRay specifications have been developed for automotive applications. The FlexRay specifications have been neither developed nor tested for non-automotive applications.

Figure 1347. FlexRay block diagram

The protocol engine has two transmitter units, TxA and TxB, and two receiver units, RxA and RxB, for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the protocol engine (PE) is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, as well as the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the controller host interface (CHI) clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the *Section 51.5.2.5: System Memory Base Address Register (FR_SYMBADR)*. All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note: The CC does not provide a memory protection scheme for the FlexRay memory area.

51.1.4 Features

The CC provides the following features:

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A-compliant protocol implementation
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0-compliant bus driver interface
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 256 configurable message buffers with
  - Individual frame ID filtering
  - Individual channel ID filtering
  - Individual cycle counter filtering
- Message buffer header, status, and payload data stored in dedicated FlexRay memory area
  - Allows for flexible and efficient message buffer implementation
  - Ensures consistent data access by means of a buffer-locking scheme
  - Application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0–254 bytes
- Two independent message buffer segments with configurable size of payload data section
  - Each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
  - Applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
  - Receive message buffer
  - Transmit message buffer
- Individual message buffers can be reconfigured
  - Individual message buffers can be disabled safely
  - Disabled message buffers can be reconfigured
- Two independent receive FIFOs
  - One receive FIFO per channel
  - Up to 255 entries for each FIFO
  - Global frame ID filtering, based on both value/mask filters and range filters
  - Global channel ID filtering
  - Global message ID filtering for the dynamic segment
- Four configurable slot error counters
- Four dedicated slot status indicators
  - Used to observe slots without using receive message buffers

- Measured value indicators for clock synchronization
  - Internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- One absolute timer
- One timer that can be configured as absolute or relative
- SECDED for protocol engine data RAM
- SEDDED for CHI lookup table RAM

51.1.5 Modes of operation

This section describes the basic operational power modes of the CC.

51.1.5.1 Disabled mode

The CC enters Disabled mode during hard reset or when the host clears the 'MEN' field in the Module Configuration Register (FR_MCR). The host can clear this field by writing '0' and only when the module is in *POC:default config* mode. The Disabled mode can be checked by reading the module enable field, MEN, in the *Module Configuration Register (FR_MCR)* .

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled mode* can be accessed for writing as stated in *Section 51.5: Memory map and register description*.

The application configures the CC by accessing the configuration fields in the *Module Configuration Register (FR_MCR)* as described in *Section 51.7.2.1: Module initialization*.

51.1.5.1.1 Leave Disabled mode

The CC leaves Disabled mode and enters Normal mode, when the application writes 1 to FR_MCR[MEN].

Note: Once the CC is enabled, it cannot be disabled later.

51.1.5.2 Normal mode

In this mode, the CC is fully functional. The CC indicates that it is in Normal mode by asserting FR_MCR[EN].

51.1.5.2.1 Enter Normal mode

This mode is entered when the application requests that the CC leave Disabled mode. If Normal mode is entered after leaving Disabled mode, the application has to perform the protocol initialization described in *Section 51.7.2.2: Protocol initialization* to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB fields in the *Module Configuration Register (FR_MCR)*, the corresponding FlexRay bus driver ports are enabled and driven.

51.2 External signal description

This section lists and describes the CC signals connected to external pins. These signals are summarized in *Table 1447* and described in detail in *Section 51.2.1: Detailed signal description*.

Note: The off-chip FR_A_RX, FR_A_TX, and $\overline{\text{FR_A_TX_EN}}$ signals are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 1447. External signal properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR_A_TX_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR_B_TX_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

51.2.1 Detailed signal description

This section provides a detailed description of the CC signals connected to external pins.

51.2.1.1 FR_A_RX – Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

51.2.1.2 FR_A_TX – Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

51.2.1.3 $\overline{\text{FR_A_TX_EN}}$ – Transmit Enable Channel A

The $\overline{\text{FR_A_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

51.2.1.4 FR_B_RX – Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

51.2.1.5 FR_B_TX – Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

51.2.1.6 $\overline{\text{FR_B_TX_EN}}$ – Transmit Enable Channel B

The $\overline{\text{FR_B_TX_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

51.2.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] – Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection, refer to *Section 51.6.16: Strobe signal support*.

51.3 Controller host interface clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

- The first constraint corresponds to the number of utilized message buffers and is specified in *Section 51.7.5: Number of usable message buffers*.
- The second constraint corresponds to the value of the TIMEOUT field in the *Section 51.5.2.33: System Memory Access Timeout Register (FR_SYMATOR)* and is specified in *Section 51.7.1.1: Configure System Memory Access Timeout Register (FR_SYMATOR)*.

51.4 Protocol engine clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select field, CLKSEL, in the *Section 51.5.2.4: Module Configuration Register (FR_MCR)*.

Note: Refer to the device clocking details for the exact clock sources used.

51.4.1 Oscillator clocking

If the protocol engine is clocked by the internal crystal oscillator, a 40 MHz crystal or CMOS-compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.*

51.4.2 PLL clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately to generate the 40 MHz and 180 degree phase-shifted 40 MHz clocks and provide them to the PE. For more details, refer to the clocking chapter of the device reference manual.

51.5 Memory map and register description

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU.

Note: The following registers are 16-bit write accessible only:

- *Strobe Signal Control Register (FR_STBSCR)*
- *PE DRAM Access Register (FR_PEDRAR)*
- *PE DRAM Data Register (FR_PEDRDR)*
- *Sync Frame ID Rejection Filter Register (FR_SFIDRFR)*
- *Slot Status Selection Register (FR_SSSR)*
- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Index Register (FR_RSBIR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*
- *Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)*
- *Message Buffer Frame ID Register (FR_MBFIDRn)*
- *Message Buffer Index Register (FR_MBIDXRn)*
- *Message Buffer Data Field Offset Register (FR_MBDORn)*
- *LRAM ECC Error Test Register (FR_LEETRn)*

51.5.1 Memory map

The complete memory map of the CC is shown in *Table 1448*. The addresses presented here are the offsets relative to the CC base address, which is defined by the MCU address map.

Table 1448. FlexRay memory map

Address offset	Register name	Location
Module configuration and control		
0x0000	Module Version Register (FR_MVR)	*Section 51.5.2.3*

51.5.2 Register descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

51.5.2.1 Register reset

All registers except the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), and Message Buffer Index Registers (FR_MBIDXRn) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are described in the detailed description of the register. The additional reset conditions are explained in *Table 1449*.

Table 1449. Additional register reset conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes RUN command “0101” to the POCCMD field in the *Section 51.5.2.12: Protocol Operation Control Register (FR_POCR)*.
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants a disable to the application by clearing the FR_MBCCSRn[EDS] bit.

51.5.2.2 Register write access

This section describes the write access restriction terms that apply to all registers.

51.5.2.2.1 Register write access restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in

Table 1450. If, for a specific register field, none of the given write access conditions is fulfilled, any write attempt to this register field is ignored without any notification. The values of the fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 1450. Register write access restrictions

Condition	Indication	Description
Anytime	—	No write access restriction.
Disabled mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled mode.
Normal mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal mode.
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSRn[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.

51.5.2.2.2 Register write access requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

51.5.2.2.3 Internal register access

The following memory-mapped registers are used to access multiple internal registers.

- Strobe Signal Control Register (FR_STBSCR)
- Slot Status Selection Register (FR_SSSR)
- Slot Status Counter Condition Register (FR_SSCCR)
- Receive Shadow Buffer Configuration Data

Each of these memory-mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If WMD is set to 0 during the write access, all fields of the internal register are updated. If WMD is set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

51.5.2.3 Module Version Register (FR_MVR)

Offset: 0x0000 Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CHIVER								PEVER							
W																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

Figure 1348. Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Table 1451. FR_MVR field descriptions

Field	Description
0:7 CHIVER	**CHI Version Number** This field provides the version number of the controller host interface.
8:15 PEVER	**PE Version Number** This field provides the version number of the protocol engine.

51.5.2.4 Module Configuration Register (FR_MCR)

Access: Read/Write
Write: SBFF, SCM, CHB, CHA, ECCE, FUM, FAM, CLKSEL, BITRATE: Disabled mode

Offset: 0x0002

Write: MEN: Disabled or *POC:default config*
SFFE: Disabled Mode or *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MEN	SBFF	SCM	CHB	CHA	SFFE	ECCE	Reserved(1)	FUM	FAM	0	CLKSEL	BITRATE			0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. It is read as 0. Application must not write 1 to this bit.

Figure 1349. Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Table 1452. FR_MCR field descriptions

Field	Description
0 MEN	**Module Enable** This bit indicates whether or not the CC is in Disabled mode. The application requests that the CC leave Disabled mode by writing 1 to this bit Before leaving Disabled mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, and BITRATE values. For details, refer to *Section 51.1.5: Modes of operation*. 0 Write: only during *POC:default config*, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled **Note:** If the CC is enabled, it can only be disabled during mode: POC:default config
1 SBFF	**System Bus Failure Freeze** This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to Freeze mode
2 SCM	**Single Channel Device Mode** This control bit defines the channel device mode of the CC as described in *Section 51.6.10: Channel device modes*. 0 CC works in Dual-Channel Device mode 1 CC works in Single-Channel Device mode
3 CHB	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 1453*.
4 CHA	**Channel Enable** protocol related parameter: *pChannels* The semantic of this control bit depends on the channel device mode controlled by the SCM bit and is given *Table 1453*.
5 SFFE	**Synchronization Frame Filter Enable** This bit controls the filtering for received synchronization frames. For details, refer to *Section 51.6.15: Sync frame filtering*. 0 Synchronization frame filtering disabled 1 Synchronization frame filtering enabled
6 ECCE	**ECC Functionality Enable** This bit controls the ECC memory error detection functionality. For details, refer to *Section 51.6.24: Memory content error detection*. 0 ECC functionality (injection, detection, reporting, response) disabled 1 ECC functionality enabled
8 FUM	**FIFO Update Mode** This bit controls the FIFO update behavior when the interrupt flags FR_GIFER[FAFAIF] and FR_GIFER[FAFBIF] are written by the application (refer to *Section 51.6.9.8: FIFO update*) 0 FIFOA/FIFOB is updated on writing 1 to FR_GIFER[FAFAIF] /FR_GIFER[FAFBIF] 1 FIFOA/FIFOB) is *not* updated on writing 1 to FR_GIFER[FAFAIF]/FR_GIFER[FAFBIF]

Table 1452. FR_MCR field descriptions (continued)

Field	Description
9 FAM	**FIFO Address Mode** This bit controls the location of the system memory base address for the FIFOs (refer to *Section 51.6.9.2: FIFO configuration*). 0 FIFO Base Address located in *Section 51.5.2.5: System Memory Base Address Register (FR_SYMBADR)* 1 FIFO Base Address located in *Section 51.5.2.71: Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)*
11 CLKSEL	**Protocol Engine Clock Source Select** This bit is used to select the clock source for the protocol engine. 0 PE clock source is generated by on-chip crystal oscillator. 1 PE clock source is generated by on-chip PLL.
12:14 BITRATE	**FlexRay Bus Bit Rate** This field defines the FlexRay bus bit rate. 000 10.0 Mbit/s 001 5.0 Mbit/s 010 2.5 Mbit/s 011 8.0 Mbit/s 100 Reserved 101 Reserved 110 Reserved 111 Reserved

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1351. System Memory Base Address Low Register (FR_SYMBADLR)

Note: The system memory base address must be set before the CC is enabled.

The system memory base address registers define the base address of the FlexRay memory area within the system memory. The base address is used by the bus master interface (BMIF) to calculate the physical memory address for system memory accesses.

Table 1454. FR_SYMBADR field descriptions

Field	Description
SMBA	**System Memory Base Address** This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if FR_MCR[FAM] is set to 1. It is defined as a byte address.

51.5.2.6 Strobe Signal Control Register (FR_STBSCR)

Offset: 0x0008

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	SEL				0	0	0	ENB	0	0	STBPSEL

1. 16-bit write access required

Figure 1352. Strobe Signal Control Register (FR_STBSCR)

This register is used to assign the individual protocol timing-related strobe signals given in *Table 1456* to the external strobe ports. Each strobe signal can be assigned to at most one strobe port. Each write access to registers overwrites the previously-written ENB and STBPSEL values for the signal indicated by SEL. If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port. If no strobe signal is assigned to a strobe port, the strobe port carries logic 0. For more detailed and timing information refer to *Section 51.6.16: Strobe signal support*.

Note: In Single-channel device mode, channel B-related strobe signals are undefined and should not be assigned to the strobe ports.

Table 1455. FR_STBSCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
4:7 SEL	**Strobe Signal Select** This control field selects one of the strobe signals given in *Table 1456* to be enabled or disabled and assigned to one of the four strobe ports.
11 ENB	**Strobe Signal Enable** The control bit is used to enable and disable the strobe signal selected by STBSSEL. 0 Strobe signal is disabled and not assigned to any strobe port. 1 Strobe signal is enabled and assigned to the strobe port selected by STBPSEL.
14:15 STBPSEL	**Strobe Port Select** This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 Assign selected signal to FR_DBG[0]. 01 Assign selected signal to FR_DBG[1]. 10 Assign selected signal to FR_DBG[2]. 11 Assign selected signal to FR_DBG[3].

Table 1456. Strobe signal mapping

SEL		Description	Channel	Type	Offset(1)	Reference

51.5.2.8 Message Buffer Data Size Register (FR_MBDSR)

Offset: 0x000C

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	MBSEG2DS							0	MBSEG1DS						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1354. Message Buffer Data Size Register (FR_MBDSR)

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Table 1458. FR_MBDSR field descriptions

Field	Description
1:7 MBSEG2DS	**Message Buffer Segment 2 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *second* message buffer segment.
9:15 MBSEG1DS	**Message Buffer Segment 1 Data Size** The field defines the size of the message buffer data section in two-byte entities for message buffers within the *first* message buffer segment.

51.5.2.9 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Offset: 0x000E

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	LAST_MB_SEG1								LAST_MB_UTIL							
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Figure 1355. Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

This register defines the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Table 1459. FR_MBSSUTR field descriptions

Field	Description
0:7 LAST_MB_SEG1	**Last Message Buffer In Segment 1** This field defines the message buffer number of the last individual message buffer that is assigned to the *first* message buffer segment. The individual message buffers in the *first* segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn with n ≤ LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1 + 1 individual message buffers. **Note:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the *second* message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 256. **Note:** If LAST_MB_SEG1 = 255, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
8:15 LAST_MB_UTIL	**Last Message Buffer Utilized** This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n ≤ LAST_MB_UTIL. **Note:** If LAST_MB_UTIL=LAST_MB_SEG1, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

51.5.2.10 PE DRAM Access Register (FR_PEDRAR)

Offset: 0x0010

Access: Read/Write(1)
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	INST				ADDR											DAD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. 16-bit write access required

Figure 1356. PE DRAM Access Register (FR_PEDRAR)

The FR_PEDRAR is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this register initiates a read or write operation on the PE DRAM. The access done status bit, DAD, is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR is written into the PE DRAM, read back from the PE DRAM, and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data is read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description, refer to *Section 51.6.24: Memory content error detection*.

Table 1460. FR_PEDRAR field descriptions

Field	Description
0:3 INST	**PE DRAM Access Instruction** This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16-bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16-bit) into FR_PEDRDR[DATA] other reserved
4:14 ADDR	**PE DRAM Access Address** This field defines the address in the PE DRAM to be written to or read from.
15 DAD	**PE DRAM Access Done** This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done

51.5.2.11 PE DRAM Data Register (FR_PEDRDR)

Offset: 0x0012

Access: Read/Write(1)
Write: Normal mode

Figure 1358. Protocol Operation Control Register (FR_POCR)

The application uses this register to issue:

- Protocol control commands
- External clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, refer to *Section 51.7.6: Protocol control command execution*.

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to *Section 51.6.11: External clock synchronization*.

Table 1462. FR_POCR field descriptions

Field	Description
0 WME	**Write Mode External Correction** This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write 1 No write to EOC_AP and ERC_AP fields on register write
4:5 EOC_AP	**External Offset Correction Application** This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 Do not apply external offset correction value 01 Reserved 10 Subtract external offset correction value 11 Add external offset correction value
6:7 ERC_AP	**External Rate Correction Application** This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21). 00 Do not apply external rate correction value 01 Reserved 10 Subtract external rate correction value 11 Add external rate correction value

Table 1462. FR_POCR field descriptions (continued)

Field	Description
8 BSY_WMC	**Protocol Control Command Write Busy (BSY)** This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR), and will not change the value of the POCCMD field. (0) Command write idle, command accepted and ready to receive new protocol command (1) Command write busy, command not yet accepted, not ready to receive new protocol command **Write Mode Command (WMC)** This bit controls the write mode of the POCCMD field. (0) Write to POCCMD field on register write (1) Do not write to POCCMD field on register write
12:15 POCCMD	**Protocol Control Command** The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTAR: Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS: Delayed(1) transition to the All Slots Transmission mode. 0010 CONFIG: Immediately transition to the *POC:config* state. 0011 FREEZE: Immediately transition to the *POC:halt* state. 0100 READY, CONFIG_COMPLETE: Immediately transition to the *POC:ready* state. 0101 RUN: Immediately transition to the *POC:startup start* state. 0110 DEFAULT_CONFIG: Immediately transition to the *POC:default config* state. 0111 HALT: Delayed transition to the *POC:halt* state 1000 WAKEUP: Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

1. Delayed means on completion of current communication cycle.

51.5.2.13 Global Interrupt Flag and Enable Register (FR_GIFER)

Offset: 0x0016

Access: Read/Write
Write: Normal mode

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1359. Global Interrupt Flag and Enable Register (FR_GIFER)

This register controls some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation scheme for these flags is depicted in *Figure 1507*. For more details on interrupt generation, refer to *Section 51.6.20: Interrupt support*. These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Table 1463. FR_GIFER field descriptions

Field	Description
0 MIF	**Module Interrupt Flag** This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set
1 PRIF	**Protocol Interrupt Flag** This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set
2 CHIF	**CHI Interrupt Flag** This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the CHI error interrupt enable bit FR_GIFER[CHIE] are set. 0 All CHI error flags are equal to 0 or the CHI error interrupt is disabled 1 At least one CHI error flag and the CHI error interrupt enable are is set
3 WUPIF	**Wakeup Interrupt Flag** This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus

Table 1463. FR_GIFER field descriptions (continued)

Field	Description
4 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or b) The current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO B almost full event has occurred **Note:** If the bit MCR[FUM] is set to 0, to clear FAFAIF or FAFBIF will also remove one element from the FIFO.
5 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** This interrupt flag is set when one of the following events occurs: a) The current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) The current number of FIFO A entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO A almost full event has occurred
6 RBIF	**Receive Message Buffer Interrupt Flag** This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application cannot clear this interrupt flag directly; instead, it is cleared by the CC when all of the MBIF interrupt flags of the individual receive message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual receive message buffers has the MBIF and MBIE flag set 1 At least one individual receive message buffer has the MBIF and MBIE flag set
7 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application cannot clear this interrupt flag directly; instead, this interrupt flag is cleared by the CC when all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set 1 At least one individual transmit message buffer has the MBIF and MBIE flag set
8 MIE	**Module Interrupt Enable** This bit controls whether the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	**Protocol Interrupt Enable** This bit controls whether the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table 1463. FR_GIFER field descriptions (continued)

Field	Description
10 CHIE	**CHI Interrupt Enable** This bit controls whether the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	**Wakeup Interrupt Enable** This bit controls whether the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
12 FAFBIE	**Receive FIFO Channel B Almost Full Interrupt Enable** This bit controls whether the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	**Receive FIFO Channel A Almost Full Interrupt Enable** This bit controls whether the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	**Receive Message Buffer Interrupt Enable** This bit controls whether the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 TBIE	**Transmit Message Buffer Interrupt Enable** This bit controls whether the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

51.5.2.14 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Figure 1360. Protocol Interrupt Flag Register 0 (FR_PIFR0)

This register holds one set of the protocol-related individual interrupt flags.

Table 1464. FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	**Fatal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. The fatal protocol errors are: – *pLatestTx* violation, as described in the MAC process of the FlexRay protocol – Transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event 1 Fatal protocol error detected
1 INTL_IF	**Internal Protocol Error Interrupt Flag** This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the *POC:halt* state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event 1 Internal protocol error detected
2 ILCF_IF	**Illegal Protocol Configuration Interrupt Flag** This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the *POC:halt* state immediately. The protocol engine checks the *listen_timeout* value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of *listen_timeout* is equal to 0, the protocol configuration setting is considered as illegal. 0 No such event 1 Illegal protocol configuration detected
3 CSA_IF	**Cold Start Abort Interrupt Flag** This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event 1 Cold start aborted and no more coldstart attempts allowed
4 MRC_IF	**Missing Rate Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	**Missing Offset Correction Interrupt Flag** This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event 1 Insufficient number of measurements for offset correction detected

Table 1464. FR_PIFR0 field descriptions (continued)

Field	Description
6 CCL_IF	**Clock Correction Limit Reached Interrupt Flag** This flag is set when the internal calculated offset or rate calculation values have reached or exceeded their configured thresholds as given by the *offset_correction_out* field in the Protocol Configuration Register 9 (FR_PCR9) and the *rate_correction_out* field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event 1 Offset or rate correction limit reached
7 MXS_IF	**Max Sync Frames Detected Interrupt Flag** This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the *node_sync_max* field in the Protocol Configuration Register 30 (FR_PCR30). 0 No such event 1 More than *node_sync_max* sync frames detected **Note:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account
8 MTX_IF	**Media Access Test Symbol Received Interrupt Flag** This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event 1 MTS symbol received
9 LTXB_IF	*pLatestTx* **Violation on Channel B Interrupt Flag** This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation, as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel B
10 LTXA_IF	*pLatestTx* **Violation on Channel A Interrupt Flag** This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the *pLatestTx* violation as described in the MAC process of the FlexRay protocol. 0 No such event 1 *pLatestTx* violation occurred on channel A
11 TBVB_IF	**Transmission across boundary on channel B Interrupt Flag** This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel B
12 TBVA_IF	**Transmission across boundary on channel A Interrupt Flag** This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel A
13 TI2_IF	**Timer 2 Expired Interrupt Flag** This flag is set whenever timer 2 expires. 0 No such event 1 Timer 2 has reached its time limit

Table 1464. FR_PIFR0 field descriptions (continued)

Field	Description
14 TI1_IF	**Timer 1 Expired Interrupt Flag** This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	**Cycle Start Interrupt Flag** This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started

The register holds one set of the protocol-related individual interrupt flags.

Table 1465. FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	**Error Mode Changed Interrupt Flag** This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event 1 ERRMODE field changed
1 IPC_IF	**Illegal Protocol Control Command Interrupt Flag** This flag is set when the PE tries to execute a protocol control command that was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case, the command is not executed. For more details, refer to *Section 51.7.6: Protocol control command execution*. 0 No such event 1 Illegal protocol control command detected
2 PECF_IF	**Protocol Engine Communication Failure Interrupt Flag** This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event 1 Protocol Engine Communication Failure detected

Table 1465. FR_PIFR1 field descriptions (continued)

Field	Description
3 PSC_IF	**Protocol State Changed Interrupt Flag** This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event 1 Protocol state changed
4 SSI3_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR3) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
5 SSI2_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR2) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
6 SSI1_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR1) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
7 SSI0_IF	**Slot Status Counter Incremented Interrupt Flag** This flag is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Register (FR_SSCR0) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
10 EVT_IF	**Even Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the even cycle. 0 No such event 1 Sync frame measurement table written
11 ODT_IF	**Odd Cycle Table Written Interrupt Flag** This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the odd cycle. 0 No such event 1 Sync frame measurement table written

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1364. CHI Error Flag Register (FR_CHIERFR)

This register holds the CHI-related error flags. The interrupt generation for each of these error flags is controlled by the CHI interrupt enable bit, CHIE, in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 1468. FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	**Frame Lost Channel B Error Flag** This flag is set if a complete frame was received on channel B but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	**Frame Lost Channel A Error Flag** This flag is set if a complete frame was received on channel A but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected

Table 1468. FR_CHIERFR field descriptions (continued)

Field	Description
2 PCMI_EF	**Protocol Command Ignored Error Flag** This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case, the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	**Receive FIFO Overrun Channel B Error Flag** This flag is set when an overrun of the FIFO for channel B has occurred. This error occurs if a semantically valid frame was received on channel B and matches all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information are lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	**Receive FIFO Overrun Channel A Error Flag** This flag is set when an overrun of the FIFO for channel A has occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information are lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	**Message Buffer Search Error Flag** This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 259 is detected in the FR_MBIDXR[MBIDX] field of a found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to *Section 51.6.7.4: Message buffer search error* for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
6 MBU_EF	**Message Buffer Utilization Error Flag** This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	**Lock Error Flag** This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected

Table 1468. FR_CHIERFR field descriptions (continued)

Field	Description
9 SBCF_EF	**System Bus Communication Failure Error Flag** This flag is set if a system bus access was not finished within the required amount of time (refer to *Section 51.6.19.1.2: System bus access timeout*). 0 No such event 1 System bus access not finished in time
10 FID_EF	**Frame ID Error Flag** This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register. 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	**Dynamic Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	**Static Payload Length Error Flag** This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	**Network Management Length Error Flag** This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case, the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
14 NMF_EF	**Network Management Frame Error Flag** This flag is set if a received message in the static segment with a Preamble Indicator flag (PP) asserted has its Null Frame indicator flag (NF) asserted as well. In this case, the Global Network Management Registers (refer to *Section 51.5.2.40: Network Management Vector Registers (FR_NMVRn)*) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	**Illegal System Bus Address Error Flag** This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (refer to *Section 51.6.19.1.1: System bus illegal address access*). 0 No such event 1 Illegal system bus address accessed

51.5.2.19 Message Buffer Interrupt Vector Register (FR_MBIVEC)

R	TBIVEC								RBIVEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1365. Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their MBIF interrupt status flag and MBIE interrupt enable bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Table 1469. FR_MBIVEC field descriptions

Field	Description
0:7 TBIVEC	**Transmit Buffer Interrupt Vector** This field provides the number of the lowest numbered enabled transmit message buffer that has its MBIF interrupt status flag and its MBIE interrupt enable bit set. If there is no transmit message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.
8:15 RBIVEC	**Receive Buffer Interrupt Vector** This field provides the message buffer number of the lowest numbered receive message buffer that has its MBIF interrupt flag and its MBIE interrupt enable bit asserted. If there is no receive message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.

51.5.2.20 Channel A Status Error Counter Register (FR_CASERCR)

Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. **A**dditional Reset: RUN Command

Figure 1366. Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits *vSS!SyntaxError, vSS!ContentError, vSS!BViolation*, and *vSS!TxConflict*. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, refer to *Section 51.6.18: Slot status monitoring*.

Table 1470. FR_CASERCR field descriptions

Field	Description
0:15 CHAERSCNT	**Channel Status Error Counter** This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

1. Additional Reset: CSAA, CSP, CPN: RUN Command

Figure 1369. Protocol Status Register 1 (FR_PSR1)

Table 1473. FR_PSR1 field descriptions

Field	Description
0 CSAA	**Cold Start Attempt Aborted Flag** protocol-related event: 'set coldstart abort indicator in CHI.' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	**Leading Cold Start Path** This status bit is set when the CC has reached the *POC:normal active* state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 *POC:normal active* reached from *POC:startup* state via leading cold start path
3:7 REMCSAT	**Remaining Coldstart Attempts** protocol-related variable: *vRemainingColdstartAttempts.* This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	**Leading Cold Start Path Noise**—protocol-related variable: *vPOC!ColdstartNoise.* This status bit is set if the CC has reached the *POC:normal active* state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 *POC:normal active* state was reached from *POC:startup* state via noisy leading cold start path
9 HHR	**Host Halt Request Pending** protocol related variable: *vPOC!CHIHaltRequest.* This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 HALT command received
10 FRZ	**Freeze Occurred** protocol related variable: *vPOC!Freeze.* This status bit is set when the CC has reached the *POC:halt* state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the *POC:default config* state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11:15 APTAC	**Allow Passive to Active Counter** protocol-related variable: *vPOC!vAllowPassivetoActive.* This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the *POC:normal passive* state due to an application-configured delay to enter *POC:normal active* state. This delay is defined by the allow_passive_to_active field in Protocol Configuration Register 12 (FR_PCR12).

51.5.2.24 Protocol Status Register 2 (FR_PSR2)

Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: RUN Command

Figure 1370. Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the network idle time (NIT), the symbol window, and the clock synchronization. The NIT-related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The symbol-window-related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol-window-related status bits remain in their reset state. The clock synchronization-related CKCORFCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Table 1474. FR_PSR2 field descriptions

Field	Description
0 NBVB	**NIT Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for NIT on channel B. This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	**NIT Syntax Error on Channel B** protocol-related variable: *vSS!SyntaxError* for NIT on channel B. This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	**Symbol Window Transmit Conflict on Channel B** protocol-related variable: *vSS!TxConflict* for symbol window on channel B. This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	**Symbol Window Boundary Violation on Channel B** protocol-related variable: *vSS!BViolation* for symbol window on channel B. This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected

Table 1474. FR_PSR2 field descriptions (continued)

Field	Description
4 SSEB	**Symbol Window Syntax Error on Channel B** protocol related variable: *vSS!SyntaxError* for symbol window on channel B. This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	**Media Access Test Symbol MTS Received on Channel B** protocol-related variable: *vSS!ValidMTS* for Symbol Window on channel B. This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	**NIT Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for NIT on channel A. This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	**NIT Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected
8 STCA	**Symbol Window Transmit Conflict on Channel A** protocol related variable: *vSS!TxConflict* for symbol window on channel A. This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	**Symbol Window Boundary Violation on Channel A** protocol-related variable: *vSS!BViolation* for symbol window on channel A. This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	**Symbol Window Syntax Error on Channel A** protocol-related variable: *vSS!SyntaxError* for symbol window on channel A. This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected

Table 1474. FR_PSR2 field descriptions (continued)

Field	Description
11 MTA	**Media Access Test Symbol MTS Received on Channel A** protocol-related variable: *vSS!ValidMTS* for symbol window on channel A. This status bit is set if the Media Access Test Symbol (MTS) was received in the symbol window on channel A. 0 No such event 1 MTS symbol received
12:15 CKCORFCNT	**Clock Correction Failed Counter** protocol -elated variable: *vClockCorrectionFailed.* This field provides the number of consecutive even/odd communication cycle pairs that have passed without a clock synchronization offset or rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the *POC:normal active* state, or when both the rate and offset correction terms have been calculated successfully.

W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: RUN Command

Figure 1376. Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Table 1480. FR_RTCORVR field descriptions

Field	Description
0:15 RATECORR	**Rate Correction Value** protocol-related variable: *vRateCorrection* (before value limitation and external rate correction). This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag (CCL_IF) is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

51.5.2.31 Offset Correction Value Register (FR_OFCORVR)

Offset: 0x003A Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OFFSETCORR															
W																
Reset(1)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: RUN Command

Figure 1377. Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Table 1481. FR_OFCORVR field descriptions

Field	Description
0:15 OFFSETCORR	**Offset Correction Value** protocol-related variable: *vOffsetCorrection* (before value limitation and external offset correction). This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **Note:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

51.5.2.32 Combined Interrupt Flag Register (FR_CIFR)

Offset: 0x003C Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1378. Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in *Figure 1509*. The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

Note: The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

Table 1482. FR_CIFR field descriptions

Field	Description
8 MIF	**Module Interrupt Flag** This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	**Protocol Interrupt Flag** This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	**CHI Interrupt Flag** This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1. 0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	**Wakeup Interrupt Flag** Provides the same value as FR_GIFER[WUPIF].
12 FAFBIF	**Receive FIFO Channel B Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFBIF].
13 FAFAIF	**Receive FIFO Channel A Almost Full Interrupt Flag** Provides the same value as FR_GIFER[FAFAIF].
14 RBIF	**Receive Message Buffer Interrupt Flag** This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted 1 At least one individual receive message buffers has the MBIF flag asserted
15 TBIF	**Transmit Message Buffer Interrupt Flag** This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted 1 At least one individual transmit message buffers has the MBIF flag asserted

1. Additional Reset: RUN Command

Figure 1380. Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 macroticks after offset correction start.

Note: If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the SFODB and SFODA values.

Table 1484. FR_SFCNTR field descriptions

Field	Description
0:3 SFEVB	Sync Frames Channel B, even cycle protocol-related variable: size of (*vsSyncIdListB* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4:7 SFEVA	Sync Frames Channel A, even cycle protocol related variable: size of (*vsSyncIdListA* for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8:11 SFODB	Sync Frames Channel B, odd cycle protocol-related variable: size of (*vsSyncIdListB* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
12:15 SFODA	Sync Frames Channel A, odd cycle protocol-related variable: size of (*vsSyncIdListA* for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.

51.5.2.35 Sync Frame Table Offset Register (FR_SFTOR)

Offset: 0x0042

Access: Read/Write
Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SFT_OFFSET															0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1381. Sync Frame Table Offset Register (FR_SFTOR)

This register defines the FlexRay memory area related offset for sync frame tables. For more details, refer to *Section 51.6.12: Sync frame ID and sync frame deviation tables*.

Table 1485. FR_SFTOR field descriptions

Field	Description
0:14 SFT_OFFSET	**Sync Frame Table Offset** The offset of the sync frame tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus, STF_OFFSET[0] is always 0.

51.5.2.36 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Offset: 0x0044

Access: Read/Write
Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	CYCNUM						ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
W	ELKT	OLKT												OPT		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1382. Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, refer to *Section 51.6.12: Sync frame ID and sync frame deviation tables*.

Table 1486. FR_SFTCCSR field descriptions

Field	Description
0 ELKT	**Even Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables
1 OLKT	**Odd Cycle Tables Lock/Unlock Trigger** This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables

Table 1486. FR_SFTCCSR field descriptions (continued)

Field	Description
2:7 CYCNUM	**Cycle Number** This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	**Even Cycle Tables Lock Status** This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables 1 Application has locked the even cycle tables
9 OLKS	**Odd Cycle Tables Lock Status** This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables 1 Application has locked the odd cycle tables
10 EVAL	**Even Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
11 OVAL	**Odd Cycle Tables Valid** This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
13 OPT	**One Pair Trigger** This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.

Table 1486. FR_SFTCCSR field descriptions (continued)

Field	Description
14 SDVEN	**Sync Frame Deviation Table Enable** This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area **Note:** If SDVEN is set to 1, then SIDEN must also be set to 1.
15 SIDEN	**Sync Frame ID Table Enable** This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

Table 1489. FR_SFIDAFMR field descriptions

Field	Description
6:15 FMSK	**Filter Mask** This field defines the mask for the sync frame acceptance filtering.

51.5.2.40 Network Management Vector Registers (FR_NMVR*n*)

Offset: 0x004C +*n**0x2 (*n*=0 to 5)

Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	NMVP															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1386. Network Management Vector Registers (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0–FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Table 1490. FR_NMVRn field descriptions

Field	Description
0:15 NMVP	**Network Management Vector Part** The mapping between the Network Management Vector Registers (FR_NMVR0–FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in *Table 1491*.

Table 1491. Mapping of FR_NMVRn to the received payload bytes NMV*x*

1. It is read as 0. Application must not write 1 to this bit.

Figure 1392. Timer 2 Configuration Register 1 (FR_TI2CR1)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to *Section 51.6.17.2: Absolute/relative timer T2*.

Table 1497. FR_TI2CR1 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
2:15 T2_MTOFFSET	**Timer T2 Macrotick Offset** This field holds the macrotick offset value for timer T2.

Table 1497. FR_TI2CR1 field descriptions (continued)

Field	Description
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
0:15 T2_MTCNT	**Timer T2 Macrotick Low Word** This field defines the low word of the macrotick value for timer T2.

Note: If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

51.5.2.47 Slot Status Selection Register (FR_SSSR)

Offset: 0x0064

Access: Read/Write(1)
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	SEL		0	SLOTNUMBER

1. 16-bit write access required

Figure 1394. Slot Status Counter Condition Register (FR_SSCCR)

This register is used to access and program the four internal non-memory-mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal Slot Status Counter Condition Registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). The correspondence is given in *Table 1501*. For a detailed description of slot status counters, refer to *Section 51.6.18.4: Slot status counter registers*.

Table 1500. FR_SSCCR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
2:3 SEL	**Selector** This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0 01 select FR_SSCCR1 10 select FR_SSCCR2 11 select FR_SSCCR3
5:6 CNTCFG	**Counter Configuration** This bit field controls the channel related incrementing of the slot status counter. 00 Increment by 1 if condition is fulfilled on channel A 01 Increment by 1 if condition is fulfilled on channel B 10 Increment by 1 if condition is fulfilled on at least one channel 11 Increment by 2 if condition is fulfilled on both channels Increment by 1 if condition is fulfilled on only one channel.
7 MCY	**Multi Cycle Selection** This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	**Valid Frame Restriction** This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	**Sync Frame Restriction** This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	**Null Frame Restriction** This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.

Table 1500. FR_SSCCR field descriptions (continued)

Field	Description
11 SUF	**Startup Frame Restriction** This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12:15 STATUSMASK	**Slot Status Mask** This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3]: This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2]: This bit enables the counting for slots with the content error indicator bit set to 1. STATUSMASK[1]: This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0]: This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

Table 1501. Mapping between internal FR_SSCCR*n* and FR_SSCR*n*

R	SLOTSTATUSCNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1396. Slot Status Counter Registers (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal Slot Status Counter Condition Register (FR_SSCCRn), which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, refer to *Section 51.6.18.4: Slot status counter registers*.

Note: If the counter has reached its maximum value 0xFFFF and is in Multicycle mode (that is, FR_SSCCRn[MCY] = 1), the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be put into Multicycle mode again.

Table 1503. FR_SSCR*n* field descriptions

Field	Description
0:15 SLOTSTATUSCNT	**Slot Status Counter** This field provides the current value of the Slot Status Counter.

1. 16-bit write access required

Figure 1409. Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter, refer to *Section 51.6.9.9: FIFO filtering*.

Table 1517. FR_RFRFCFR field descriptions

Field	Description
0 WMD	**Write Mode** This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL and IBD field only on write access
1 IBD	**Interval Boundary** This control bit selects the interval boundary to be programmed with the SID value. 0 Program lower interval boundary 1 Program upper interval boundary
2:3 SEL	**Filter Selector** This control field selects the frame ID range filter to be accessed. 00 Select frame ID range filter 0 01 Select frame ID range filter 1 10 Select frame ID range filter 2 11 Select frame ID range filter 3
5:15 SID_A/SID_B	**Slot ID** Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

51.5.2.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Offset: 0x009A

Access: Read/Write
Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1410. Receive FIFO Range Filter Control Register (FR_RFRFCTR)

This register is used to enable and disable each frame ID range filter and to define whether it is running as an acceptance or rejection filter.

Table 1518. FR_RFRFCTR field descriptions

Field	Description
4 F3MD	**Range Filter 3 Mode** This control bit defines the filter mode of the frame ID range filter 3. 0 Range filter 3 runs as acceptance filter 1 Range filter 3 runs as rejection filter
5 F2MD	**Range Filter 2 Mode** This control bit defines the filter mode of the frame ID range filter 2. 0 Range filter 2 runs as acceptance filter 1 Range filter 2 runs as rejection filter
6 F1MD	**Range Filter 1 Mode** This control bit defines the filter mode of the frame ID range filter 1. 0 Range filter 1 runs as acceptance filter 1 Range filter 1 runs as rejection filter
7 F0MD	**Range Filter 0 Mode** This control bit defines the filter mode of the frame ID range filter 0. 0 Range filter 0 runs as acceptance filter 1 Range filter 0 runs as rejection filter
12 F3EN	**Range Filter 3 Enable** This control bit is used to enable and disable the frame ID range filter 3. 0 Range filter 3 disabled 1 Range filter 3 enabled
13 F2EN	**Range Filter 2 Enable** This control bit is used to enable and disable the frame ID range filter 2. 0 Range filter 2 disabled 1 Range filter 2 enabled
14 F1EN	**Range Filter 1 Enable** This control bit is used to enable and disable the frame ID range filter 1. 0 Range filter 1 disabled 1 Range filter 1 enabled
15 F0EN	**Range Filter 0 Enable** This control bit is used to enable and disable the frame ID range filter 0. 0 Range filter 0 disabled 1 Range filter 0 enabled

51.5.2.65 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

Offset: 0x009C Access: Read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1412. Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Table 1520. FR_LDTXSLBR field descriptions

Field	Description
5:15 LDYNTXSLOTB	**Last Dynamic Transmission Slot Channel B** Protocol-related variable: *zLastDynTxSlot* channel B. Number of the last transmission slot in the dynamic segment for channel B. If no frame was transmitted during the dynamic segment on channel B the value of this field is set to 0.

51.5.2.67 Protocol configuration registers

The following configuration registers provide the necessary configuration information to the protocol engine. The individual values in the registers are described in *Table 1521*. For more

details about the FlexRay related configuration parameters and the allowed parameter ranges, refer to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

Table 1521. Protocol configuration register fields

Name	Description[1]	Min	Max	Unit	FR_PCR
coldstart_attempts	gColdstartAttempts	—	—	number	3
action_point_offset	gdActionPointOffset - 1	—	—	MT	0
cas_rx_low_max	gdCASRxLowMax - 1	—	—	gdBit	4
dynamic_slot_idle_phase	gdDynamicSlotIdlePhase	—	—	minislot	28
minislot_action_point_offset	gdMinislotActionPointOffset - 1	—	—	MT	3
minislot_after_action_point	gdMinislot - gdMinislotActionPointOffset - 1	—	—	MT	2
static_slot_length	gdStaticSlot	—	—	MT	0
static_slot_after_action_point	gdStaticSlot - gdActionPointOffset - 1	—	—	MT	13
symbol_window_exists	gdSymbolWindow!=0	0	1	bool	9
symbol_window_after_action_point	gdSymbolWindow - gdActionPointOffset - 1	—	—	MT	6
tss_transmitter	gdTSSTransmitter	—	—	gdBit	5
wakeup_symbol_rx_idle	gdWakeupSymbolRxIdle	—	—	gdBit	5
wakeup_symbol_rx_low	gdWakeupSymbolRxLow	—	—	gdBit	3
wakeup_symbol_rx_window	gdWakeupSymbolRxWindow	—	—	gdBit	4
wakeup_symbol_tx_idle	gdWakeupSymbolTxIdle	—	—	gdBit	8
wakeup_symbol_tx_low	gdWakeupSymbolTxLow	—	—	gdBit	5
noise_listen_timeout	(gListenNoise * pdListenTimeout) - 1	—	—	µT	16/17
macro_initial_offset_a	pMacroInitialOffset[A]	—	—	MT	6
macro_initial_offset_b	pMacroInitialOffset[B]	—	—	MT	16
macro_per_cycle	gMacroPerCycle	—	—	MT	10
macro_after_first_static_slot	gMacroPerCycle - gdStaticSlot	—	—	MT	1
macro_after_offset_correction	gMacroPerCycle - gOffsetCorrectionStart	—	—	MT	28
max_without_clock_correction_fatal	gMaxWithoutClockCorrectionFatal	—	—	cyclepairs	8
max_without_clock_correction_passive	gMaxWithoutClockCorrectionPassive	—	—	cyclepairs	8
minislot_exists	gNumberOfMinislots!=0	0	1	bool	9
minislots_max	gNumberOfMinislots - 1	—	—	minislot	29
number_of_static_slots	gNumberOfStaticSlots	—	—	static slot	2
offset_correction_start	gOffsetCorrectionStart	—	—	MT	11
payload_length_static	gPayloadLengthStatic	—	—	2 bytes	19

Table 1521. Protocol configuration register fields (continued)

Name	Description[1]	Min	Max	Unit	FR_PCR
max_payload_length_dynamic	pPayloadLengthDynMax	—	—	2 bytes	24
first_minislot_action_point_offset	max(gdActionPointOffset, gdMinislotActionPointOffset) - 1	—	—	MT	13
allow_halt_due_to_clock	pAllowHaltDueToClock	—	—	bool	26
allow_passive_to_active	pAllowPassiveToActive	—	—	cyclepairs	12
cluster_drift_damping	pClusterDriftDamping	—	—	µT	24
comp_accepted_startup_range_a	pdAcceptedStartupRange - pDelayCompensation[A]	—	—	µT	22
comp_accepted_startup_range_b	pdAcceptedStartupRange - pDelayCompensation[B]	—	—	µT	26
listen_timeout	pdListenTimeout - 1	—	—	µT	14/15
key_slot_id	pKeySlotId	—	—	number	18
key_slot_used_for_startup	pKeySlotUsedForStartup	—	—	bool	11
key_slot_used_for_sync	pKeySlotUsedForSync	—	—	bool	11
latest_tx	gNumberOfMinislots - pLatestTx	—	—	minislot	21
sync_node_max	gSyncNodeMax	—	—	number	30
micro_initial_offset_a	pMicroInitialOffset[A]	—	—	µT	20
micro_initial_offset_b	pMicroInitialOffset[B]	—	—	µT	20
micro_per_cycle	pMicroPerCycle	—	—	µT	22/23
micro_per_cycle_min	pMicroPerCycle - pdMaxDrift	—	—	µT	24/25
micro_per_cycle_max	pMicroPerCycle + pdMaxDrift	—	—	µT	26/27
micro_per_macro_nom_half	round(pMicroPerMacroNom / 2)	—	—	µT	7
offset_correction_out	pOffsetCorrectionOut	—	—	µT	9
rate_correction_out	pRateCorrectionOut	—	—	µT	14
single_slot_enabled	pSingleSlotEnabled	—	—	bool	10
wakeup_channel	pWakeupChannel	Refer to *Table 1522*			10
wakeup_pattern	pWakeupPattern	—	—	number	18
decoding_correction_a	pDecodingCorrection + pDelayCompensation[A] + 2	—	—	µT	19
decoding_correction_b	pDecodingCorrection + pDelayCompensation[B] + 2	—	—	µT	7
key_slot_header_crc	header CRC for key slot	0x000	0x7FF	number	12
extern_offset_correction	pExternOffsetCorrection	—	—	µT	29
extern_rate_correction	pExternRateCorrection	—	—	µT	21

1. Refer to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A* for detailed protocol parameter definitions.

Table 1523. FR_STPWR field descriptions

Field	Description
0:15 STPW	Stop Watch Count Register This is the value of the stop watch counter running on system clock. This starts on cycle start even and stops on an external event “OS_tick”. For details, refer to *Section 51.6.26*. This is a read reset type register, which means that when all the 32 bits are read, it automatically clears.

Figure 1447. Receive FIFO Start Data Offset Register (FR_RFSDOR)

Table 1525. FR_RFSDOR field descriptions

Field	Description
0:15 SDO_A/SDO_B	Start Data Field Offset This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO’s first message buffer header field. For configuration constraints, refer to *Section 51.7.1.2: Configure data field offsets*.

Note: Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses, the content of the FR_RFSDOR register corresponds to the start address of the payload area of the selected FIFO.

51.5.2.71 Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)

Offset: 0x00E8

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1451. Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs.

Table 1528. FR_RFFLPCR field descriptions

Field	Description
0:7 FLB_PCB	Fill Level FIFO B (FLB) This field provides the current number of entries in the FIFO B. Pop Count FIFO B (PCB) This field defines the number of entries to be removed from FIFO B.
8:15 FLA_PCA	Fill Level FIFO A (FLA) This field provides the current number of entries in the FIFO A. Pop Count FIFO A (PCA) This field defines the number of entries to be removed from FIFO A.

Note: If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, then the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

51.5.2.74 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

Figure 1452. ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC-related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description, refer to *Section 51.6.24.2*.

Table 1529. FR_EEIFER field descriptions

Field	Description
Error overflow flags	
0 LRNE_OF	LRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *but not corrected* on CHI LRAM and interrupt flag LRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of CHI LRAM. 0 No such event 1 Non-Corrected Error overflow detected on CHI LRAM
1 LRCE_OF	LRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected *and corrected* on CHI LRAM and interrupt flag LRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of CHI LRAM. 0 No such event 1 Corrected Error overflow detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
2 DRNE_OF	DRAM Non-Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *but not corrected* on PE DRAM and interrupt flag DRNE_IF is already 1. b) Memory errors are detected *but not corrected* on at least two banks of the PE DRAM. 0 No such event 1 Non-Corrected Error overflow detected on PE DRAM
3 DRCE_OF	DRAM Corrected Error Overflow Flag This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected *and corrected* on PE DRAM and interrupt flag DRCE_IF is already 1. b) Memory errors are detected *and corrected* on at least two banks of PE DRAM. 0 No such event 1 Corrected Error overflow detected on PE DRAM

Table 1529. FR_EEIFER field descriptions (continued)

Field	Description
Error interrupt flags	
4 LRNE_IF	LRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on the CHI LRAM. 0 No such event 1 Non-Corrected Error detected on CHI LRAM
5 LRCE_IF	LRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on the CHI LRAM. 0 No such event 1 Corrected Error detected on CHI LRAM **Note:** Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
6 DRNE_IF	DRAM Non-Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected but not corrected* on PE DRAM. 0 No such event 1 Non-Corrected Error detected on PE DRAM
7 DRCE_IF	DRAM Corrected Error Interrupt Flag This interrupt flag is set to 1 when a memory error is *detected and corrected* on PE DRAM. 0 No such event 1 Corrected Error detected on PE DRAM
Error interrupt enables	
12 LRNE_IE	**LRAM Non-Corrected Error Interrupt Enable** This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 LRCE_IE	**LRAM Corrected Error Interrupt Enable** This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 DRNE_IE	**DRAM Non-Corrected Error Interrupt Enable** This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 DRCE_IE	**DRAM Corrected Error Interrupt Enable** This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

51.5.2.75 ECC Error Report and Injection Control Register (FR_EERICR)

Offset: 0x00F2

Access: Read/Write

W					rwm	EDT	LCKT									w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Additional Reset: CMT, DUP, DVAL, MBIF: Message Buffer Disable

Figure 1460. Message Buffer Configuration, Control and Status Register *n* (FR_MBCCSR*n*)

The content of these registers comprises message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in *Section 51.6.6: Individual message buffer functional description*.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Table 1539. FR_MBCCSR*n* field descriptions

Field	Description
Message buffer configuration	
3 MTD	Message Buffer Transfer Direction This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
Message buffer control	
4 CMT	Commit for Transmission This bit indicates if the transmit message buffer data are ready for transmission. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
Message buffer status	
11 DUP	Data Updated This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and message buffer data field not updated 1 Frame Header and message buffer data field updated
12 DVAL	Data Valid For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers, the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 Receive message buffer contains no valid frame data / message is transmitted for the first time. 1 Receive message buffer contains valid frame data / message will be transferred again.
13 EDS	Enable/Disable Status This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled 1 Message buffer is enabled

Table 1539. FR_MBCCSR*n* field descriptions (continued)

Field	Description
14 LCKS	Lock Status This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application 1 Message buffer is locked by the application
15 MBIF	Message Buffer Interrupt Flag This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled

51.5.2.83 Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

Offset: 0x0802 +*n**0x8 (*n* = 0 to 255)

Access: Read/Write(1)
Write: *POC:config* or MB_DIS

Figure 1461. Message Buffer Cycle Counter Filter Registers (FR_MBCCFR*n*)

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to *Section 51.6.7.1: Message buffer cycle counter filtering*.

Table 1540. FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event Transmission mode 1 State Transmission mode
1 CHA	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 1541*.
2 CHB	Channel Assignment This control bits defines the channel assignment and control the receive and transmit behavior of the message buffer according to *Table 1541*.
3 CCFE	Cycle Counter Filtering Enable This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled

Table 1540. FR_MBCCFR*n* field descriptions (continued)

Field	Description
4:9 CCFMSK	Cycle Counter Filtering Mask This field defines the filter mask for the cycle counter filtering.
10:15 CCFVAL	Cycle Counter Filtering Value This field defines the filter value for the cycle counter filtering.

Table 1541. Channel assignment description

CHA	CHB	Transmit message buffer		Receive message buffer	
		Static segment	Dynamic segment	Static segment	Dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Note: If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.

51.5.2.84 Message Buffer Frame ID Registers (FR_MBFIDR*n*)

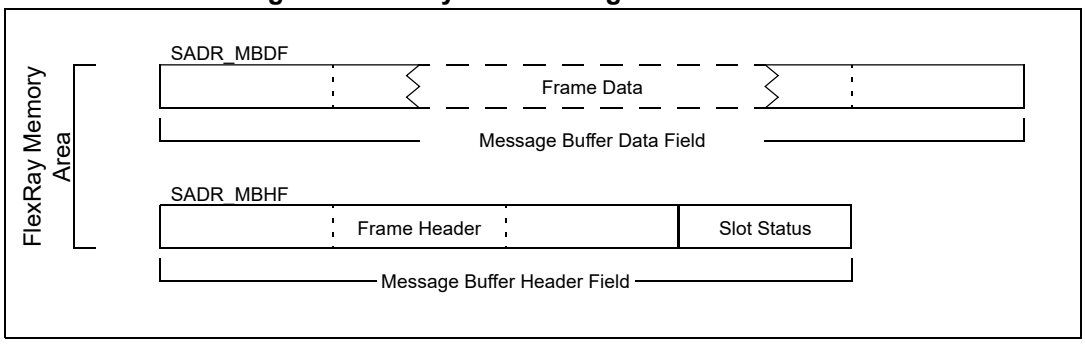
51.6 Functional description

This section provides a detailed description of the functionality implemented in the CC.

51.6.1 Message buffer concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts: the *message buffer control data* and the *physical message buffer.* The message buffer control data is located in dedicated registers. The structure of the message buffer control data depends on the message buffer type, described in *Section 51.6.3: Message buffer types*. The physical message buffer is located in the FlexRay memory area and is described in *Section 51.6.2: Physical message buffer*.



51.6.2 Physical message buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area. The structure of a physical message buffer is depicted in *Figure 1466*.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

Figure 1466. Physical message buffer structure

51.6.2.1 Message buffer header field

The message buffer header field is a contiguous region in the FlexRay memory area that occupies eight bytes. It contains the frame header and the slot status. Its structure is shown in *Figure 1466*. The physical start address SADR_MBHF of the message buffer header field must be 16-bit aligned.

51.6.2.1.1 Frame header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the usage and the content of the frame header is provided in *Section 51.6.5.2.1: Frame header description*.

51.6.2.1.2 Slot status

The slot status occupies the last 2 bytes of the message buffer header field. It provides the slot and frame status-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in *Section 51.6.5.2.2: Slot status description*.

51.6.2.2 Message buffer data field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in *Section 51.6.3: Message buffer types*.

51.6.3 Message buffer types

The CC provides three different types of message buffers.

- Individual Message Buffers
- Receive Shadow Buffers
- Receive FIFO Buffers

For each message buffer type, the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

51.6.3.1 Individual message buffers

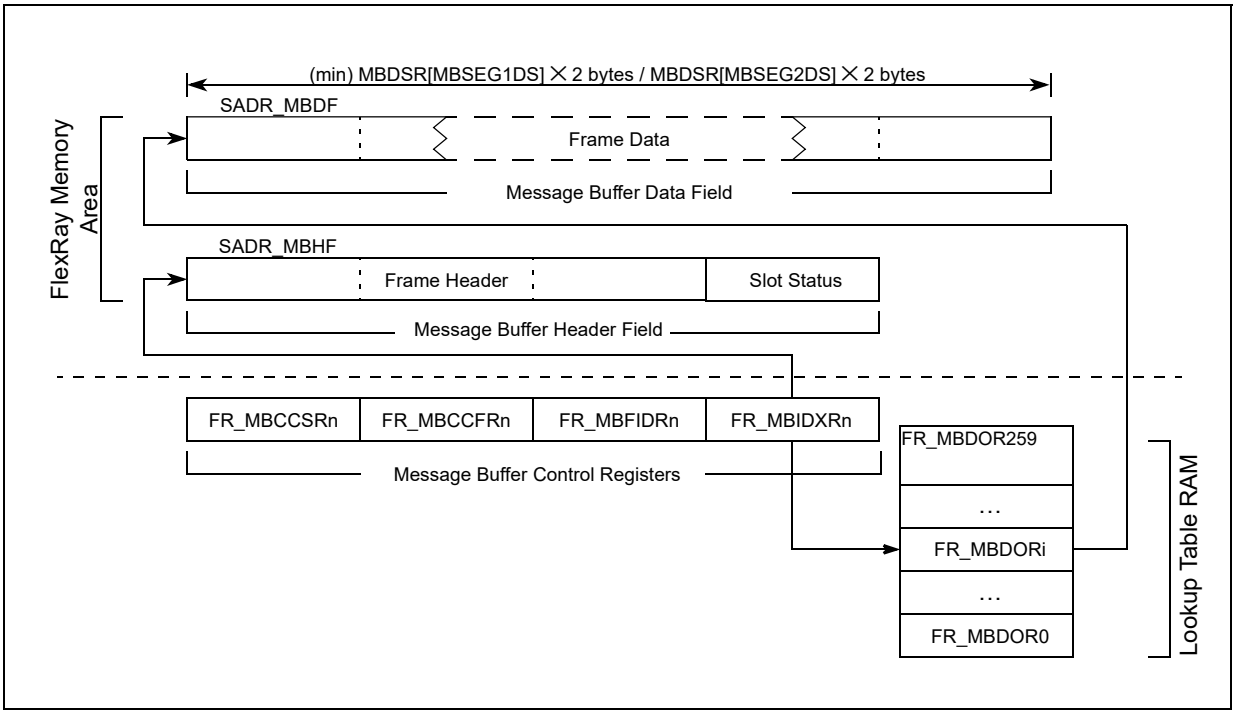
The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in *Section 51.6.6: Individual message buffer functional description*.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in *Figure 1467*.

Each individual message buffer has a message buffer number *n* assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n* and FR_MBIDXR*n*.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field, MBIDX, in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 35*.

Equation 35 $\text{SADR_MBHF} = (\text{FR_MBIDXR}n[\text{MBIDX}] \times 8) + \text{SMBA}$



The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i, the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to *Equation 36*.

Equation 36 $\text{SADR_MBDF} = [\text{Data Field Offset}] + \text{SMBA}$

The FR_MBDOR*n* are stored in the module internal memory LRAM. Refer to *Section 51.7.2.3: CHI LRAM initialization* for the setup of the data field offset values.

Figure 1467. Individual message buffer structure

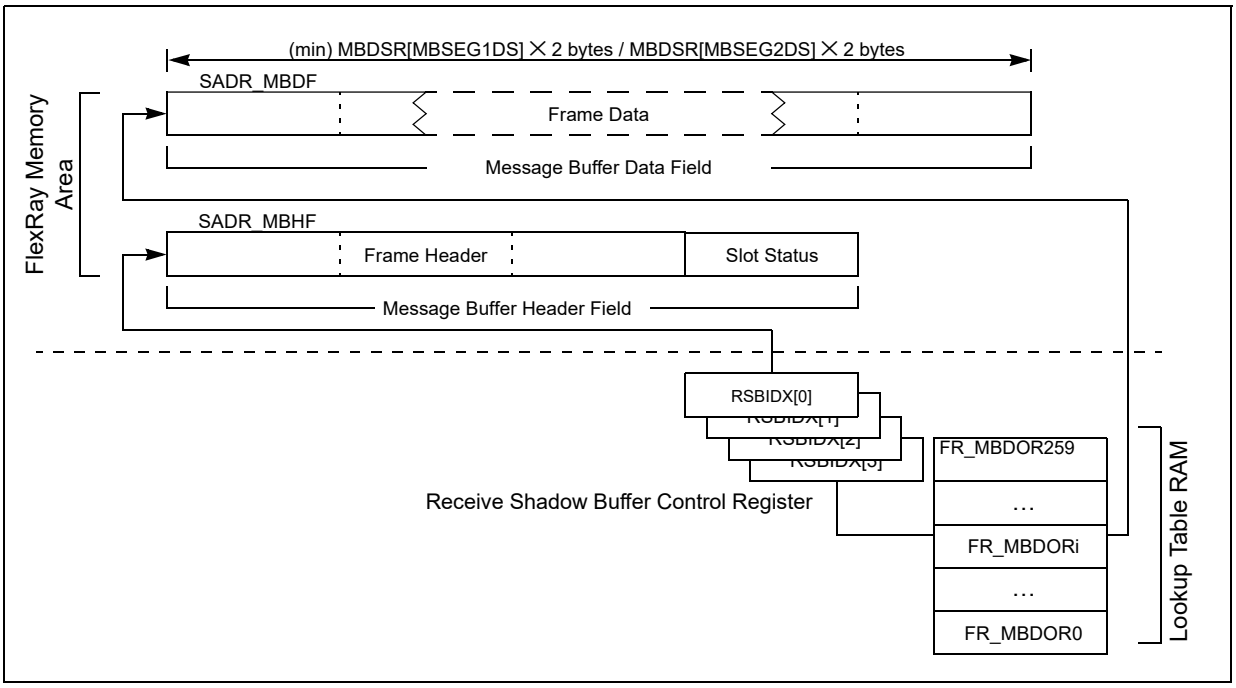
51.6.3.1.1 Individual message buffer segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- All physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length.
- The minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes.
- The minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.

51.6.3.2 Receive shadow buffers

The receive shadow buffers are required for the individual message buffers' frame reception process. The CC provides four receive shadow buffers: one receive shadow buffer per channel and per message buffer segment.



Each receive shadow buffer consists of two parts: the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in *Figure 1468*. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to *Equation 37*.

Equation 37 $\quad$ **SADR_MBHF = (FR_RSBIR[RSBIDX] × 8) + SMBA**

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

Figure 1468. Receive shadow buffer structure

51.6.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in *Figure 1469*.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR)/Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM], refer to *Section 51.5.2.4: Module Configuration Register (FR_MCR)*.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to *Equation 38*.

Equation 38 SADR_MBHF[1] = (8 × FR_RFSIR[SIDX]) + SMBA

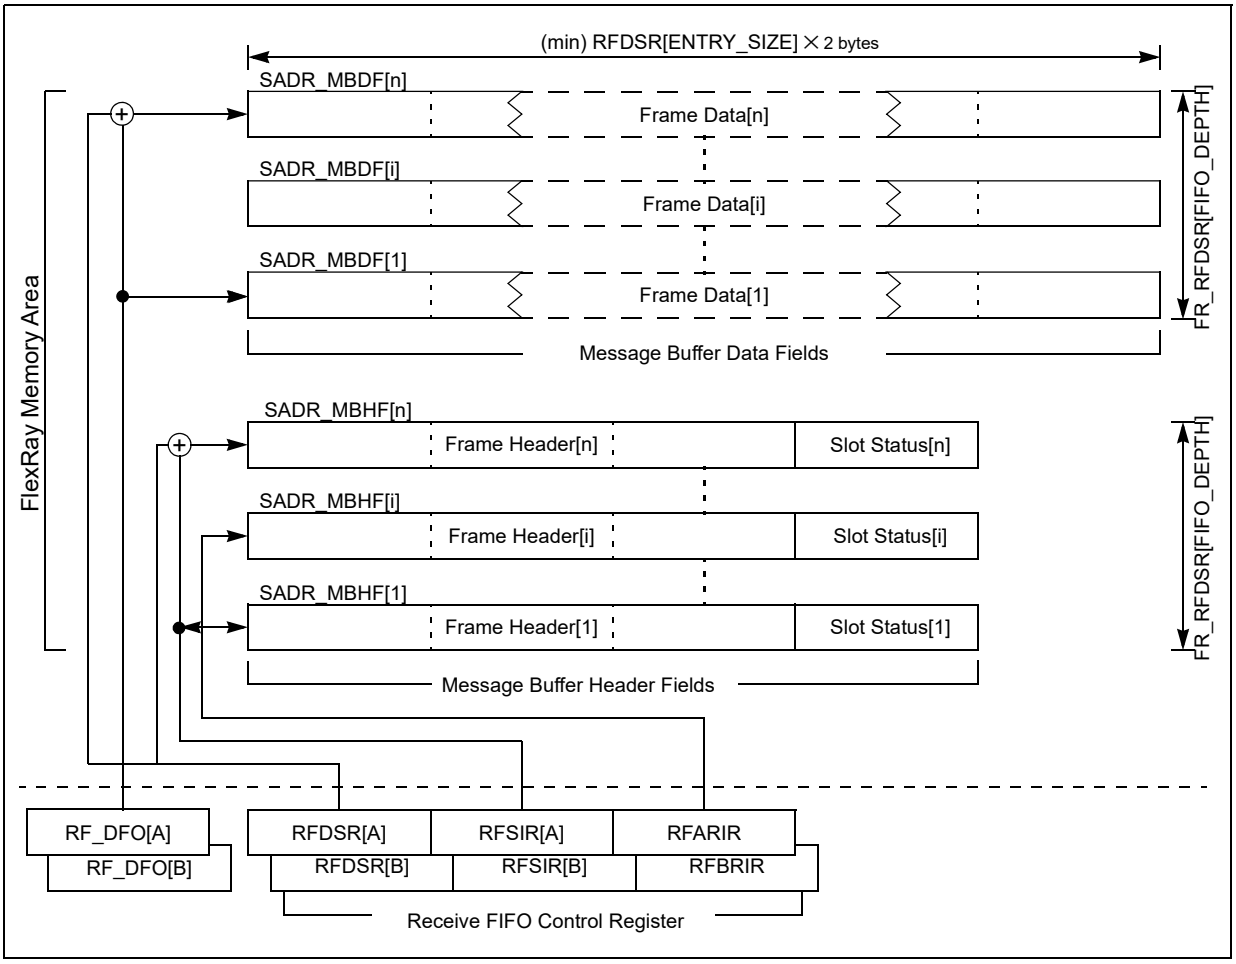
The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according to *Equation 39*.

Equation 39 SADR_MBHF[n] =
(8 × (FR_RFSIR[SIDX] + FR_RFDSR[FIFO_DEPTH])) + SMBA

The required information to access the current entry of the FIFO is given in the following registers:

- The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.
- The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

Equation 40 RF_DFO[X] =
FR_RFSDOR[X] + (FR_RFDSR[X][ENTRY_SIZE] × 2) × (i - R_RFSIR[SIDX])



Note: The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to Section 51.6.9.8: FIFO update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

Figure 1469. Receive FIFO structure

Note: The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 40. They are not stored in a register.

51.6.3.4 Message buffer configuration and control data

This section describes the configuration and control data for each message buffer type.

51.6.3.4.1 Individual message buffer configuration data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

51.6.3.4.2 Common configuration data

The set of common configuration data for individual message buffers is located in the following registers:

- Message Buffer Data Size Register (FR_MBDSR)
  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.
- Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)
  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, refer to *Section 51.6.3.1.1: Individual message buffer segments*.

51.6.3.4.3 Specific configuration data

The set of message buffer specific configuration data for individual message buffers is located in the following registers:

- Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
  The MTD bit configures the message buffer type.
- Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)
  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.
- Message Buffer Frame ID Registers (FR_MBFIDRn)
  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.
- Message Buffer Index Registers (FR_MBIDXRn)
  This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.

51.6.3.5 Individual message buffer control data

During normal operation, each individual message buffer can be controlled by the CMT, LCKT, EDT, and MBIE control and trigger bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn).

51.6.3.6 Receive shadow buffer configuration data

Before the individual message buffers can receive frames, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

51.6.3.7 Receive FIFO control and configuration data

This section describes the configuration and control data for the two receive FIFOs.

51.6.3.7.1 Receive FIFO configuration data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- Receive FIFO Periodic Timer Register (FR_RFPTR)

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- Receive FIFO Watermark and Selection Register (FR_RFWMSR)
- Receive FIFO Start Index Register (FR_RFSIR)
- Receive FIFO Start Data Offset Register (FR_RFSDOR)
- Receive FIFO Depth and Size Register (FR_RFDSR)
- Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
- Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
- Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
- Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
- Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

51.6.3.7.2 Receive FIFO control data

The application can access the FIFOs at any time using the control bits in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

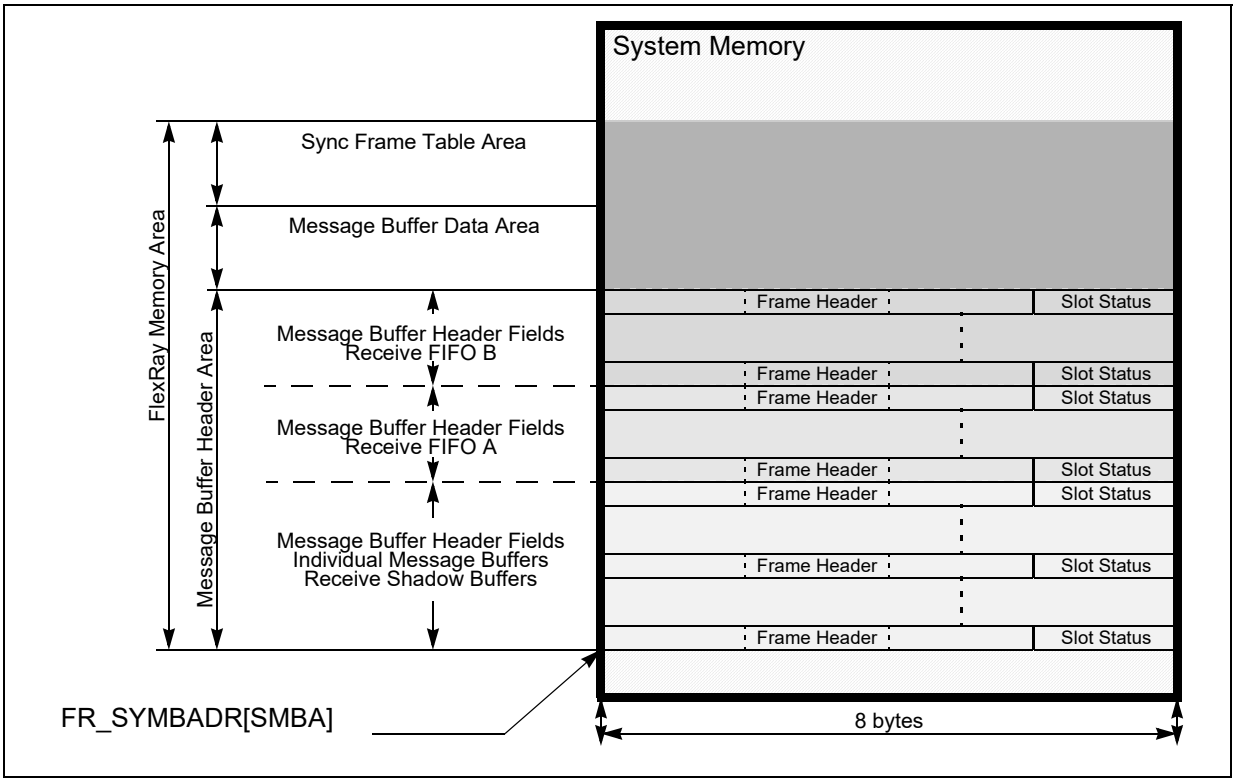
51.6.3.7.3 Receive FIFO status data

The current status of the receive FIFO is provided in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO A Read Index Register (FR_RFARIR)
- Receive FIFO B Read Index Register (FR_RFBRIR)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

51.6.4 FlexRay memory area layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].



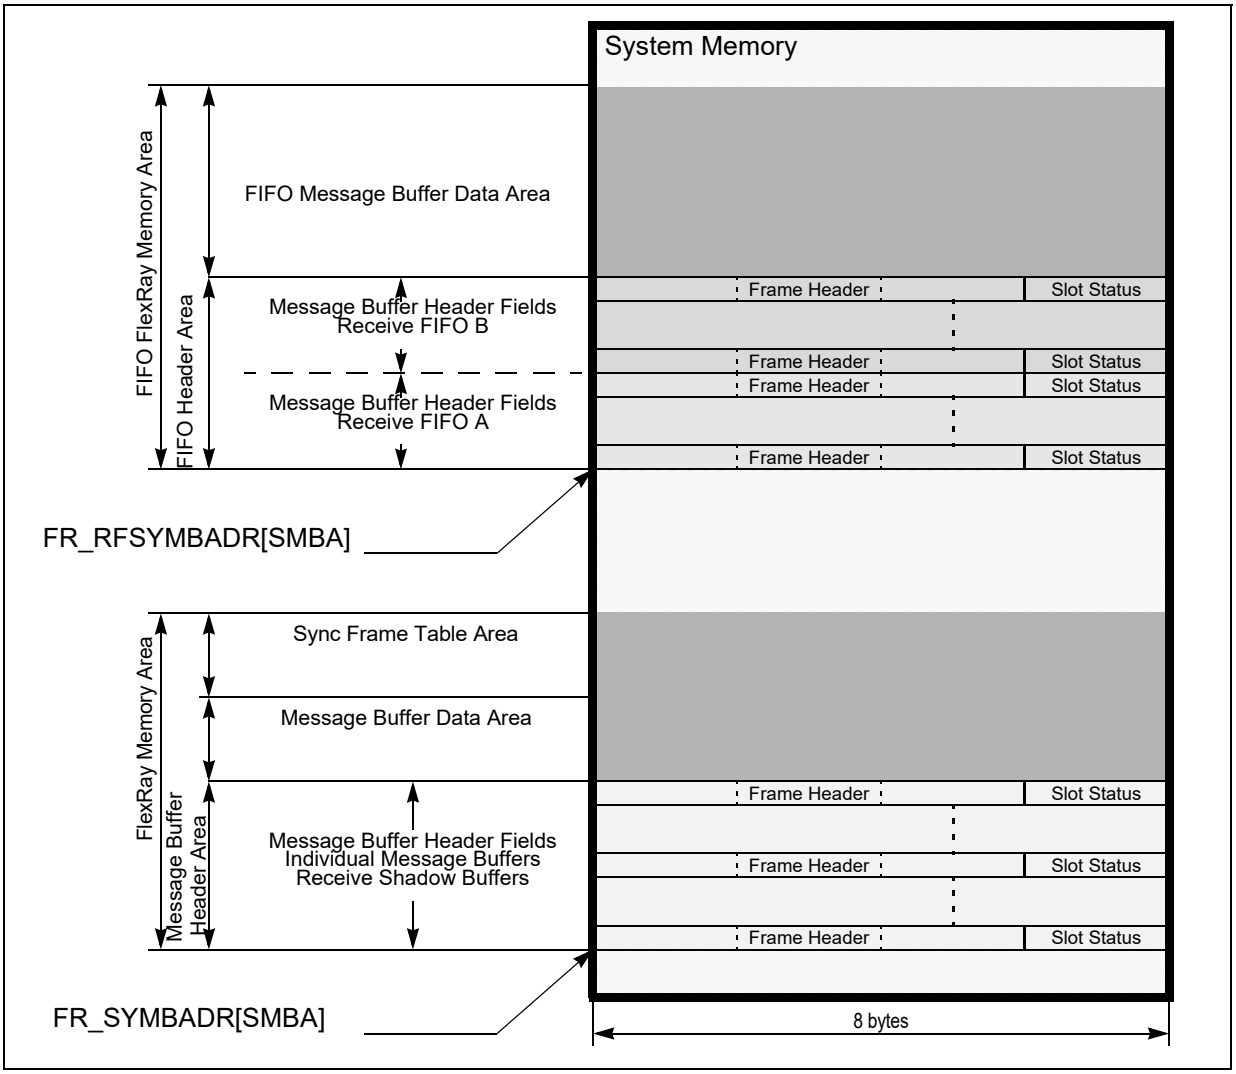
51.6.4.1 FlexRay memory area layout (FR_MCR[FAM] = 0)

Figure 1470 shows an example layout for the FIFO address mode FR_MCR[FAM] = 0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is a maximum of 64 KB.
- The FlexRay memory area starts at a 16 byte boundary.

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

Figure 1470. Example of FlexRay memory area layout (FR_MCR[FAM] = 0)



51.6.4.2 FlexRay memory area layout (FR_MCR[FAM] = 1)

Figure 1471 shows an example layout for the FIFO address mode FR_MCR[FAM] = 1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

Figure 1471. Area example of FlexRay memory area layout (FR_MCR[FAM] = 1)

51.6.4.3 Message buffer header area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rule applies to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 41*.

Equation 41 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 259)$$

2. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill *Equation 42*.

Equation 42 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 1023)$$

3. The message buffer header fields for each FIFO must be a contiguous area.

51.6.4.4 Message buffer header area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill *Equation 43*.

Equation 43 $$SADR_MBHF = (i \times 8) + FR_SYMBADR[SMBA];\ (0 \leq i \leq 259)$$

51.6.4.5 FIFO message buffer header area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill *Equation 44*.

Equation 44 $$SADR_MBHF = (i \times 8) + FR_RFSYMBADR[SMBA];\ (0 \leq i \leq 1023)$$

2. The message buffer header fields for each FIFO have to be a contiguous area.

51.6.4.6 Message buffer data area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

51.6.4.7 Sync frame table area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to *Section 51.6.12: Sync frame ID and sync frame deviation tables* for the description of the sync frame table area.

51.6.5 Physical message buffer description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer: the message buffer header field and the message buffer data field.

51.6.5.1 Message buffer protection and data consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

51.6.5.2 Message buffer header field description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in *Section 51.6.2.1: Message buffer header field*. Each message buffer header field consists of two sections: the frame header section and the slot status section.

51.6.5.2.1 Frame header description

51.6.5.2.1.1 Frame header content

The semantic and content of the frame header section depend on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in *Figure 1472*. A detailed description is given in *Table 1547*.

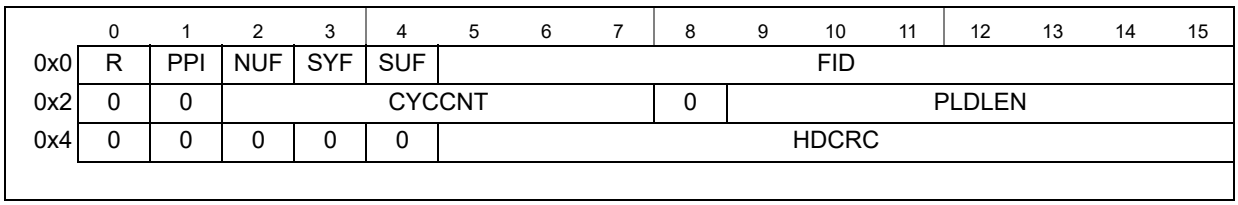


Figure 1472. Frame header structure (receive message buffer and receive FIFO)

The structure of the frame header in the message buffer header field for transmit message buffers is given in *Figure 1473*. A detailed description is given in *Table 1548*. The checks that will be performed are described in Frame Header Checks.

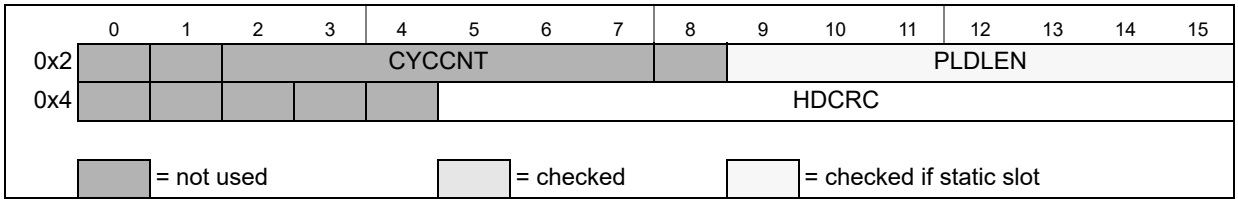

Figure 1473. Frame header structure (transmit message buffer)

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in *Figure 1474*.

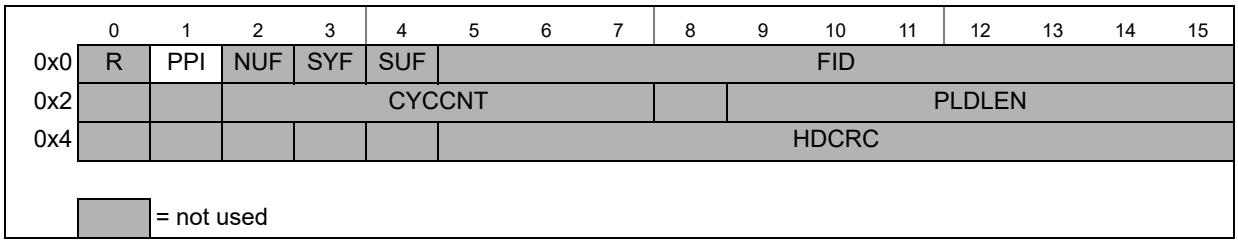

Figure 1474. Frame header structure (transmit message buffer for key slot)

51.6.5.2.1.2 Frame header access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 1546*. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 1546. Frame header write access constraints (transmit message buffer)

Field	Static segment	Dynamic segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	
		MB_LCK

51.6.5.2.1.3 Frame header checks

As shown in *Figure 1473* and *Figure 1474*, not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag, FID_EF, in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDRn).

For transmit message buffers assigned to the static segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 1547. Frame header field descriptions (receive message buffer and receive FIFO)

Field	Description
R	Reserved Bit This is the value of the *Reserved bit* of the received frame stored in the message buffer.
PPI	Payload Preamble Indicator This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	Null Frame Indicator This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	Sync Frame Indicator This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	Startup Frame Indicator This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	Frame ID This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	Cycle Count This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	Payload Length This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	Header CRC This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 1548. Frame header field descriptions (transmit message buffer)

Field	Description
R	Reserved Bit This bit is not used. The value of the Reserved bit is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
PPI	Payload Preamble Indicator This bit provides the value of the Payload Preamble Indicator for the frame transmitted from the message buffer.
NUF	Null Frame Indicator This bit is not used, the value of the Null Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

Table 1548. Frame header field descriptions (transmit message buffer) (continued)

Field	Description
SYF	Sync Frame Indicator This bit is not used. The value of the Sync Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
SUF	Startup Frame Indicator This bit is not used. The value of the Startup Frame Indicator is generated internally according to the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.
FID	Frame ID This field is checked as described in Frame Header Checks.
CYCCNT	Cycle Count This field is not used, the value of the transmitted Cycle Count field is taken from the internal communication cycle counter.
PLDLEN	Payload Length This field is checked and used as described in Frame Header Checks.
HDCRC	Header CRC This field provides the value of the Header CRC field for the frame transmitted from the message buffer.

51.6.5.2.2 Slot status description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depend on the message buffer type.

51.6.5.2.2.1 Receive message buffer and receive FIFO slot status description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given by *Table 1549*.

Table 1549. Receive message buffer slot status content

Receive message buffer type	Slot status content
Individual Receive Message Buffer assigned to both channels FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 1	Refer to *Figure 1475*
Individual Receive Message Buffer assigned to channel A FR_MBCCFR*n*[CHA] = 1 and FR_MBCCFR*n*[CHB] = 0	Refer to *Figure 1476*
Individual Receive Message Buffer assigned to channel B FR_MBCCFR*n*[CHA] = 0 and FR_MBCCFR*n*[CHB] = 1	Refer to *Figure 1477*
Receive FIFO Channel A Message Buffer	Refer to *Figure 1476*
Receive FIFO Channel B Message Buffer	Refer to *Figure 1477*

The meaning of the bits in the slot status structure is explained in *Table 1550*.

51.6.5.2.2.2 Transmit message buffer slot status description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given by *Table 1551*.

Table 1551. Transmit message buffer slot status content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=1	Refer to *Figure 1478*
Individual Transmit Message Buffer assigned to channel A FR_MBCCFR*n*[CHA]=1 and FR_MBCCFR*n*[CHB]=0	Refer to *Figure 1479*
Individual Transmit Message Buffer assigned to channel B FR_MBCCFR*n*[CHA]=0 and FR_MBCCFR*n*[CHB]=1	Refer to *Figure 1480*

The meaning of the bits in the slot status structure is described in *Table 1552*.

51.6.5.3 Message buffer data field description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in *Table 1553*. The structure of the message buffer data field is given in *Figure 1481*.

Table 1553. Message buffer data field minimum length

Physical message buffer assigned to	Minimum length defined by
Individual message buffer in segment 1	FR_MBDSR[MBSEG1DS]
Receive shadow buffer in segment 1	FR_MBDSR[MBSEG1DS]
Individual message buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive shadow buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note: The CC will not access any locations outside the message buffer data field boundaries given by Table 1553.

	0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15
0x0	DATA0 / MID0 / NMV0		DATA1 / MID1 / NMV1	
0x2	DATA2 / NMV2		DATA3 / NMV3	
…	…		…	
0xN-2	DATA N-2		DATA N-1	

Figure 1481. Message buffer data field structure

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

51.6.5.3.1 Message buffer data field read access

For transmit message buffers, the CC will not modify the content of the message buffer data field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXRn). While the message buffer is locked, the CC will not update the message buffer data field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

51.6.5.3.2 Message buffer data field write access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in *Table 1554*.

Table 1554. Frame data write access constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 1555. Frame data field descriptions

Field	Description
DATA 0, DATA 1, … DATA N–1	Message Data Provides the message data received or to be transmitted. For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	Message Identifier If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0, NMV 1, … NMV 11	Network Management Vector If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

51.6.6 Individual message buffer functional description

The CC provides the following basic types of individual message buffers:

- Transmit message buffers
- Receive message buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in *Section 51.6.3.4.1: Individual message buffer configuration data*.

51.6.6.1 Individual message buffer configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

51.6.6.1.1 Common configuration data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. This data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

51.6.6.1.2 Specific configuration data

The second part of the message buffer configuration data is specific for each message buffer.

This data can be changed only when either

- The protocol is in the POC:config state, or
- The message buffer is disabled (that is, FR_MBCCSR*n*[EDS] = 0)

The individual message buffer type is defined by the MTD bit in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) as given in *Table 1556*.

Table 1556. Individual message buffer types

FR_MBCCSRn[MTD]	Individual message buffer description
0	Receive message buffer
1	Transmit message buffer

The message-buffer-specific configuration data includes the following:

1. MTD bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
2. All fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)
3. All fields in the Message Buffer Frame ID Registers (FR_MBFIDRn)
4. All fields in the Message Buffer Index Registers (FR_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions. Refer to *Section 51.6.6.2: Transmit message buffers* and *Section 51.6.6.3: Receive message buffers* for further information.

51.6.6.2 Transmit message buffers

The section provides a detailed description of the functionality of single-buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number *n* is configured to be a transmit message buffer by the following setting:

- FR_MBCCSR*n*[MTD] = 1 (transmit message buffer)

51.6.6.2.1 Access regions

For certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in *Figure 1482*. A description of the regions is given in *Table 1558*. If a region is active as indicated in *Table 1559*, the access scheme given for that region applies to the message buffer.

Figure 1482. Transmit message buffer access regions

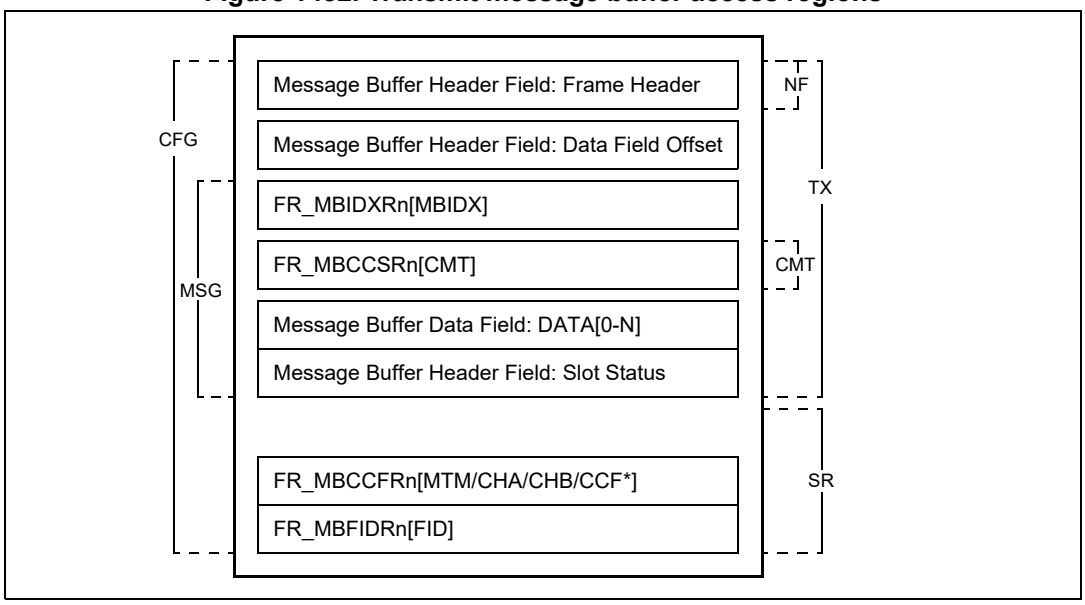

Table 1557. Transmit message buffer access regions description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration
MSG	Read/write	—	Message data and slot status access
NF	—	Read-only	Message header access for null frame transmission
TX	—	Read/write	Message transmission and slot status update
CMT	—	Read-only	Message buffer validation
SR	—	Read-only	Message buffer search

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT], and the interrupt enable bit FR_MBCCSR*n*[MBIE], are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in *Figure 1483*. A description of the states is given in *Table 1558*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

51.6.6.2.2 Message buffer states

This section describes the transmit message buffer states and provides a state diagram.

Figure 1483. Transmit message buffer states

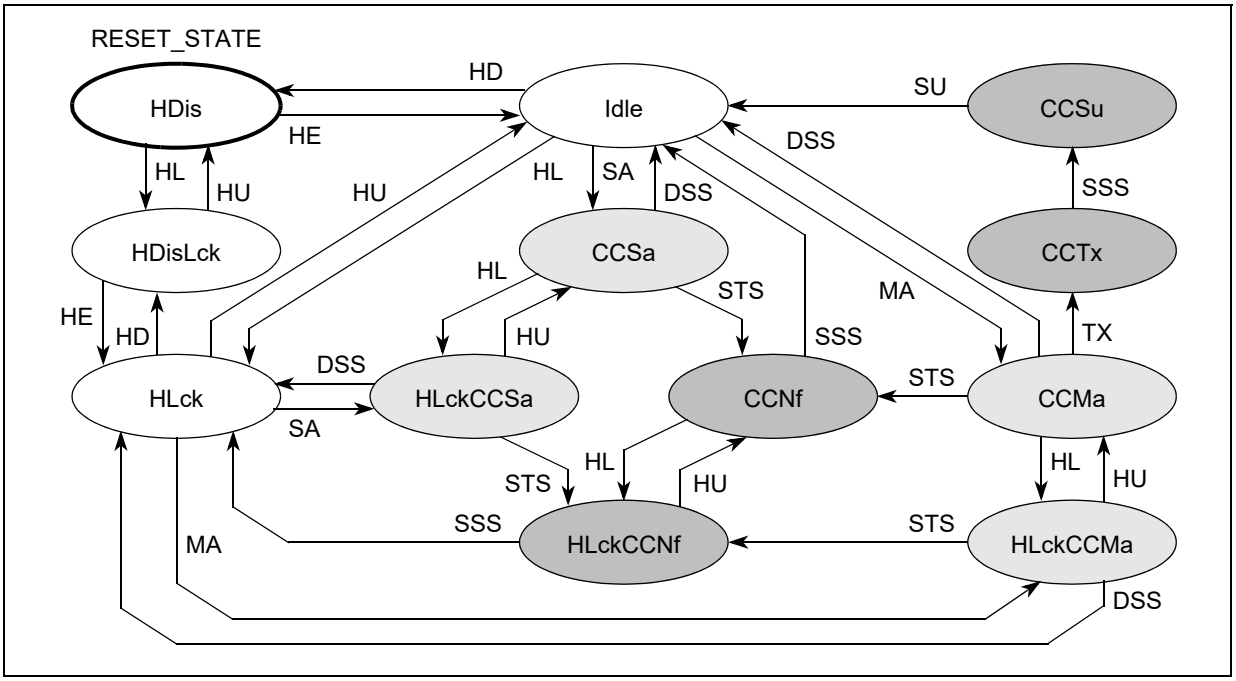

Table 1558. Transmit message buffer state description

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	CMT, SR	Idle – Message Buffer is idle. Included in message buffer search
HDis	0	0	CFG	—	Disabled – Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message Buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	SR	Locked – Application access to data, control, and status. Included in message buffer search.
CCSa	1	0	—	—	Slot Assigned – Message buffer assigned to next static slot. Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	—	Locked and Slot Assigned – Application access to data, control, and status.Message buffer assigned to next static slot.
CCNf	1	0	—	NF	Null Frame Transmission – Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	Locked and Null Frame Transmission – Application access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	—	CMT	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.

Table 1558. Transmit message buffer state description (continued)

State	FR_MBCCSR*n*		Access region		Description
	EDS	LCKS	Appl.	Module	
HLckCCMa	1	1	MSG	—	Locked and Message Available – Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	—	TX	Message Transmission – Message buffer data transmit. Payload data from buffer transmitted.
CCSu	1	0	—	TX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

51.6.6.2.3 Message buffer transitions

51.6.6.2.3.1 Application transitions

The application transitions can be triggered by the application using the commands described in *Table 1564*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

- Message Buffer Enable and Disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

- Message Buffer Lock and Unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 1559. Transmit message buffer application transitions

Transition	Command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable.

Table 1559. Transmit message buffer application transitions (continued)

Transition	Command	Condition	Description
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock.

51.6.6.2.3.2 Module transitions

The module transitions that can be triggered by the CC are described in *Table 1560*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1560. Transmit message buffer module transitions

Transition	Condition	Description
SA	Slot match and static slot	Slot Assigned – Message buffer is assigned to next static slot.
MA	Slot match and CycleCounter match	Message Available – Message buffer is assigned to next slot and cycle counter filter matches.
TX	Slot start and FR_MBCCSR*n*[CMT] = 1	Transmission Slot Start – Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	Status updated	Status Updated – Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	Static slot start	Static Slot Start – Start of static slot.
DSS	Dynamic slot start or symbol window start or NIT start	Dynamic Slot or Segment Start – Start of dynamic slot or symbol window or NIT.
SSS	Slot start or symbol window start or NIT start	Slot or Segment Start – Start of static slot or dynamic slot or symbol window or NIT.

51.6.6.2.3.3 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of *Table 1561*, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and, subsequently, the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions are given in the second part of *Table 1561*.

Table 1561. Transmit message buffer transition priorities

State	Priorities	Description
Module vs. application		
Idle, HLck	SA > HD MA > HD	Slot Assigned > Message Buffer Disable Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
Module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS TX > DSS	Transmission Slot Start > Static Slot Start Transmission Slot Start > Dynamic Slot Start

51.6.6.2.4 Transmit message setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit, CMT, in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). The physical access to the message buffer data field is described in *Section 51.6.3.1: Individual message buffers*.

As indicated by *Table 1552*, the application will write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the following states: HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in *Table 1552*. The state change is indicated through the FR_MBCCSR*n*[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters the HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa state, the FR_MBCCSR*n*[DVAL] flag is negated.

51.6.6.2.5 Message transmission

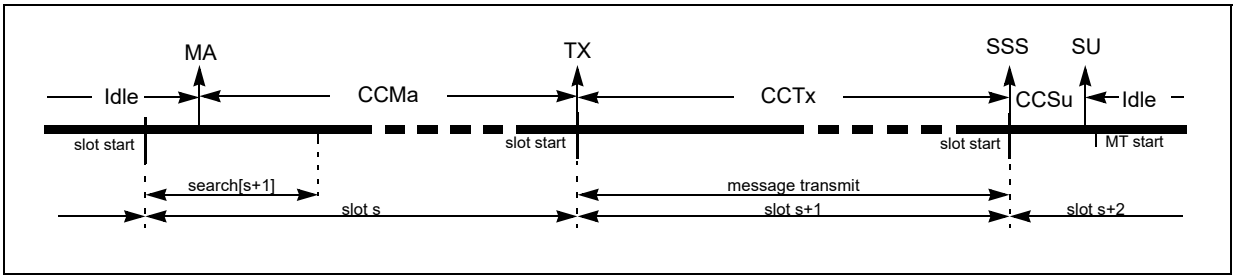
As a result of the message buffer search described in *Section 51.6.7: Individual message buffer search*, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. The message buffer is in the message available state CCMa
2. The message data is still valid (that is, FR_MBCCSR*n*[CMT] = 1)

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in *Figure 1484*. In this example, the message buffer with message buffer number *n* is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid (that is, FR_MBCCSR*n*[CMT] = 1).

Figure 1484. Message transmission timing



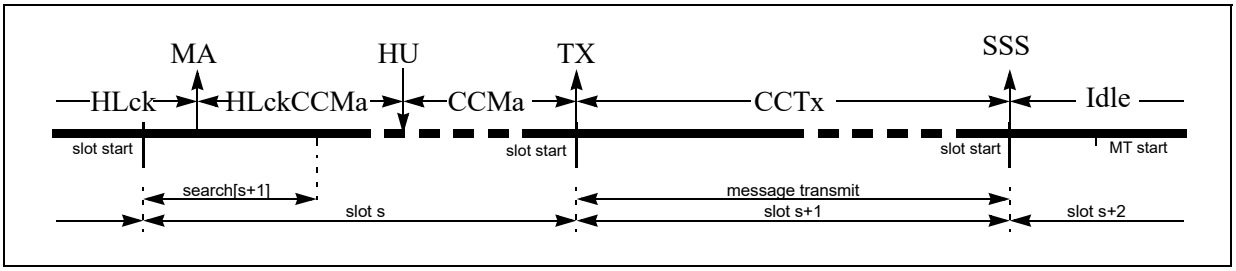


Figure 1485. Message transmission from HLck state with unlock

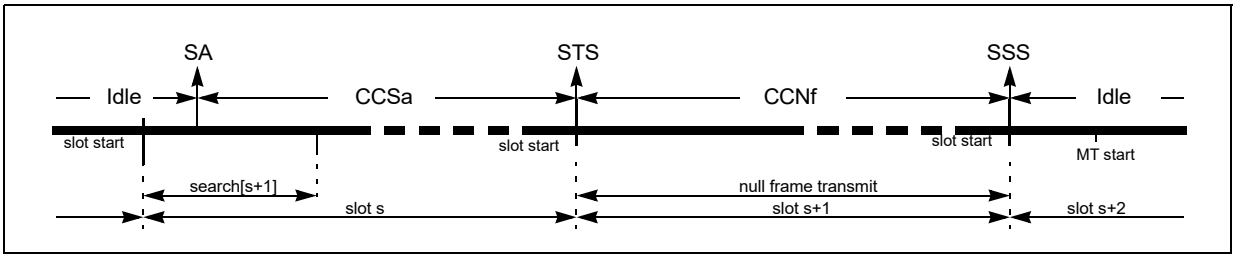
The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items:

1. The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. The value of the PLDLEN field in the message buffer header field, as described in *Section 51.6.5.2.1: Frame header description*

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN ≤ MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

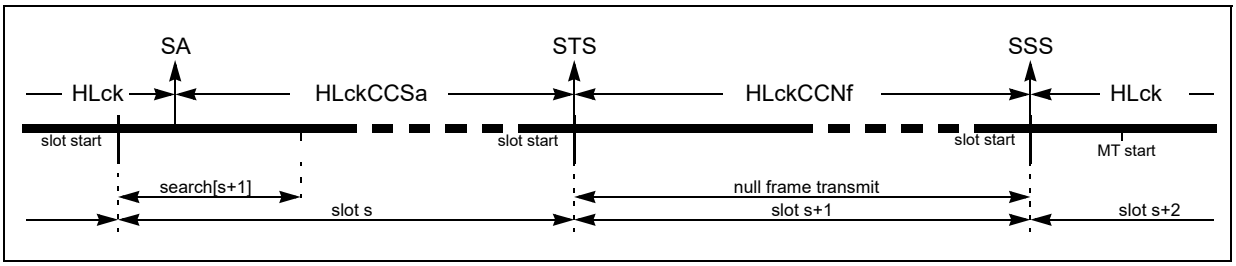
51.6.6.2.6 Null frame transmission



A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDR*n*[FID] set to S and FR_MBCCFR*n*[CHA] set to 1. A null frame is transmitted in the static slot *s* on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDR*n*[FID] = S and FR_MBCCFR*n*[CHA] = 1 are either not committed (that is FR_MBCCSR*n*[CMT] = 0), or are locked by the application (that is, FR_MBCCSR*n*[LCKS] = 1), or the cycle counter filter is enabled and does not match.

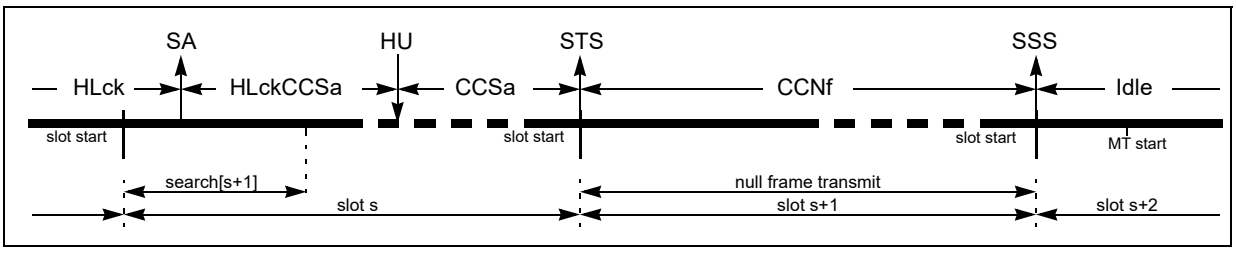
Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in *Section 51.6.7: Individual message buffer search*, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or



from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in *Figure 1486*.

Figure 1486. Null frame transmission from Idle state



A message buffer timing and state change diagram for null frame transmission from HLck state is given in *Figure 1487*.

Figure 1487. Null frame transmission from HLck state

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 1488*.

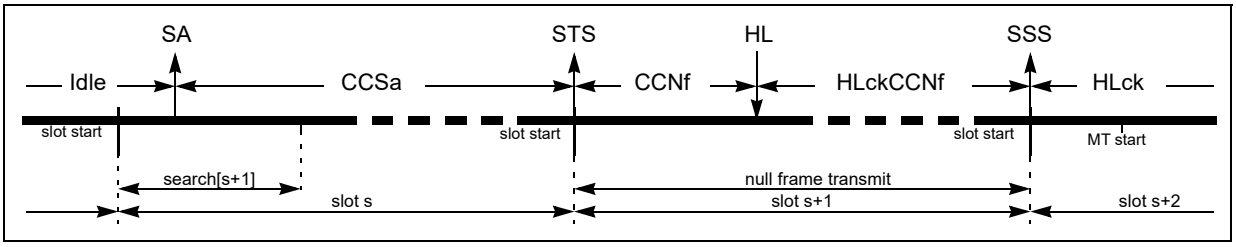


Figure 1488. Null frame transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in *Figure 1489*.

MT start

Figure 1489. Null frame transmission from Idle state with locking

51.6.6.2.7 Message buffer status update

After the end of each slot, the PE generates the slot status vector. Depending on the status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

51.6.6.2.7.1 Message buffer status update after complete message transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer was sent to the FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSR*n*[MBIF] to indicate the successful message transmission.

Depending on the Transmission Mode flag FR_MBCCFR*n*[MTM], the CC changes the commit flag FR_MBCCSR*n*[CMT] and the valid flag FR_MBCCSR*n*[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in *Event Transmission mode.* In this case, each committed message is transmitted only once. The commit flag FR_MBCCSR*n*[CMT] is cleared with the SU transition. If the FR_MBCCFR*n*[MTM] flag is asserted, the message buffer is in the *State Transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSR*n*[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSR*n*[DVAL] to indicate that the message will be transmitted again.

51.6.6.2.7.2 Message buffer status update after incomplete message transmission

The term *incomplete message transmission* refers to the fact that not all payload data that should be transmitted was sent to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

In either of these two cases, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

51.6.6.2.7.3 Message buffer status update after null frame transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

51.6.6.3 Receive message buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used, the related receive shadow buffer must be configured as described in *Section 51.6.3.2: Receive shadow buffers*.

A receive message buffer is used to receive a message from the FlexRay bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application:

- Message data received
- Information about the reception process
- Status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration setting:

- FR_MBCCSR*n*[MTD] = 0 (receive message buffer)

Both the application and the CC have access to certain message buffers. To ensure data consistency, a message buffer locking scheme controls the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in *Figure 1490*. A description of the regions is given in *Table 1562*. If a region is active as indicated in *Table 1563*, the access scheme given for that region applies to the message buffer.

Figure 1490. Receive message buffer access regions

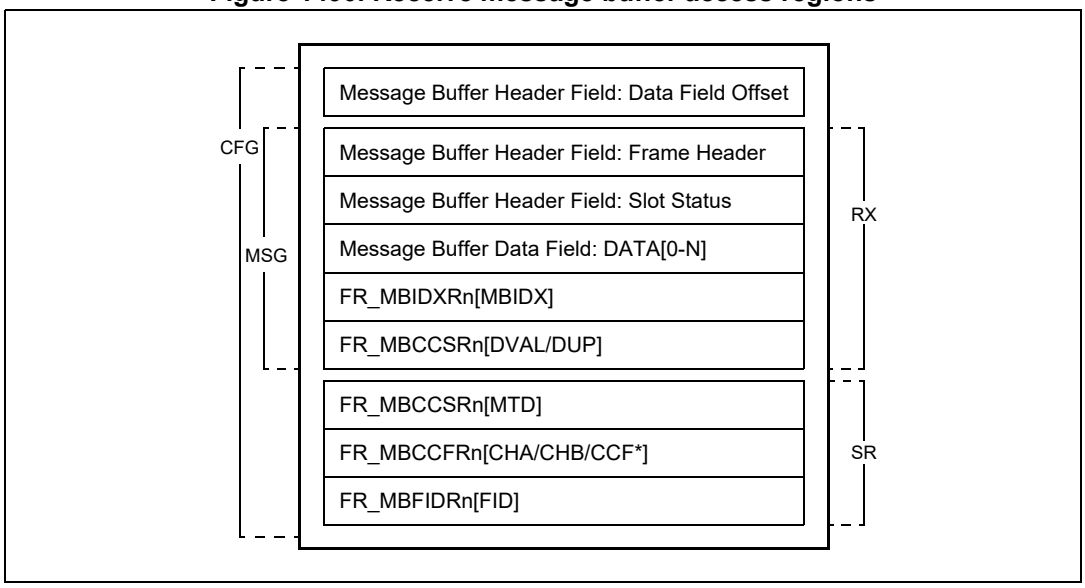

Table 1562. Receive message buffer access region description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration, message data, and status access
MSG	Read/write	—	Message data, header, and status access
RX	—	Write-only	Message reception and status update
SR	—	Read-only	Message buffer search data

The trigger bits FR_MBCCSR*n*[EDT] and FR_MBCCSR*n*[LCKT] and the interrupt enable bit FR_MBCCSR*n*[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSR*n*[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in *Figure 1491*. A description of the message buffer states is given in *Table 1558*, which also provides the access scheme for the access regions.

The status bits FR_MBCCSR*n*[EDS] and FR_MBCCSR*n*[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

Figure 1491. Receive message buffer states

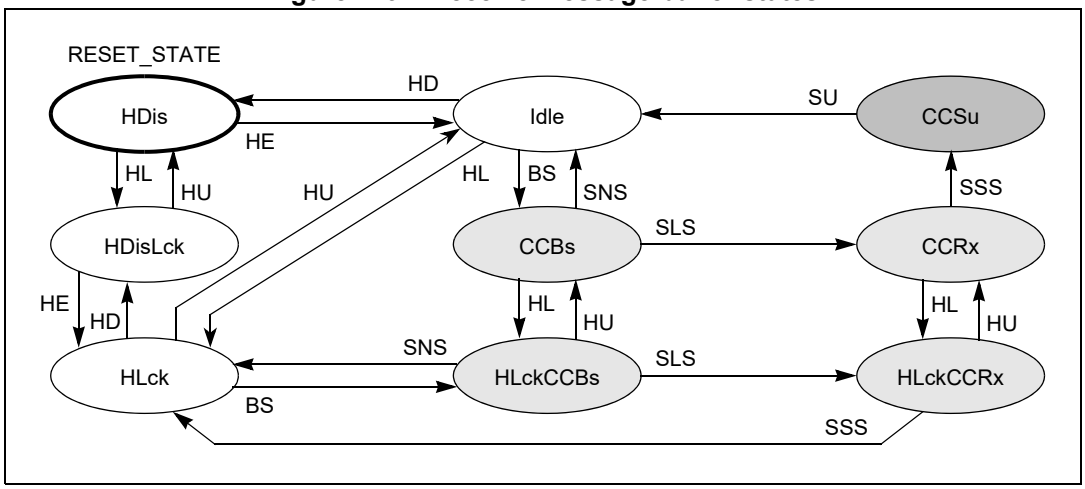

Table 1563. Receive message buffer states and access

State	FR_MBCCSR*n*		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	SR	Idle – Message buffer is idle. Included in message buffer search.
HDis	0	0	CFG	—	Disabled – Message buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked – Message buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	—	Locked – Application access to data, control, and status. Included in message buffer search.
CCBs	1	0	—	—	Buffer Subscribed – Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	—	Locked and Buffer Subscribed – Application access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	—	—	Message Receive – Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	—	Locked and Message Receive – Application access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	—	RX	Status Update – Message buffer status update. Update of status flags, the slot status field, and the header index.

51.6.6.3.1 Message buffer transitions

51.6.6.3.1.1 Application transitions

The application transitions that can be triggered by the application using the commands are described in *Table 1559*. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

Message buffer enable and disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[EDT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSR*n*[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCBs, HLckCCBs, or CCRx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

Message buffer lock and unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSR*n*[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSR*n*[LCKS]. If the command triggers the lock transition HL while the message buffer is in the CCRx state, the lock transition has no effect (command is ignored) and the message buffer state is not changed.

In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 1564. Receive message buffer application transitions

Transition	Host command	Condition	Description
HE	FR_MBCCSR*n*[EDT] = 1	FR_MBCCSR*n*[EDS] = 0	Application triggers message buffer enable
HD		FR_MBCCSR*n*[EDS] = 1	Application triggers message buffer disable
HL	FR_MBCCSR*n*[LCKT] = 1	FR_MBCCSR*n*[LCKS = 0	Application triggers message buffer lock
HU		FR_MBCCSR*n*[LCKS] = 1	Application triggers message buffer unlock

Module Transitions

The module transitions that can be triggered by the CC are described in *Table 1565*. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1565. Receive message buffer module transitions

Transition	Condition	Description
BS	Slot match and cycle counter match	Buffer Subscribed – The message buffer filter matches next slot and cycle.
SLS	Slot start	Slot Start – Start of either Static Slot or Dynamic Slot.
SNS	Symbol window start or NIT start	Symbol Window or NIT Start – Start of either Symbol Window or NIT.
SSS	Slot start, symbol window start, or NIT start	Slot or Segment Start – Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	Status updated	Status Updated – Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

51.6.6.3.1.2 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in *Table 1566*, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the CCBs buffer subscribed state and the module triggers the SLS slot start transition at the same time that the application locks the message buffer through the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state, HLckCCRx.

Table 1566. Receive message buffer transition priorities

State	Priorities	Description
Module vs. Application		
Idle	BS > HD	Buffer subscribed > Message buffer disable

Table 1566. Receive message buffer transition priorities (continued)

State	Priorities	Description
HLck	BS > HD	Buffer subscribed > Message buffer disable
CCRx	SSS > HL	Slot or segment start > Message buffer lock

51.6.6.3.2 Message reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffer is assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot, the module triggers the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data is written into the shadow buffers. For details on receive shadow buffers, refer to *Section 51.6.6.3.5: Receive shadow buffer concept*. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

51.6.6.3.3 Message buffer update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer is in the locked state HLckCCRx, no update will be performed. The received data is lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state, it is now in the CCSu state. After the evaluation of the slot status provided by the PE, the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to, as described in *Table 1567*.

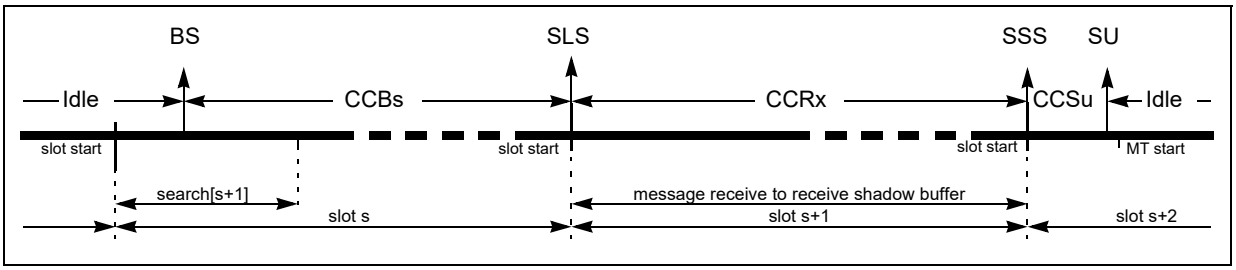

Table 1567. Receive message buffer update

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
1	1	Valid non-null frame received. – Message Buffer Data field updated. – Frame Header field updated. – Slot Status field updated. – DUP = 1 – DVAL = 1 – MBIF = 1
1	0	Valid null frame received. – Message Buffer Data field *not* updated. – Frame Header field *not* updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed – MBIF = 1
0	x	No valid frame received. – Message Buffer Data field not updated. – Frame Header field not updated. – Slot Status field updated. – DUP = 0 – DVAL *not* changed. – MBIF = 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: vSS!ValidFrame = 0 and vSS!SyntaxError = 0 and vSS!ContentError = 0 and vSS!BViolation = 0.

Note: If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > n will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in *Figure 1492*.

Figure 1492. Message reception timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following items:

- The message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
- The message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR).
- The number of bytes received over the FlexRay bus.

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

51.6.6.3.4 Received message access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in *Section 51.6.3.1: Individual message buffers*.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

51.6.6.3.5 Receive shadow buffer concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in *Section 51.6.3.2: Receive shadow buffers*.

The receive shadow buffers temporarily store the received frame header and message data. The slot status information is generated after the slot boundary. If the slot status information indicates the reception of the valid non-null frame (refer to *Table 1567*), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXRn) with the content of the corresponding internal shadow buffer index register. In all cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXRn).

51.6.7 Individual message buffer search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel whether a slot *s* in a communication cycle *c* is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm invoked at the following protocol-related events:

- NIT start
- Slot start in the static segment
- Minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *s* searches for message buffers assigned or subscribed to slot *s* + *1*.

In general, the message buffer search for the next slot *s* considers only message buffers that

1. Are enabled (that is, FR_MBCCSR*n*[EDS] = 1), and
2. Match the next slot *s*, (that is, FR_MBFIDR*n*[FID] = *s*)

On top of that, for the static segment, only those message buffers are considered that match the condition of at least one row of *Table 1568*. For the dynamic segment, only those message buffers are considered that match the condition of at least one row of *Table 1569*. These message buffers are called *matching* message buffers.

For each enabled channel, the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers, the message buffers with highest priority according to *Table 1568* for the static segment and according to *Table 1569* for the dynamic segment are selected.

Table 1568. Message buffer search priority (static segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(Highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	1	—	0	1	Transmit buffer, matches cycle count, not committed	SA
	1	1	—	1	Transmit buffer, matches cycle count, locked	SA
2	1	—	—	—	Transmit buffer	SA
3	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(Lowest) 4	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, refer to *Section 51.6.7.1: Message buffer cycle counter filtering*.

Table 1569. Message buffer search priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM(1)	Description	Transition
(Highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	Receive buffer, matches cycle count, not locked	BS
(Lowest) 2	0	1	n/a	1	Receive buffer, matches cycle count, locked	BS

1. Cycle Counter Filter Match, refer to *Section 51.6.7.1: Message buffer cycle counter filtering*

If there are multiple message buffers with highest priority, the message buffer with the lowest message buffer number is selected. All message buffers that have the highest priority must have a consistent channel assignment as specified in *Section 51.6.7.2: Message buffer channel assignment consistency*.

Depending on the message buffer channel assignment, the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in *Section 51.6.3.1: Individual message buffers*.

51.6.7.1 Message buffer cycle counter filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled (CCFE = 0), this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

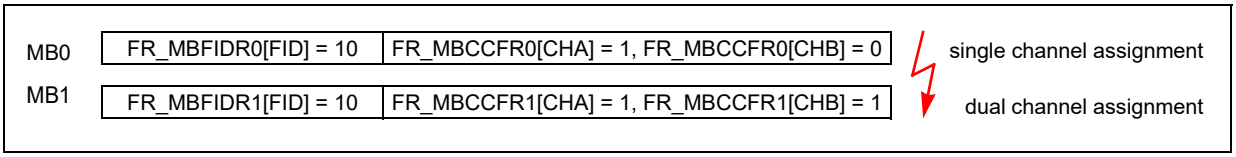
The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following condition is true.

Equation 45

$$MBCCFRn[CCFE] = 0$$

Equation 46

$$CYCCNT \& MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \& MBCCFRn[CCFMSK]$$



51.6.7.2 Message buffer channel assignment consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFR*n*[CHA] = 1 and transmits or receives on channel B if FR_MBCCFR*n*[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The

behavior of the message buffer search is not defined if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in *Figure 1493*.

Figure 1493. Inconsistent channel assignment

51.6.7.3 Node-related slot multiplexing

The term *node-related slot multiplexing* applies to the dynamic segment only and refers to the functionality if transmit as well as receive message buffers are configured for the same slot.

According to *Table 1569* the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

51.6.7.4 Message buffer search error

There are two kinds of error that may occur during message buffer search[v].

51.6.7.4.1 Message buffer search start while running

If the message buffer search is running in slot *s – 1* and the next message buffer search start event appears due to the start of slot *s*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *s*. Additionally, the search engine will not be started in slot *s*, and consequently no individual message buffer is identified for transmission or reception in slot *s + 1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency, refer to *Section 51.7.5: Number of usable message buffers*.

51.6.7.4.2 Illegal message buffer index found

If the message buffer search has finished the message buffer search in slot *s – 1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) and no individual message buffer is identified for transmission or reception in slot *s*. The legal message buffer index values for the individual and receive shadow

v. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to a search error, the received frame is considered for FIFO reception.

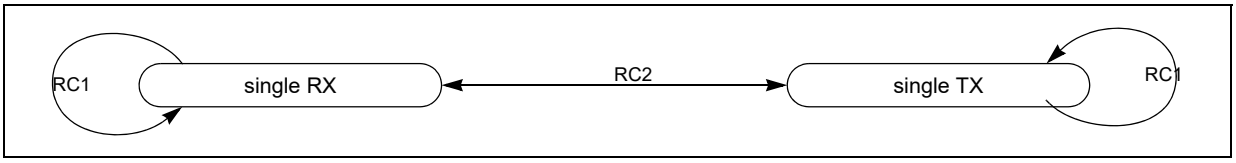
buffers are specified in *Section 51.5.2.53: Receive Shadow Buffer Index Register (FR_RSBIR)* and *Section 51.5.2.85: Message Buffer Index Registers (FR_MBIDXRn)*.

51.6.8 Individual message buffer reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data cannot be reconfigured when the protocol is out of the *POC:config* state.

51.6.8.1 Reconfiguration schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.



51.6.8.1.1 Basic type not changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSR*n*[MTD] is not changed. This type of reconfiguration is denoted by RC1 in *Figure 1494*. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

51.6.8.1.2 Buffer type not changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in *Figure 1494*. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

Figure 1494. Message buffer reconfiguration scheme

51.6.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

51.6.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A.* One FIFO is assigned to channel A, and the other FIFO is assigned to channel B. Both FIFOs work independently from each other.

The message buffer structure of each FIFO is described in *Section 51.6.3.3: Receive FIFO*. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- The FIFO system memory base address.
- The index of the first FIFO entry given by the Receive FIFO Start Index Register (FR_RFSIR).
- The data field offset of the data field belonging to the first FIFO entry given by the Receive FIFO Start Data Offset Register (FR_RFSDOR).
- The number of FIFO entries and the length of each FIFO entry as given by the Receive FIFO Depth and Size Register (FR_RFDSR).

51.6.9.2 FIFO configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO Address Mode bit FAM in the Module Configuration Register (FR_MCR).

51.6.9.2.1 Single System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is the System Memory Base Address Register (FR_SYMBADR).

51.6.9.2.2 Dual System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is the Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data is given in *Section 51.6.3.7: Receive FIFO control and configuration data*. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details, refer to *Section 51.6.4: FlexRay memory area layout*.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

1. Configure the FIFO update and address modes in Module Configuration Register (FR_MCR).
2. Configure the FIFO system memory base address.
3. Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO.
4. Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO.
5. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size.
6. Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth.
7. Configure the FIFO filters.

51.6.9.3 FIFO periodic timer

The FIFO periodic timer is used to generate a FIFO almost-full interrupt at a certain point in time, if the almost-full watermark is not reached but the FIFO is not empty. This can be used to prevent frames from getting stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd,* greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

51.6.9.4 FIFO reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case, the FIFO filter path shown in *Figure 1495* is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented.If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

51.6.9.5 FIFO almost-full interrupt generation

If the FIFO fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM (that is, FLA > WM_A (FLB > WM_B)), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.If the periodic timer expires, and FIFOA (FIFOB) is not empty (that is, FLA > 0 (FLB > 0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

51.6.9.6 FIFO overflow error generation

If the FIFOA (FIFOB) is full (that is, FLA = $FIFO_DEPTH_A$ (FLB=$FIFO_DEPTH_B$)) and the conditions for a FIFO reception as described in *Section 51.6.9.4: FIFO reception* are fulfilled, then the FIFO overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

51.6.9.7 FIFO message access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the (Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to *Equation 40*.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, then the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case, the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to *Equation 40*. The application can access the message data as described in *Section 51.6.3.3: Receive FIFO*. When the application has read the message buffer data and status information, it can update the FIFO as described in *Section 51.6.9.8: FIFO update*.

51.6.9.8 FIFO update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

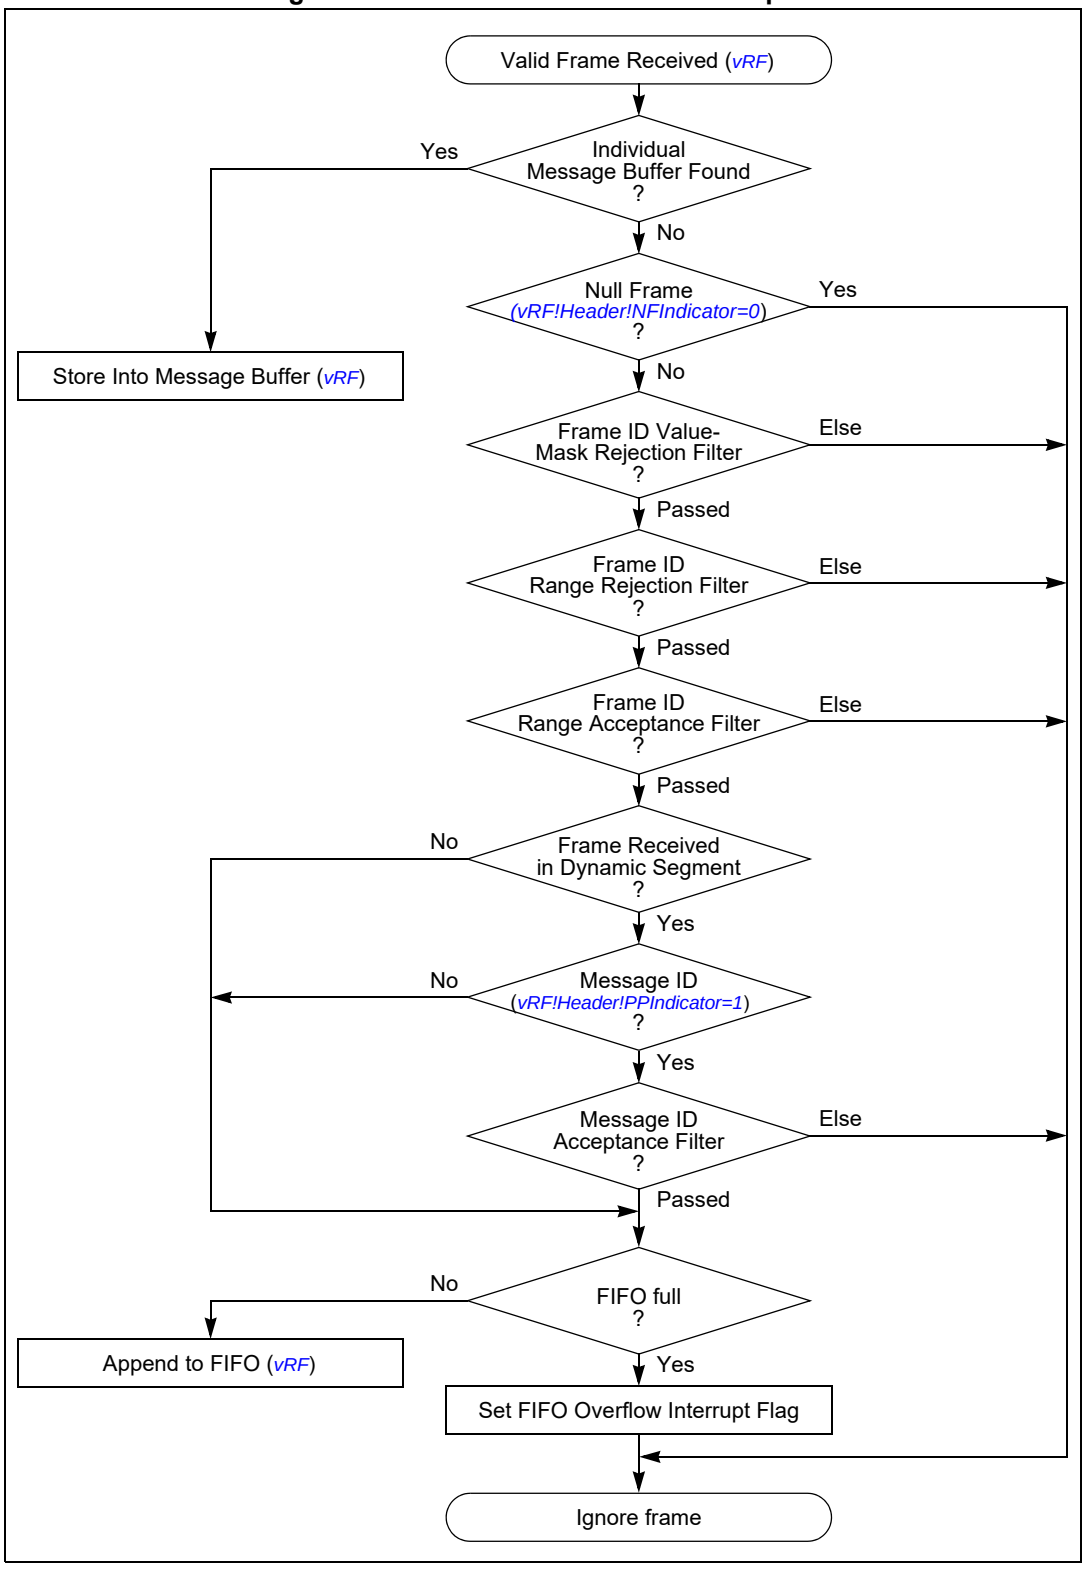
If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

51.6.9.8.1 FIFO interrupt flag update

The FIFO Interrupt Flag Update mode is configured when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode, FIFOA (FIFOB) will be updated by one entry when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.



The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1 if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

51.6.9.9 FIFO filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides four sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in *Figure 1495*.

Figure 1495. Received frame FIFO filter path

A received frame passes the FIFO filtering if it has passed all four types of filter.

51.6.9.9.1 RX FIFO Frame ID Value-mask Rejection filter

The Frame ID Value-mask Rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter (that is, it is not rejected).

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-mask Rejection filter if *Equation 47* is fulfilled.

Equation 47

$$FID \,\&\, FR_RFFIDRFMR[FIDRFMSK] \neq FR_RFFIDRFVR[FIDRFVAL] \,\&\, FR_RFFIDRFMR[FIDRFMSK]$$

The RX FIFO Frame ID Value-mask Rejection filter can be configured to pass all frames by using the following setting:

FR_RFFIDRFVR[FIDRFVAL] = 0x000 and FR_RFFIDRFMR[FIDRFMSK] = 0x7FF

Using the setting above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-mask Rejection filter can be configured to reject all frames by using the following setting:

FR_RFFIDRFMR[FIDRFMSK] = 0x000

Using the setting above, *Equation 47* can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

51.6.9.9.2 RX FIFO Frame ID Range Rejection filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range Rejection filters if either no rejection filter is enabled, or, if for all of the enabled RX FIFO Frame ID Range Rejection filters (that is, FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1), *Equation 48* is fulfilled.

Equation 48

$$(FID < FR_RFRFCFR_{SEL}[SID_{IBD=0}]) \text{ or } (FR_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Consequently, all frames with a frame ID that fulfills *Equation 49* for at least one of the enabled rejection filters will be rejected and thus not pass.

Equation 49

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

51.6.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, if for at least one of the enabled RX FIFO Frame ID Range acceptance filters (that is, FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1), *Equation 50* is fulfilled.

Equation 50

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

51.6.9.9.4 RX FIFO Message ID Acceptance filter

The RX FIFO Message ID Acceptance filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance filter if *Equation 51* is fulfilled.

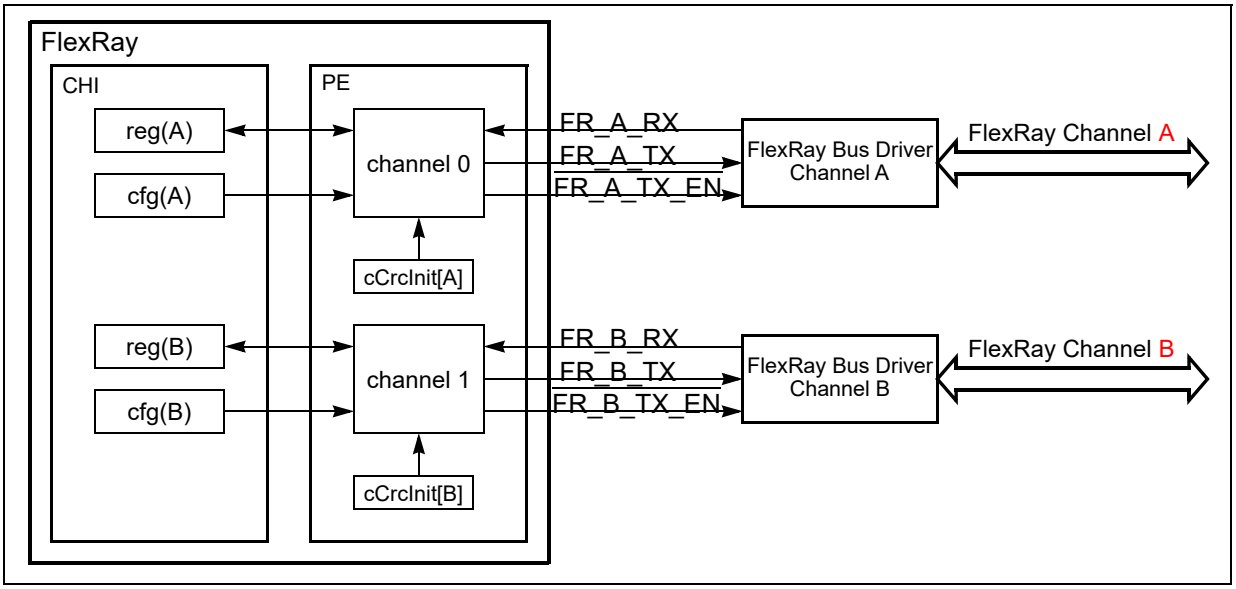
Equation 51

$$MID \,\&\, FR_RFMIDAFMR[MIDAFMSK] = FR_RFMIDAFMR[MIDAFVAL] \,\&\, FR_RFMIDAFMR[MIDAFMSK]$$

The RX FIFO Message ID Acceptance filter can be configured to accept all frames by setting

- FR_RFMIDAFMR[MIDAFMSK]:= 0x000

Using the setting above, *Equation 51* is always fulfilled and all frames will pass.



51.6.10 Channel device modes

This section describes the two FlexRay channel device modes that are supported by the CC.

51.6.10.1 Dual-Channel Device mode

In Dual-Channel Device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and FR_A_TX_EN is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and FR_B_TX_EN is connected to the physical bus channel B. The dual-channel system is shown in *Figure 1496*.

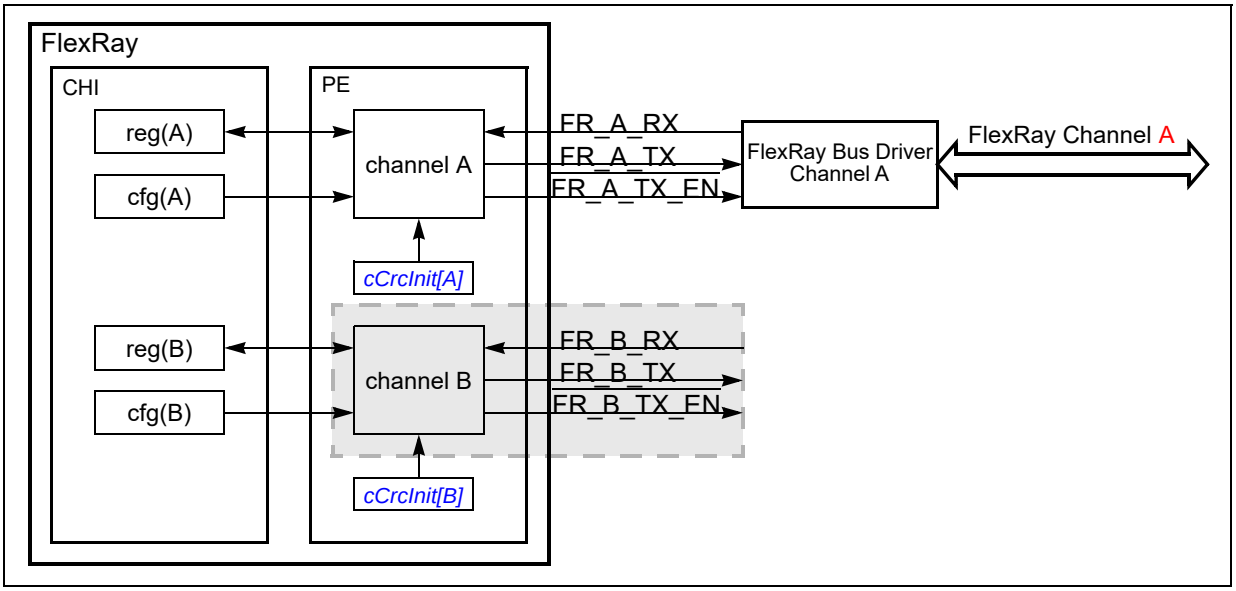
Figure 1496. Dual-Channel Device mode

51.6.10.2 Single-channel device mode

Single-Channel Device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and FR_A_TX_EN and can be connected to either the physical bus channel A (shown in *Figure 1497*) or the physical bus channel B (shown in *Figure 1498*).

If the device is configured as a single-channel device by setting FR_MCR[SCM] to 1, only the internal channel A and FlexRay port A are used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay channel A or FlexRay channel B. The bit FR_MCR[CHA] must be set, if FlexRay port A is connected to FlexRay channel A. The bit FR_MCR[CHB] must be set if FlexRay port B is connected to FlexRay channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single-channel device, the application can access and configure only the registers related to internal channel A.

Figure 1497. Single-channel device mode (channel A)



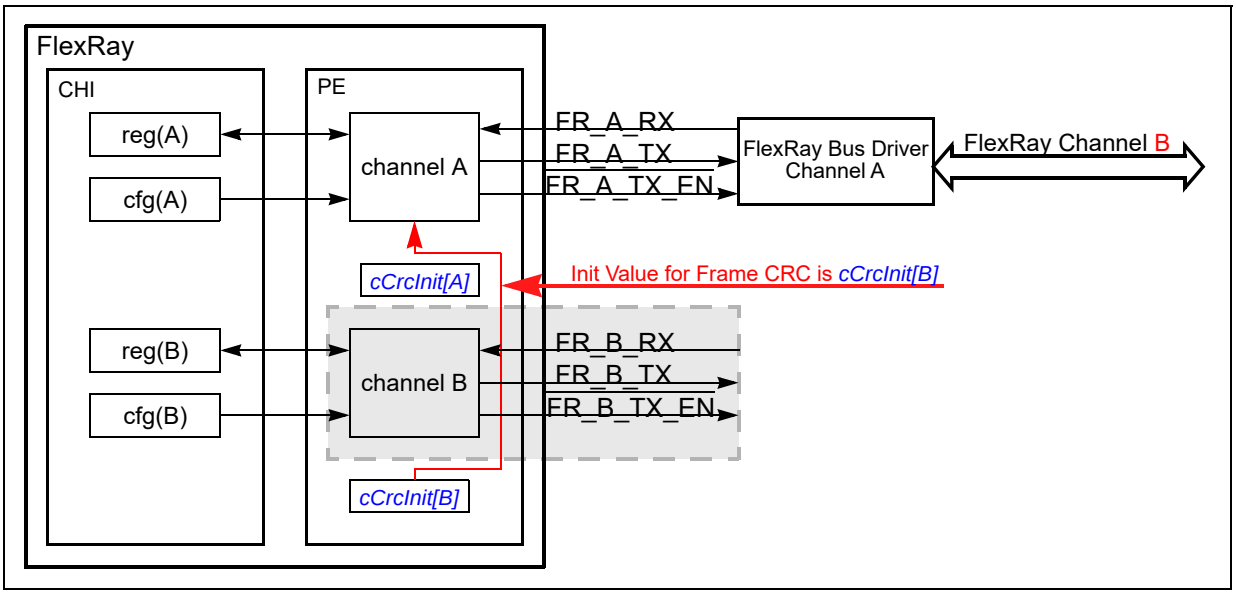


Figure 1498. Single-channel device mode (channel B)

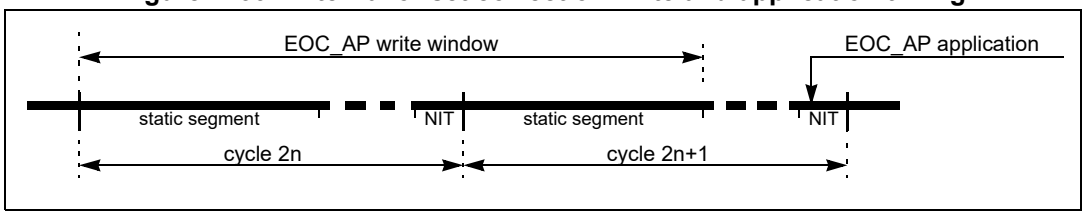
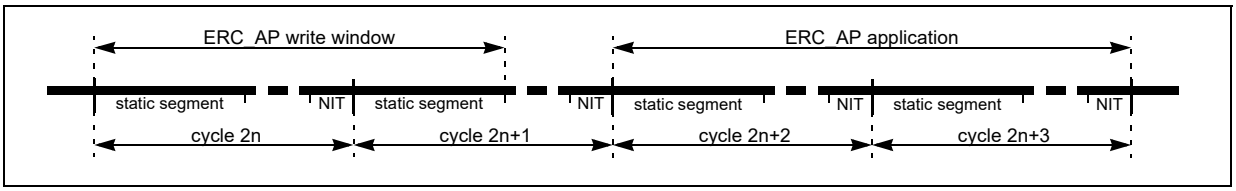
51.6.11 External clock synchronization



The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in *Figure 1499* and *Figure 1500*.

Note: The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these values were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n + 1 will be affected by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end



of the static segment of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle 2n + 1. If the value is not applied in cycle 2n + 1, then the value will be applied in the cycle 2n+3. Refer to *Figure 1499* for timing details.

Figure 1499. External offset correction write and application timing

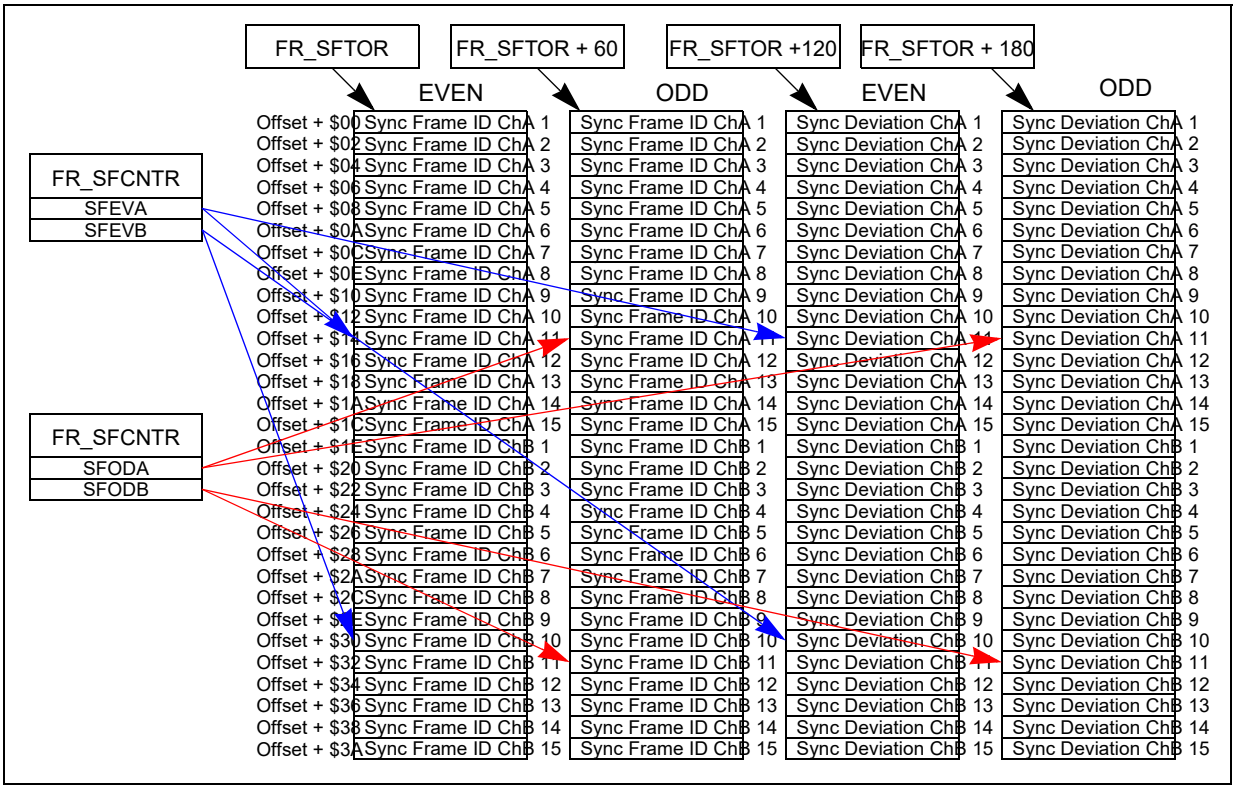
If the rate correction for the cycle pair [2n + 2, 2n + 3] will be affected by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n + 1. If this field is written to after the end of the static segment of cycle 2n + 1, it is not guaranteed that the external correction value is applied in cycle pair [2n + 2, 2n + 3]. If the value is not applied for cycle pair [2n + 2, 2n + 3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to *Figure 1500* for details.

Figure 1500. External rate correction write and application timing

51.6.12 Sync frame ID and sync frame deviation tables

The FlexRay protocol requires the provision of a snapshot of the synchronization frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note: Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.



51.6.12.1 Sync frame ID table content

The sync frame ID table is a snapshot of the protocol-related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

51.6.12.2 Sync frame deviation table content

The sync frame deviation table is a snapshot of the protocol-related variable zsDev(id)(oe)(ch)!Value. Each sync frame deviation table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the sync frame ID table.

Figure 1501. Sync table memory layout

51.6.12.3 Sync frame ID and sync frame deviation table setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in *Figure 1501*. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

51.6.12.4 Sync frame ID and sync frame deviation table generation

The application controls the generation process of the sync frame ID and sync frame deviation tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in *Table 1570*.

Table 1570. Sync frame table generation modes

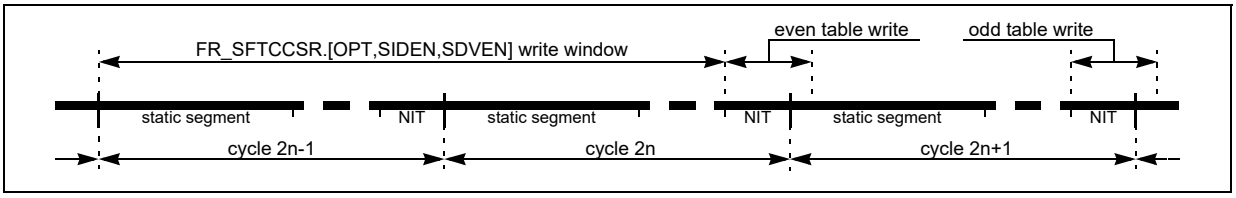
FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No sync frame table copy
0	0	1	Sync frame ID tables will be copied continuously
0	1	0	Reserved

Table 1570. Sync frame table generation modes (continued)

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	1	1	Sync frame ID tables and sync frame deviation tables will be copied continuously
1	0	0	No sync frame table copy
1	0	1	Sync frame ID tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync frame ID tables and sync frame deviation tables for next even-odd-cycle pair will be copied

The sync frame table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even-cycle-related tables after the start of the NIT of the next even cycle. The CC checks whether the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. When all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.



To read the generated tables, the application must lock the tables to prevent the CC from updating them. The locking is initiated by writing a 1 to the Even Table Lock trigger, FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding status information fields, SFRA and SFRB, in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in *Figure 1501*.

After reading all the data from the locked tables, the application must unlock the table by writing to the Even Table Lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

Figure 1502. Sync frame table trigger and generation timing

51.6.12.5 Sync frame table access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in *Figure 1501*. During the table write, the application cannot lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

51.6.12.5.1 Sync frame table locking and unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

51.6.13 MTS generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol (MTS) in the symbol window on channel A or channel B.

The application can configure the set of communication cycles that transmit the MTS over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT if *Equation 52*, *Equation 53*, and *Equation 54* are fulfilled.

Equation 52

FR_PSR0[PROTSTATE] = *POC:normal active*

Equation 53

FR_MTSACRF[MTE] = 1

Equation 54

CYCCNT & FR_MTSACFR[CYCCNTMSK] = FR_MTSACFR[CYCCNTVAL] & FR_MTSACFR[CYCCNTMSK]

The MTS is transmitted over channel B in the communication cycle with number CYCCNT if *Equation 52*, *Equation 55* and *Equation 56* are fulfilled.

Equation 55

$$FR_MTSBCRF[MTE] = 1$$

Equation 56

$$CYCCNT \& FR_MTSBCFR[CYCCNTMSK] = FR_MTSBCFR[CYCCNTVAL] \& FR_MTSBCFR[CYCCNTMSK]$$

51.6.14 Key slot transmission

51.6.14.1 Key slot assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less than or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2); otherwise no key slot is assigned.

51.6.14.2 Key slot transmission in *POC:startup*

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

51.6.14.3 Key slot transmission in *POC:normal active*

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in *Table 1571* is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (refer to *Section 51.6.6.2.5*). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (refer to *Section 51.6.6.2.6*).

Table 1571. Key slot frame type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	Normal frame
0	1	Normal frame(1)
1	0	Sync frame
1	1	Startup frame

1. The frame transmitted has a semantically incorrect header and will be detected as an invalid frame at the receiver.

51.6.15 Sync frame filtering

Each received synchronization frame must pass the Sync Frame Acceptance filter and the Sync Frame Rejection filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled (that is, the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared), all received synchronization frames are considered for clock synchronization. If a received synchronization frame did not pass at

least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

51.6.15.1 Sync frame acceptance filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if *Equation 57* or *Equation 58* evaluates to true.

Equation 57

$$FR_MCR[SFFE] = 0$$

Equation 58

$$FID \,\&\, FR_SFIDAFMR[FMSK] = FR_SFIDAFVR[FVAL] \,\&\, FR_SFIDAFMR[FMSK]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

51.6.15.2 Sync frame rejection filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if *Equation 59* or *Equation 60* evaluates to true.

Equation 59

$$FR_MCR[SFFE] = 0$$

Equation 60

$$FID \neq FR_SFIDRFR[SYNFRID]$$

Note: Sync frames are transmitted in the static segment only. Thus FID ≤ 1023.

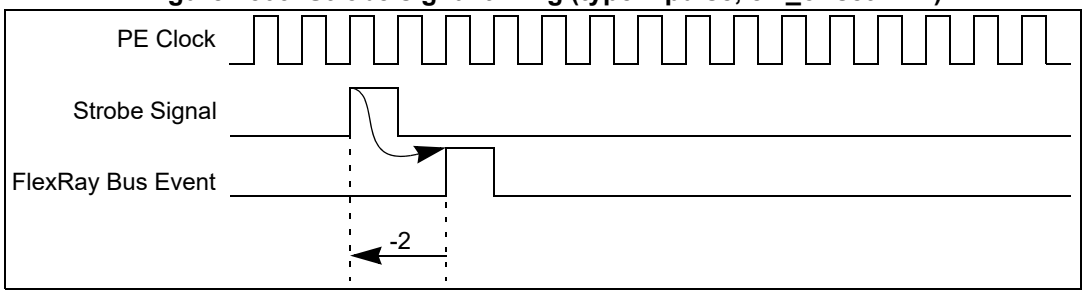
51.6.16 Strobe signal support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in *Table 1456*.

51.6.16.1 Strobe signal assignment

Each of the strobe signals listed in *Table 1456* can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

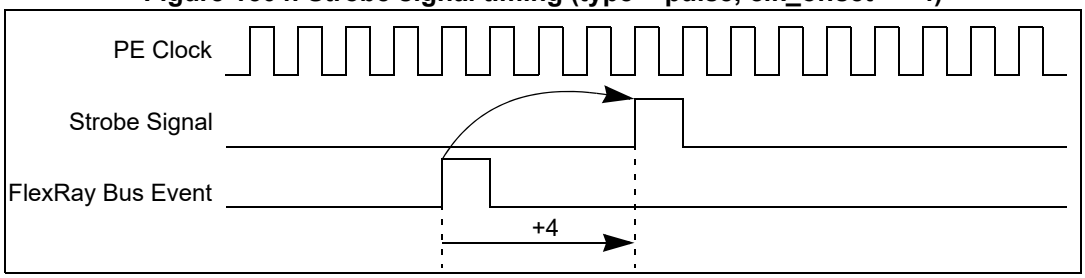
To read out the current settings for a strobe signal with number *n*, the application must execute the following sequence.



1. Write to FR_STBSCR with WMD = 1 and SEL = *n*. (Updates the SEL field only.)
2. Read STBCSR.
   The SEL field provides *n* and the ENB and STBPSEL fields provides the settings for signal *n*.

51.6.16.2 Strobe signal timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.



The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay bus. These signals are listed in *Table 1456* with a negative clock offset. An example waveform is given in *Figure 1503*.

Figure 1503. Strobe signal timing (type = pulse, clk_offset = –2)

Other signals refer to events that occurred on the FlexRay bus some cycles before the strobe signal is changed. These signals are listed in *Table 1456* with a positive clock offset. An example waveform is given in *Figure 1504*.

Figure 1504. Strobe signal timing (type = pulse, clk_offset = +4)

51.6.17 Timer support

The CC provides two timers that run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In Non-repetitive mode, the timer stops if it expires. In Repetitive mode, the timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

51.6.17.1 Absolute timer T1

Absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if *Equation 61* and *Equation 62* are fulfilled.

Equation 61

$$CYCTR[CTCCNT] \& FR_TI1CYSR[T1_CYC_MSK] = FR_TI1CYSR[T1_CYC_VAL] \& FR_TI1CYSR[T1_CYC_MSK]$$

Equation 62

$$FR_MTCTR[MTCT] = FR_TI1MTOR[T1_MTOFFSET]$$

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding interrupt condition (that is, when *Equation 61* and *Equation 62* are fulfilled) also leads to an event-out indication on an output port (fr_evt_tim1) based on the FR_PEOER[TIM1_EE].

51.6.17.2 Absolute/relative timer T2

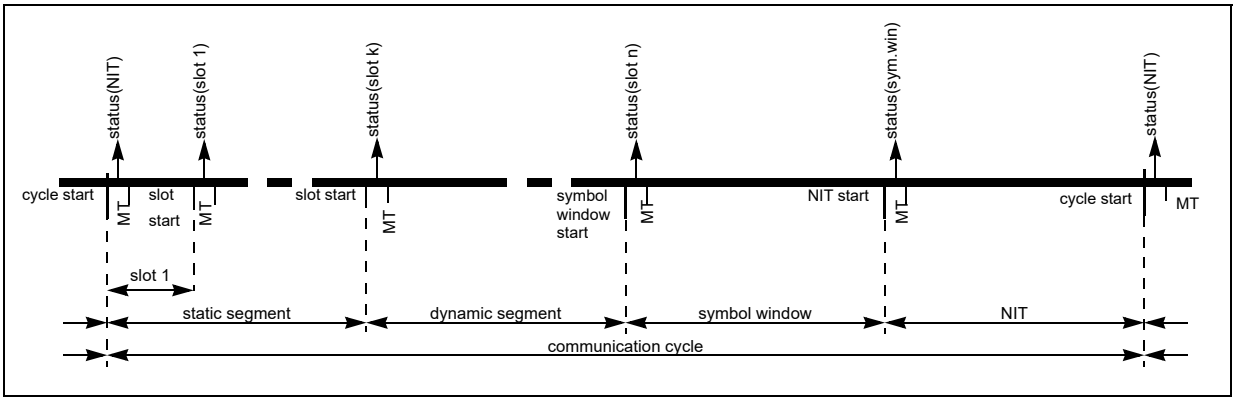
Timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

51.6.17.2.1 Absolute timer T2

If timer T2 is configured as an absolute timer, it has the same functionality as timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. When timer T2 expires, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

51.6.17.2.2 Relative Timer T2



If timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set when the programmed amount of macroticks MT[31:0] – defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) – has elapsed since the trigger or restart of timer T2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.The corresponding interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the FR_PEOER[TIM2_EE].

51.6.18 Slot status monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per-channel base. The content of the slot status vector is described in *Table 1572*. The PE provides the

slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in *Figure 1505*.

Figure 1505. Slot status vector update

Note: The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 1572. Slot status content

Slot	Status content

Static/dynamic slot	Slot-related status
	vSS!ValidFrame: valid frame received
	vSS!SyntaxError: syntax error occurred while receiving
	vSS!ContentError: content error occurred while receiving
	vSS!BViolation: boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict: reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict: reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	Received-frame-related status
	extracted from
	a) header of valid frame, if vSS!ValidFrame = 1
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator: null frame indicator (0 for null frame)
	vRF!Header!SuFIndicator: startup frame indicator
	vRF!Header!SyFIndicator: sync frame indicator

Symbol window	Window-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: reception ongoing while transmission starts Received-symbol-related status *vSS!ValidMTS*: valid Media Test Access Symbol received Received-frame-related status see static/dynamic slot

Table 1572. Slot status content (continued)

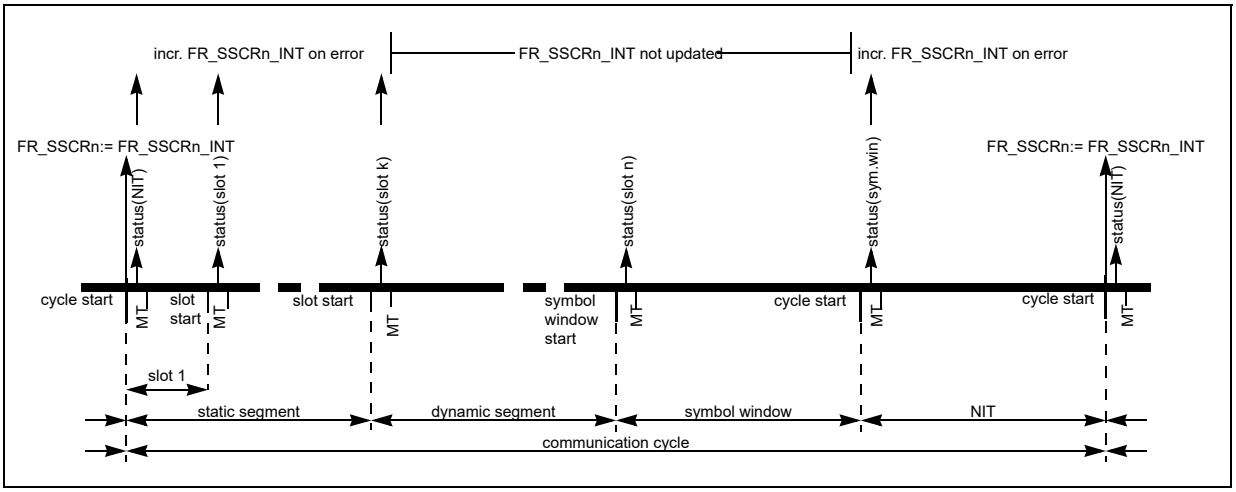
Slot	Status content
NIT	NIT-related status *vSS!ValidFrame*: always 0 *vSS!ContentError*: content error occurred while receiving *vSS!SyntaxError*: syntax error occurred while receiving *vSS!BViolation*: boundary violation while receiving *vSS!TxConflict*: always 0 Received-frame-related status see static/dynamic slot

51.6.18.1 Channel status error counter registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR) are incremented by one if at least one of four slot status error bits, *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap around after they have reached the maximum value.

51.6.18.2 Protocol status registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the NIT and the symbol window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.



51.6.18.3 Slot status registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status-related and received frame/symbol-related status information, as given in *Table 1572*, except for the *first valid* indicator for non-transmission slots.

51.6.18.4 Slot status counter registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in *Figure 1506*.

Figure 1506. Slot status counting and FR_SSCR*n* update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCR*n* register reflects, in cycle n, the status of the NIT of cycle n – 2, and the status of all static slots and the symbol window of cycle n – 1.

The increment condition for each slot status counter consists of two parts: the frame-related condition part and the slot-related condition part. The internal slot status counter FR_SSCR*n*_INT is incremented if at least one of the following conditions is fulfilled:

1. Frame-related condition:

- (FR_SSCCR*n*[VFR] | FR_SSCCR*n*[SYF] | FR_SSCCR*n*[NUF] | FR_SSCCR*n*[SUF]) // count on frame condition
  = 1;

cycle start

and

- ((~FR_SSCCR*n*[VFR] | vSS!ValidFrame) & // valid frame restriction
  (~FR_SSCCR*n*[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction
  (~FR_SSCCR*n*[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction
  (~FR_SSCCR*n*[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction
  = 1;

Note: The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus, the VFR must always be set whenever the count-on-frame condition is used.

2. Slot-related condition:

- ((FR_SSCCR*n*[STATUSMASK[3]] & vSS!ContentError) | // increment on content error
  (FR_SSCCR*n*[STATUSMASK[2]] & vSS!SyntaxError) | // increment on syntax error
  (FR_SSCCR*n*[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation
  (FR_SSCCR*n*[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict
  = 1;

If the slot status counter is in Single-cycle mode (that is, FR_SSCCR*n*[MCY] = 0), the internal slot status counter FR_SSCR*n*_INT is reset at each cycle start. If the slot status counter is in Multicycle mode (that is, FR_SSCCR*n*[MCY] = 1), the counter is not reset and incremented until the maximum value is reached.

51.6.18.5 Message buffer slot status field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in *Table 1572* for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update sections in *Section 51.6.3.4.1*.

51.6.19 System bus access

This section provides a description of the system bus access failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in *Section 51.6.19.1*.

The behavior of the CC after the occurrence of a system bus access failure is described in *Section 51.6.19.2*.

51.6.19.1 System bus access failure types

This section describes the two types of system bus access failures.

51.6.19.1.1 System bus illegal address access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions that are treated as a system bus illegal address access:

- The system bus subsystem detects a CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (refer to *Section 51.6.24.3.1*).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

51.6.19.1.2 System bus access timeout

A system bus access timeout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (refer to *Section 51.7.1.1*).

If a system bus access timeout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

51.6.19.2 System bus access failure response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

51.6.19.2.1 Continue after system bus access failure

If FR_MCR[SBFF] is 0, the CC will continue its operation after the occurrence of the system bus access failure, but it will not generate any system bus accesses until the start of the next communication cycle. Since no data is read from or written to the FlexRay memory

area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated in which the remaining header and frame data are replaced by all zeros. Depending on the point in time, this can affect the PPI bit, the header CRC, the payload length in the case of a dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted or received, except for the key slot; a sync or startup null-frame is transmitted if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

51.6.19.2.2 Freeze after system bus access failure

If FR_MCR[SBFF] is set to 1, the CC will go into Freeze mode immediately after the occurrence of one of the system bus access failures.

51.6.20 Interrupt support

The CC provides 300 individual interrupt sources and five combined interrupt sources.

51.6.20.1 Individual interrupt sources

51.6.20.1.1 Message buffer interrupts

The CC provides 256 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSR*n*[MBIF] and an interrupt enable bit FR_MBCCSR*n*[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

51.6.20.1.2 FIFO interrupts

The CC provides two FIFO interrupt sources.

Each of the two FIFOs provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding receive FIFO fill level exceeds the defined watermark.

51.6.20.1.2.1 Wakeup interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

51.6.20.1.2.2 Protocol interrupts

The CC provides 25 interrupt sources for protocol-related events. For details, refer to the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

51.6.20.1.2.3 CHI interrupts

The CC provides 16 interrupt sources for CHI-related error events. For details, refer to the CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

51.6.20.2 Combined interrupt sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

51.6.20.2.1 Receive message buffer interrupt

The receive message buffer interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

51.6.20.2.2 Transmit message buffer interrupt

The transmit message buffer interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

51.6.20.2.3 Protocol interrupt

The protocol interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set.

51.6.20.2.4 CHI interrupt

The CHI interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

51.6.20.2.5 Module interrupt

The module interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

Figure 1507. Scheme of FR_GIFER interrupt signal generation

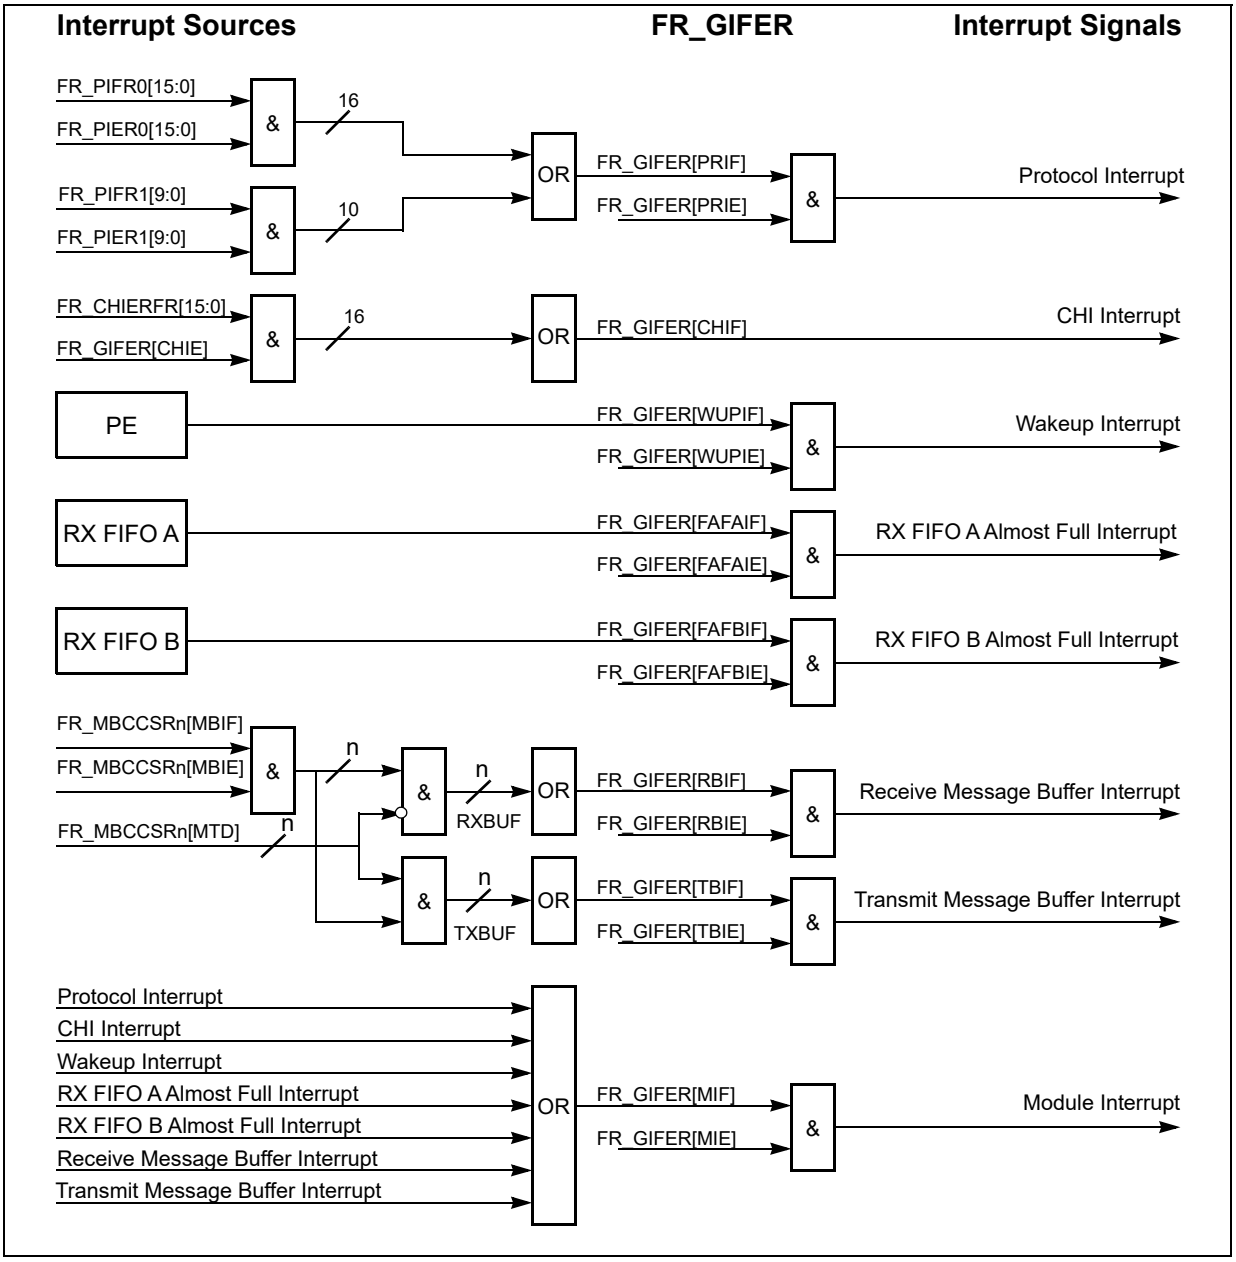


Figure 1508. FR_EEIFER interrupt signal generation scheme

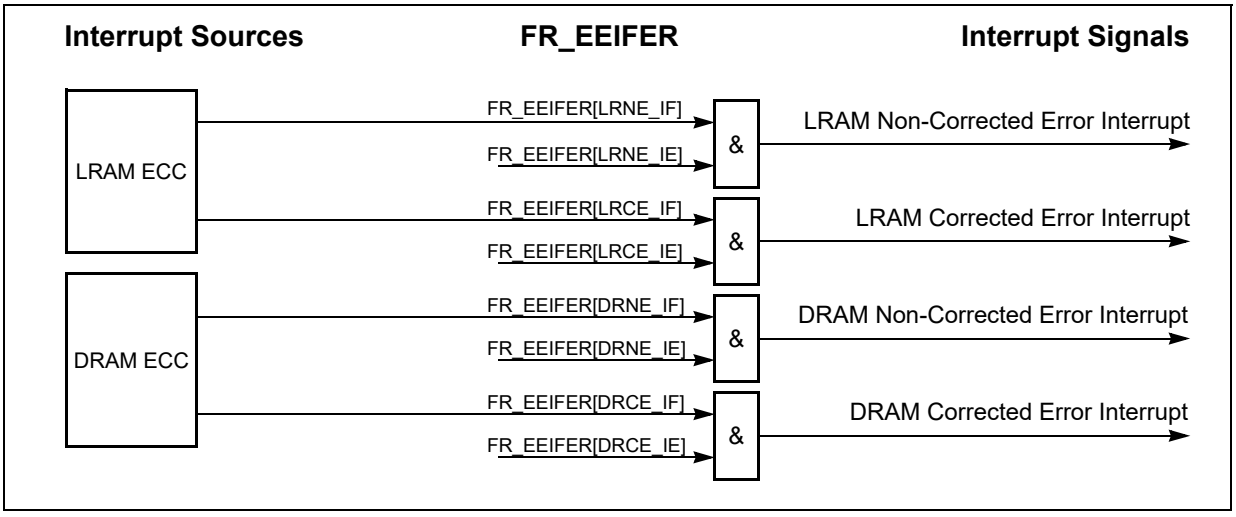

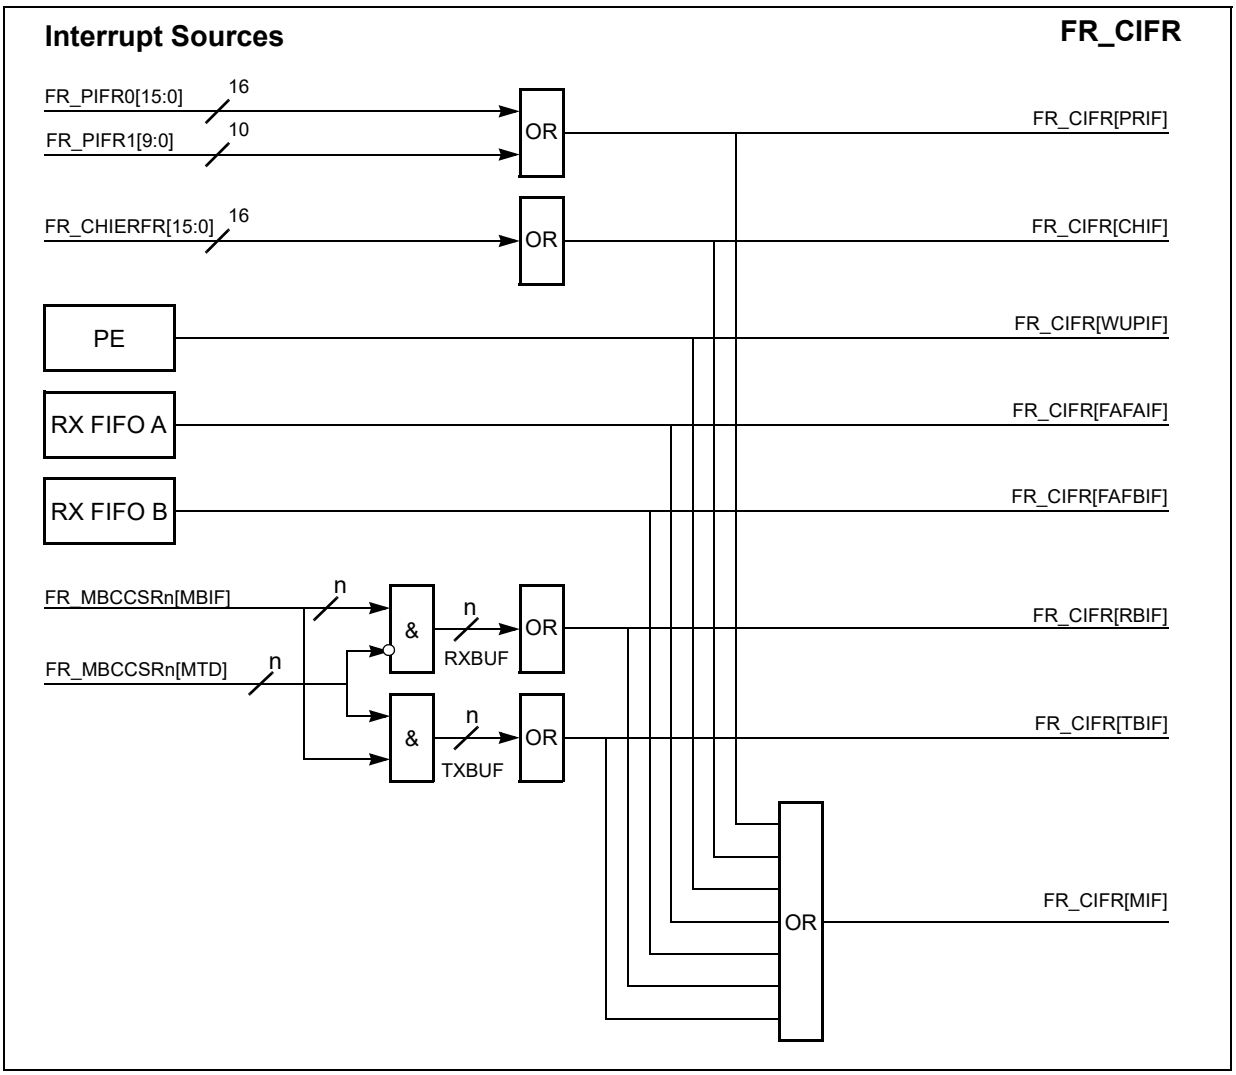

Figure 1509. FR_CIFR flag generation scheme

51.6.21 Lower bit rate support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset.* The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings, and the related protocol parameter values are shown in *Table 1573*.

Table 1573. FlexRay channel bit rate control

FlexRay channel bit rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick* [ns]	*gdSampleClockPeriod* [ns]	pSamplesPerMicrotick	cSamplesPerBit	cStrobeOffset
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note: The bit rate of 8 Mbit/s is not defined by the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

51.6.22 PE data memory (PE DRAM)

The PE data memory (PE DRAM) is 128 word, 16-bit wide memory with byte access that contains the program data of the PE internal CPU. The PE DRAM is divided into two banks of 8 bits each. The memory data [7:0] is assigned to BANK0 and the memory data [15:8] is assigned to BANK1.

Table 1574. PE DRAM layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via *Section 51.5.2.10: PE DRAM Access Register (FR_PEDRAR)* and *Section 51.5.2.11: PE DRAM Data Register (FR_PEDRDR)*. This functionality is used to check the memory error detection.

51.6.22.1 PE DRAM read access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;
   // INST=0x5; ADDR=070
2. Wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA];
   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

51.6.22.2 PE DRAM write access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;
   // write value to be written into data register
2. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
3. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
4. val = FR_PEDRDR[DATA];
   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

If the conditions given in *Section 51.6.22.3: PE DRAM write access limitations* are fulfilled, the data provided in PE DRAM Access Register (FR_PEDRAR) is written into the PE DRAM, read back in the next clock cycle, and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data is not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

51.6.22.3 PE DRAM write access limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not in *POC:default config* state, only PE DRAM address 0x70 is writable.

51.6.23 CHI lookup-table memory (CHI LRAM)

The CHI lookup-table memory (CHI LRAM) is a CHI-internal memory that contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or six data field offsets are contained in one memory row. The CHI LRAM is divided into six memory banks.

Table 1575. CHI LRAM layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x7F	FR_MBIDXR255	FR_MBFIDR255	FR_MBCCFR255	FR_MBIDXR254	FR_MBFIDR254	FR_MBCCFR254
0x80	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0xAB	-	-	-	-	FR_MBDOR259	FR_MBDOR258
0xAC	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

51.6.23.1 CHI LRAM read and write access

The CHI LRAM is accessed by the application via regular register read and write accesses.

51.6.24 Memory content error detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses a standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED). The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

51.6.24.1 Memory error types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as a special case. The FlexRay module detects and indicates the memory errors as shown in *Table 1576*. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error-free bank has been read.

Table 1576. Detected memory error types

Memory	Priority	Memory data	Indication
CHI LRAM	0 (highest)	All zeros	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM		All ones	Non-corrected error
PE DRAM			
CHI LRAM	1 (lowest)	One bit flipped	Non-corrected error
PE DRAM			Corrected error
CHI LRAM		Two bits flipped	Non-corrected error
PE DRAM			
CHI LRAM		Three or more bits flipped	One out of {no error, non-corrected error}, defined by coding given in *Section 51.6.24.2.3* and *Section 51.6.24.2.4*
PE DRAM			One out of {no error, corrected error, non-corrected error}, defined by coding given in *Section 51.6.24.2.1* and *Note: on page 2386*

51.6.24.2 Memory error reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories, there are two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.
- If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to the above, the error indications (corrected/non-corrected) along with the failing address are sent out from the module for external error logging and corrective actions by the software.

51.6.24.2.1 PE DRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 1576*. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1577. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4(1)	X	X	X	X	X	X	X	X	X	X	X	X
3(2)	—	—	—	—	X	X	X	X	—	—	—	—
2	—	—	—	—	X	—	—	—	X	X	X	—
1	—	—	—	—	—	X	X	—	X	X	—	X
0	—	—	—	—	—	X	—	X	X	—	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is an even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is an odd number of 1's in all columns with X.

Note: This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words written into the memory.

51.6.24.2.2 PE DRAM syndrome

The coding of the syndrome reported in the ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in *Table 1578*.

Table 1578. FR_EERCR[CODE] PE DRAM syndrome coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected error (parity bit 0)
0x0	0x2	Corrected error (parity bit 1)
0x0	0x3	Corrected error (data bit 0)
0x0	0x4	Corrected error (parity bit 2)
0x0	0x5	Corrected error (data bit 1)
0x0	0x6	Corrected error (data bit 2)
0x0	0x7	Corrected error (data bit 3)
0x0	0x8	Corrected error (parity bit 3)
0x0	0x9	Corrected error (data bit 4)
0x0	0xA	Corrected error (data bit 5)
0x0	0xB	Corrected error (data bit 6)
0x0	0xC	Corrected error (data bit 7)
0x0	0xD–0xF	Non-corrected error
0x1	0x1–0xF	Non-corrected error

51.6.24.2.3 CHI LRAM checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 1579*. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1579. CHI LRAM checkbits coding

CODE(1)	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	—	—	—	—	—	—	—	—	—	—	—
3	—	—	—	—	—	X	X	X	X	X	X	X	—	—	—	—
2	X	X	—	—	—	X	X	X	X	—	—	—	X	X	X	—
1	—	—	X	X	—	X	X	—	—	X	X	—	X	X	—	X
0	X	—	X	—	X	X	—	X	—	X	—	X	X	—	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is an odd number of 1's in all columns with X.

51.6.24.2.4 CHI LRAM syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in *Table 1580*.

Table 1580. FR_EERCR[CODE] CHI LRAM syndrome coding

FR_EERCR[CODE]	Description
0x00	No Error (never appears in error report registers)
0x01–0x1F	Non-corrected error

51.6.24.3 Memory error response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case a *corrected* memory error is detected, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

51.6.24.3.1 CHI LRAM error response after CC read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access, the error response of the module depends on LRAM location where the error occurred.

- If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current

search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.

  – If the affected message buffer is a Tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is an Rx message buffer, no frame will be received to this message buffer in the next slot.

- If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx, the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs with respect to payload access for the complete frame.

51.6.24.3.2 CHI LRAM error response after application read

The application can read the content of the CHI LRAM by reading the FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBIDXR*n*, FR_MBDOR*n* and FR_LEETR*n* registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read, and continues its normal operation.

51.6.24.3.3 PE DRAM error response after CC read

If the CC detects a non-corrected memory error during an internal read of program data contained in PE DRAM, this is considered a fatal protocol error and the module enters the protocol freeze state immediately.

51.6.24.3.4 PE DRAM error response after application read in *POC:default config* state

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered a fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

51.6.24.3.5 PE DRAM error response after application read out of *POC:default config*

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is not in the *POC:default config* state, this error is not considered a fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

51.6.25 Memory error injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

Error Injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).When error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

51.6.25.1 CHI LRAM error injection

The following sequence describes a memory error injection sequence for the CHI LRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke a distortion of the memory content. The content of the CHI LRAM is described in *Table 1575*.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config,* refer to *Section 51.7.3*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 1;
   // select CHI LRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // select address for error injection; I_ADDR ≤ 0xAC
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application write access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;
If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;
If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;
If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;
If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;
If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;
// write DATA to the defined injection bank and injection address (refer to *Table 1575*).

51.6.25.2 PE DRAM error injection

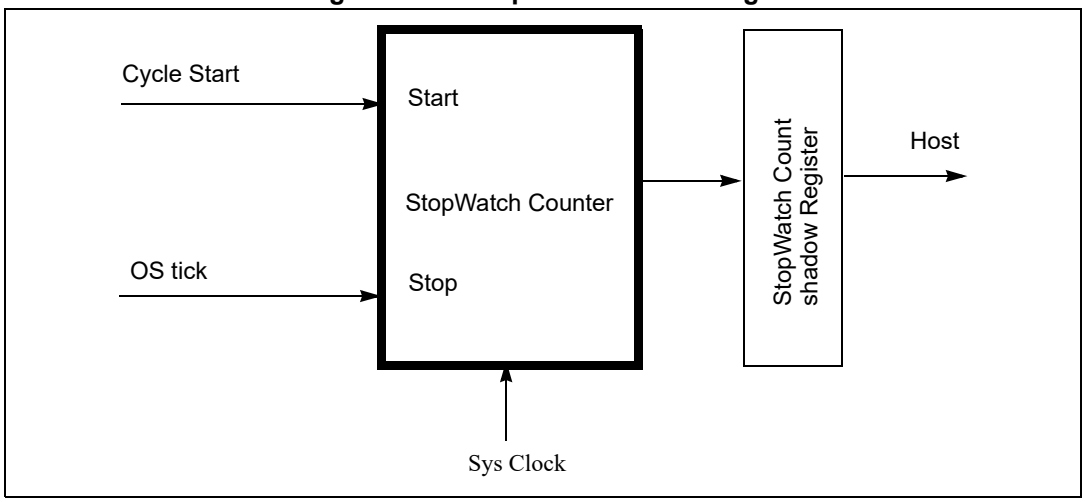
The following sequence describes a memory error injection sequence for the PE DRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke a distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config,* refer to *Section 51.7.3.2*.

Injector setup:

1. FR_MCR[ECCE]:= 1;
   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;
   // configure error injection mode
3. FR_EEIAR[MID]:= 0;
   // select PE DRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
   // define bank for error injection; I_BANK = {0,1}
5. FR_EEIAR[ADDR]:= I_ADDR;
   // define address for error injection; I_ADDR ≤ 0x7F
6. FR_EEIDR[DATA]:= D_DIST;
   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;
   // enable error injection

Application write access (for example, I_ADDR=0x70):



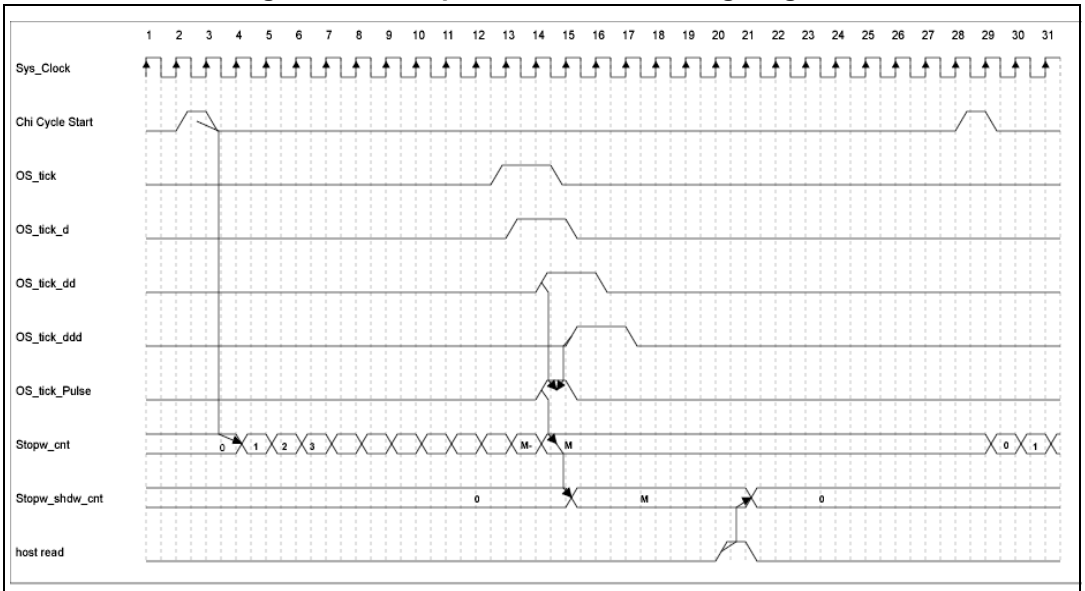
1. FR_PEDRAR:= 0x30E0;
   // INST=0x3; ADDR=0x70
2. wait until FR_PEDRAR[DAD] == 1;
   // wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA]; |
   // get read back PE DRAM data

Note: The write access to the PE DRAM triggers a subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

51.6.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick.

Figure 1510. StopWatch counter logic



As shown here, there is a 32-bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (*Section 51.5.2.68: Stop Watch Count Register (FR_STPWR)*) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared.

The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (*Section 51.5.2.69: Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)*. The counter runs only when this bit is set.

Figure 1511 shows the actual timing of the stopwatch counter logic operation.

Figure 1511. StopWatch function timing diagram

Note: 'Host read' implies that all 32 bits have been read out completely. Any partial read (that is for 8/16 bits access) will not clear the StopWatch count register.

If cycle start and OS tick occur simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and Cycle_start has a single stage synchronizer into Chi clock domain. So simultaneously here means OS_tick_Pulse and Chi_Cycle_Start occurring at the same cycle.

51.7 Application information

51.7.1 Module configuration

This section describes the essential parts of the module configuration.

51.7.1.1 Configure System Memory Access Timeout Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in the System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill *Equation 63*[w].

Equation 63

$$0 \leq \text{SYMATOR[TIMEOUT]} \leq \lfloor 0.45 \cdot f_{CHI} - 8 \rfloor$$

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in *Table 1581*.

w. Refer to *Section 51.3: Controller host interface clocking* for all constraints of minimum CHI clock frequency.

Table 1581. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
≥ 18 MHz	0	≥ 100 MHz	≤ 37
≥ 23 MHz	≤ 2	≥ 120 MHz	≤ 46
≥ 27 MHz	≤ 4	≥ 140 MHz	≤ 55
≥ 32 MHz	≤ 6	≥ 160 MHz	≤ 64
≥ 60 MHz	≤ 19	≥ 180 MHz	≤ 73
≥ 80 MHz	≤ 28	≥ 200 MHz	≤ 82

51.7.1.1.1 System bus wait state constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single-channel configurations and situations in which the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0), no timeout will be detected if fewer than 2 × SYMATOR[TIMEOUT] + 1 wait states will be seen on the system bus for each system bus access.

For dual-channel configurations, or situations in which the sync frame table generation functionality is used, no timeout will be detected if fewer than SYMATOR[TIMEOUT] – 1 wait states will be seen on the system bus for each system bus access.

51.7.1.2 Configure data field offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDORn) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers that are used.

When the module is enabled, the initialization value of the FR_MBDOR*n*[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (refer to *Section 51.6.19.1.1*).

51.7.2 Initialization sequence

This section describes the steps required to initialize the CC. The first subsection describes the steps required after a system reset; the second section describes the steps required after preceding shutdown of the CC.

51.7.2.1 Module initialization

This section describes the module-related initialization steps after a system reset.

1. Configure the CC.
   a) Configure the control bits in the Module Configuration Register (FR_MCR).
   b) Configure the system memory base address in the System Memory Base Address Register (FR_SYMBADR).
2. Enable the CC.
   a) Write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR).

The CC now enters Normal mode. The application can commence with the protocol initialization described in *Section 51.7.2.2*.

51.7.2.2 Protocol initialization

This section describes the protocol-related initialization steps.

1. Configure the Protocol Engine.
   a) Issue CONFIG command via the Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:config* in the Protocol Status Register 0 (FR_PSR0).
   c) Configure the FR_PCR0,..., FR_PCR30 registers to set all protocol parameters.
2. Configure the message buffers and FIFOs.
   a) Set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
   b) Define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR).
   c) Configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), and Message Buffer Index Registers (FR_MBIDXRn).
   d) Configure the FIFOs.
   e) Issue CONFIG_COMPLETE command via the Protocol Operation Control Register (FR_POCR).
   f) Wait for *POC:ready* in the Protocol Status Register 0 (FR_PSR0).

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

51.7.2.3 CHI LRAM initialization

The CHI LRAM initialization is performed by the CC when it leaves Disabled mode. The initialization runs for 173 CHI clock cycles. All fields in the FR_MBCCSR*n*, FR_MBCCFR*n*, FR_MBFIDR*n*, FR_MBDOR*n* and LEETR*n* registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

51.7.2.4 PE DRAM initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs and will delay the state transition from *POC:default config* into *POC:config*.

51.7.3 Memory error injection out of *POC:default config*

This section provides information for application-driven memory error injection out if *POC:default config.* The CC provides the means to inject memory errors from the application without any impacts to the internal protocol operation of the CC.

51.7.3.1 CHI LRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independently from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in *Section 51.6.25.1*.

51.7.3.2 PE DRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM locations to inject memory errors into the PE DRAM. The injection sequence is described in *Section 51.6.25.2*.

51.7.4 Shutdown sequence

This section describes a secure shutdown sequence to stop the CC gracefully. The main targets of this sequence are:

- Finish all ongoing reception and transmission
- Do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication

For a graceful shutdown, the application should perform the following tasks:

1. Disable all enabled message buffers.
   a) Repeatedly write 1 to FR_MBCCSR*n*[EDT] until FR_MBCCSR*n*[EDS] == 0.
2. Stop the Protocol Engine.
   a) Issue HALT command via Protocol Operation Control Register (FR_POCR).
   b) Wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0).

51.7.5 Number of usable message buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[x].

Additional constraints for the minimum CHI clock frequency are given in *Section 51.3*.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of the slot and must be finished before the start of the next slot.

x. Refer to *Section 51.3: Controller host interface clocking* for all constraints of minimum CHI clock frequency.

The shortest FlexRay slot is a corrected empty dynamic slot. A corrected empty dynamic slot is a mini-slot and consists of *gdMinislot* corrected macroticks with a duration of *gdMacrotick*. The minimum duration of a corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of a correct slot.

Equation 64

$$\Delta_{slotmin} = 39 \cdot pdMicrotick \cdot gdMinislot$$

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

Equation 65

$$\Delta_{search} = \frac{1}{f_{chi}} \cdot (FR_MBSSUTR[LAST_MB_UTIL]+27)$$

The message buffer search must be finished within one slot which requires that *Equation 66* must be fulfilled:

Equation 66

$$\Delta_{search} \leq \Delta_{slotmin}$$

This results in the formula given in *Equation 67* which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

Equation 67

$$f_{chi} \geq \frac{(FR_MBSSUTR[LAST_MB_UTIL]+27)}{39 \cdot pdMicrotick \cdot gdMinislot}$$

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 255 is given in *Table 1582*.

Table 1582. Minimum CHI clock frequency [MHz] examples (256 message buffers used)

pdMicrotick [ns]	gdMinislot					
	2	3	4	5	6	7
25.0	145.2	96.8	72.6	58.1	48.4	41.5
50.0	72.6	48.4	36.3	29.1	24.2	20.8

Note: If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to Section 51.5.2.18: CHI Error Flag Register (FR_CHIERFR) for details.

51.7.6 Protocol control command execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of *Table 1462* by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in *Table 1583*. If the current protocol state does not allow the execution of this protocol command (refer to POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by *Table 1583*. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 1583. Protocol control command priorities

Protocol command	Priority	Interrupted by	Cleared and terminated by
FREEZE	(Highest) 1	None	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLET, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(Lowest) 10		FREEZE, READY, CONFIG_COMPLETE, fatal protocol error

51.7.7 Message buffer search on simple message buffer configuration

This section describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

51.7.7.1 Simple message buffer configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *s*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has the following configuration.

Table 1584. Transmit buffer configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	Transmit buffer
FR_MBCCFR*t*	MTM	0	Event Transition mode
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000011	Cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	S	Assigned to slot s

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number *r* and has the following configuration.

Table 1585. Receive buffer configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	Receive buffer
FR_MBCCFR*r*	MTM	—	N/A
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000001	Cycle set = {2n} = {0,2,4,6,…}
	CCFVAL	000000	
FR_MBFIDR*r*	FID	S	Subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSR*t*[EDS] = 1 and FR_MBCCSR*r*[EDS] = 1).

Note: The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

51.7.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *s* in the *static* segment.

The configuration of a transmit buffer for a static slot *s* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *s.* In any case, the result of the message buffer search will be the transmit message buffer *t.* The receive message buffer *r* will not be found, no reception is possible.

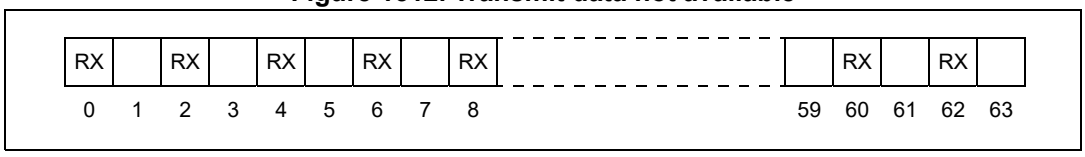
51.7.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *s* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

51.7.7.3.1 Transmit Data Not Available



If transmit data are not available, that is the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 or locked FR_MBCCSR*t*[LCKS]=1, or both.

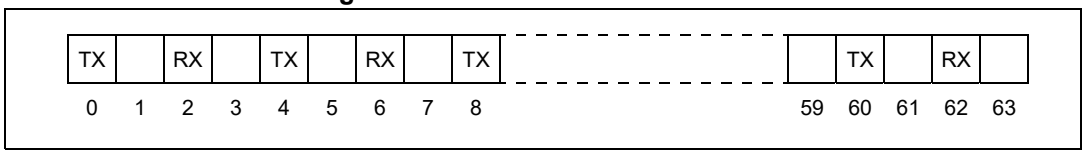
a) For the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and,

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in *Figure 1512*.

Figure 1512. Transmit data not available

51.7.7.3.2 Transmit data available



If transmit data are *available,* that is, the transmit buffer is committed FR_MBCCSR*t*[CMT] = 1 and not locked FR_MBCCSR*t*[LCKS] = 0,

a) For the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.

b) For the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in *Figure 1513*.

Figure 1513. Transmit data available

52 Inter-Integrated Circuit (I2C)

52.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- *Section 52.2: Introduction to I2C*
- *Section 52.3: External signal descriptions*
- *Section 52.4: Memory map and register definition*
- *Section 52.5: Functional description*
- *Section 52.6: Initialization and application information*

52.2 Introduction to I2C

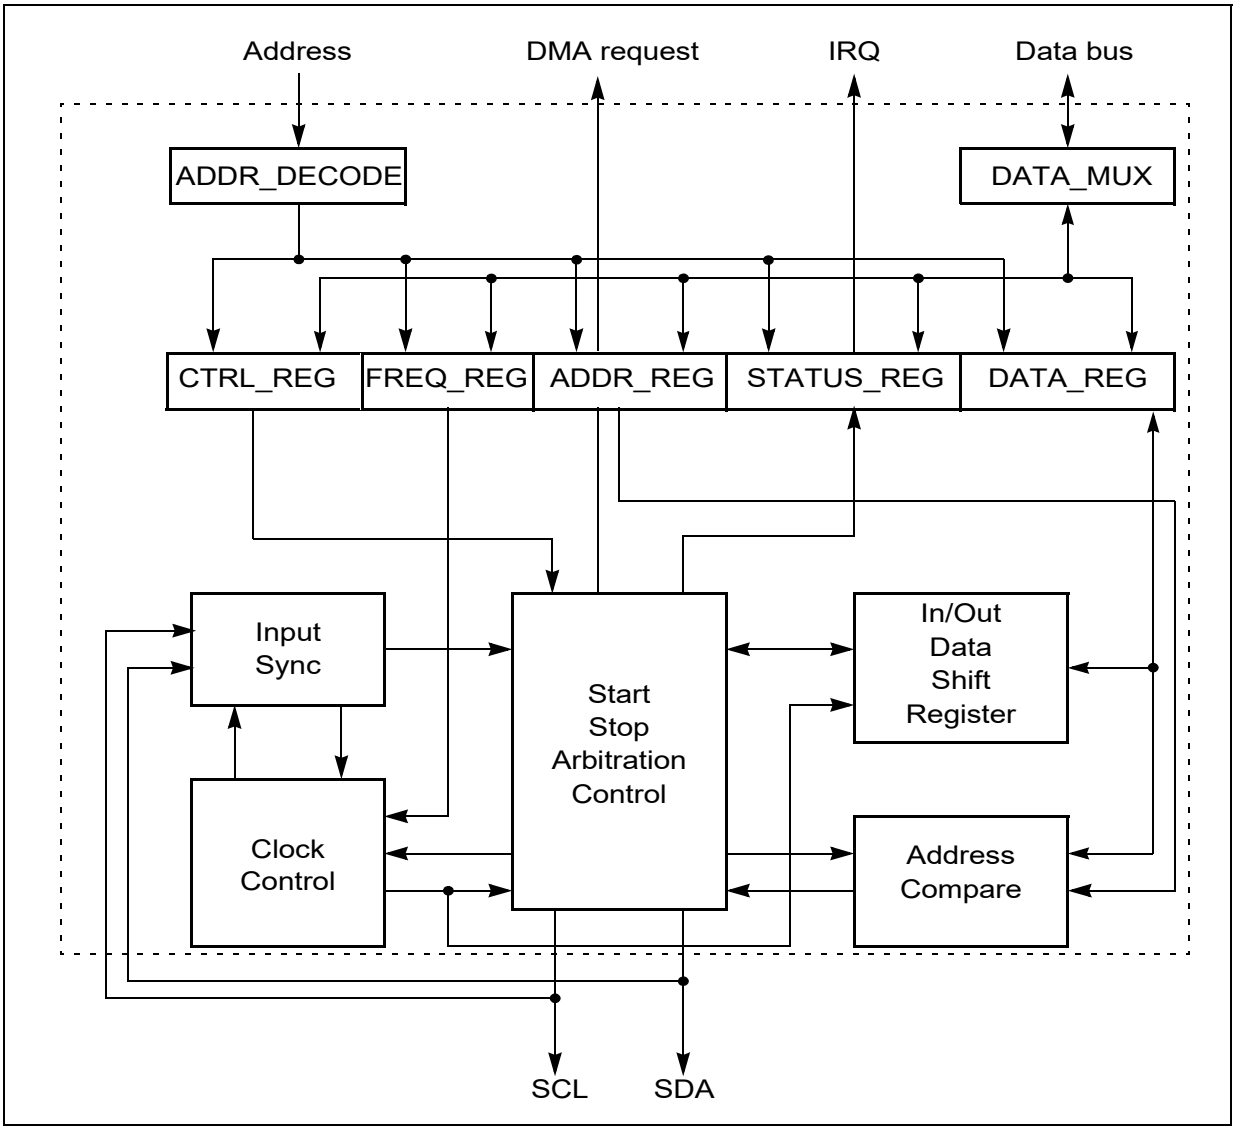
This section presents the following topics:

- *Section 52.2.1: Definition: I2C module*
- *Section 52.2.2: Advantages of the I2C bus*
- *Section 52.2.3: Module block diagram*
- *Section 52.2.4: Features*
- *Section 52.2.5: Modes of operation*
- *Section 52.2.6: Definition: I2C conditions*

52.2.1 Definition: I2C module

The I^2C module is a functional unit that provides a two-wire – serial data (SDA) and serial clock (SCL) – bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

52.2.2 Advantages of the I2C bus



The synchronous, multiple-master two-wire I^2C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

52.2.3 Module block diagram

Figure 1514 shows a block diagram of the I^2C module.

Figure 1514. I²C block diagram

52.2.4 Features

The I^{2}C module has the following key features:

- Compatible with I^{2}C bus standard[y]
- Operating speeds
  - Up to 100 kbps in Standard Mode
  - Up to 400 kbps in Fast Mode
  - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

52.2.5 Modes of operation

The I^{2}C module supports the chip modes described in *Table 1586*.

Table 1586. Chip modes supported by the I^{2}C module

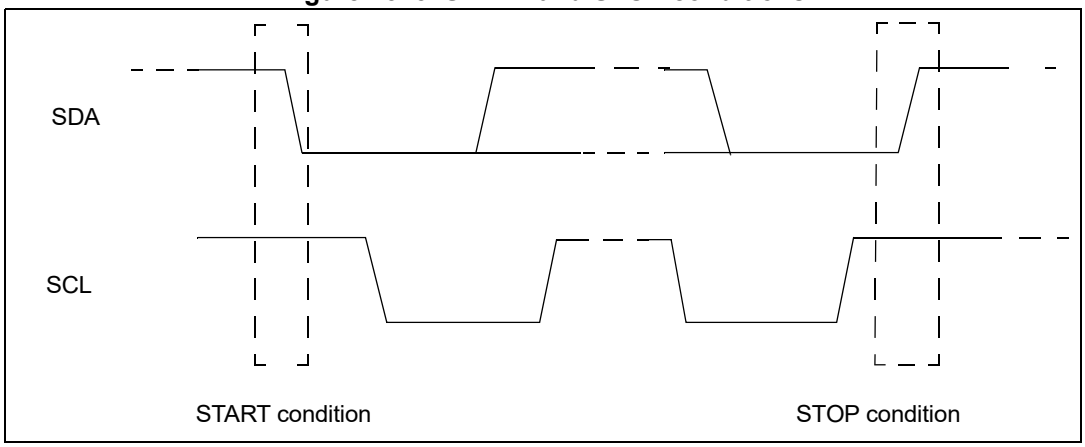
Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^{2}C module	The I^{2}C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. Refer to *Section 52.5.6: IPG STOP mode*.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging.	Refer to *Section 52.5.7: IPG DEBUG mode*.

In addition to chip modes, the I^{2}C module has several module-specific modes. These are described in *Table 1587*.

y. Compliant with I^{2}C 2.0 standard with the exception that HS (high speed) mode is not supported

Table 1587. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I²C module is the driver of the SDA line.	– Do not use the I²C module's slave address as a calling address. – The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	– Enable the I²C module before a START condition from a non-I²C master is detected. – By default the I²C module performs as a slave receiver.



52.2.6 Definition: I²C conditions

Table 1588 shows the I²C-specific conditions defined for the I²C module.

Table 1588. I²C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in *Figure 1515*.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in *Figure 1515*.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

Figure 1515. START and STOP conditions

52.3 External signal descriptions

This section presents the following topics:

- *Section 52.3.1: Signal overview*
- *Section 52.3.2: Detailed external signal descriptions*

52.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, refer to the data sheet for this chip.

52.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in *Table 1589*.

Table 1589. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

52.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- *Section 52.4.1: I2C memory map*
- *Section 52.4.2.1: Register accessibility*
- *Section 52.4.2.2: I2C Bus Address register (IBAD)*
- *Section 52.4.2.3: I2C Bus Frequency Divider register (IBFD)*
- *Section 52.4.2.4: I2C Bus Control Register (IBCR)*
- *Section 52.4.2.5: I2C Bus Status Register (IBSR)*
- *Section 52.4.2.6: I2C Bus Data I/O Register (IBDR)*
- *Section 52.4.2.7: I2C Bus Interrupt Config register (IBIC)*
- *Section 52.4.2.8: I2C Bus Debug register (IBDBG)*

52.4.1 I^2C memory map

The memory map for the I^2C module is given below in *Table 1590*. The total address for each register is the sum of the base address for the I^2C module and the address offset for each register.

Table 1590. I²C memory map

Address Offset	Register	Section
0x0000	I²C Bus Address Register (IBAD)	*Section 52.4.2.2*
0x0001	I²C Bus Frequency Divider Register (IBFD)	*Section 52.4.2.3*
0x0002	I²C Bus Control Register (IBCR)	*Section 52.4.2.4*
0x0003	I²C Bus Status Register (IBSR)	*Section 52.4.2.5*
0x0004	I²C Bus Data I/O Register (IBDR)	*Section 52.4.2.6*
0x0005	I²C Bus Interrupt Config Register (IBIC)	*Section 52.4.2.7*
0x0006	I²C Bus Debug Register (IBDBG)	*Section 52.4.2.8*
0x0007–0x3FFF	Reserved(1)	

1. If enabled at the SoC level, reads or writes to these registers will cause bus aborts. Refer to the System Services Module documentation for more details.

52.4.2 Registers definition

52.4.2.1 Register accessibility

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

52.4.2.2 I²C Bus Address register (IBAD)

This register contains the address the I²C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0000

	0	1	2	3	4	5	6	7
R	ADR							0
W								
Reset	0	0	0	0	0	0	0	0

Figure 1516. I²C Bus Address register (IBAD)

Table 1591. IBAD field descriptions

Field	Description
0:6 ADR	Slave Address Specific slave address to be used by the I^2C Bus module. **Note:** The default mode of I^2C Bus is slave mode for an address match on the bus.

52.4.2.3 I^2C Bus Frequency Divider register (IBFD)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0001

	0	1	2	3	4	5	6	7
R W	IBC							
Reset	0	0	0	0	0	0	0	0

Figure 1517. I^2C Bus Frequency Divider register (IBFD)

Table 1592. IBFD field descriptions

Field	Description
0:7 IBC	I-Bus Clock Rate This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 0:1 Selects the prescaled shift register (refer to *Table 1601*) 2:4 Selects the prescaler divider (refer to *Table 1602*) 5:7 Selects the shift register tap point (refer to *Table 1603*)

52.4.2.4 I^2C Bus Control Register (IBCR)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0002

	0	1	2	3	4	5	6	7
R	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	0
W						RSTA		
Reset	1	0	0	0	0	0	0	0

Figure 1518. I^2C Bus Control Register (IBCR)

Table 1593. IBCR field descriptions

Field	Description
0 MDIS	Module disable This bit controls the software reset of the entire I^2C Bus module. 0 The I^2C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect. 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled. **Note:** If the I^2C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I^2C Bus module losing arbitration, after which, bus operation would return to normal.
1 IBIE	I-Bus Interrupt Enable 0 Interrupts from the I^2C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I^2C Bus module are enabled. An I^2C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
3 TXRX	Transmit/Receive mode select This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
4 NOACK	Data Acknowledge disable This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I^2C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **Note:** Values written to this bit are only used when the I^2C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, acknowledge bit = 1).

Table 1593. IBCR field descriptions (continued)

Field	Description
5 RSTA	Repeat Start Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect 1 Generate repeat start cycle
6 DMAEN	DMA Enable When this bit is set, the DMA Tx and Rx lines will be asserted when the I^2C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I^2C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. Refer to the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals

52.4.2.5 I^2C Bus Status Register (IBSR)

Access:
Supervisor mode only
(user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Offset: 0x0003

	0	1	2	3	4	5	6	7
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

Figure 1519. I^2C Bus Status Register (IBSR)

Table 1594. IBSR field descriptions

Field	Description
0 TCF	Transfer complete While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **Note:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
3 IBAL	Arbitration Lost The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: – SDA is sampled low when the master drives a high during an address or data transmit cycle. – SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. – A start cycle is attempted when the bus is busy. – A repeated start cycle is requested in slave mode. – A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
5 SRW	Slave Read/Write When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave

Table 1594. IBSR field descriptions (continued)

Field	Description
6 IBIF	I-Bus Interrupt Flag The IBIF bit is set when one of the following conditions occurs: – Arbitration lost (IBAL bit set) – Byte transfer complete (TCF bit set and DMAEN bit not set) – Addressed as slave (IAAS bit set) – NoAck from Slave (MS & Tx bits set) – I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

52.4.2.6 I^2C Bus Data I/O Register (IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

Note: The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/$\overline{W}$ bit (in position D0).

Note: When the I^2C is configured in master mode and receiving data from a slave that is transmitting data bytes on an irregular basis, the master cannot know whether the data received in the IBDR is the old latched data or the new data received from the slave. To avoid this, 2 consecutive intermittent data bytes from slave should be different.

Access:
Supervisor mode only

Table 1597. IBDBG field descriptions

Field	Description
6 IPG_DEBUG_HALTED	Debug Halted Bit This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
7 IPG_DEBUG_EN	Debug enable bit This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode **Note:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited.

52.5 Functional description

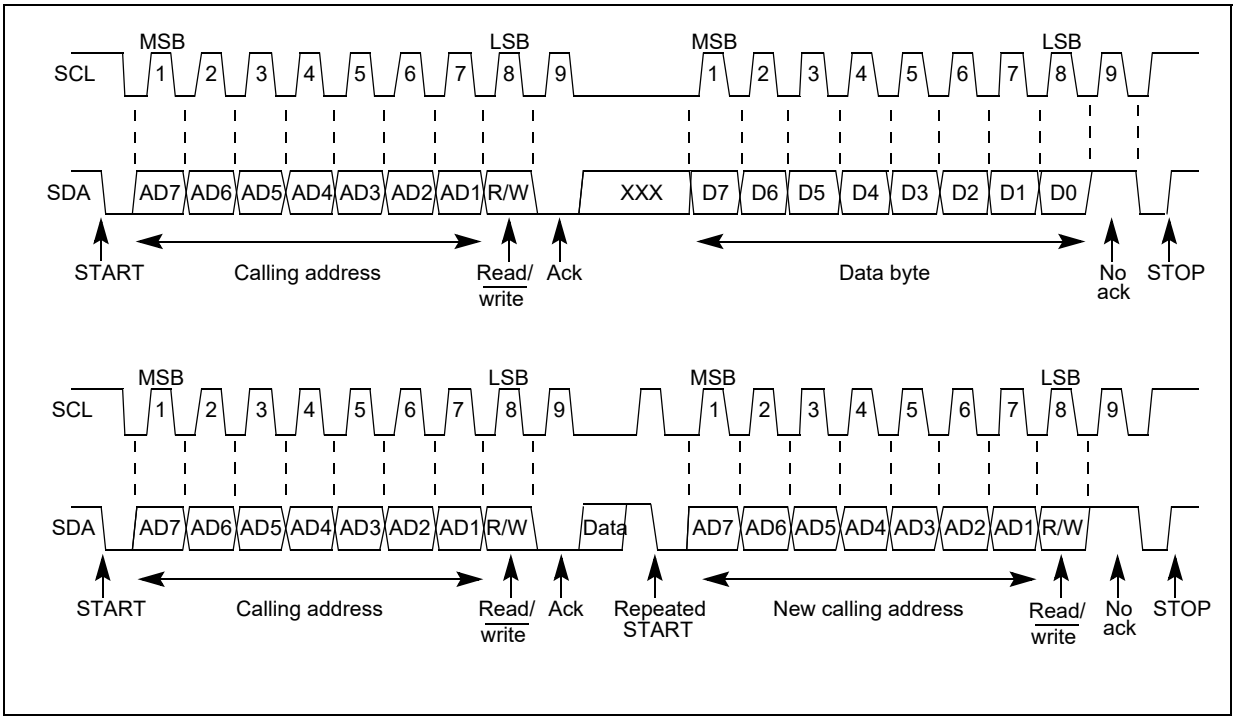
This section presents the following topics:

- *Section 52.5.1: Notes about module operation*
- *Section 52.5.2: Transactions*
- *Section 52.5.3: Arbitration procedure*
- *Section 52.5.4: Clock behavior*
- *Section 52.5.5: Interrupts*
- *Section 52.5.7: IPG DEBUG mode*
- *Section 52.5.8: DMA interface*

52.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

52.5.2 Transactions



This section presents the following topics:

- *Section 52.5.2.1: Protocol overview*
- *Section 52.5.2.2: Transaction protocol definitions*
- *Section 52.5.2.4: High-level protocol steps*
- *Section 52.5.2.5: START condition*
- *Section 52.5.2.6: Slave address transmission*
- *Section 52.5.2.7: Data transmission*
- *Section 52.5.2.8: STOP condition*
- *Section 52.5.2.9: Repeated START condition*

52.5.2.1 Protocol overview

Figure 1523 shows the behavior of SCL and SDA during a typical I^2C transaction.

Figure 1523. I²C transaction protocol

52.5.2.2 Transaction protocol definitions

This section defines several important terms presented in *Figure 1523*.

Table 1598. I²C definitions

Term	Definition
START	A START condition, as defined in *Section 52.2.6: Definition: I2C conditions*"
STOP	A STOP condition, as defined in *Section 52.2.6: Definition: I2C conditions*"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in *Section 52.5.2.3: I2C calling address requirements*."
Read/write (R/$\overline{W}$)	A bit that specifies the direction of the data transfer to the slave as follows: 0 The data is being transferred from the master to the slave ("write"). 1 The data is being transferred from the slave to the master ("read").
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

52.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

52.5.2.4 High-level protocol steps

The I^{2}C protocol conceptually supports two types of transfers, which are illustrated in *Figure 1523*. The significant steps in these transfers are presented in *Table 1599*. Details of each of these steps are presented in subsequent sections.

Table 1599. I^{2}C high-level protocol steps

Standard transfer	Repeated START transfer
1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. STOP condition 6. (repeat Steps 1–4)	1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. Repeated START condition 6. (repeat Steps 2–4 as needed) 7. STOP condition 8. (repeat Steps 1–7)

52.5.2.5 START condition

When the bus is free, that is no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (refer to *Section 52.2.6*). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

52.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (refer to *Section 52.5.2.5*). The process of slave address transmission is presented in *Table 1600*.

Table 1600. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/$\overline{W}$ bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: – The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. – The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

52.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/$\overline{W}$ bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

52.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (refer to *Section 52.2.6*). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, refer to *Section 52.5.2.9*.

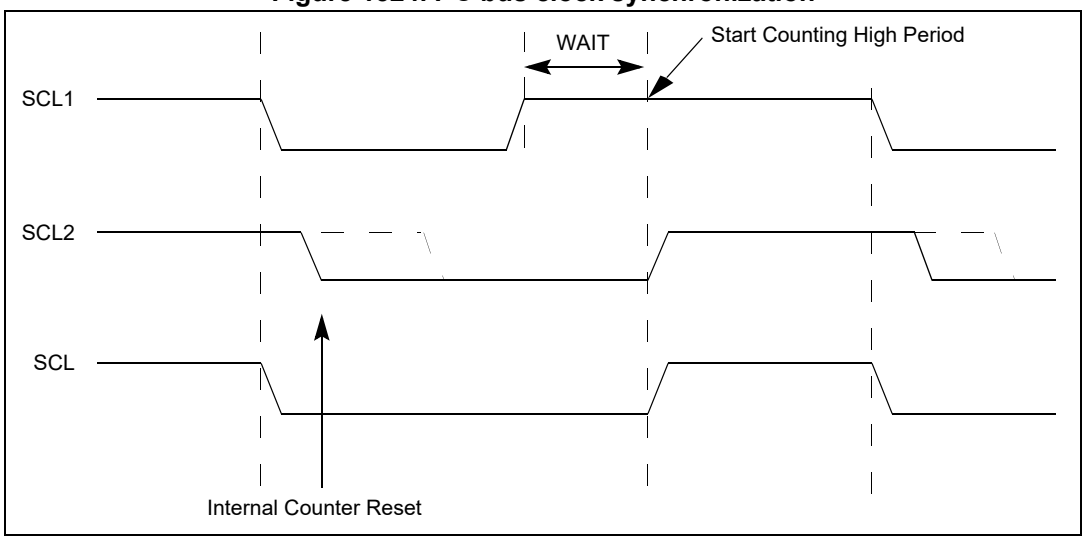
52.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of *Figure 1523*.

52.5.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic “1” while another master transmits logic “0”. The losing masters immediately switch over to slave receive mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

52.5.4 Clock behavior



This section presents the following topics:

- *Section 52.5.4.1: Clock synchronization*
- *Section 52.5.4.2: Clock stretching*
- *Section 52.5.4.3: Handshaking*
- *Section 52.5.4.4: Clock rate and IBFD settings*

52.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (refer to *Figure 1524*). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

Figure 1524. I²C bus clock synchronization

52.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

52.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

52.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (refer to *Section 52.4.2.3: I2C Bus Frequency Divider register (IBFD)*).

Table 1601. I-Bus multiplier factor

IBC[0:1]	MUL

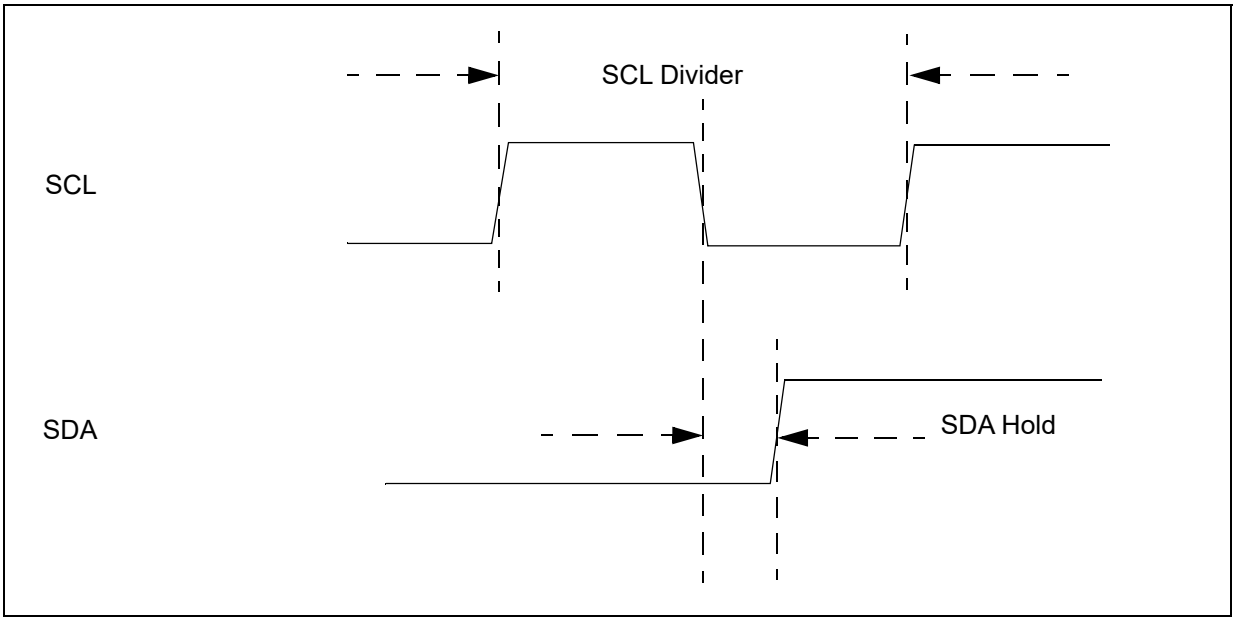
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of *Table 1602*. All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in *Table 1602*. The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

Figure 1525. SDA Hold time



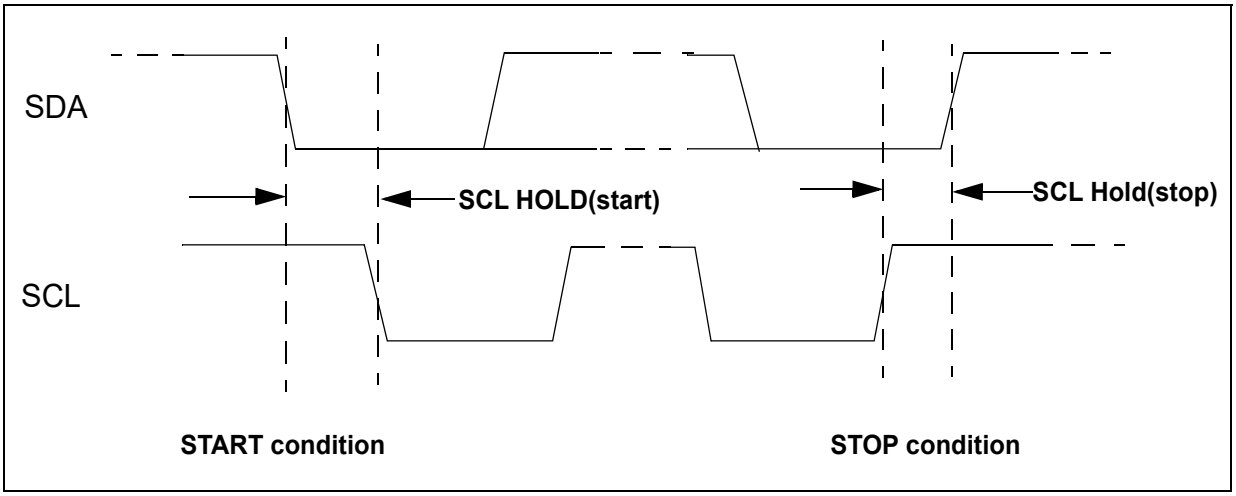


Figure 1526. SCL divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

Equation 68 SCL Divider = MUL x {2 x (scl2tap + [(SCL_Tap -1) x tap2tap] + 2)}

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in *Table 1604*. The equation used to generate the SDA Hold value from the IBFD bits is:

Equation 69 SDA Hold = MUL x {scl2tap + [(SDA_Tap - 1) x tap2tap] + 3}

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

Equation 70 SCL Hold(start) = MUL x [scl2start + (SCL_Tap - 1) x tap2tap]

Equation 71 SCL Hold(stop) = MUL x [scl2stop + (SCL_Tap - 1) x tap2tap]

Table 1604. I²C divider and hold values

52.5.5 Interrupts

This section presents the following topics:

- *Section 52.5.5.1: Interrupt vector*
- *Section 52.5.5.2: Interrupt description*

52.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 1605. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I^2C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

52.5.5.2 Interrupt description

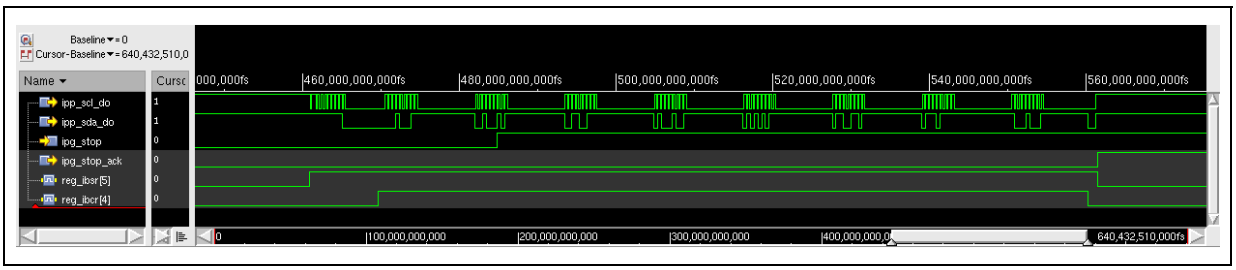
There are five types of internal interrupts in the I^2C. The interrupt service routine can determine the interrupt type by reading the Status register.

I^2C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I^2C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

52.5.6 IPG STOP mode



This mode allows the software to put the I^2C module in power-down state. Once the STOP request is asserted, the I^2C module comes to a graceful halt after completing all the ongoing transactions.

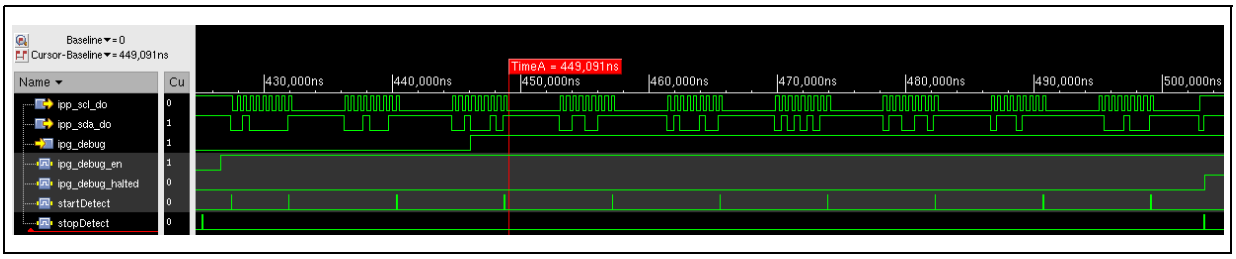
As soon as the I^2C module enters IPG STOP mode:

- The I^2C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I^2C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. Refer to *Figure 1527* for more details.

Figure 1527. I^2C stop mode behavior when master is in Rx and slave is in Tx

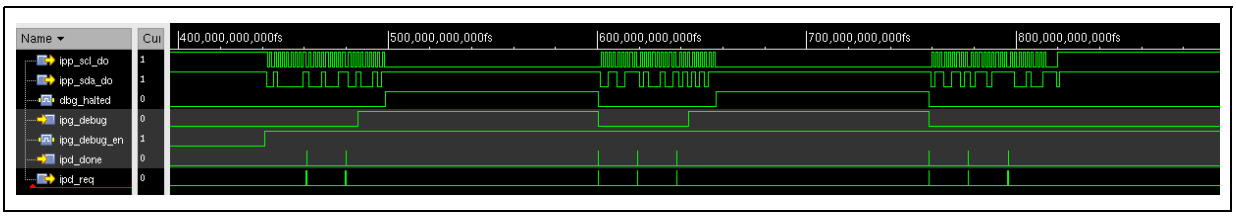
52.5.7 IPG DEBUG mode



This mode allows CPU to debug the I²C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I²C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I²C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.



The I²C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. Refer to the simulation result in *Figure 1528* for more details.

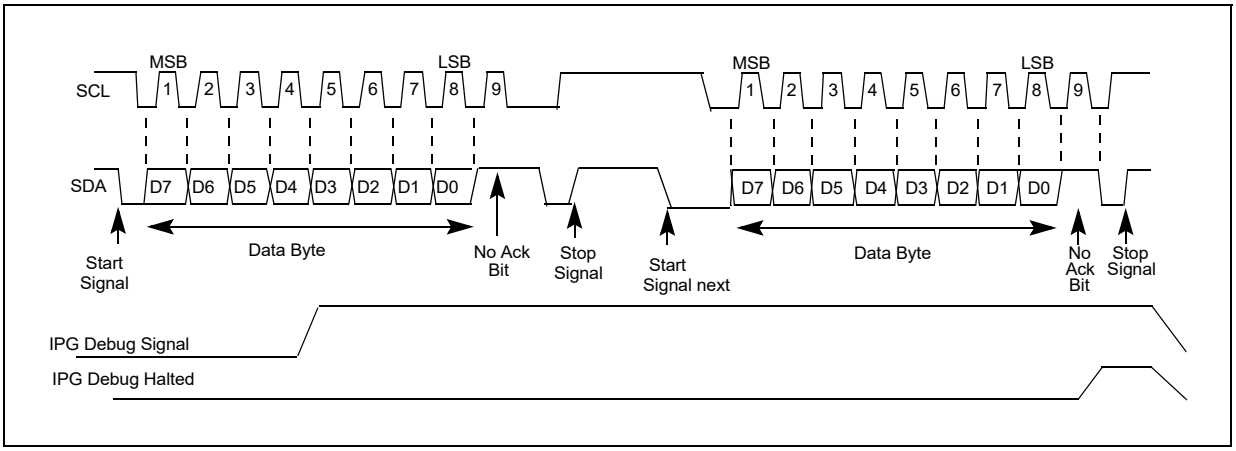
Figure 1528. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I²C module enters IPG DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits IPG DEBUG mode, transmission or reception of the remaining bytes resumes. Refer to the simulation snapshot shown in *Figure 1529* for details where the I²C is transmitting 8 bytes using DMA and IPG DEBUG mode is requested while a second byte is being transmitted. IPG DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits IPG DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

Figure 1529. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I²C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I²C module has entered the IPG DEBUG mode. Refer to *Figure 1530* for more details.

Figure 1530. PG DEBUG mode



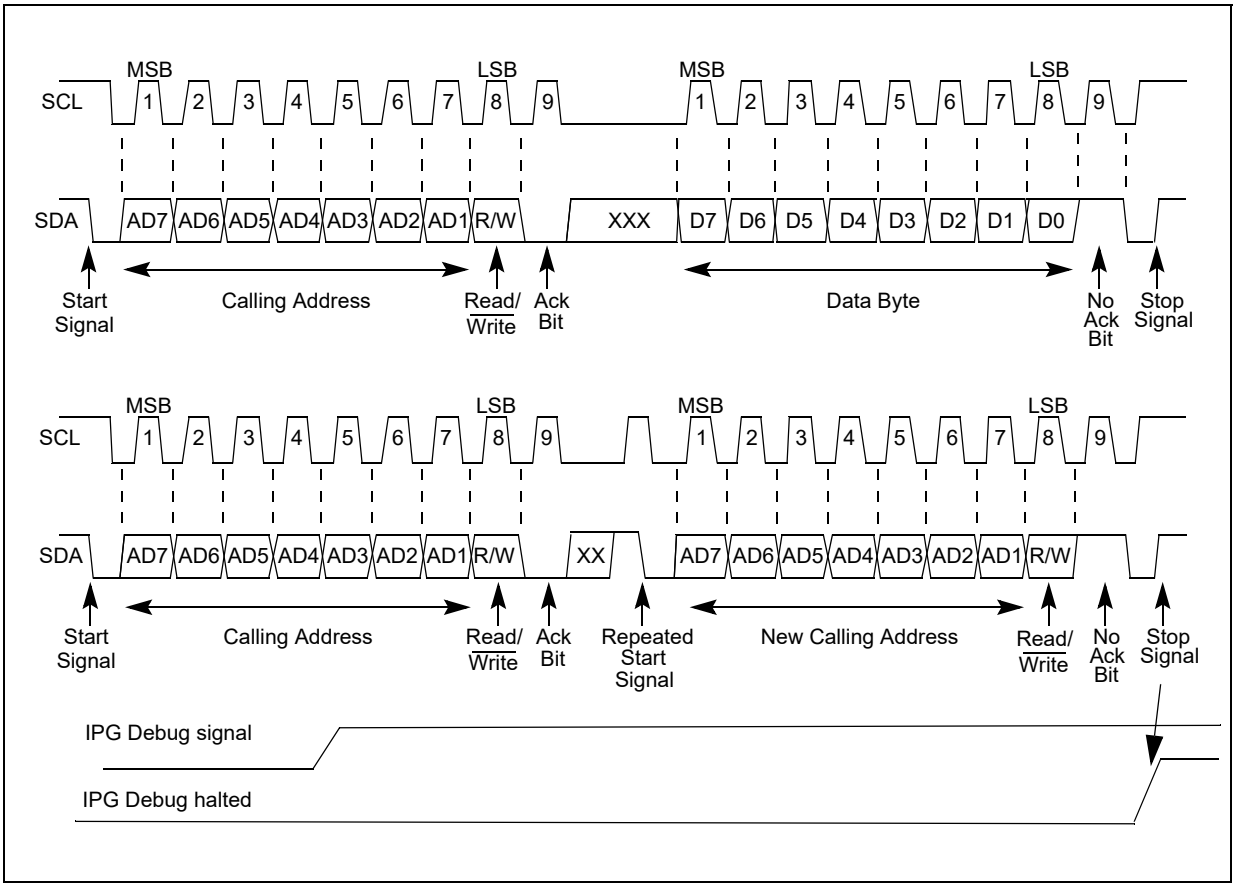


Figure 1531 shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters IPG DEBUG mode.

Figure 1531. IPG debug mode with repeated start

52.5.8 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (refer to *Section 52.6.5*). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

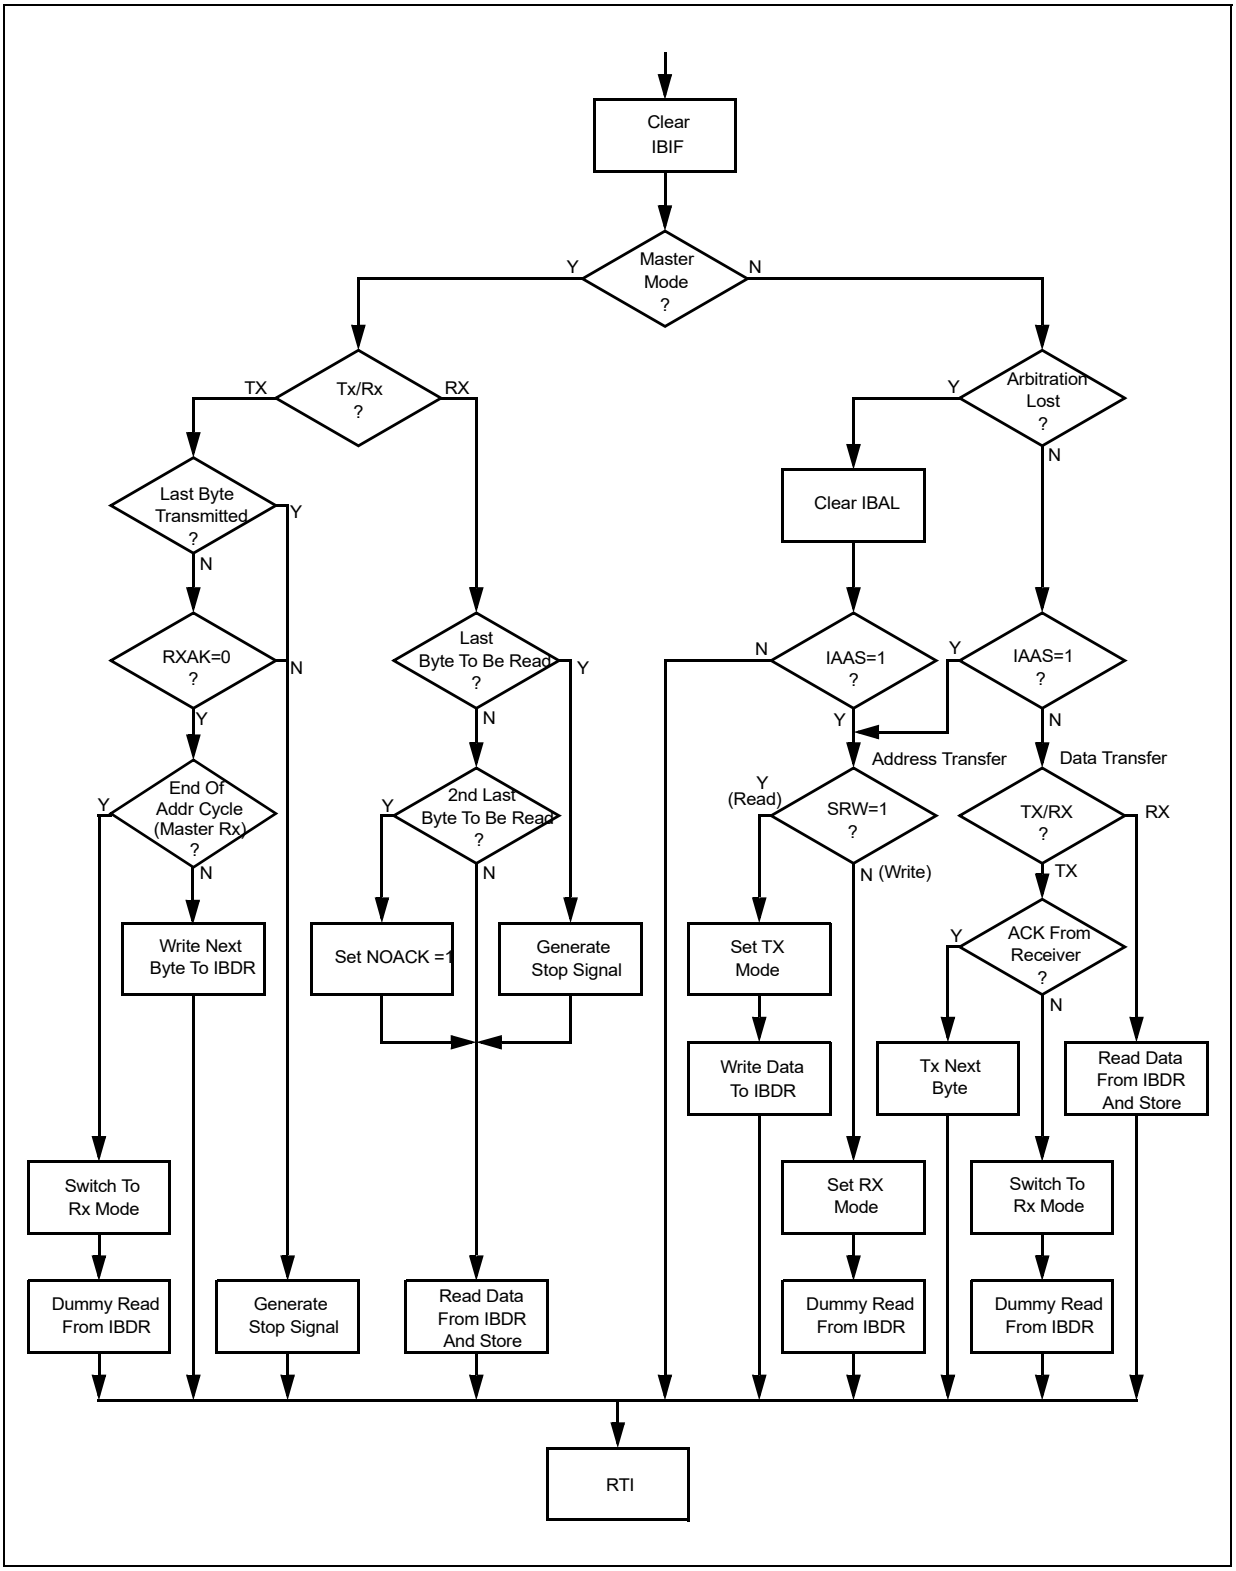
The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the *Section 52.6*.

52.6 Initialization and application information



This section presents the following topics:

- *Section 52.6.1: Recommended interrupt service flow*
- *Section 52.6.2: General programming guidelines (for both master and slave mode)*
- *Section 52.6.3: Programming guidelines specific to master mode*
- *Section 52.6.4: Programming guidelines specific to slave mode*
- *Section 52.6.5: DMA application information*

52.6.1 Recommended interrupt service flow

Figure 1532 shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

Figure 1532. Recommended I²C interrupt service routine flowchart

52.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^{2}C module in both master and slave mode. It presents the following topics:

- *Section 52.6.2.1: Initializing the I2C module*
- *Section 52.6.2.2: Software response after a transfer*

52.6.2.1 Initializing the I^{2}C module

The following sequence initializes the I^{2}C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[IBDIS] bit to enable the I^{2}C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

52.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^{2}C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^{2}C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^{2}C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a “Transfer Complete” interrupt occurs at the end of the address cycle, the master will always be in transmit mode, that is the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

52.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- *Section 52.6.3.1: Generating START*
- *Section 52.6.3.2: Transmit/receive sequence*
- *Section 52.6.3.3: Generating STOP*
- *Section 52.6.3.4: Generating repeated START*
- *Section 52.6.3.5: Loss of arbitration*

52.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB = 0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (that is the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                  // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1      // master and transmit mode, that is,
                                      // generate start condition
IBDR = calling_address                // send the calling address to the data
register
while (bit 5, IBSR ==0)               // wait in loop for IBB flag to be set
```

52.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 1606. Master transmit sequence

Step	Action
a	Use the IBFD register to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Use the IBCR to select Master mode, Transmit mode and interrupt enable.
d	Write 0 to IBSR[IBIF].

Table 1606. Master transmit sequence (continued)

Step	Action
e	Write data to IBDR.
f	Observe changes in IBSR[TCF]: – When IBSR[TCF] becomes 0, the transfer is in progress. – When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until IBSR[IBIF] = 1.
h	Read the fields in the IBSR to determine what happened: – If TCF = 1, the transfer completed. – If RXAK = 1, a No Acknowledge condition occurred. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** Address Detect (IAAS = 1) can be ignored for master mode (it is valid only for slave mode).
i	Examine IBSR[RXAK] for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 1607. Master receive sequence

Step	Action
a	Follow steps a through i in *Table 1606* for address dispatch.
b	Write 0 to IBSR[IBIF].
c	Write 0 to IBCR[TXRX] to select Receive mode.
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** The No Acknowledge condition (RXAK = 1) can be ignored in receive mode.
h	Read the IBDR to determine the data received from the slave.

Table 1608. Slave transmit sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
c	Write data to IBDR.
d	Wait until IBSR[IBIF] = 1.

Table 1608. Slave transmit sequence (continued)

Step	Action
e	Wait until IBSR[RXAK] = 0.
f	Write 0 to IBSR[IBIF].
g	Repeat steps c through for the next consecutive data transfers.

Table 1609. Slave receive sequence

Step	Action
a	Write 0 to IBCR[IBDIS] to enable the I2C interface system.
b	Examine fields in the IBSR as follows: – If IAAS = 1, examine IBSR[SRW]. – If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
c	Write 0 to IBSR[IBIF].
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: – If TCF = 1, the reception completed. – If IBB = 0, the bus transitioned from Busy to Idle state. – If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **Note:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read the IBDR to determine the data received from the master.

52.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the “master” device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or          // check to see if all data bytes have been
transmitted
    (bit 0, IBSR == 1) {       // or if no ACK generated
         clear bit 5, IBCR     // generate stop condition
        }
else {
IBDR = data_to_transmit        // write byte of data to DATA register
         tx_count --           // decrement counter
      }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --                  // decrease the rx counter
if (rx_count ==1)            // 2nd last byte to be read ?
   bit 3, IBCR = 1           // disable ACK
if (rx_count == 0)           // last byte to be read ?
  bit 5, IBCR = 0            // generate stop signal
else
data_received = IBDR         // read RX data and store
```

52.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown below.

```
bit 2, IBCR = 1              // generate another start (restart)
IBDR == calling_address      // transmit the calling address
```

52.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL = 1 and MS/SL = 0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

52.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an “end of data” signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

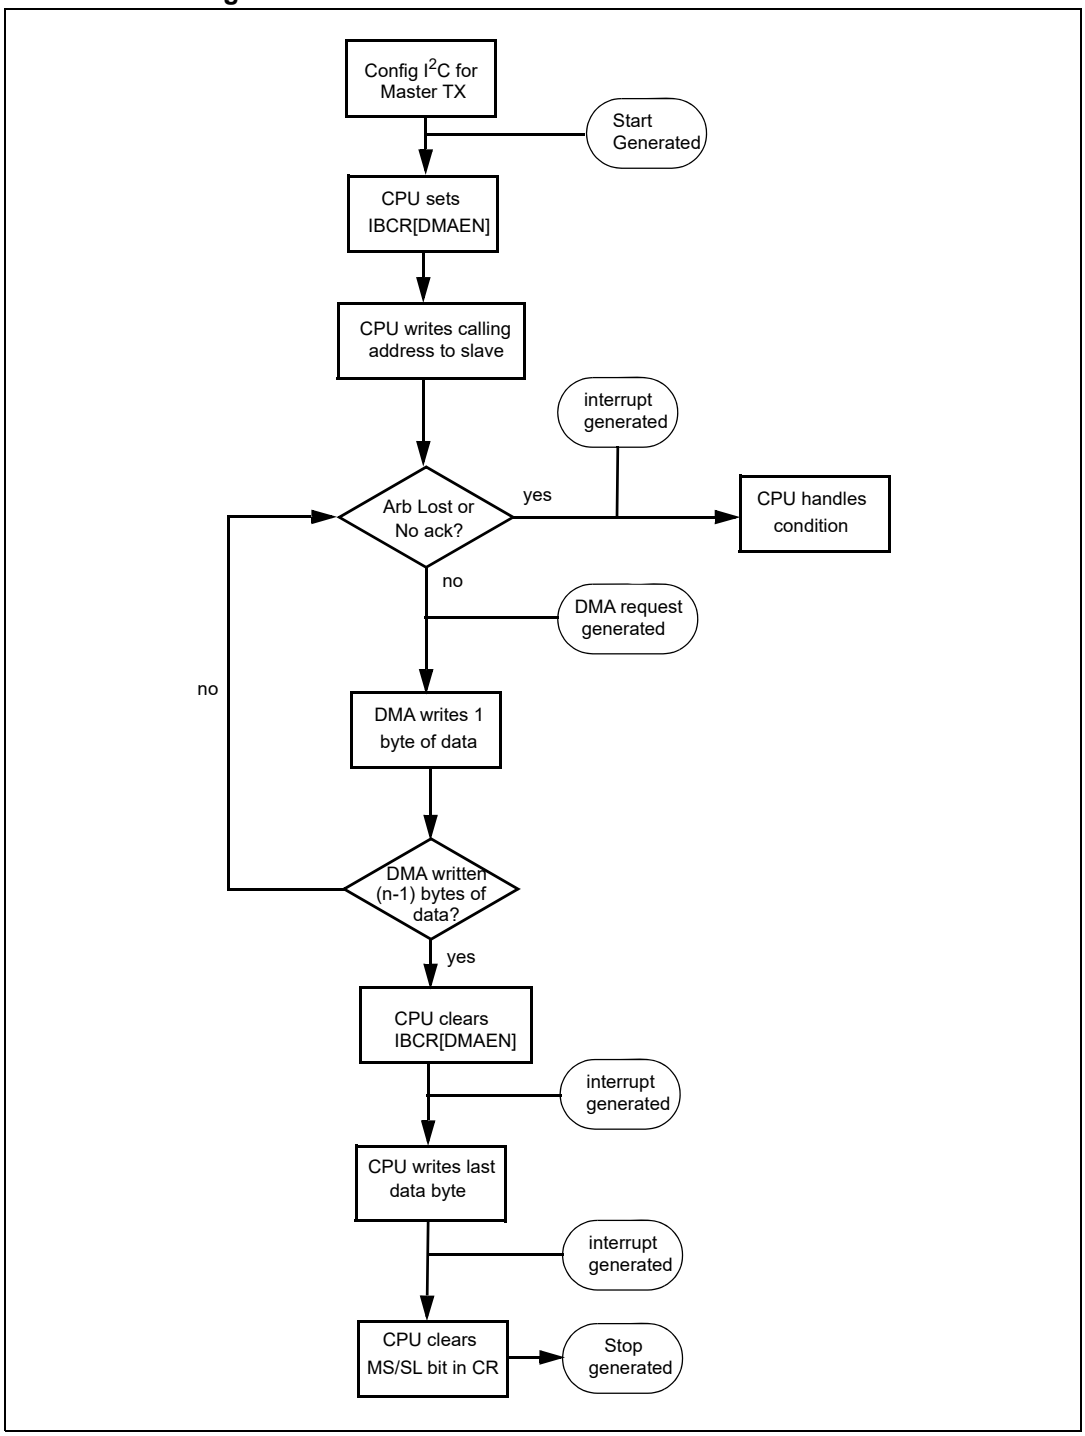
52.6.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master

transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.



The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- *Section 52.6.5.1: DMA mode, master transmit*
- *Section 52.6.5.2: DMA mode, master reception*
- *Section 52.6.5.3: Exiting DMA mode, system requirement considerations*

52.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit ‘n’ data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

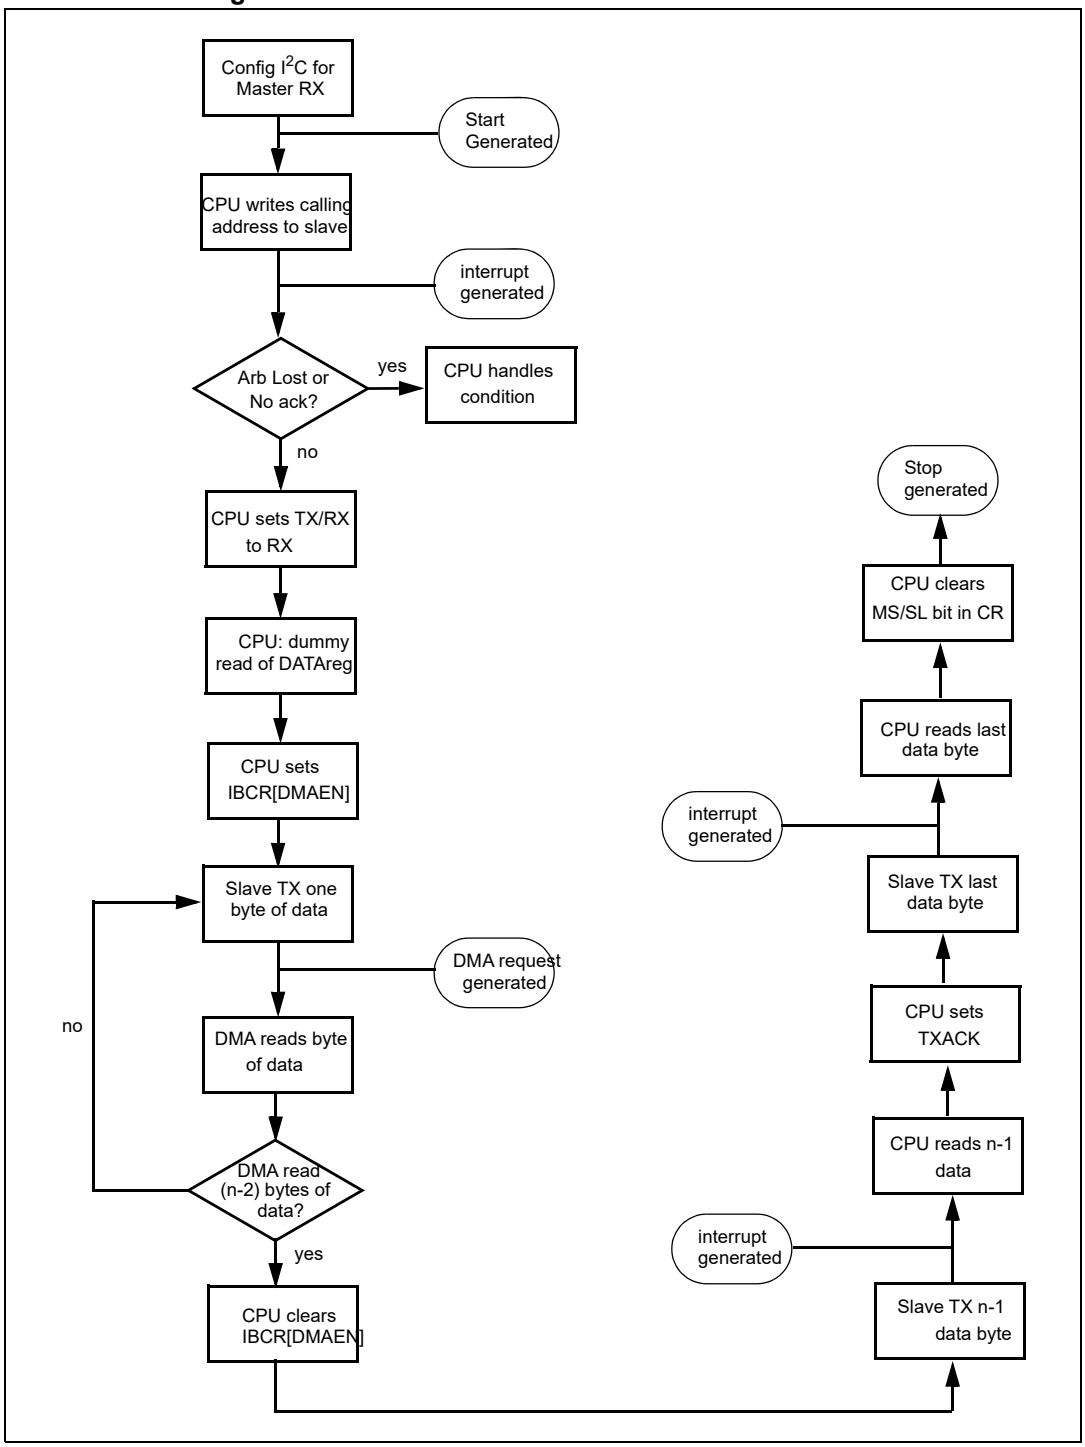


Figure 1533. Flow-Chart of DMA mode master transmit

52.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive ‘n’ data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

Figure 1534. Flow-Chart of DMA mode master receive

52.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^{2}C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is

that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For “fast reaction” the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

Equation 72 $T_R = 8 \times T_{SCL}$

In fast mode, with 400 kbit/s, T_{SCL} is 2.5 µs, so T_R is 20 µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note: The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

Note: Make sure, at system level, that no higher priority DMA requests occur between the two linked TCDs as they could create a slow reaction scenario again.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload

the initial TCD upon completion, bringing the system back into a “ready-for-I^2C-transfer” state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note: Make sure, at system level, that no higher priority DMA requests occur during the scatter/gather process, as they could create a slow reaction scenario again.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

Equation 73 $4 \times T_{IPI} = 4 / 16 \text{ MHz} = 250 \text{ ns}$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

Equation 74 $8 \times T_{AHB} = 8 / 32 \text{ MHz} = 250 \text{ ns}$

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I2C could be faster):

Equation 75 $4 \times T_{IPI} = 4/150 \text{ MHz} = 26.6 \text{ ns}$

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

Equation 76 $4 \times T_{AHD} = 4/150 \text{ MHz} = 26.6 \text{ ns}$

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

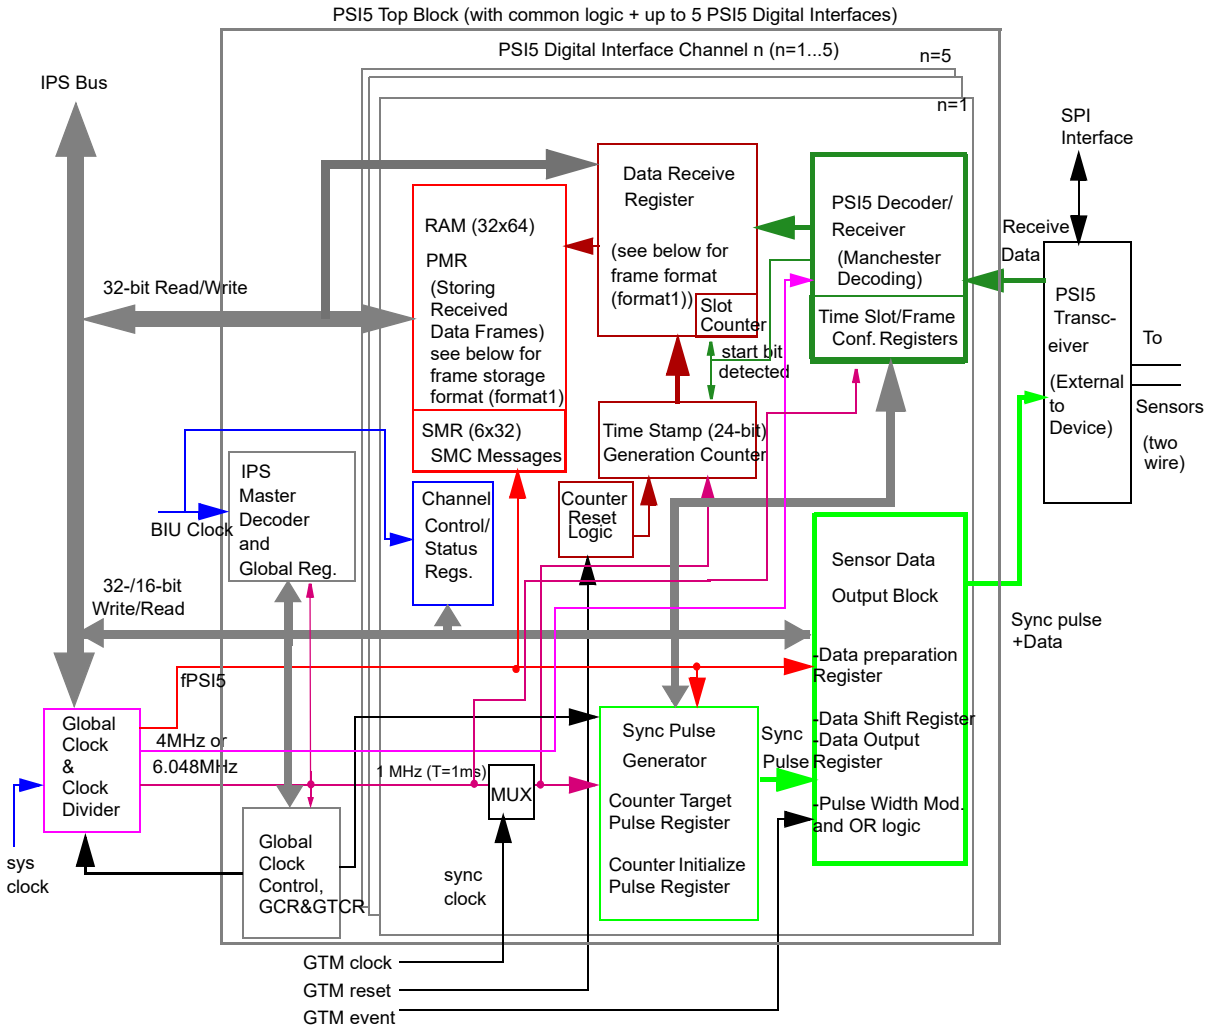
53 Peripheral Sensor Interface (PSI5)

53.1 Introduction

The PSI5 interface offers power supply and data transfer between the application and multiple sensors over a two-wire interface. Data transmission from the application to the sensor or sensors is achieved through modulation of the power supply voltage (sync pulse). Data reception from the sensor or sensors to the application is achieved through modulation of the current drawn by a sensor using Manchester encoding.

At the system level, the PSI5 interface consists of mechanisms integrated on the microcontroller and an external physical layer that provides the high-voltage supply and converts the current drawn by the sensor into a digital Manchester-encoded data stream.

53.1.1 Overview



The PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make the PSI5 also suitable for many other automotive sensor applications. The development goal of the PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented free of charge.

The main features of the PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s or optional 189 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

In short, PSI5 standardizes the low-level communication between peripheral sensors and electronic control units. Note that the physical layer for the IP (transceiver) is to be implemented separately outside the IP.

Figure 1535. PSI5 digital interface block diagram

Format1: Stored in RAM Registers

O	F	EM	E	T	Slot Counter	Time Stamp	Header+ Sensor Data(i)	CRC or Parity bits	C

1. **"C"** is set to 1 when CRC or Parity check identifies Error.
2. **"T"** is set to 1 at timing errors of the incoming frame.
3. **"E&EM"** is set to 1 at electric errors at any bit PSI5/SMC
4. **"F"** is set to 1 if no frame received in the slot.
5. **"O"** is set to 1 if any new frame overwrites previous Unread.Fr.
6. **"Slot Counter"** Gives the slot number in which the start bits of the frame were detected.
7. **"Sensor Data"** are stored in RAM automatically after all data bits are received in data receive register.
8. **"Time Stamp"** is appended to received frame in once start bits are received or rise edge of sync pulse.

Note: GTM is not supported by this device

53.1.2 Features

- IPS interface for register read/write (big endian)
- Supports bidirectional full duplex operations, but with differing baud rate—low, ECU-to-sensor, fast sensor to ECU
- Manchester decoder operating at both 125 Kbit/s and 189 Kbit/s bit rates with ×32 sample clock rate
- One 64-bit sensor data receive register to which the decoded received sensor data—including header, data, timestamp, frame counter, status bits (E, EM, T, C, F) and CRC, but not including start bits—are written
- A 24-bit time stamp register with a 1 µs resolution. When first rising edge of start bits (S0) of a message or the rising edge of the SYNC pulse is recognized, the value in the time stamp register will be written to the data receive register
- Single 32 × 64-bit RAM buffer for storing (moving) content of the data receive register once end of message is recognized
  - Related to each RAM buffer are two diagnostic registers, N and EI. Register N is used to identify the occurrence of new messages in the corresponding RAM buffer, while register EI identifies the error status of these messages. The errors that can set the EI register bits are the F (no frame), E (electrical error), EM (electrical error for SMC bits embedded in PSI5 messages), T (Timing bit error) and C (CRC error). Which of these errors actually set the EI register bits is configurable.
- DMA support for transferring RAM data (including diagnostic data) to system memory
- DMA transfer through IPS bus
- Support for optional serial messaging channel (SMC) and additional logic to extract SMC frames from PSI5 frames
- Operating modes supported:
  - Asynchronous mode (sensor periodically sends data, no sync pulse, one sensor per interface)
  - Synchronous mode (sync pulse generated, multiple sensor per interface)
- Sync pulse generation for synchronous modes:
  - The start of each time slot (1 to 6) (see *Figure 1582*) on the bus (after the end of the sync pulse) can be defined with a 1 µs resolution
  - The end of the last time slot on the bus can be defined with a 1 µs resolution, up to a maximum sync period time of 16 ms
  - Trigger logic to generate sync pulses
    - 16-bit Channel Trigger Counter (CTC) used to generate the sync pulses by comparing the values with CIPR and CTPR
    - Counter Initialize Pulse Register (CIPR) to allow configuration of initialization (offset) period
    - Channel Trigger Period (CTP) register to allow configuration of sync period. Value in CTP is the value to which the CTC is updated after each sync pulse generation
    - Possibility to have a common 1 MHz clock source
- An upstream register bit chain consisting of Preparation Register, Buffer Register, Shift register (output data) and pulse width modulation logic, is implemented. Using this, it is possible to send a data word to the sensors through use of data sync pulses: logic 1 with programmable data sync pulse width W1, logic 0 with programmable data sync

pulse width W0. The data sync pulse timing can be configured to be dependent on the periodic or event driven timing SYNC pulse. Further, there is no difference between timing sync pulse and data sync pulse during transmission (ECU-to-sensor communication).

53.1.3 Modes of operation

53.1.3.1 Disable mode

Disable mode in the PSI5 reduces power consumption. This mode is entered by setting GCR[GLOBAL_DISABLE_REQ]. All the channels enter Disable mode at once when this bit is set, irrespective of the setting of PCCR[PSI5_CH_EN] and PCCR[PSI5_CH_CONFIG]. In this mode the RX, TX and common time base counters are disabled for any operation. This is the default state after module reset is released. PSI5 can exit Disable mode by clearing the GLOBAL_DISABLE_REQ bit and enabling individual PSI5 channels (setting PCCR[PSI5_CH_EN]). Note that when entering Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter AND the internal sync pulse generator are, however, reset when entering Disable mode.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of PCCR[PSI5_CH_CONFIG].

53.1.3.2 Initialization/Configuration mode

This is the configuration phase, in which all PSI5 global, channel specific configuration/control registers can be written. The receiver and transmitter sub-blocks are disabled in this mode. The message receive registers/buffers can be accessed in this mode. This mode can be entered by clearing GCR[GLOBAL_DISABLE_REQ] and setting PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN]. All the channel specific control registers can be programmed only in the CONFIG mode. This prevents the software from accidentally causing a change in any critical register.

53.1.3.3 Normal mode (NORMAL mode)

In Normal mode, the receiver and the transmitter blocks become active, error handling is enabled and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. Data Preparation Register, Shift Register and data output registers are writable in this mode. Apart from them, there are some register bits that can be written in this mode also. Refer to the detailed register description. This mode can be entered clearing GCR[GLOBAL_DISABLE_REQ], clearing PCCR[PSI5_CH_CONFIG], and setting PCCR[PSI5_CH_EN].

53.1.3.3.1 PSI5 topology

The different PSI5 user operation modes define topology and parameters of the communication between ECU and sensors such as communication mode, number of data bits, error detection, cycle time, number of time slots per cycle, and bit rate.

These modes as generally denoted as

PSI5-(A / P / U / D)-dd-(P / CRC)-tttt / n(L / H)

Table 1610 provides a key for these notations.

Table 1610. Normal operating states

Communication modes		Description
A	Asynchronous mode	PSI5-A describes a point-to-point connection for unidirectional, asynchronous data transmission. Each sensor is connected to the ECU by two wires. After switching on the power supply, the sensor starts transmitting data to the ECU periodically. Timing and repetition rate of the data transmission are controlled by the sensor. No Sync pulse is send from ECU side.
P	Synchronous Parallel Bus mode	The synchronous operation modes work according to the TDMA method (Time Division Multiple Access). Each sensor is connected to the ECU by two wires. The sensor data transmission is synchronized by the ECU using voltage modulation. Synchronization (sync pulses) can be optionally used for point-to-point configurations; it is mandatory for bus modes. The sensors can be arranged as parallel bus, universal bus and daisy chain topology based on sensor addressing and interchangeability of sensors.
U	Synchronous Universal Bus mode	
D	Synchronous Daisy Chain Bus mode	
Data bits		
dd	No. of data bits	—
Error detection		
P	1 parity bit	—
CRC	3-bit Cyclic Redundancy Check (CRC)	—
Cycle time		
tttt	Cycle Time in µs	—
n	Number of time slots per cycle	—
Bit rate		
L	125 Kbit/s	—
H	189 Kbit/s	—

53.1.3.4 Stop mode

When the Stop mode request is asserted, and if there is no active PSI5 transaction ongoing, then the acknowledgment to stop the clocks is given immediately. If start bits of any PSI5 packet have been detected (successful detection of both S0 and S1) then the concerned PSI5 packet is successfully stored and then the Stop mode acknowledgment is generated by the IP. Note that for generating the acknowledgment, the IP does not wait for the complete reception of any ongoing SMC message, but only waits for the complete reception of any ongoing PSI5 packet transaction.

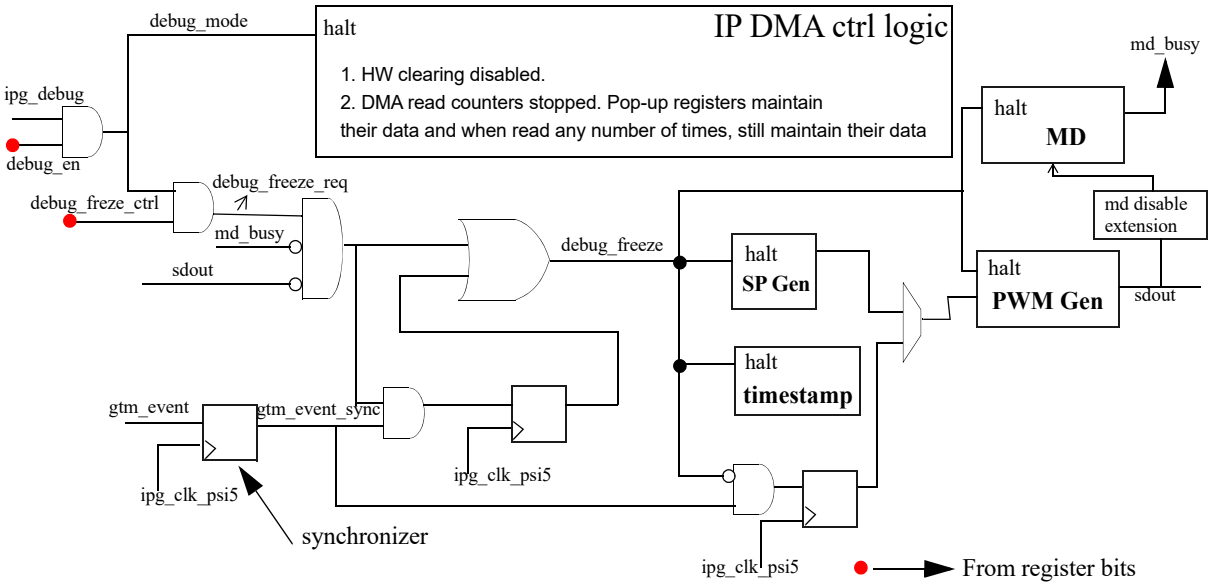
If the PSI5 transceiver is asynchronous to the PSI5 IP receiver then loss of data can result when the STOP mode is deasserted. Hence the following guidelines should be followed :

- If the IP is in synchronous mode of operation, then the IP gets resynchronized on the next available sync pulse which occurs after STOP mode deassertion. Hence the PSI5

packets occurring between the STOP mode deassertion event and the subsequent synch pulse would not be reliable and should be ignored by the application.

- If the IP is configured in asynchronous mode, then it should be ensured that the idle time gap between PSI5 packets is greater than or equal to the length of one PSI5 message. In this case only one PSI5 message will get corrupted, but the IP will sample the subsequent PSI5 messages correctly.

53.1.3.5 Debug mode



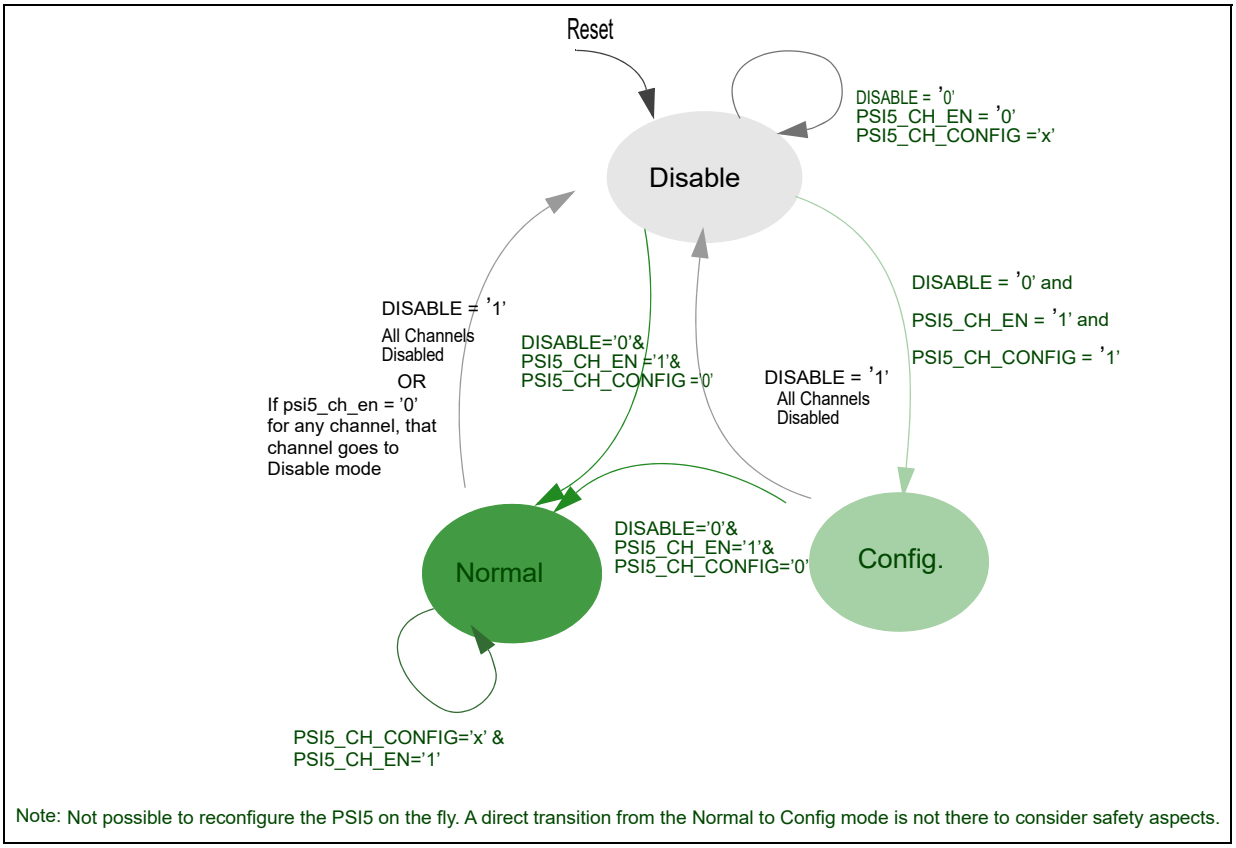
In order to enter this mode the debugger has to be connected and it has to encounter a breakpoint. In addition, the DEBUG_EN bit has to be written to 1. The DEBUG_EN bit can be written by either the CPU or by the debugger but only in Configuration mode. Once the above conditions are satisfied the IP enters the Debug Mode. There are two debugging modes available. For simplicity these are being referred to as the “Freeze” and “Open” modes. The IP enters one of the above debugging modes, based on the configuration of a register bit DEBUG_FREEZE _CTRL mentioned in the *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*.

In “Open” mode, the core of the IP keeps on working normally and all the registers are updated from the hardware; just like they were being done in the functional mode (when the IP was out of the debug mode). Thus, even a long term entry to the Debug Mode, wont affect the normal operation of the various registers that are to be updated by the hardware. Down side is that the IP can keep on changing the internal status bits and the registers as the time progresses.

In “Freeze” mode, the core of the IP, the output and the input paths are all stopped coherently. Once the input and the output paths are stopped coherently, then all the internal status bits and registers maintain their status and value irrespective of the time progression. Coherent halting of the input path would mean that there is no active reception ongoing in the Manchester decoder. Thus, if the Manchester decoder has already detected valid start bits(S0 and S1) and then there is a request to enter the “Freeze” mode, then the current reception is completed before the IP enters the Freeze mode. Coherent halting of the output path would mean that the “sdout” output pin of the IP should be at a logic 0. Once the above conditions are satisfied, only then can the IP enter the “Freeze” mode. Once the IP enters the Freeze mode, the time stamp counter is also halted.

In both the above modes, the various interface registers would be completely visible to the debugger, but debugger action would have no impact on the various status bits and counters that normally get affected by a CPU/DMA read. In this mode, the read pointers of the FIFO do not get incremented, when being read through the Pop-up registers. Thus in Debug mode, reading the DMA PSI5 Message Register (PSI5_CH0_DPMR),DMA SMC Frame Register (PSI5_CH0_DSFR) or the DMA Diagnostic Status Register (PSI5_CH0_DDSR) would keep on returning the same data. Hence the interrupts related to DMA completion operation would not get generated. Further the hardware clearing related to FAST_CLR_SMC and FAST_CLR_PSI5 bits would not have any effect and the hardware clearing would remain disabled. This is also highlighted in *Figure 1536*.

Figure 1536. Block Diagram of Debug Mode



1. “halt” in the above block means, that when “1”, then the specified block will stall its operation.
2. When “debug_mode” == 1, then the IP enters debug mode.
3. When “md_busy” is “1”, it means that MD is busy in reception of some data.
4. “ipg_debug” when “1” is an indication from the Debugger Logic that a breakpoint has been encountered and IP has to stop its operation.
5. Once the “debug_freeze_req” is asserted, then the “debug_freeze” is asserted ONLY when no pending reception is there in the MD and the “sdout” has a low level. Once the “debug_freeze” == 1, then the blocks are halted as shown above.
6. During deassertion of the “debug_freeze_req”, if the “gtm_event_sync” is already high, then the “debug_freeze” is not de-asserted until the “gtm_event” goes low. This is to prevent an “untimed” sync pulse from going to the output path.
7. “debug_en” bit allows selective disabling of the debug mode of the IP.

The debugger can write to all the registers just like the CPU can. However, no special privilege is given to the debugger as compared to the CPU. The read/write behavior of the debugger for various registers in Normal/Configuration mode is identical to the behavior of the CPU. Note that the various status bit and counter protections become active ONLY in Debug mode.

53.1.3.6 Operating modes

Figure 1537 shows the operating modes and *Table 1611* shows the state transition.

Figure 1537. Operating modes

Note: Not possible to reconfigure the PSI5 on the fly. A direct transition from the Normal to Config mode is not there to consider safety aspects.

Table 1611. State transition table

GCR [GLOBAL_DISABLE_REQ]	PCCR		State	
	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
1	x	x	x	All channel Disable
0	x	0	x	Specific channel Disable
0	1	1	Disable	Config
0	0	1	Config	Normal
0	x	1	Normal	Normal
0	0	1	Disable	Normal

53.2 External signal description

Table 1612. PSI5 port list

Name	Function	I/O
Signals to/from pads		
SDINn_PSI5_m(1)	Digital sensor data input pin of PSI5 module	I
SDOUTn_PSI5_m (1)	Digital sensor data output pin of PSI5 module (sync pulse + data)	O

1. “n” is the Channel Number and “m” is the Module Instance Number.

53.3 Memory map and register description

53.3.1 Memory map

Table 1613 shows the memory map.

Table 1613. PSI5 memory map

Address offset (hex)	Register(1)	Access(2)			Reset value(3) (hex)	Location (section)

1. Refer to the Device Configuration Chapter for instance specific PSI5 channels.
2. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot, always read as 0,” D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable. All 16-bit registers are half word/byte addressable for write. Read is always word addressable. Trying to access any register space of PSI5, other than those mentioned in the memory map, results in the generation of transfer error. Note that the generation of transfer error is confined to this scenario only.
3. In this column, the format of the reset value indicates the register width. Thus, reset values of the formats 0xHH, 0xHHHH, and 0xHHHH_HHHH, where “H” is a hexadecimal digit, indicate 8-bit, 16-bit, and 32-bit registers, respectively.
4. This register is not present if the specific instance is configured as a slave. Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave then its operating mode and staggering can only be controlled by another master instance. Refer to the Device Configuration Chapter for instance specific details.

5. The reset value is dependent on the parameter PSI5_PDIS_RST:
When PSI5_PDIS_RST = 0 then the reset value is “0x0000”(PSI5 module is enabled after reset).
When PSI5_PDIS_RST = 1 then the reset value is “0x0001” (PSI5 module is disabled after reset).
For the value of parameter PSI5_PDIS_RST refer to the Device Configuration File.
6. Not all the register bits are writable in this mode. Refer to the Register Description section for details.
7. The bits can be cleared by hardware or by software using w1c. This is controlled by the “fast_clr_xxx” bit in the PSI5_PCCR. However not all bits of this register have this behavior. Refer to the Register Description section for details.
8. Writable ONLY in Config mode for test purposes. Otherwise updated by hardware.
9. The bits are set by hardware. Alternatively the software can also set these bits by writing to the corresponding SET registers. This provision should be used only for test purpose. Clearing of these bits is either by w1c or by hardware depending on the setting of the “fast_clr_xxx” bit in the PSI5_PCCR.
10. Few bits are writable to One Shot. Refer to the Register Description section for details.
11. The bits of this register are writable ONLY when the corresponding DxR_RDY bit in the PSI5_GISR is equal to 1.
12. Refer to the Device Configuration Chapter for instance specific PSI5 reserved locations.

53.3.2 Register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

Note that, an access (read/write) to any register in the unimplemented register space will result in the generation of transfer error. All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to do a word operation on 16-bit registers will NOT result in the generation of any transfer error. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error. Trying to write to any register outside its intended mode of write (Normal/config) will be ignored without the generation of any transfer error.

For a summary of the register bit accesses in various device modes, refer to *Section 53.3.2.42: Device modes and Register bit accesses*

53.3.2.1 Global Control Register (PSI5_GCR)

The Global Control Register (PSI5_GCR) provides control functions for all the PSI5 channels simultaneously.

Address: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CTC_GED	GLOBAL_DISABLE_REQ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—(1)

Figure 1538. Global Control Register (PSI5_GCR)

1. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is “0” (PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1 then the reset value is “1” (PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST refer to the Device Configuration Chapter.

Table 1614. PSI5_GCR(1) field descriptions

Field	Description
14 CTC_GED	Channel Target Counter (CTC) Global Enable/Disable. 0 All the CTC counters having PCCR[CTC_GED_SEL] = 1 are reset. 1 Simultaneously starts the CTC of all the channels that have PCCR[CTC_GED_SEL] = 1. **Note:** This bit is writable in all modes.
15 GLOBAL_ DISABLE_REQ	PSI5 Receive Global disable request. When set, all PSI5 channels enter Disable mode (from individual Normal or Config modes) regardless of the settings of the PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN] bits. When cleared, each PSI5 channel enters Config mode or Normal mode based on the setting of the PCCR[PSI5_CH_CONFIG] bit if PCCR[PSI5_CH_CONFIG] is set for that channel; otherwise, that particular channel continues to stay in Disable mode. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is "0"(PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1then the reset value is "1"(PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST refer to the Device Configuration Chapter. This bit is writable in all the modes. 0 PSI5 channel(s) enters Normal or Config mode, depending on the value of the PCCR[PSI5_CH_CONFIG] bit. 1 All PSI5 Channels are in Disable mode. **Note:** When GLOBAL_DISABLE_REQ == 1 then all the clock enables (shown in *Figure 1603*) from the IP go to a 0 (inactive) state.

1. This register is not present if the specific instance is configured as a slave. Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave then its operating mode and staggering can only be controlled by another master instance. Refer to the Device Configuration Chapter for instance specific details.

53.3.2.2 PSI5 Channel Control Register (PSI5_CH0_PCCR)

Figure 1539. PSI5 Channel Control Register (PSI5_CH0_PCCR)

1. This is a redundant bit and RW will not have any effect.

Table 1615. PSI5_CH0_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting. **Note:** This bit is writable in Normal mode and the Config mode.

Table 1615. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
3:7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access. Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0x00 Indicates that only 1 location of the memory is available for storage. 0x1F (31) Indicates that all the 32 locations of the memory are available for storage. **Note:** Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. For more details refer to description of DMA_PM_DS_CONFIG in the DCRs. The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the Manchester decoder. The memory area above the configured MEM_DEPTH size will always be read as 0. Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
11 ERROR_SELECT4	The ERROR_SELECT bitfield indicates which of the C, E, EM, T or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_SELECT2	Error_Select[2] or EM_INT_SEL 0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_SELECT1	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.

Table 1615. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
15 ERROR_SELECT0	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_FREEZE_CTRL	0 When the IP enters the Debug mode then it goes into the "Open" mode, that is, the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. **Note:** In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 When the IP enters the "Debug mode" then it goes into the "Freeze Mode". Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the "freeze mode", if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the "sdout" line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit. 0 The 1 MHz clock generated from the CGM goes for clocking the Time Stamp Unit and sync pulse generator. 1 Reserved. **Note:** The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the CGM. The clock selected using this bit is called SP_TS_CLK.

Table 1615. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled. **Note:** This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c.

Table 1615. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
27 FAST_CLR_PSI5	This bit controls the clearing mechanism of bits in NDSR (in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR (in conf2 and conf3 modes). 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1) **Note:** This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: – In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. – In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. – In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresponding to a specific location are always cleared simultaneously. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. – In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/PMRL register. Hence the OWSR has to be cleared only by w1c. – In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. – Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c.

Table 1615. PSI5_CH0_PCCR field descriptions (continued)

Field	Description
28 BIT_RATE	This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects one of the two driven clocks (4 MHz or 6.048 MHz) in CGM. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 189 Kbit/s bit rate selected (6.048 MHz clock).
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_CONFIG	PSI5 Channel Config mode request If this bit is set (and PCCR[PSI5_CH_EN] = ’1’) this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set cannot be changed until this bit is set again after entering the Disable mode 1 (If PCCR[PSI5_CH_EN] = ’1’ and GCR[GLOBAL_DISABLE_REQ] = ’0’) - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = ’1’ and GCR[GLOBAL_DISABLE_REQ] = ’0’) PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a “0” in the Normal mode will not change the operation mode of the device. **Note:** This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details refer to *Figure 1537* and to *Table 1611*. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. 0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode. **Note:** When PSI5_CH_EN == 0 then the clock enable for that particular channel that goes from the IP, goes to “0” (inactive state). “”Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.

53.3.2.3 DMA Control Register (PSI5_CH0_DCR)

Figure 1540. DMA Control Register (PSI5_CH0_DCR)

Table 1616. PSI5_CH0_DCR field descriptions

Field	Description
3:7 DMA_PM _DS_WM	0–31 Valid Water Mark levels Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words is present. The default and minimum value of dma_pm_ds_wm is '0', that is, 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, that is, the actual watermark = 32 RAM locations. **Note:** These bits are ineffective if DMA_PM_DS_CONFIG = conf1. These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO, before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
13 IE_DMA_TF_SF	Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
14 IE_DMA_TF _PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
20 IE_DMA_PM_DS_ FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases that generate these FIFO FULL conditions, refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. **Note:** This bit is writable in Config and Normal modes.

Table 1616. PSI5_CH0_DCR field descriptions (continued)

Field	Description
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, that is, it is empty. Default value is 0. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
23 IE_DMA_PM _DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.

Table 1616. PSI5_CH0_DCR field descriptions (continued)

Field	Description
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30:31 DMA_PM_DS _CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. 00 **c**onf1 The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 conf2 After transferring the “dma_pm_ds_wm” number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 conf3 “dma_pm_ds_wm” number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 conf4 Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. **Note:** For more details refer to the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message that was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA.

53.3.2.4 DMA Status Register (PSI5_CH0_DSR)

Figure 1541 shows the DMA Status Register.

Address: 0x0010 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1541. DMA Status Register (PSI5_CH0_DSR)

Table 1617. PSI5_CH0_DSR field descriptions

Field	Description
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes. For the various configurations of this request refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.

Table 1617. PSI5_CH0_DSR field descriptions (continued)

Field	Description
20 IS_DMA_PM_DS _FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to the DMA request ipd_psi5_dma_req_pm_ds. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. conf1: FIFO FULL disabled conf2 and conf3: FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. conf4: FIFO FULL occurs when there is a “REGISTER FULL” in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
23 IS_DMA_PM_ DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. conf1: underflow disabled conf2 and conf3: Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). conf4: Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. 0 No underflow has occurred. 1 Underflow has occurred. The bits are cleared by a w1c.

53.3.2.5 General Interrupt Control Register (PSI5_CH0_GICR)

The General Interrupt Control Register (PSI5_GICR) contains the bits for controlling the SMC message related interrupts, interrupts related to ECU-to-sensor communication, and interrupts to the Time Stamp.

Address: 0x0014 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1542. General Interrupt Control Register (PSI5_CH0_GICR)

Table 1618. PSI5_CH0_GICR field descriptions

Field	Description
2:7 IE_CESM[6:1]	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.

Table 1618. PSI5_CH0_GICR field descriptions (continued)

Field	Description
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** This bit is writable in Config and Normal modes.
18:23 IE_OWSM[6:1]	Interrupt request enable for the SMC message Overwrite bits. The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. **Note:** These bits are writable in Config and Normal modes.
26:31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5}, that is, during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

53.3.2.6 New Data Interrupt Control Register (PSI5_CH0_NDICR)

The New Data Interrupt Control Register (PSI5_NDICR) contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

Address: 0x0018 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1543. New Data Interrupt Control Register (PSI5_CH0_NDICR)

Table 1619. PSI5_CH0_NDICR field descriptions

Field	Description
0:31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

53.3.2.7 Overwrite Interrupt Control Register (PSI5_CH0_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

Address: 0x001C + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1545. Error Interrupt Control Register (PSI5_CH0_EICR)

Table 1621. PSI5_CH0_EICR field descriptions

Field	Description
0:31 IE_ERROR	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31]. This interrupt is generated only when the corresponding RAM buffer is Ready with new data. Which error condition (any of C, E, EM, T, or F) generates the interrupt is selectable by the PCCR[ERROR_SELECT] field. If all are selected, then which of C,E,EM,T or F is set can be isolated by reading the corresponding received message. 0 Interrupt is disabled. 1 Interrupt is enabled. **Note:** These bits are writable in Config and Normal modes.

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

53.3.2.9 General Interrupt Status Register (PSI5_CH0_GISR)

The General Interrupt Status Register (PSI5_GISR) contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Address: 0x0024 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1546. General Interrupt Status Register (PSI5_CH0_GISR)

Table 1622. PSI5_CH0_GISR field descriptions

Field	Description
0 IS_DEBUG_FREEZE	This flag is set to “1” when the IP enters the debug freeze mode. Refer to *Section 53.1.3.5: Debug mode* for details about the debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode 1 IP in debug freeze mode
2:7 IS_CESM[6:1]	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1 or by w1c.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.

Table 1622. PSI5_CH0_GISR field descriptions (continued)

Field	Description
13 DSR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When “0” it indicates that there is a ongoing command transmission of the data in DSR, or the CPU has done a “w1c” to this bit leading to the new command transmission. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, and PSI5_DOBCR[SW_READY] == 1, then it indicates to the IP that the data in DSR is valid and is to be used for command shifting. This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit refer to *Section 53.4.3.4: Data transmission*.
14 DBR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When “0” it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR. This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit refer to *Section 53.4.3.4: Data transmission*.
15 DPR_RDY(1)	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Preparation register is ready to receive new data from the system bus side. When “0” it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == “7” then this bit remains at value “0”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR. For detailed action of this bit refer to *Section 53.4.3.4: Data transmission*.
18:23 IS_OWSM[6:1]	Status for the SMC message overwrites bits. Each of the 6 locations corresponds to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are cleared automatically upon message read when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1 or by w1c.
26:31 IS_NVSM[6:1]	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are cleared automatically upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1 or by w1c.

1. For these register bits individual “bit setting” commands should not be used. Rather, the normal register read/write commands should be used.

53.3.2.10 DMA PSI5 Message Register (PSI5_CH0_DPMR)

Figure 1547 shows the DMA PSI5 Message Register.

Address: 0x0028 + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1547. DMA PSI5 Message Register (PSI5_CH0_DPMR)

Table 1623. PSI5_CH0_DPMR field descriptions

Field	Description
0:31 PSI5_RXDATA	PSI5_RXDATA[31:0] This popup register contains the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations, the DATA is pushed sequentially until all the data corresponding to the programmed watermark is complete, after which the DMA request is deasserted. The depth of the FIFO is 32 × 64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG = conf2 then it pops the PSI5 message, followed by NDSR, followed by EISR. When DMA_PM_DS_CONFIG = conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG = conf4, it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details refer to the *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 53.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, and *Section 53.3.2.4: DMA Status Register (PSI5_CH0_DSR)*.

53.3.2.11 DMA SMC Frame Register (PSI5_CH0_DSFR)

Figure 1548 shows the DMA SMC Frame Register.

Address: 0x002C + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1548. DMA SMC Frame Register (PSI5_CH0_DSFR)

Table 1624. PSI5_CH0_DSFR field descriptions

Field	Description
0:31 SMC_RXDATA	When the DMA_EN_SF = 1, then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted until all the registers that have pending data, have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location pointed to by the DMA read pointer.

53.3.2.12 DMA Diagnostic Status Register (PSI5_CH0_DDSR)

Figure 1549 shows the DMA Diagnostic Status Register.

Address: 0x0030 + *i**0x1C0 (*i*=0) Access: User read-only

Figure 1549. DMA Diagnostic Status Register (PSI5_CH0_DDSR)

Table 1625. PSI5_CH0_DDSR field descriptions

Field	Description
0:31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details refer to the *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*,*Section 53.3.2.3: DMA Control Register (PSI5_CH0_DCR)* and *Section 53.3.2.4: DMA Status Register (PSI5_CH0_DSR)*.

Note: No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR or EISR directly) or the DMA (reading the DDSR successively).

53.3.2.13 PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

Figure 1550. PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

Table 1626. PSI5_CH0_PMRRL field description

Field	Description
0:27 DATA_REGION	These are application-specific optional bits + data payload of received message. See *Section 53.4.2.1: Reception of data frames* for more details. The data is left-aligned, that is, Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 <= n <= 28). If n < 28 remaining bit positions are filled with '0's, that is, between last received bit and CRC field.
28:30 CRCP	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

53.3.2.14 PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

Figure 1551. PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

Table 1627. PSI5_CH0_PMRRH field descriptions

Field	Description
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, that is, at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error, that is, frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5:7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. For asynchronous modes the slot counter has a fixed value of “1”. The six slots are numbered as Slot1, Slot2,....Slot6.
8:31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the *Section 53.3.2.27: Slot n Frame Configuration Register (PSI5_CH0_SnFCR)*. In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependent on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”.

Note: Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer.

When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occurred.

53.3.2.15 PSI5 Message Register Low *n* (PSI5_CH0_PMRL*n*)

Figure 1552 shows the PSI5 Message Register Low *n*.

Address: 0x003C + *i**0x1C0 (*i*=0) + *n**0x8 (*n*=0 to 31) Access: User read/write

Figure 1552. PSI5 Message Register Low *n* (PSI5_CH0_PMRL*n*)

Table 1628. PSI5_CH0_PMRL*n* field descriptions

Field	Description
0:27 DATA_REGION	These are application-specific optional bits + data payload of received message. See *Section 53.4.2.1: Reception of data frames*for more details. The data is left-aligned, that is, Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 <= n <= 28). If n < 28 remaining bit positions are filled with '0's, that is, between last received bit and CRC field. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
28:30 CRCP	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRCP[2] bits denotes the parity. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
31 C	This bit will be set if CRC/Parity recalculation return an Error.

53.3.2.16 PSI5 Message Register High *n* (PSI5_CH0_PMRH*n*)

Figure 1553 shows the PSI5 Message Register High *n*.

Figure 1553. PSI5 Message Register High *n* (PSI5_CH0_PMRH*n*)

Table 1629. PSI5_CH0_PMRH*n* field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error). In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0, M1), that is, at least one bit is absent during the Tbit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
3 E	This Bit Indicates Electrical Error, that is, at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
4 T	This bit indicates timing error, that is, frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

Table 1629. PSI5_CH0_PMRH*n* field descriptions (continued)

Field	Description
5:7 Slot_Counter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of “1”. **Note:** The six slots are numbered as Slot1, Slot2,...., Slot6.In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
8:31 Time_Stamp _Value	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the *Section 53.3.2.27: Slot n Frame Configuration Register (PSI5_CH0_SnFCR)*. In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependent on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”. In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

53.3.2.17 SMC Frame Register *n* (PSI5_CH0_SFR*n*)

Figure 1554 shows the SMC Frame Register *n*.

Address: 0x013C + *i**0x1C0 (*i*=0) + (*n*-1)*0x4 (*n*=1 to 6) Access: User read/write

Figure 1554. SMC Frame Register *n* (PSI5_CH0_SFR*n*)

Table 1630. PSI5_CH0_SFR*n* field descriptions

Field	Description
0:2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
3 CER	CRC Error 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message. **Note:** If the corresponding SOWSM bits in the SSESR have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set.
5:10 CRC	6-bit CRC for slow serial message **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
11 C	Configuration bit 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
12:15 ID	Message ID: If C = ’0’ indicates ID[7:4], if C = ’1’ indicates ID[3:0]. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
16:19 IDDATA	Message ID/DATA: If C = ’0’ indicates ID[3:0], if C = ’1’ indicates DATA[15:12]. **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).
20:31 DATA[11:0]	DATA payload **Note:** In the normal mode, it is auto updated by hardware and not writable by any other sources. It is writable in configuration mode (for test purposes).

Note: Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

53.3.2.18 New Data Status Register (PSI5_CH0_NDSR)

Figure 1555 shows the New Data Status Register.

Figure 1561. Set SMC Error Status Register (PSI5_CH0_SSESR)

Table 1637. PSI5_CH0_SSESR field descriptions

Field	Description
2:7 SCESM[6:1]	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** These bits are writable in Config and Normal modes.
18:23 SOWSM[6:1]	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** These bits are writable in Config and Normal modes.
26:31 SNVSM[6:1]	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as ’0’ (w1s). **Note:** This bit is writable in Config and Normal modes.

53.3.2.25 Sync Time Stamp Read Register (PSI5_CH0_STSRR)

Figure 1563. Data Time Stamp Read Register (PSI5_CH0_DTSRR)

Table 1639. PSI5_CH0_DTSRR field descriptions

Field	Description
5:7 SLOT_COUNTER	3-bit Slot Counter, which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode, the slot counter has a fixed value of “1”.
8:31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected, the value of the Time Stamp counter captured at the rising edge of the S0 is stored in this register at the rising edge of S1.

Note: If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter, both will correspond to the first slot (S0)

53.3.2.27 Slot *n* Frame Configuration Register (PSI5_CH0_S*n*FCR)

Figure 1564. Slot *n* Frame Configuration Register (PSI5_CH0_S*n*FCR)

Table 1640. PSI5_CH0_S*n*FCR field descriptions

Field	Description
13 SLOT_EN	0 This particular slot is disabled, that is, not in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) have no effect. 1 This particular slot is enabled, that is, in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) are applicable.
14 TS_CAPT	0 Time stamp value captured at rising edge of S0 and stored Start sequence first edge. 1 Time stamp value captured at corresponding Tsync pulse (posedge) and stored with corresponding slot PSI5 message.

Table 1640. PSI5_CH0_S*n*FCR field descriptions (continued)

Field	Description
16 SMCL	Serial Messaging Channel field 0 Serial Messaging Channel (optional) not present on Rx Message during Time Slot 'n' 1 2-bit{M1,M0} Serial Messaging Channel present on Rx Message during Time Slot 'n' This field is used to enable the detection of start sequence of SMC frame on particular slot. Detection is not done if this field is '0'.
26:30 DRL	Data Region Length[4:0] This field represents Length of Data region (including Frame Control, Status, Data payload1&2 regions and optional messaging bits M0, M1) in Rx Message during Time Slot 'n' 00000 invalid ... 00111 Invalid 01000 8 bit long data region 01001 9 bit long data region .... 11011 27 bit long data region 11100 28 bit long data region 11101 invalid 11111 Invalid
31 CRCP	0 3 bit CRC[2:0] present on Rx Message during Time Slot 'n' 1 1 bit Parity field present on Rx Message during Time Slot 'n'

Note: In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

53.3.2.28 Slot *n* Start Boundary Register (PSI5_CH0_S*n*SBR)

Figure 1565 shows the Slot *n* Start Boundary Register (PSI5_S*n*SBR).

Total of six registers for each of the six slots. These are S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Here *n* = 1 to 6 corresponding to each of the six slots.

Address: 0x0190 + *i**0x1C0 (*i*=0) (PSI5_CH0_S1SBR)
0x0192 + *i**0x1C0 (*i*=0) (PSI5_CH0_S2SBR)

Figure 1565. Slot *n* Start Boundary Register (PSI5_CH0_S*n*SBR)

Table 1641. PSI5_CH0_S*n*SBR field descriptions

Field	Description
1:15 S*n*SBT	Slot *n* Start Boundary Time This field specifies the time in intervals of 1 µs, occurring after the *rising edge* of the timing sync pulse, at which the slot *n* should start. n = 1 to 6 dedicated for each of the six slots.

53.3.2.29 Slot *n* End Boundary Register (PSI5_CH0_SNEBR)

Figure 1565 shows the Slot *n* Start Boundary Register (PSI5_S*n*SBR).

Slot n End Boundary register is a single register, which can be programmed to define the “end” of the nth slot. The n can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR+, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SNEBR (Slot n End Boundary register) defines the end of the nth slot. The n is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SNEBR. The SNEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the S*n*FCR. When the start slot boundaries are properly defined in the SnSBR (Slot *n* Start Boundary Register) register but the slot_en bit = 0 in the corresponding S*n*FCR (Slot *n* Frame Configuration register) register, then the corresponding slot is treated as “available” but “unconfigured.” For such a slot the data/diagnostic bits all remain 0*. The “T” bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots.* Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if “S0” and “S1” are detected in different slots then a T-bit error is set.

Figure 1566. Slot *n* End Boundary Register (PSI5_CH0_SNEBR)

Table 1642. PSI5_CH0_SNEBR field descriptions

Field	Description
13:15 SLOT_NO	The field indicates the Slot number{1–6} for which Slot End Boundary Time is defined. Any value other than 1–6 is defaulted to 0. A value 0 here would mean that the Manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
17:31 SNEBT	Slot *n* End Boundary Time This field specifies the time in intervals of 1 µs, occurring after the rising edge of timing sync pulse, at which the slot *n* should end.

Note: The start slot boundaries in the SnSBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SNEBR are treated as being unavailable (that is, the data in all the slots occurring after the SNEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the SNEBR and define the end boundary of the third slot in SNEBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the SNEBR by putting slot_no = 6 and define the end boundary of the sixth slot in SNEBR.

53.3.2.30 Data Output Block Configuration Register (PSI5_CH0_DOBCR)

Figure 1567 shows the Data Output Block Configuration Register.

Address: 0x01A0 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W							DBR_RST	DSR_RST								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1567. Data Output Block Configuration Register (PSI5_CH0_DOBCR)

Table 1643. PSI5_CH0_DOBCR field descriptions

Field	Description
0-5 DATA_LENGTH	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard), then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0 then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH=1 then the length of the command that can be written to DSR and the DBR is 2 and so on until a maximum of 64-bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits, that shift out of DSR register once the DSR_RDY goes low. After these many shifts have happened, then the value corresponding to “DEFAULT_SYNC” starts getting shifted out and DSR_RDY goes as “1”.
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as “1” then the contents of the DBR are reset to all “0s” (if DEFAULT_SYNC= = 0) or all “1s” (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a “0” (w1s). Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register. When this bit is written as “1” then the contents of the DSR are reset to all “0s” (if DEFAULT_SYNC= = 0) or all “1s” (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data. Reading this bit would always return a “0” (w1s). Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
8-10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. *Table 1644* is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to “0” then the default value of DSR and DBR registers are all “0s”; when this bit is set to 1 then the default value of DBR and DSR registers are all “1s”. This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 1 Reserved 0 SP module gets the data from the DSR

Table 1643. PSI5_CH0_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects the driving source of the "ipp_do_psi5_sdout" port. 0 Reserved 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending. Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1, will the transfer happen. This bit can be written in CONFIG and the Normal modes.

Table 1644. CMD_TYPE details

CMD_TYPE	PSI5 Frame	Effect on registers	Writable Register lengths
"000" - 0	Short Frame with 31 "1s" as the start condition(1)	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15 bits(2) in DBR/DSR.
"001" - 1	Short Frame with 5 "0s" as the start condition(1)	-do-	-do-
"010" - 2	Long Frame with 31 "1s" as the start condition(1)	-do-	16 bits in DPR. 29 bits(2) in DBR/DSR.
"011" - 3	Long Frame with 5 "0s" as the start condition(1)	-do-	-do-
"100" - 4	X-Long Frame with 31 "1s" as the start condition(1)	-do-	22 bits in DPR. 37 bits(2) in DBR/DSR
"101" - 5	X-Long Frame with 5 "0s" as the start condition(1).	-do-	-do-
"110" - 6	XX-Long	-do-	24 bits in DPR. 43 bits(2) in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCR[DATA_LENGTH] field.

1. The start condition (31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command; neither is this visible in any register.
2. This is also the length of the command, that will be shifted out during the ECU to Sensor communication, irrespective of how many "actual" number of bits are written to DBR/DSR.

Table 1645. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL(1)	SP_PULSE_SEL	OP_SEL
State1(2)	0	1	1
State2(2)	0	0	1
State3(2)	1	1	1
State4(2)	1	0	1
State5(2)	1	x	0

1. GTM is not supported by this device
2. These states are shown in *Section 53.8.2: Valid states for integrated sync pulse generator*. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

Note: Refer to Figure 1601 for the details about the above bits.

53.3.2.31 Manchester Decoder Disable Offset Register (PSI5_CH0_MDDIS_OFF)

The Manchester decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 µs, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 µs to 128 µs. This works on the 1 µs clock from the CGM.

Address: 0x01A2 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1568. Manchester Decoder Disable Offset Register (PSI5_CH0_MDDIS_OFF)

Table 1646. PSI5_CH0_MDDIS_OFF field descriptions

Field	Description
9:15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the Manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse. Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester decoder BEYOND the Sync Pulse High Time as well. *Figure 1606* shows the "MDDIS_OFF" definition.

53.3.2.32 Pulse Width for Data Bit 0 Register (PSI5_CH0_PW0D)

Figure 1569 shows the Pulse Width for Data Bit 0 Register.

Address: 0x01A4 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	Pulse_Width0						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1569. PSI5_Pulse Width for Data Bit 0 Register (PSI5_CH0_PW0D)

Table 1647. PSI5_CH0_PW0D field descriptions

Field	Description
9:15 Pulse_Width0	This defines the width (in µs) of data value ’0’ to be sent from Data Output Register. It is the number of clock cycles (1µs clock) counted up to width “Pulse_Width0”; starting as soon as trigger appears from the ISPG (Internal Sync Pulse Generator). Can take max value of 127. When, intending to use the” tooth gap method” of PSI5 command transmission, the Pulse_Width0 should be configured to 0. *Figure 1606* shows the definition of “Pulse_Width0”.

53.3.2.33 Pulse Width for Data Bit 1 Register (PSI5_CH0_PW1D)

Figure 1570 shows the Pulse Width for Data Bit 1 Register.

Address: 0x01A6 + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	Pulse_Width1						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1570. PSI5_Pulse Width for Data Bit 1 Register (PSI5_CH0_PW1D)

Table 1648. PSI5_CH0_PW1D field descriptions

Field	Description
9:15 Pulse_Width1	This defines the width (in µs) of data value ’1’ to be sent from Data Output Register. It is the number of clock cycles (1µs clock) counted up to width “Pulse_Width1”; starting as soon as trigger appears from the ISPG(Internal Sync Pulse Generator). Can take max value of 127. *Figure 1606* shows the definition of “Pulse_Width1”.

Note: When using the “tooth gap method” of PSI5 command transmission, the pulse width is NOT disabled. In this case, PSI5_PW0D has to be programmed as 0. PSI5_PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

53.3.2.34 Counter Target Pulse Register (PSI5_CH0_CTPR)

Figure 1571 shows the Counter Target Pulse Register.

Address: 0x01A8 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1571. Counter Target Pulse Register (PSI5_CH0_CTPR)

Table 1649. PSI5_CH0_CH0_CTPR field descriptions

Field	Description
0:15 CTPR	Counter Target Pulse Register This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16-bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the time period of the internally generated sync pulses. The un-modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles, that is, the duty cycle of the un-modulated internally generated sync pulses is (4/|CTPR| *100). The 4 sp_ts_clk cycles is just the nascent value of the pulse that, actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in *Section 53.8.2: Valid states for integrated sync pulse generator*. This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length, which is governed by the PWD registers.

Note: Refer to Section 53.8.1 for details about the Sync Pulse generation and coordination.

53.3.2.35 Counter Initialize Pulse Register (PSI5_CH0_CIPR)

Figure 1572 shows the Counter Initialize Pulse Register.

Address: 0x01AA + *i**0x1C0 (*i*=0) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	CIPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1572. Counter Initialize Pulse Register (PSI5_CH0_CIPR)

Table 1650. PSI5_CH0_CIPR field descriptions

Field	Description
0:15 CIPR	Counter initialization pulse register This is the value at which the CTC gets reset the first time, after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be |CIPR_channel1 - CIPR_channel2| sp_ts_clk cycles. Thus if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

Note: The CIPR resolution is in terms of the time period of the "sp_ts_clk" ($T_{sp_ts_clk}$). Therefore the total "CIPR" time is "CIPR$T_{sp_ts_clk}$", beginning from when the CIPR counters are enabled using the sync pulse trigger bits(PSI5_PCCR[CTC_ED] or PSI5_GCR[CTC_GED]). Due to internal Flop synchronization, this time would not exactly be CIPR*$T_{sp_ts_clk}$ but would have an inaccuracy of $1T_{sp_ts_clk}$. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy.*
The CTPR resolution is also in terms of the "sp_ts_clk". Therefore the total "CTPR" time is "CTPR$T_{sp_ts_clk}$". However when measured on the "sdout" pin of the IP this time would not exactly be "CTPR*$T_{sp_ts_clk}$". Due to internal Flop synchronization on the 1Mhz clock, an in accuracy of "1µs" would be added. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy. Hence the "CTPR" period measured on the "sdout" pin, can range from (CTPR*$T_{sp_ts_clk}$) -1µs -$T_{ipg_clk_psi5}$ to (CTPR*$T_{sp_ts_clk}$) +1µs + $T_{ipg_clk_psi5}$. Refer to Figure 1606 for more details about this inaccuracy.*

Refer to Section 53.8.1 for details about the Sync Pulse generation and coordination.

53.3.2.36 Data Preparation Register Low (PSI5_CH0_DPRL)

Figure 1573 shows the Data Preparation Register Low.

Address: 0x01AC + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1573. Data Preparation Register Low (PSI5_CH0_DPRL)

Table 1651. PSI5_CH0_DPRL field descriptions

Field	Description
8:31 DPR	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length, standard ECU-to-Sensor commands, comprising of the address, data and other fields. Note that the IP is transparent to the arrangement of the address, data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writable only when using the standard length PSI5 frames. For details about CRC calculation refer to *Section 53.4.3.4: Data transmission*. The writable bits in this register are governed by the PSI5_DOBCR[CMD_TYPE] bit fields as per *Table 1652*. Note that the unwritable bits in this register field are always read as “0s”. This register has to be written by the CPU. These bits can be written only in the Normal mode.

Table 1652. DPR details

PSI5_DOBCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writable bits in PSI5_DPRL
“0” or “1”	Short Frame	6(DPR[5:0])
“2” or “3”	Long Frame	16(DPR[15:0])
“4” or “5”	X-Long Frame	22(DPR[21:0])
“6”	XX-Long Frame	24(DPR[23:0])
“7”	Not Available for write	Not Available for write

Note: This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when PSI5_GISR[DPR_RDY] == 1. Whenever PSI5_GISR[DPR_RDY] == 1, then each bit of this register defaults to 0. Writing to this register when PSI5_GISR[DPR_RDY] == 0 will cause the PSI5_GISR[IS_PROW] status bit to be set and the generation of an error interrupt, if it is enabled. Further, trying to write to this register when PSI5_DOBCR[CMD_TYPE] = “7” results in the setting of the PSI5_GISR[IS_PROW] bit and the resulting write is rejected.

Figure 1575. Data Buffer Register Low (PSI5_CH0_DBRL)

Table 1654. PSI5_CH0_DBRL field descriptions

Field	Description
0:31 DBR	This register contains the Lower 32 bits(DBR[31:0]) of the max-64 bit length command (DBR[63:0]). The higher bits, DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU (when PSI5_GISR[DBR_RDY] == 1 in the Normal mode). Hardware update occurs when PSI5_GISR[DPR_RDY]== 0 and PSI5_GISR[DBR_RDY] == 1. It cannot be written in Config mode. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in *Table 1655*. The tables (except when PSI5_DOBCR[CMD_TYPE] = “7”) show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == “7”), then only the CPU can write to these registers.

Table 1655. DBRL[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
“7” (Non Standard Length)	DBR[31:0]]	Variable length of writable bits, as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]
“6”(XX Long)	DBR[31:30]	DPR[19:18]
	DBR[29]	1’b0(stuff)
	DBR[28:23]	DPR[17:12]
	DBR[22]	1’b0(stuff)
	DBR[21:16	DPR[11:6]
	DBR[15]	1’b0(stuff)
	DBR[14:9]	DPR[5:0
	DBR[8:0]	“011111110”
“4” or “5” (X-Long)	DBR[31]	1’b1(stuff)
	DBR[30:28]	DPR[20:18]
	DBR[27]	1’b1(stuff)

	DBR[6:4]	DPR[2:0]
	DBR[3]	1'b1(stuff)
	DBR[2:0]	"010"(start seq)

This register is CPU writable only in Normal mode.

Note: When DEFAULT_SYNC == 0 then default value of this register is 00000000. When DEFAULT_SYNC== 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

53.3.2.39 Data Buffer Register High (PSI5_CH0_DBRH)

Figure 1576 shows the Data Buffer Register High.

Address: 0x01B8 + *i**0x1C0 (*i*=0) Access: User read/write

Figure 1577. Data Shift Register Low (PSI5_CH0_DSRL)

Table 1658. PSI5_CH0_DSRL field descriptions

Field	Description
0:31 DSR	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[*CMD_TYPE*] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRL. Thus when updated by the hardware, then DSR[31:0] = DBR[31:0]. Hardware update occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the update of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode, when PSI5_GISR[DSR_RDY] == 1'b1. It cannot be written in Config mode.

This register is CPU writable only in Normal mode.

Note: When DEFAULT_SYNC == 0 then default value of this register is 00000000. When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addition to PSI5_GISR[DSR_RDY] == 1.

53.3.2.41 Data Shift Register High (PSI5_CH0_DSRH)

Figure 1578 shows the Data Shift Register High.

Address: 0x01C0 + *i**0x1C0 (*i*=0) Access: User read/write

Field	Description
0:31 DSR	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[*CMD_TYPE*] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRH. Thus when updated by the hardware, then DSR[63:32]] = DBR[63:32]. Hardware update occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the update of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode, when PSI5_GISR[DSR_RDY] == 1'b1. It cannot be written in Config mode.

This register is writable only in Normal mode.

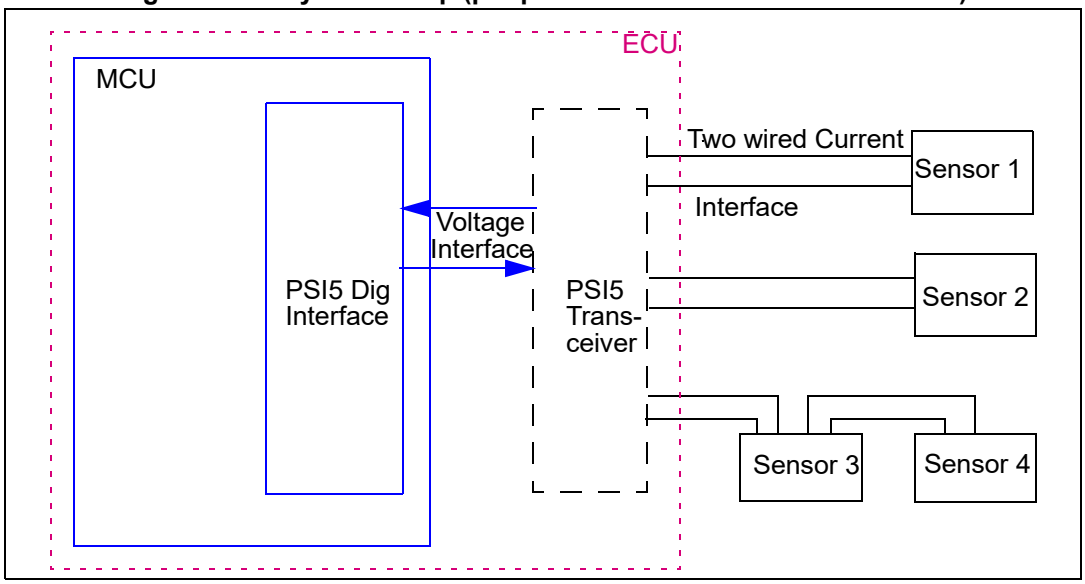
Note: When DEFAULT_SYNC == 0 then the default value of this register is 00000000. When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of this register is always "00000000". The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addition to PSI5_GISR[DSR_RDY] == 1.

53.3.2.42 Device modes and Register bit accesses

1. The following bits are writable in all modes (Normal, Config, and Disable).
   - GCR[GLOBAL_DISABLE_REQ]
   - PCCR[PSI5_CH_CONFIG]
   - PCCR[PSI5_CH_EN]
   - Global Counter Enable/Disable (GCR[CTC_GED]). This is to allow the Sync Pulse Generator to be enabled/disabled independently among those channels that are used for staggering, irrespective of the state of the channels NOT being used for staggering.
2. The following register is writable only in Normal mode and is initialized to all 0s.
   - DPRL
3. The following registers are writable ONLY in Normal mode. Initial is at ion in Config mode depends on the value of PSI5_DOBCR[DEFAULT_SYNC] bit. When PSI5_DOBCR[DEFAULT_SYNC] == 1 in Config mode, then the below registers are initialized to all 1s in Normal mode. When PSI5_DOBCR[DEFAULT_SYNC] = 0 in Config mode, then the below registers are initialized to all 0s in Normal mode. Once in

Normal mode, these registers can then be programmed for any command that needs to be sent.



- DBRH/DBRL
- DSRH/DSRL

4. The following registers are writable in Config and Normal modes only:
   - All interrupt control registers
   - All SET registers (the one shot registers that are used to set the error flags for software drivers)
   - Channel Enable/Disable (PCCR[CTC_ED]). Using this it is possible to allow the Sync Pulse Generator to be enabled/disabled in Normal mode. The counter is reset when CTC_ED == 0
   - All w1c bits
5. Apart from these, all other register bits can be written only in Config mode, including the Data registers (PMRH/PMRL/SFRn), that, in Normal mode, are updated by the hardware only.
6. Debug mode: If the device is in Normal mode and the debug mode is enabled, then ONLY the registers in *1.*,*2.*,*3.*,*4.* of *Section 53.3.2.42: Device modes and Register bit accesses*: can be written by the debugger. Register in *5.* of *Section 53.3.2.42: Device modes and Register bit accesses* will not be available for write through the debugger. In case the debugger has to change any register, then the device has to be brought in the Disable → Config mode. The debugger can, however, read any register in any mode.

53.4 Functional description

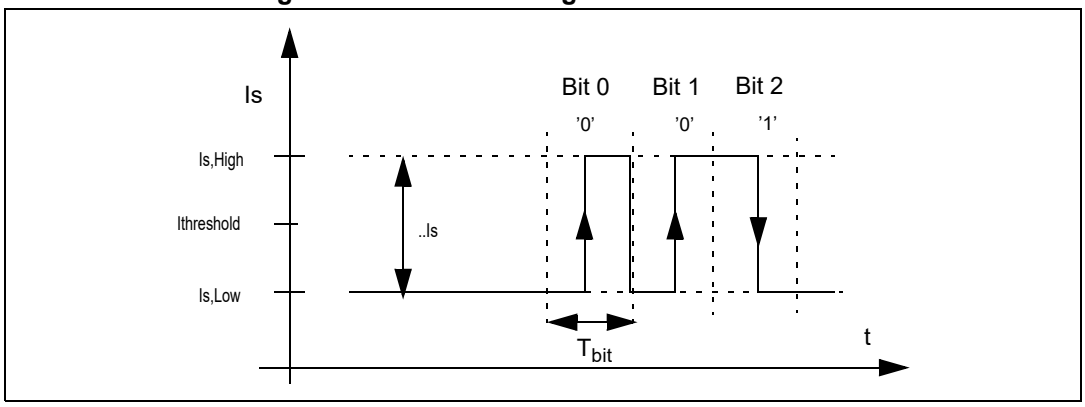
The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. *Figure 1579* shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1579. System setup (peripheral sensor connected to device)

ECU (Electronic Control Unit) is comprised of PSI5 digital interface and the PSI5 transceiver (present externally).

53.4.1 Sensor-to-ECU communication

53.4.1.1 Physical layer



The PSI5 uses two wires to provide both power supply and data transmission to the sensors. The ECU provides a pre-regulated voltage to the sensors. Data transmission from the sensor to the ECU is done by current modulation on the power supply lines. Current oscillations are damped by the ECU.

53.4.1.2 Bit encoding

A “low” level ($I_{S,Low}$) is represented by the Normal (quiescent) current consumption of the sensor(s). A “high” level ($I_{S,High}$) is generated by an increased current sink of the sensor ($I_{S,Low}$ + ...I_S). The current modulation is detected within the PSI5 transceiver.

Manchester coding is used for data transmission. A logic 0 is represented by a rising slope and a logic 1 by a falling slope of the current in the middle of T bit.

Figure 1580. Bit encoding of data from sensor

53.4.1.3 Synchronization

For synchronized operation and bus mode, a sync pulse is generated by the PSI5 receiver. The sync pulse is output from the integrated PSI5 receiver to an external PSI5 transceiver that processes these pulses to a pre-regulated voltage level on supply lines to sensors. The voltage change is detected within the sensors.

53.4.2 Data Link Layer

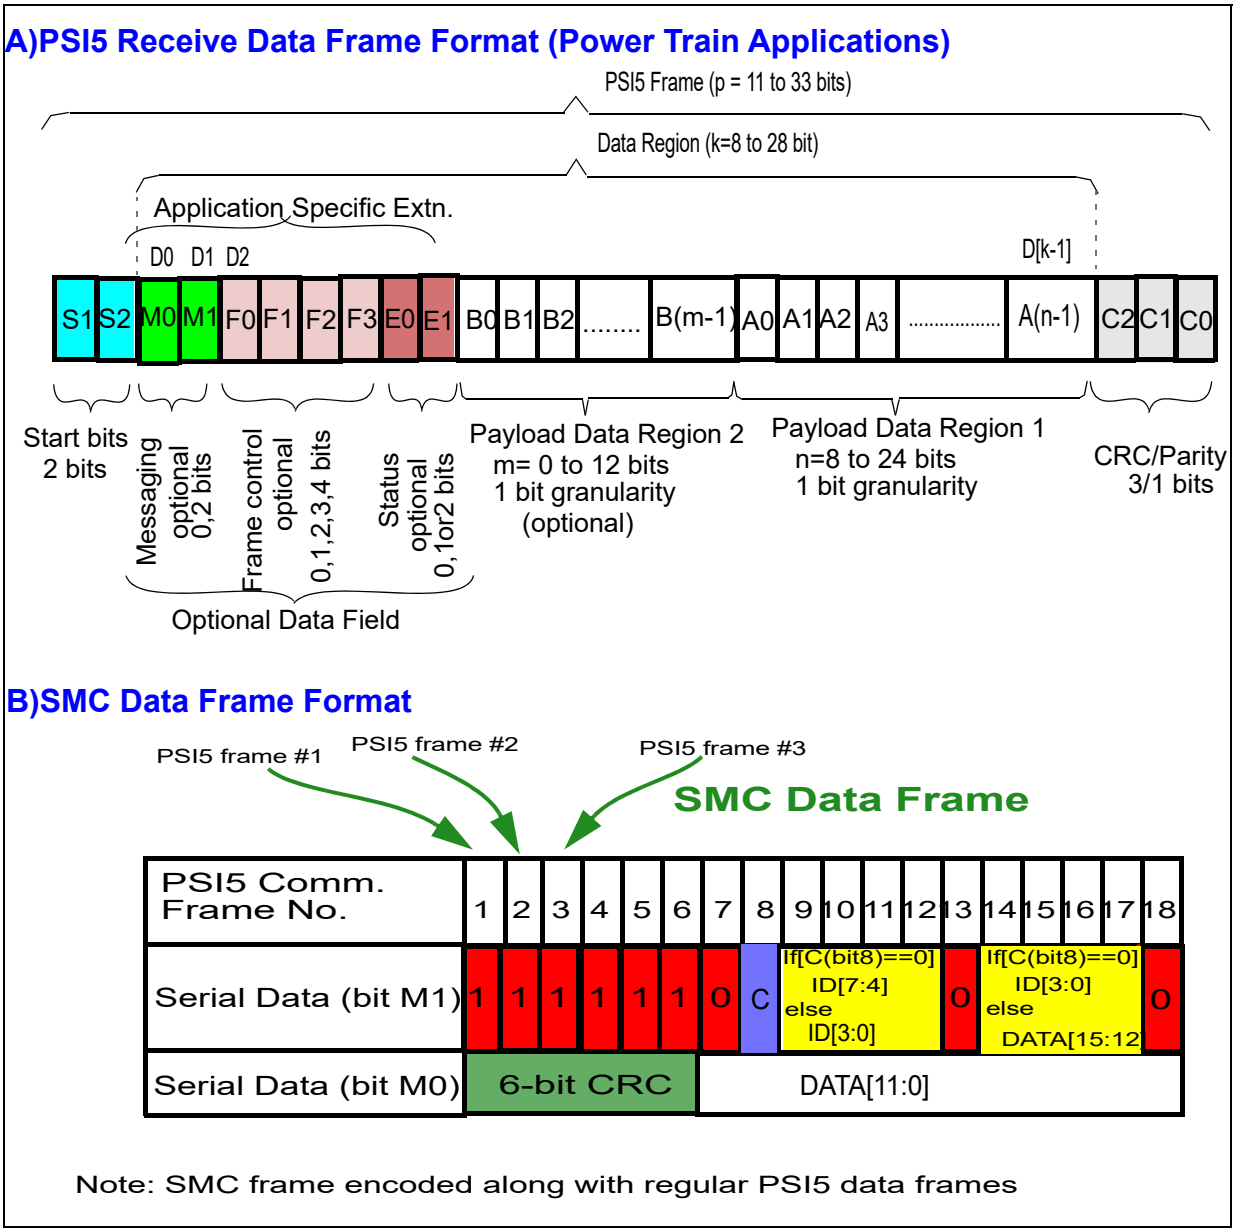
The PSI5 message is received as serial Manchester-coded bits. The bit stream is passed through a Manchester decoder stage that converts it to normal NRZ format bit by bit and stores it serially in the receive register (64 bits). This block clearly identifies start (00) and end of receive frame using preprogrammed frame configuration registers.

- The Manchester-coded bits can be received at the rate of 125 Kbit/s or 189 Kbit/s (selectable by programming frame configuration registers).
- The Manchester decoder is designed to consider data with duty cycle of 30–70%.
- The bit decoding is done using an oversampling and counting algorithm with majority voting and edge recognition. (125/189 kHz) × 32, that is, (4/6.048 MHz also referred as 32× clock) clocks are supplied from a common clock generator (to be implemented in CGM) module. This clock is used for oversampling of the receive bit and thereby decoding it as normal 1 or 0 (NRZ).
- The Manchester decoder is masked (switched off) for the duration when the sync pulse is transmitted. In addition to this, it can be configured to be off for an additional time, after the falling edge of the sync pulse. The duration of this time is configurable in the MDDIS_OFF register. It uses a 2oo3 voter to recognize the encoded half bits.
- There is a 3oo5 majority voting glitch filter at the data input of the Manchester decoder.

53.4.2.1 Reception of data frames

The extended PSI5 (Power Train Applications) receive data frame consists of *p* bits containing:

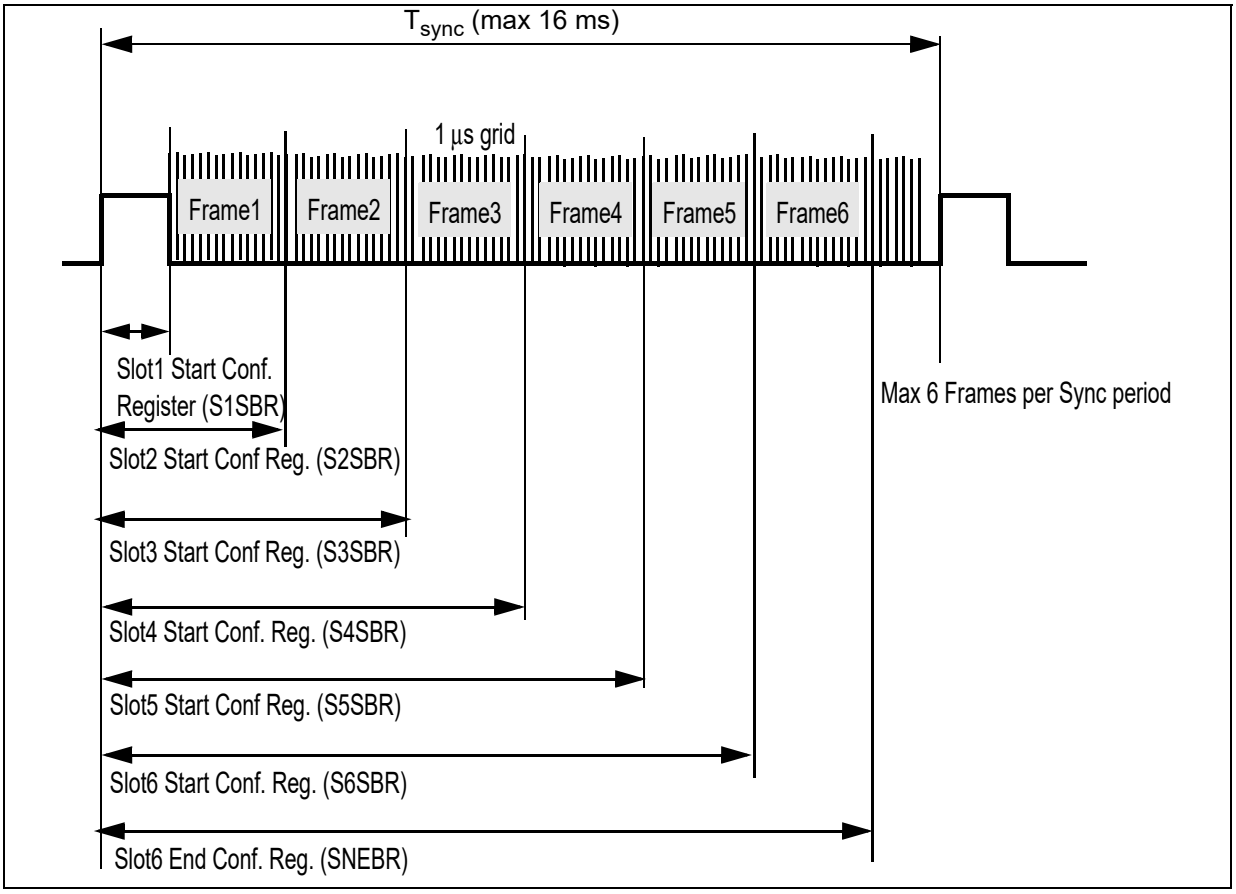
- Two start bits (S1 and S2) {S1=0, S2=0}.
- One parity bit (P) with even parity (or 3 CRC bits C0, C1, and C2).
- A data region (D0.....D[*k* – 1]) with *k* = 8 to 28 bits with 1-bit granularity.
- The total length of a PSI5 frame is p = *k* + 3 data bits (in case of frames with parity bit) or p = *k* + 5 data bits (in case of frames with CRC).
- Data bits are received LSB first. The parity or CRC check bits cover the bits of the entire data region.



The length of the data region can vary between *k* = 8 to 28 bits (with 1-bit granularity). The data region can be split into the following fields and regions:

- The bits D0 and D1 can optionally represent Serial Messaging Channel M0, M1.
  - This Serial Messaging Channel (SMC) is used to receive initialization data during fast startup phase or slow acknowledgment/response messages (to command transmitted from ECU requesting data or diagnostic information from the sensor).

Note that the maximum length of the entire data region is 28 bits. Thus the signal payload region and the optional data fields cannot concurrently be used at their maximum length in some cases.



As the PSI5 module is targeted for powertrain applications, the data frame format differs from standard PSI5 frames for safety applications specified in version 1.3 of the PSI5 specifications. More specifically for supporting the version 2.0 powertrain substandard. The Powertrain data frame format and optional Serial Messaging Channel (SMC) frame format are shown in *Figure 1581*.

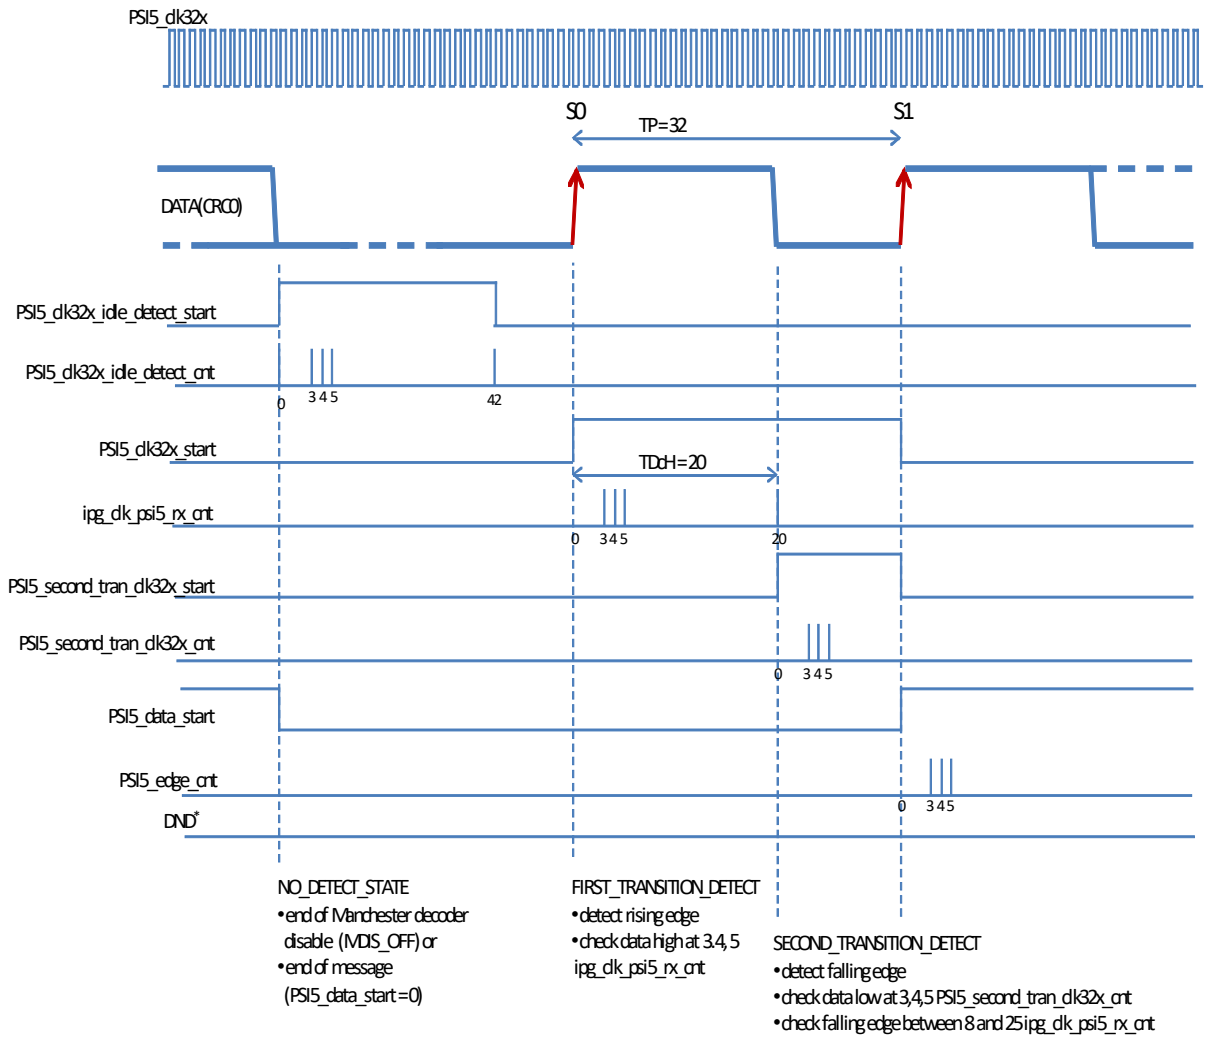
Figure 1581. Receive data frame format

53.4.2.2 Data Frame Configuration control

Figure 1582. Data frame configuration and sampling

At the receive path, as many as six frame slots (reception windows) can be programmed with a start time of consecutive slots (slot1 to slot6) and end time or last slot, which can be configured through the Slot *n* Start/End Configuration Registers (*Section 53.3.2.28: Slot n Start Boundary Register (PSI5_CH0_SnSBR)* and *Section 53.3.2.29: Slot n End Boundary Register (PSI5_CH0_SNEBR)*) there are seven registers for six slots. The slot time value is with respect to timing sync pulse.

The following range is always maintained for T_{sync} (during programming of the GCR and CTPR registers) when timing (sync) pulses are generated through the Sync Pulse Generator.



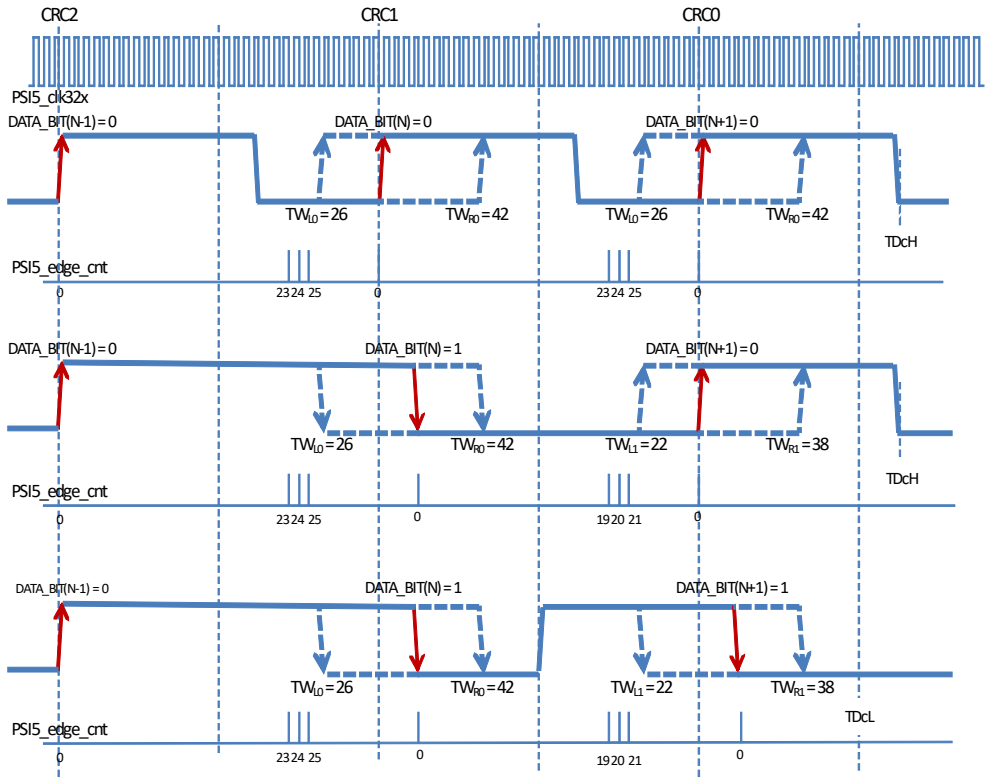
Equation 77 T_{sync} < 16 ms

For the maximum defined six frame slots, six frame configuration registers (S1FCR, S2FCR, S3FCR, S4FCR, S5FCR, and S6FCR) are also available. In these registers it is possible to configure the payload region of the expected frames, in addition to other channel-specific parameters.

53.4.2.3 Data frame handling

Figure 1583 shows the detection of the start bits and the various parameters for the same.

Figure 1583. Start bit detection



(*) If DND is set to '1' because a message has overlapped with the Manchester decoder disable phase, then the Manchester decoder disable phase will be extended till the end of the first configured slot. DND will be cleared to '0' at the end of this first slot and NO_DETECT_STATE will be entered immediately. No idle detection will be carried out (that is PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of slot2 will be captured.

If DND is set to '1' because a first message (MSGn) has overlapped with a second message (MSGn+1), then MSGn+1 will be ignored, that is the Manchester decoder will be disabled until the end of the slot in which MSGn+1 was expected. This will be the case whether the first transition detection of MSGn+1 occurs in the expected slot of MSGn or MSGn+1. At the end of the slot in which MSGn+1 was expected, DND will be cleared to '0' and NO_DETECT_STATE will be entered immediately. No idle detection will be carried out (that is PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of the slot in which the next message (MSGn+2) is expected will be captured.

Figure 1584 shows how the bits are differentiated into a “1” or a “0” based on the various margins and sample points.

Figure 1584. Bit extraction

Start Sequence Measured: Tp = 32 and TDcH = 20
Calculations:
TDcL = Tp – TDcH == 12; DeltaDC = TDcH – Tp/2 == 4; TMarginL = TDcL/2 == 6; TMarginH = TDcH/2 == 10
If DATA_BIT(N) = 0, TWI = TDcH + TMarginL == 26; signal sampled at TWI -3, -2 and -1
- if signal low, expect rising edge between TWL0 and TWR0 then DATA_BIT(N+1) == 0. TWL0 = TDcH+TMarginL, TWR0 = Tp + TMarginH.
- if signal high. expect falling edge between TWL0 and TWR0 then DATA_BIT(N+1) == 1. TWL0 = TDcH+TMarginL, TWR0 = Tp + DeltaDC + TMarginL.

If DATA_BIT(N) = 1, TWI = TDcL + TMarginH == 22; signal sampled at TWI -3, -2 and -1
- if signal low, expect rising edge between TWL1 and TWR1 then DATA_BIT(N+1) == 0. TWL1 = TDcL+TMarginH, TWR1 = Tp - DeltaDC + TMarginH.
- if signal high. expect falling edge between TWL1 and TWR1 then DATA_BIT(N+1) == 1. TWL1 = TDcL+TMarginH, TWR1 = Tp + TMarginL.

PSI5_edge_cnt will be stopped (PSI5_data_start low) at TDcH if CRC0 is logic 0 or TDcL if CRC0 is logic 1.

53.4.2.3.1 Start of frame recognition

The start of frame recognition is as follows:

- With the Manchester decoder in NO_DETECT state, the first rising edge of the incoming data signal is captured and assumed to be the midpoint transition of the first start bit S0.
- As soon as the first rising edge (S0) on the bus is recognized, the 24-bit time stamp value is captured internally. On the rising edge of the S1 this value is stored in the data

receive register and available for processing. If a valid S1 edge is NOT recognized then this time stamp value is discarded and not stored in any register.

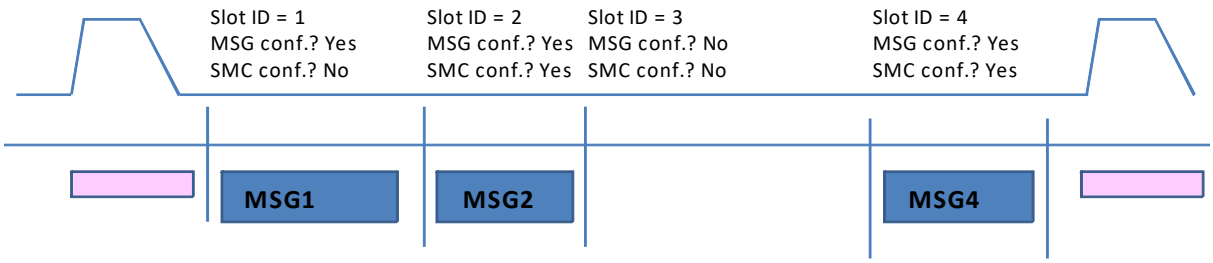
- The middle transition from the first start bit S0 to the second start bit S1 is assumed to be the bit duration for the rest of the bits.
- The time of the high period is measured using the 32x sample clock to enable analysis of the data signal duty cycle. The measured value is used in the data state to calculate the appropriate sample time of the first half-bit of the following data bits
- The second rising edge of the incoming data (S1) is captured and assumed to be the mid-point transition from the second start bit S1 if it appears in the allowed range of samples of the 32x sample clock.
- The time between the first and second rising edge is measured using the 32x sample clock to enable analysis of the sensor clock tolerance. The measured value is used together with the calculated duty cycle to set the window for capturing the mid-point bit transition the following data bits.
- *Figure 1583* and *Figure 1584* show the start bit and the data bit extraction mechanisms respectively, in the Manchester decoder.

53.4.2.3.2 Data state

In the data state, the Manchester decoder samples the number of data bits corresponding to the configured length of the data payload region and 3-bit CRC or 1-bit parity.

53.4.2.3.3 Message diagnostic checks

During the data state, electrical correctness of each bit in regard of Manchester encoding is checked. If an incorrect bit is detected, a 0 is written into the data payload region. Following completion of reception, correctness of the entire message is checked with the CRC and timing of the message reception.



- CRC is recalculated for the data and compared with received CRC bits. The CRC comparison result is stored as a status bit, denoted as the C field in the receive register and the RAM register. Irrespective of the value of the “C” bit the, the frame is always stored in the RAM register and is never discarded.
- If at least one bit is electrically faulty (apart from M0M1), then the bit field E is set to 1 and stored as status bit in the receive register and the RAM register.
- The EM bit is set to 1 if any of M0 or M1 bits are electrically faulty. Note that the E and the EM bits can be set only when a valid start sequence has been detected.
- Set status bit field T in the receive register to 1 if the frame received is in the wrong slot (boundary violations). This bit is NOT set for asynchronous modes.
- Set status bit F if no frame is received in defined frame slot. This bit is NOT set for asynchronous modes.
- The incoming frames after the sync pulse are to be numbered from 1 to 6 (max). This is done by a 3-bit slot counter, which is incremented automatically after the end of each slot irrespective of whether a valid message is received or not. This 3-bit value is stored in the receive register and the RAM registers as the “slot_counter” field.

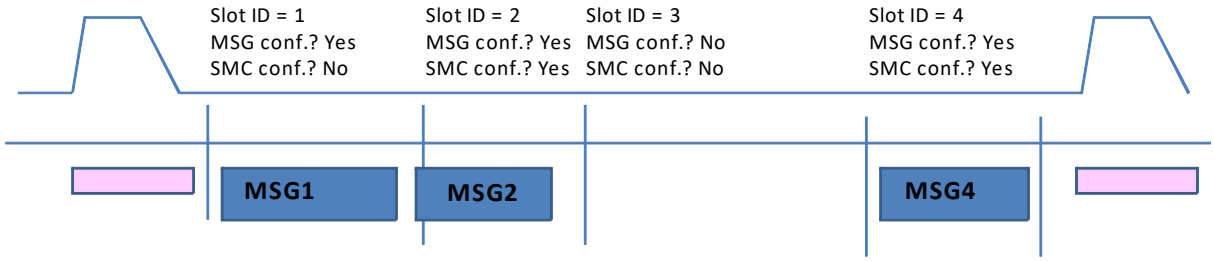
  T-bit Handling

The following paragraphs describe how the IP handles error cases that generate T bit errors. A number of examples are shown, including the error free case, which is used to explain the reception process.

53.4.2.3.3.1 Error free case

Figure 1585. Error free case

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1



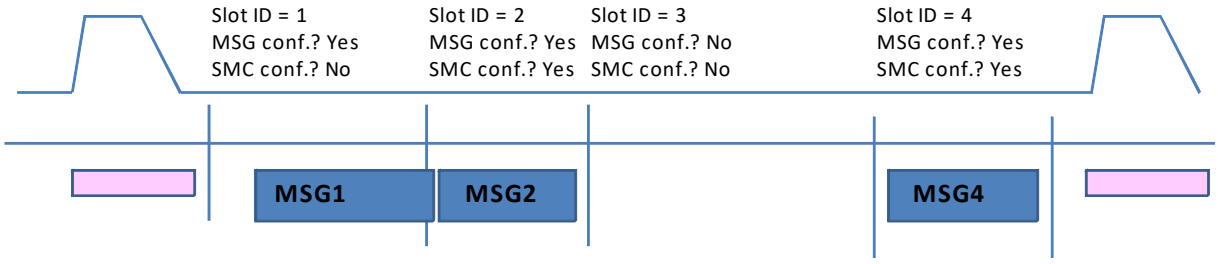
In this case, all messages are received in the correct slots.

- As soon as the Manchester decoder block is enabled (after the SYNC pulse has finished and any configured disable offset has expired, pink region) the IP checks for the first configured message and starts monitoring the output of the PSI5 transceiver.
- The IP identifies a correct start of message sequence (S0, S1)== '00', and captures the slot counter when the first rising edge of the start sequence is detected. This first rising edge detected is the mid-point transition of the Manchester encoded S0 bit of the message start sequence
- The expected number of bits configured in the message is received and decoded. Any error in the Manchester encoded bits of the message E bit is set - unless the error is in one of the first two bits and SMC message is configured, in which case the EM bit is set.
- After the final bit is received, a check is made that the message CRC or parity is correct. If the CRC or parity check is not correct, C bit is set for the message.
- Once the CRC checks have been made, the received message — along with the status bits, slot counter in which the start sequence was received, the timestamp of the message, the message data and CRC or parity is saved to the channel message FIFO.
- As soon as the received message has been stored, the idle state of the bus is verified and monitoring of the transceiver output restarts to check for the next configured message
- If the serial message channel (SMC) is configured, the first two data bits are extracted from a sequence of 7 PSI5 messages as long as no electrical error is detected in those bits (EM error). If the correct start sequence for the SMC message is detected on M1 (6 logical 1s and a logical 0) in those 7 messages, M0 and M1 from the following 11 messages are also extracted and saved in the SMC buffer allocated to the slot in which

the PSI5 message is received (in total, 18 PSI5 messages are needed to build one SMC message). When the SMC has been received, the CRC is checked and the status of the check is saved in the SMC buffer. If an EM error occurs after a start sequence has been detected and before the end of the message is reached, M0 and M1 are both saved as 0 and the rest of the message is received, at which point the CRC is checked as normal.

53.4.2.3.3.2 Message Too early

Figure 1586. Message Too early



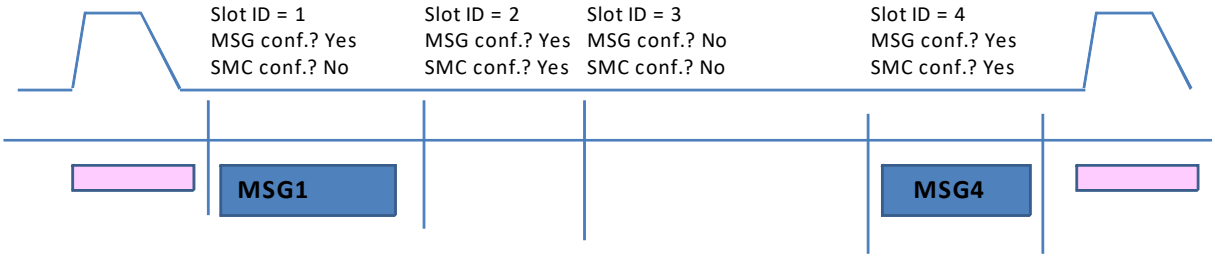
Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	1	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception starts early, before slot 2 boundary is crossed, and so the slot counter is captured as “1” and because the message starts in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG2 has been received but not entirely in its correct slot. The status of the message will include the T bit set and slot counter will be 1, so software can interpret that MSG2 was too early.

The SMC message is received correctly.

53.4.2.3.3.3 Message Too late

Figure 1587. Message Too late



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

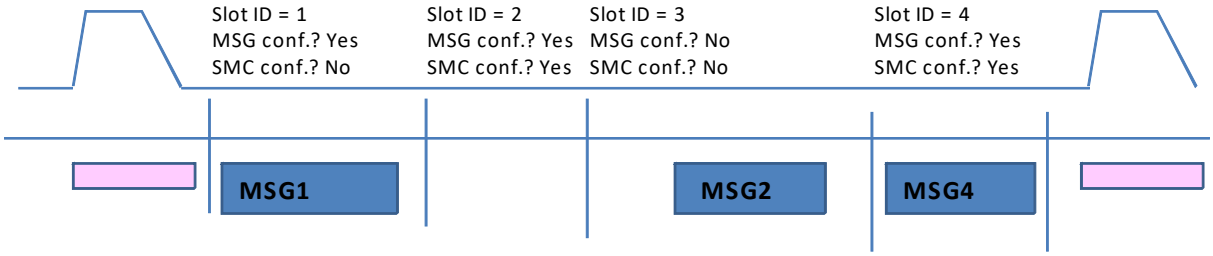
In this scenario, MSG1 reception starts later than expected and ends after slot 2 boundary is crossed. The slot counter is captured as “1” and because the message ends in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG1 has been received but not entirely in its correct slot. The status of the message will include the T bit set and slot counter will be “1”, so software can interpret that MSG1 was late.

The SMC message is received correctly.

53.4.2.3.3.4 Message missing

Figure 1588. Message missing

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	Yes	No	No	2	0/0
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, MSG2 is missing.

At the end of slot 2, the IP writes message buffer location 2 (MSG2 location) with slot counter 2 and the F bit set. The data and timestamp regions are filled with 0s.

The IP waits until the start of the next configured slot (slot 4) to update the SMC buffer 2 with “00”. If slot 4 was not configured, the SMC for the missing MSG2 would be updated at the end of the final slot.

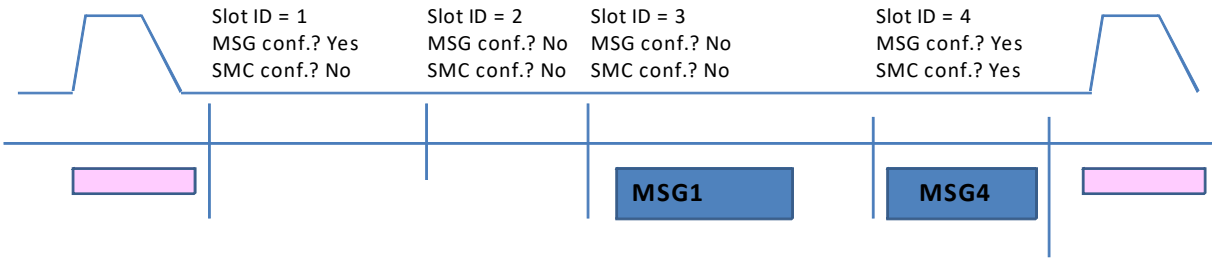
53.4.2.3.3.5 Message Much too late (in unconfigured slot)

Figure 1589. Message Much too late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2a	2	No	Yes	No	No	2	No update
MSG2b	3	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception does not start in its own slot, and the F bit is set for message buffer location 2 (MSG2a).

Because slot 3 is unconfigured, the IP continues to wait for MSG2 in slot 3 and does not update the SMC message buffer 2. The IP recognizes the MSG2 start condition in the normal way and updates PSI5 message buffer 3 (MSG2b), capturing slot 3 as the start slot counter and setting T bit, so that the software can recognize that MSG2 has come in slot 3.



When MSG2 has been received, SMC message buffer 2 is updated at the end of slot 3. MSG4 is received normally.

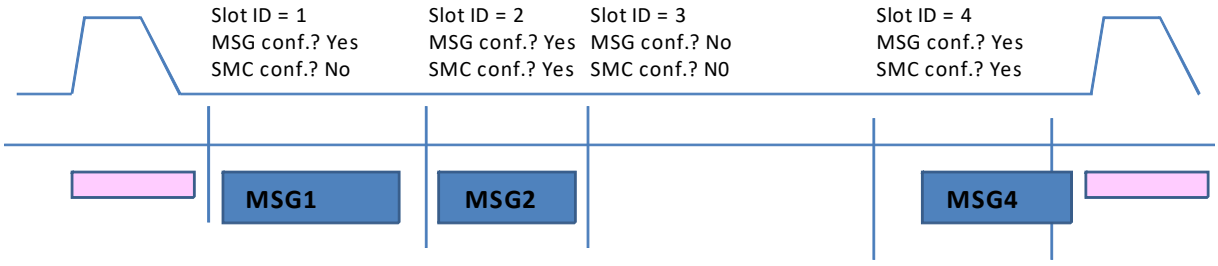
Note: *Any scenario where an expected message arrives in an unconfigured slot, leads to an issue when DMA access is used to read the PSI5 message buffer. This is because instead of the expected three entries in the PSI5 message buffer, there will be four, and assuming the DMA watermark is set for the expected three messages, the DMA request will be activated before MSG4 has been received.*

In order to overcome this, if DMA access is required, no slots can be left unconfigured and the DMA watermark must be set to the number of slots in the SYNC period. In that way, the DMA will always be synchronized, but depending on how the 'empty' slot is configured, when a message is too late as described here, the result can be that the late message and its associated SMC content is lost.

53.4.2.3.3.6 Message Much too late (in unconfigured slot)

Figure 1590. Message Much too late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1a	1	No	Yes	No	No	No	No
MSG1b	3	Yes	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, MSG1 is received much too late, in the second of two unconfigured slots.

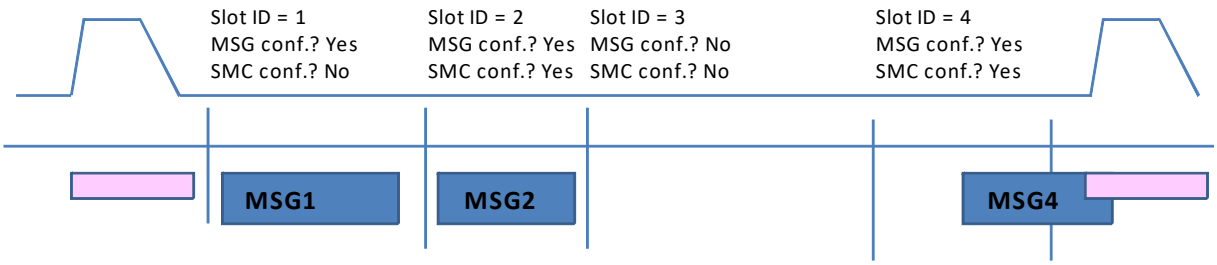
When MSG1 does not arrive in slot 1, MSG1a is saved in the message buffer with F bit set. The IP waits throughout the two unconfigured slots and is received in slot 3 with slot counter 3. Because MSG1b is received completely in slot 3 it is saved in the message buffer with T bit set.

MSG4 is received normally.

53.4.2.3.3.7 Message too late (in last slot)

Figure 1591. Message too late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	No	No	4	M0/M1



In this scenario, the last message is received late.

MSG1 and MSG2 are received error free.

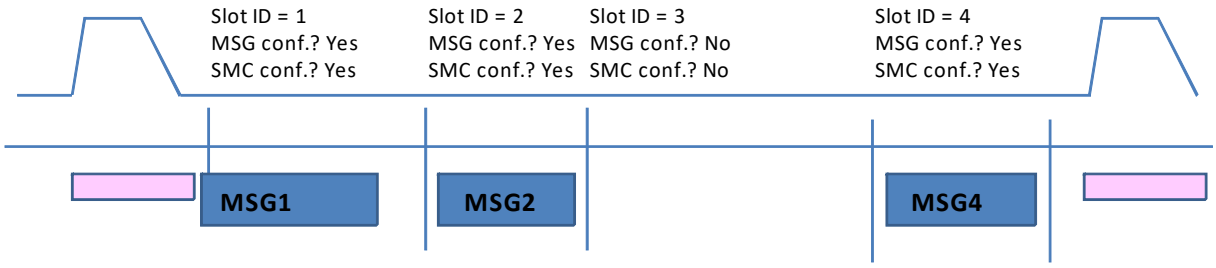
MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the end of the final slot, but before the Manchester decoder is disabled by the SYNC pulse on the bus. The message is received correctly with the T bit set.

53.4.2.3.3.8 Message Too late (in last slot)

Figure 1592. Message Too late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	Yes	Yes	4	M0/M1 or 0/0

In this scenario, the last message is received late in the last slot.



MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the Manchester decoder is disabled by the SYNC pulse on the bus, so the last part of the message cannot be received correctly. Nevertheless, the message reception is completed and the message is stored in the message buffer with the T bit set and 0 written in the buffer for all bits received while the Manchester decoder is disabled. This leads to E and C bit errors.

In an extreme case, it could also lead to EM bit errors, in which case the SMC buffer will also be written with (0,0) otherwise, the correct bits are written to the SMC buffer.

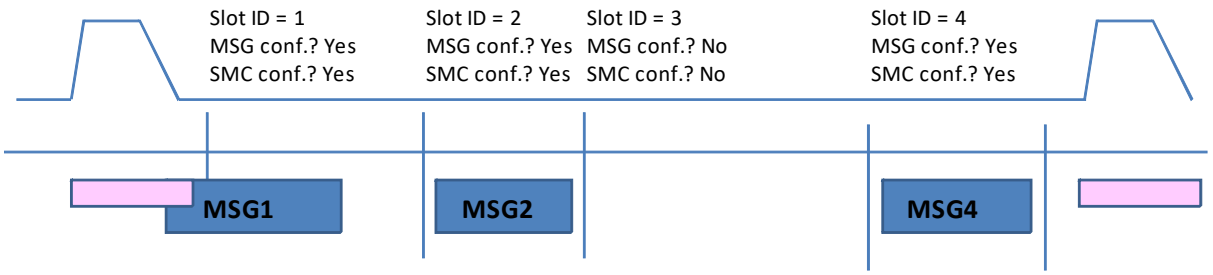
53.4.2.3.3.9 Message Too early (in first slot)

Figure 1593. Message Too early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	0	Yes	No	No	No	1	M0/M1
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, the first message is received early.

As soon as the Manchester decoder disable phase has ended, the IP verifies the idle condition on the signal line and then looks for the first message start sequence. MSG1 start sequence is received before the start of slot 1 with slot counter 0 captured. MSG1 is then received normally and saved with slot counter 0 and T bit set.



SMC bits M0/M1 are saved to SMC buffer 1.

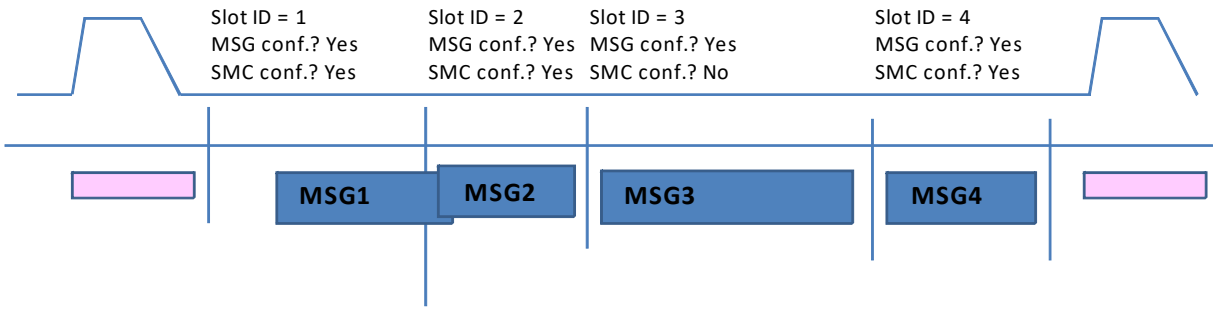
MSG2 and MSG4 are received normally.

Note: This scenario can be avoided if the start of slot 1 is configured to coincide with the end of the Manchester decoder disable phase.

53.4.2.3.3.10 Message Too early (in first slot and overlaps Manchester Decoder disable)

Figure 1594. Message Too early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	Yes	No	No	1	0/0
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1



In this scenario, the first message is received early and overlaps with the Manchester decoder disable phase.

As soon as the Manchester decoder disable phase has ended, the IP starts looking for “idle condition” on the signal line by monitoring it for 42 counts of the sample clock. If the signal line is found to be initially high or if a valid transition occurs in the time frame of 42 samples of the sample clock, the Manchester decoder stops decoding until the end of slot 1. Decoding will restart at the beginning of slot 2.

MSG1 is assumed to be lost and the “F” bit is set for that message with the Slot Counter as “1”. If MSG1 SMC is configured then SMC is saved with “00” appended for the M0/M1 bits.

53.4.2.3.3.11 Message Too late (overlaps next message)

Figure 1595. Message Too late (overlaps next message)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	Yes	Yes	1	M0/M1
MSG2	2	No	Yes	No	No	2	0/0
MSG3	3	No	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG1 is received too late and overlaps with MSG2.

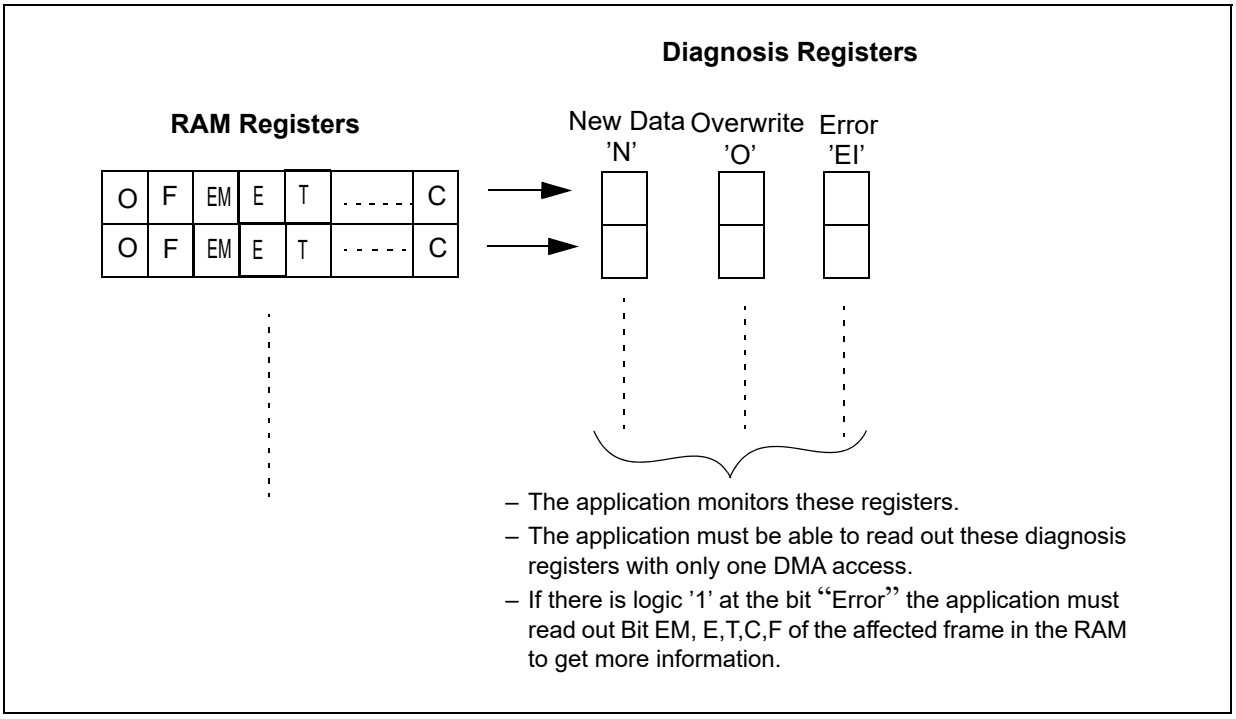
MSG1 start is recognized in slot 1. The last bits of MSG1 are disrupted by the start of MSG2 leading to likely E and C bit errors.

At the end of MSG1, idle time is found to be violated by either the signal line being high as soon as NO_DETECT_STATE is entered or FIRST_TRANSITION_DETECT occurs within 42 counts of the idle detect sample clock. The Manchester decoder stops decoding until the end of slot 2. Decoding is restarted at the start of slot3. MSG2 is not received and MSG2 location in the memory will be saved with the F-bit set. The SMC buffer 2 will be updated with 00.

MSG3 and MSG4 are received correctly in their own slots.

53.4.2.3.4 Data Frame storage

Once the data frame is received and all required status fields updated (for example, Time stamp, C, E, EM, T, F and Frame Counter), this 64-bit value in the data receive register is moved to the RAM Register (PMB).



- This RAM buffer is a 32 (depth) × 64 (frame size) register array with DMA transfer capability (both single or burst).
- Also, the individual RAM locations can be accessed directly by the microcontroller core any time.
- Care needs to be taken that receive data is assigned to the sensor and frame slot unambiguously.

53.4.2.3.5 Message diagnostics

Apart from the regular status bits (mentioned above), a few more diagnostic checks are done and stored as status bits along with each data frame location in RAM. These are:

- Diagnosis registers are associated with each sensor data RAM buffer to indicate:
  - RAM buffer has been filled with data.
  - RAM buffer has been overwritten before data previously stored was read.
  - Data written to buffer includes an error bit (E, EM, C, T, or F, configurable).
- The diagnosis registers are able to be read with a single DMA access.
- After successfully completing a read access, these registers are reset by hardware. This is done by mapping these diagnosis bits byte-wise so that one byte access clears a single bit without affecting other bits.

Figure 1596. Diagnosis Information attached to every frame

Note: See Section 53.8.3: Implementation of EI diagnostic register for more detail.

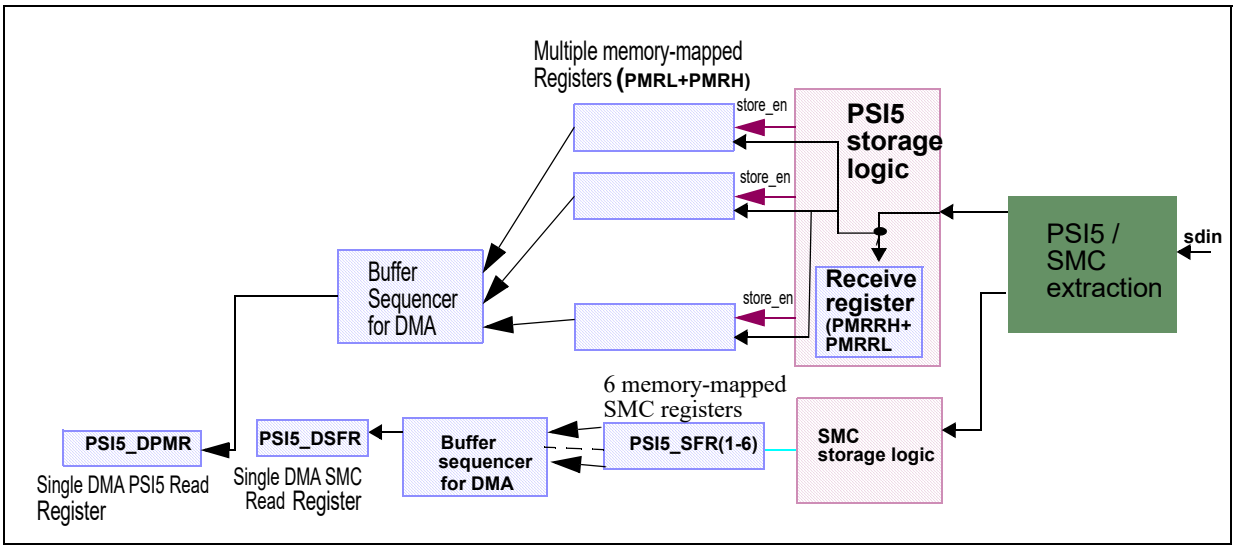
53.4.2.3.6 SMC message extraction

The optional messaging channel M0, M1 (shown in *Figure 1581*) is used by sensors to send an SMC frame along with the normal PSI5 frame. It takes 18 PSI5 frames to send one SMC frame.

The extraction of SMC bits is done for each slot separately and stored separately into the SMC frame receive buffers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame, as defined below).

The extraction logic works as follows:

- Search for SMC start sequence 111111 followed by 0 on M1 and keep storing last 6 bits {CRC} on M0.
- If the start sequence is detected it continues with further extraction and storage of M1 and M0.
  - Store the extracted frame on the corresponding slot buffer.
  - Move the SMC frame to corresponding SFR[i] register period. Once complete, the SMC frame is extracted and generates an interrupt, so that it can be read by the CPU.
  - If the start sequence is not detected, it continues with the search.



The SMC frame is extracted in hardware and stored separately as memory-mapped registers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame).

53.4.2.4 Message Read Logic

PSI5 supports two kinds of read access to received sensor data.

- Read access through memory-mapped RAM registers. These registers can be read by the CPU any time or, specifically, when the concerned interrupts are raised. Applicable for both the SMC and the PSI5 messages.
- Read access through DMA request. Here the DMA sequencer treats the memory-mapped registers as a block and reads them sequentially. Note that even if the DMA is used, the CPU can read the RAM registers any time by addressing them. This is applicable for both the SMC and the PSI5 messages. When reading the PSI5 messages, it is possible to read only the PSI5 messages or PSI5 + diagnostic registers.

Figure 1597. PSI5 and SMC Message Read Logic block

53.4.2.5 CRC recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1598. CRC calculation scheme

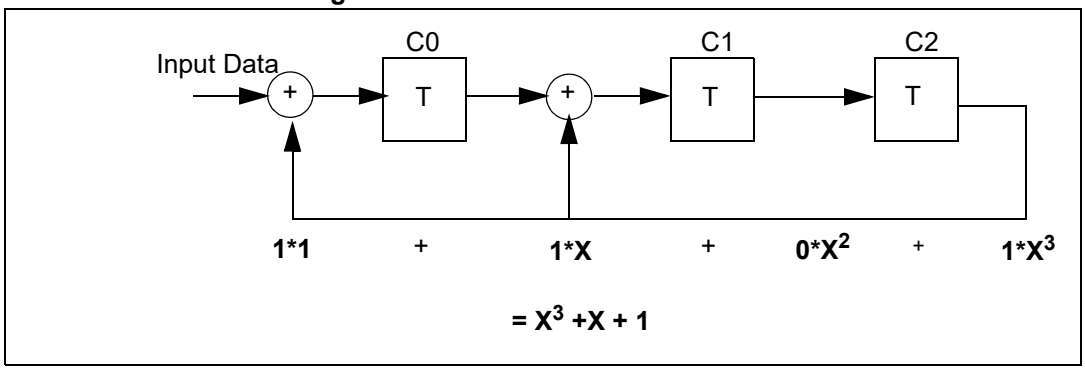


Table 1660. CRC calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1661. Transmitted and Received sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1662. CRC re-calculation (At Receiver side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

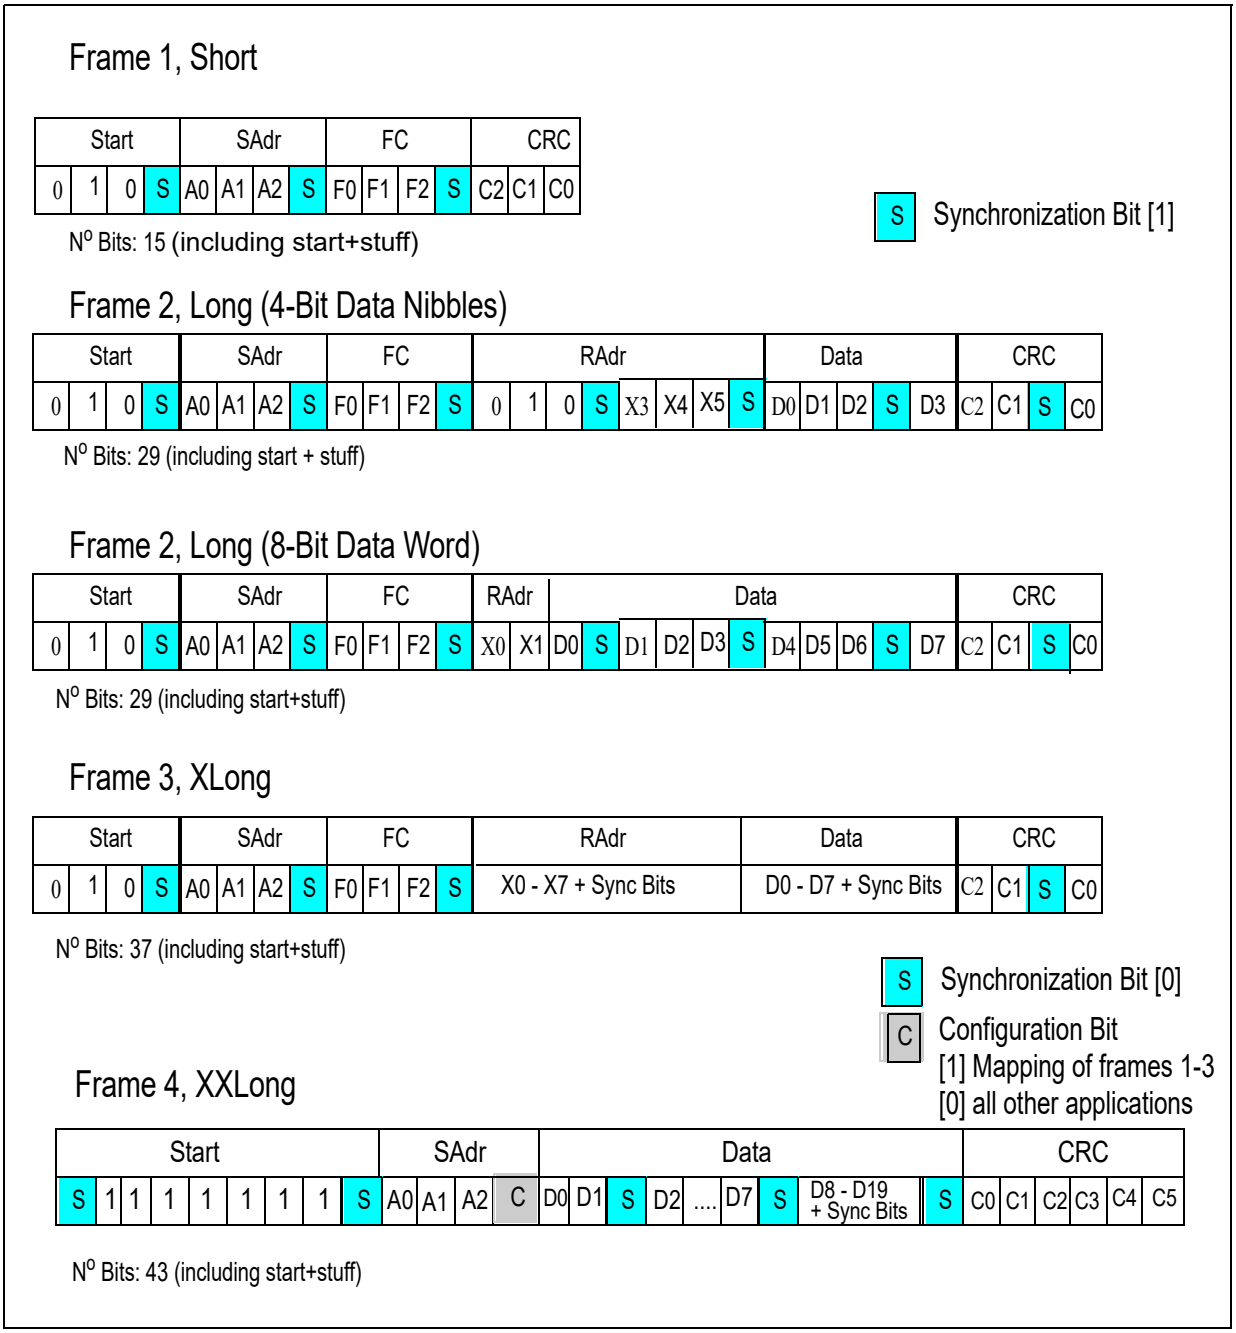
53.4.3 ECU-to-sensor communication

Whereas the sensor-to-ECU communication is realized by current modulation, voltage modulation on the supply lines is used to transmit commands to the sensors. A predefined start sequence allows the sensors to recognize that a command is being transmitted during all synchronous operation modes.

53.4.3.1 Physical layer

A logical 1/0 is represented by data sync pulse of variable length, a logical 1 by the sync pulse of width W1(programmable from 0 to 127 µs) and logical ’0’ by sync pulse with W0{programmable from 0 to 127 µs}.

53.4.3.2 Data Link Layer



53.4.3.3 Bit coding

The bit period is the cycle time as specified for the operation mode, for example, 500 µs in the PSI5-P10P-500/3L mode. (For details about this topology, refer to *Section 53.1.3.3.1: PSI5 topology*.) The lower limit depends on the filter characteristics of the hardware circuitry used for the sync signal detection (subsequent sync signals might vary the internal $V_{ss,\ base}$ reference).

53.4.3.4 Data transmission

The IP supports the standard and the Non-Standard ECU to Sensor communication Formats. In the Non-Standard mode of communication it can be used to send any frame size programmable from 1-64 bits. The IP supports the PSI5 ECU to Sensor Communication formats as briefed below in *Figure 1599* and the text that follows it.

Figure 1599. Standard Frame formats supported

- Short: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “C2, C1, C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor

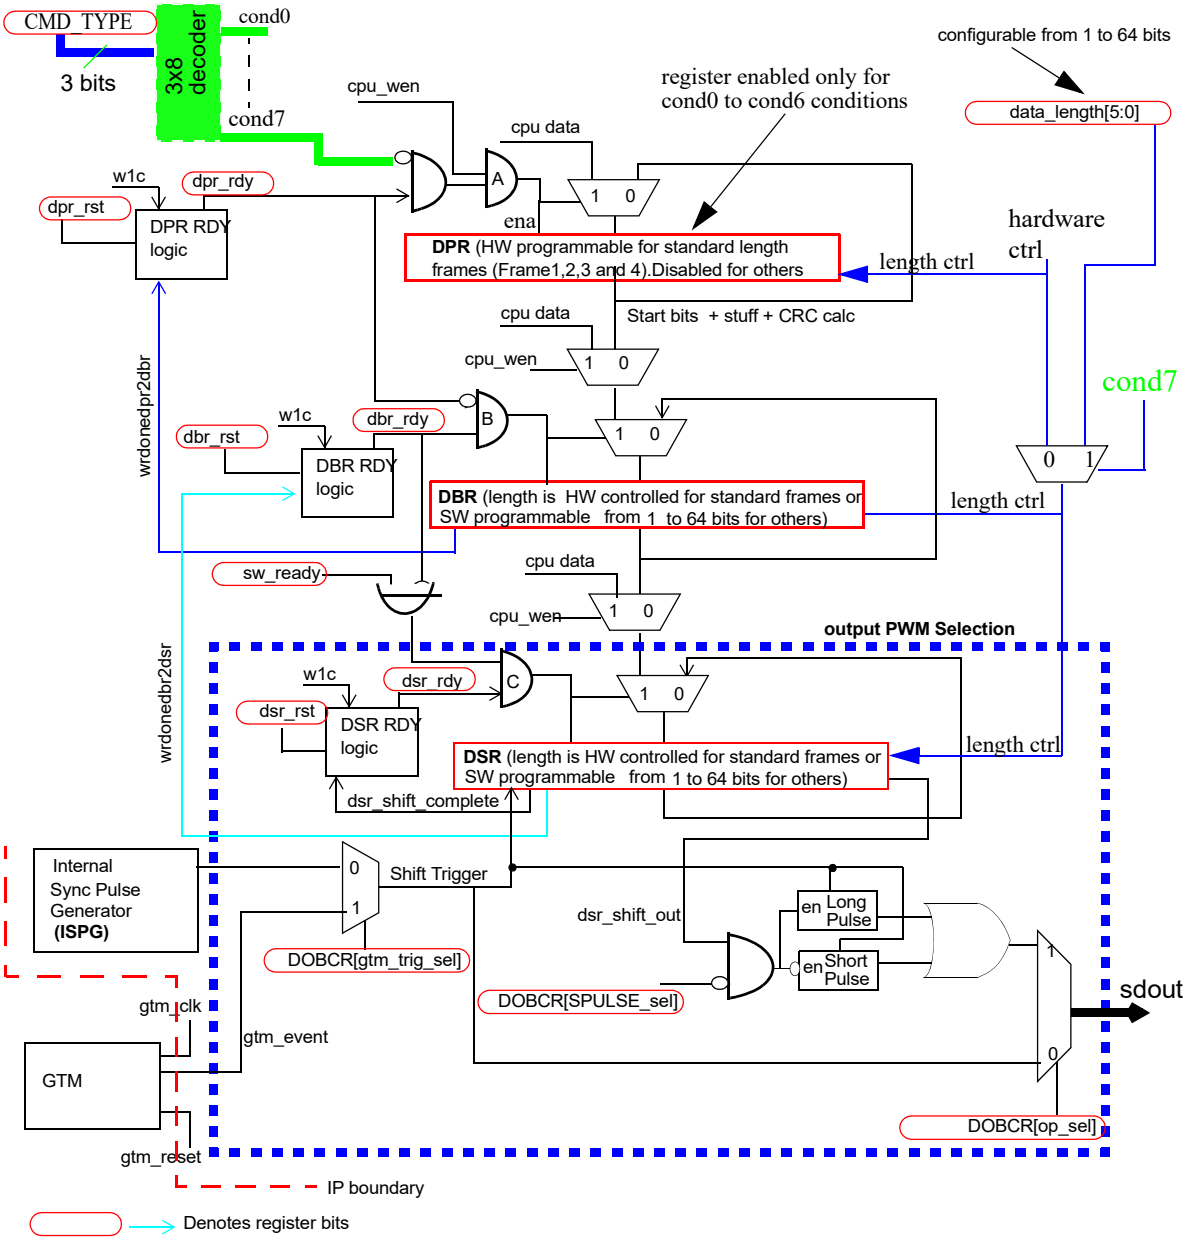
address, F0-F2 are the functional codes and “C2-C0” is the CRC. Refer *Figure 1599* for the frame structure.

  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[5],000) with DPR[0] being fed first in the CRC calculator.

- Long (4-bit Data Nibble): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, X2”, S, “X3, X4, X5, S, “D0, D1, D2”, S,“D3, C2, C1”,S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1599* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X5,D0...D3,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- Long (8-bit Data Word): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, D0”, S, “D1, D2, D3, S, “D4, D4, D6”, S,“D7, C2, C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,”X0-X1” is the Range Address, “D0-D7” is the data and “C2-C0” is the CRC. Refer *Figure 1599* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X1,D0...D7,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- X-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0, A1, A2”, S, “F0, F1, F2”, S, “X0, X1, X2”, S, “X3, X4, X5”, S, “X6, X7, D0”, S, “D1, D2, D3”, S, “D4, D5, D6”, S,“D7, C2, C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is

the sensor address, F0-F2 are the functional codes,"X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Refer to *Figure 1599* for the frame structure.

- The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0...F2,X0...X7,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[21],000) with DPR[0] being fed first in the CRC calculator.



- XX-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - "011111110", "A0, A1, A2", "C", "D0, D1", S, "D2, D3, D4" D5, D6, D7, S, "D8, D9, D10, D11, D12, D13", S,"D14, D15, D16, D17, D18, D19", S, "C0, C1, C2, C3, C4, C5" where "011111110" is the start sequence "S" is the stuff bit(0), A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Refer to *Figure 1599* for the frame structure.
  - The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0).
  - The transmitter extends the data bits by six zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,D0...D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[23],000000) with DPR[0] being fed first in the CRC calculator.

53.4.3.4.1 Transmission Data Framing

The output data transmission block is constructed of seven sub-blocks:

- Data preparation register
- Buffer register
- Data shift register
- Periodic Sync Pulse Trigger Generator
- Pulse length modulation block
- OR gate

Figure 1600. Data transmission block

cond0 = Frame 1(short) - start condition: at least 31 "1s"
cond1 = Frame 1(short) - start condition: at least 5 "0s"
cond2 = Frame 2(long) - start condition: at least 31 "1s"
cond3 = Frame 2(long) - start condition: at least 5 "0s"
cond4 = Frame 3(x-long) - start condition: at least 31 "1s"
cond5 = Frame 3(x-long) - start condition: at least 5 "0s"
cond6 = Frame 4(xx-long)
cond7 = Non standard frames - programmable <data_length> 1 to 64 bits

When <sw_ready> == 0 the data from DBR to DSR is NOT transferred and remains pending even if DSR_RDY becomes 1. Only when <sw_ready> becomes 1, is the data from DBR to DSR transferred.

53.4.3.4.2 Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0)

Up to 24 bits of this register can be written by the CPU. These register bits contain the ECU to sensor command that needs to be transmitted after being appended with the CRC, start bits and stuff bits. The hardware automatically calculates the CRC, adds the start and the stuff bits, before transferring the command to DBR.

- When DPR_RDY == 1, the data to be transmitted to sensors is written to this register via system bus with order data bit to be transmitted first at LSB and furthest on MSB. This register can only be used for writing standard length data frames. Data to this register can be written only when PSI5_DOBCR[CMD_TYPE]!= 7. When PSI5_DOBCR[CMD_TYPE] == 7 then DPR_RDY remains at “0” and the commands cannot be written to this register. Bits writable in different settings of the PSI5_DOBCR[CMD_TYPE] can be seen in *Section 53.3.2.36: Data Preparation Register Low (PSI5_CH0_DPRL)*. Note that PSI5_DPRH is always = 0.
- Having written the data to the DPR, the DPR_RDY bit has be cleared with a w1c. This indicates to the internal logic that the data in the DPR is valid and is to be processed.
- If DPR_RDY = 0 and a new command is written to the DPR then the command is rejected and GISR[IS_PROW] is set.
- If the CRC or parity bit calculation is finished, then the data is shifted to the Buffer register with the start bits and the sync bits appended as well. This transfer is done to the Buffer register only if the Buffer register is ready for new data, which is indicated by GISR[DBR_RDY] == 1.
- As mentioned above, once this transfer is done, the DPR_RDY becomes 1 and a new command can be written to it.

53.4.3.4.3 Data Buffer Register (64-bit register)

- This register has two sub registers DBRH (higher register) and DBRL (lower register). Both of them are collectively referred to as DBR. DBR is of length 64 bits DBR[63:0]
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field refer bit description in *CMD_TYPE*
- When DPR_RDY == 0 and DBR_RDY goes to 1 then internal logic automatically transfers the data from the DPR (with CRC + stuff bits + sync bits) to the DBR. DBR_RDY goes low and DPR_RDY goes 1. In order to check the calculation of the DPR, register DBR can be read at this stage, that is, when DPR_RDY becomes “1”.
- If DBR_RDY == 1 AND DPR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping preparation register in case application includes the start and sync bits and calculates the CRC/Parity itself. If the CPU writes to the DBR when DBR_RDY == 1 but DPR_RDY == 0 and

PSI5_DOBCR[CMD_TYPE]!= 7, then the results can be unpredictable since the DPR has a pending data that needs to be transferred to DBR.

- If the CPU is writing to the DBR as mentioned above, then the DBR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DBR is valid and is to be used for the shift operation.
- If while DBR_RDY == 0, and a new command is directly written to the DBR then the command is rejected and GISR[IS_BROW] bit is set.
- If while DBR_RDY == 0 a new command HAS to be written in the DBR then DOBCR[DBR_RST] has to be written to 1. Writing a 1 to DBR_RST will reject the current command in the DBR and generate DBR_RDY = 1.
- If the Data Shift Register signals that it is ready for new data (PSI5_GISR[DSR_RDY] == 1), the data of the Buffer register is shifted into the data shift register provided PSI5_DOBCR[SW_READY] is 1.
- If PSI5_DOBCR[SW_READY] == 0 then the data from the DBR is NOT transferred to the DSR automatically even if the DSR_RDY goes as 1. In such a case the IP waits for the software to make the PSI5_DOBCR[SW_READY] bit as 1; only then does it transfer the contents to the DSR.

53.4.3.4.4 Data Shift Register (64-bit register)

- This register has two sub registers DSRH (higher register) and DSRL (lower register). Both of them are collectively referred to as DSR.DSR is of length 64 bits DSR[63:0]. This register has a 1-1 correspondence with the bits in the DBR register when this register is updated automatically by the hardware.
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field refer to bit description in *CMD_TYPE*.
- When DBR_RDY == 0 and DSR_RDY goes to 1 then internal logic automatically transfers the data from the DBR to the DSR provided PSI5_DOBCR[SW_READY] == 1'b1, else this transfer remains pending until PSI5_DOBCR[SW_READY] is '0'. Once the transfer is complete, DSR_RDY goes low and DBR_RDY goes 1. DSR contents that would finally get transferred, can be read at this stage, that is, when DBR_RDY becomes "1".
- Making PSI5_DOBCR[SW_READY] now as '0' will not interrupt the ongoing transfer in the DSR.
- If DPR_RDY == 1 AND DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY == 1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- When PSI5_DOBCR[CMD_TYPE] == 7 and If DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY ==

1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.

- If the CPU is writing to the DSR as mentioned above then the DSR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DSR is valid and is to be used for the shift operation.
- If while DSR_RDY == 0, and a new command is directly written to the DSR then the command is rejected and GISR[IS_DSROW] is set.
- If while DSR_RDY == 0 a new command HAS to be written in the DSR then DOBCR[DSR_RST] has to be written to 1. Writing a 1 to DSR_RST will reject the current command in the DSR and generate DSR_RDY = 1.
- This register is clocked by the ISPG pulses, as described in *Section 53.4.3.4.5: Sync Pulse Trigger Generation*.
- Once the shift operation is complete in the DSR then DSR_RDY becomes 1.

53.4.3.4.5 Sync Pulse Trigger Generation

The sync pulse trigger can be used to generate the timing pulses or the data pulses.

The sync pulse can be generated based on triggers from two different sources:

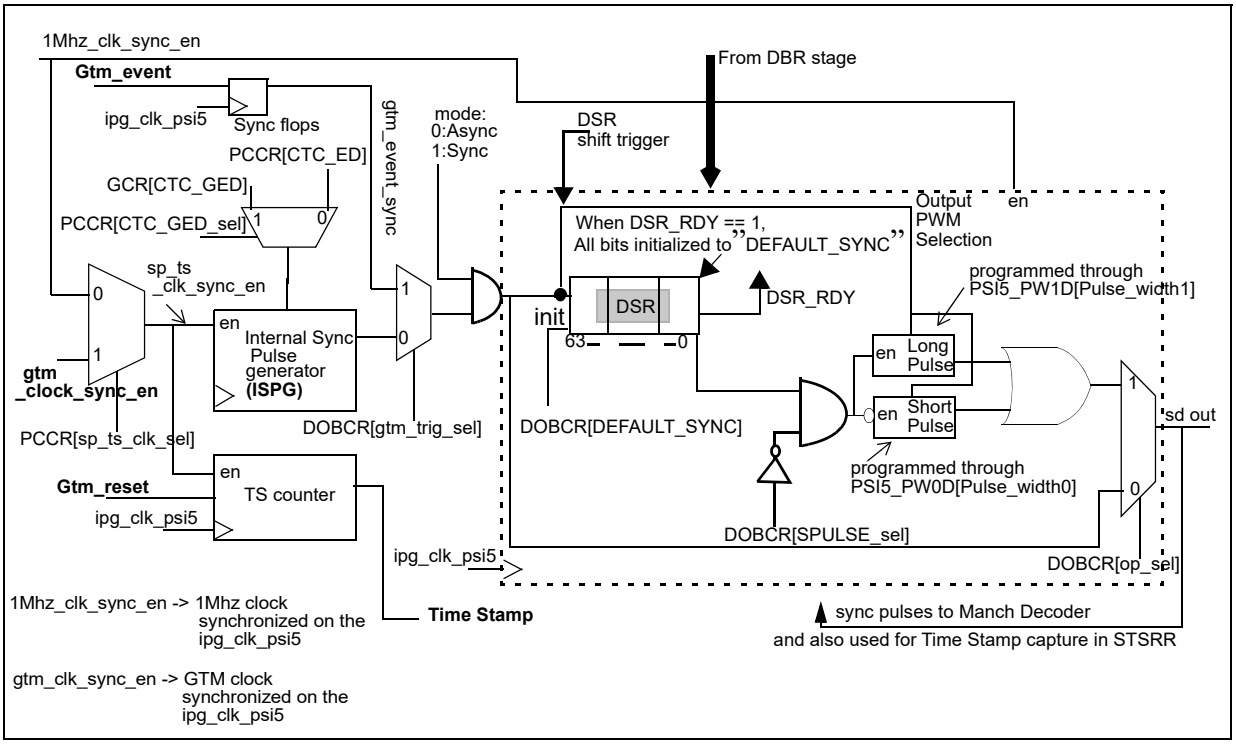
- ISPG (Internal Sync Pulse Generator): Composed of CTPR, CIPR and Channel Target Counter (per channel). The internal sync pulse generator is clocked by the internal 1 MHz clock. The Channel Target Counter operates with a 1 µs resolution (when using the 1Mhz clock). The ISPG is implemented to allow generation of internal periodic trigger. Refer to *Figure 1607* for the ISPG structure and *Figure 1605* for the CTPR and CIPR explanation. The ISPG uses the Channel Target Counters (CTCs) for generating the sync pulse. The CTCs can be triggered globally (simultaneous for all channels) or locally (individual to each channel). The CTC_GED bit in the Global Control Register (GCR) ensures that all the CTCs start/stop simultaneously. The individual target values when the trigger pulse is generated are set in the Counter Target Pulse Register (CTPR) and the Channel Initial Pulse Register (CIPR). These registers are present for each channel. When staggering the channels, the CTC_GED bit should be used for providing a simultaneous trigger to the staggered channels. It is also possible for a subset of channels to work on the above arrangement while the remaining channels independently generate trigger pulses for which start/stop is controlled locally to the channels.
  - For each channel, it is possible to configure the trigger period by software using sync pulse generator control/configuration register and setting compare values in Counter Target Pulse Register(s). The Counter Initial Pulse Register (CIPR) can be used to provide the initial offset between various channels.
  - It is possible to deactivate each channel separately for the purpose of sync pulse generation.
  - The periodic pulses can be used to synchronize sensor-to-ECU communication (synchronization timing pulses) [State 1 of *Section 53.8.2: Valid states for integrated sync pulse generator*] or can be used as data pulse during ECU-to-sensor communication (through the DOBCR) [State 2 of *Section 53.8.2*].
  - When programming the CTPR, the Tsync period should be programmed >= 6 SP_TS_CLK cycles (For details of SP_TS_CLK, refer to Bit 23 of *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*).
- Programming and control: For achieving the various states of ISPG control, the 2 equivalent bits (SPULSE_SEL and OP_SEL) belonging to the DOBCR, can be

programmed, as shown in *Figure 1600* and *Figure 1601*. The programming of various states mentioned above, with reference to the *Section 53.8.2: Valid states for integrated sync pulse generator* can be seen in *Table 1645* and also shown in *Figure 1609*. The sending of the ECU to sensor commands, can be controlled by PSI5_GISR[DPR_RDY,DBR_RDY,DSR_RDY] bits and the PSI5_DOBCR register bits.

53.4.3.4.5.1 Timing Pulses

Timing pulses can also be produced without pulse width modulation also. These timing pulses can be generated through two sources:

- Periodic sync pulse from ISPG. In this case the synchro pulse from the internal sync pulse generator can be made available without any modulation. Referring to *Figure 1601*, in synchronous mode, if DOBCR[OP_SEL] == 0 then the internal sync pulse generator output can be made available without any modulation. The high time of this pulse is fixed at 4 µs.



53.4.3.4.5.2 Data pulse generation

Data pulses are produced by the Pulse Length Modulation Block based on triggers from the selectable source, the ISPG, during ECU-to-sensor communication. The two sync sources are selected by software programming of the Pulse Length Control/Configuration Register.

- A logical 1 in the Data Output Register LSB is coded as data sync pulse of width W1 {up to 127 µs}.
- A logical 0 in the Data Output Register LSB is coded as data sync pulse of width W0 {up to 127 µs}.
- The two widths are programmable in the Pulse Length Control/Configuration Register.
- The Data Shift Register is shifted right every time a bit is transmitted.

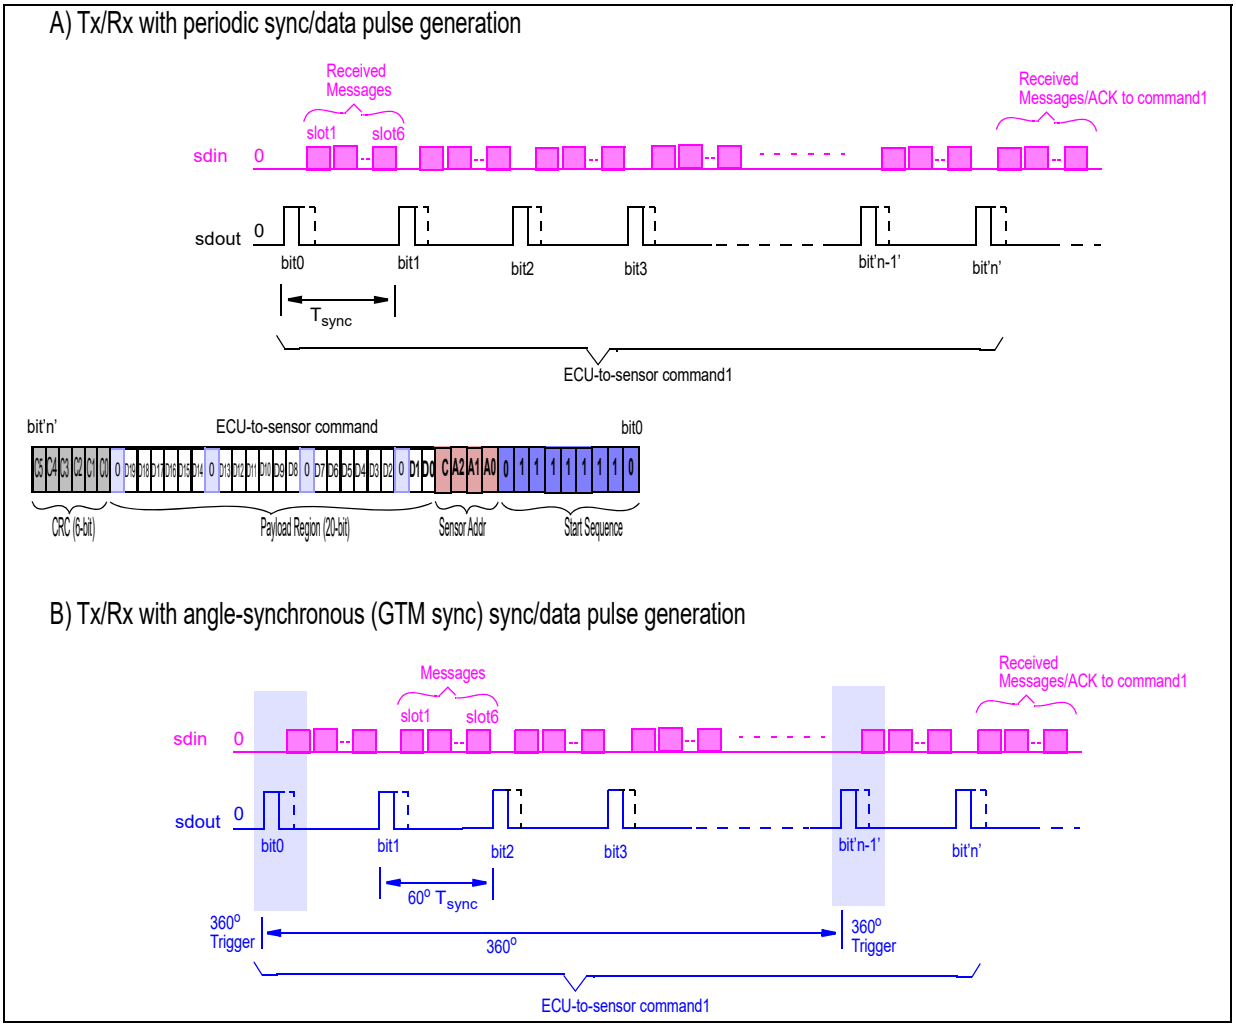
Figure 1600 shows the data transmission block.

Figure 1601. ECU-to-sensor communication registers

Note: GTM is not supported by this device

Figure 1601 details the implementation of *Figure 1600* and shows how the various bits mentioned in *Section 53.3.2.30: Data Output Block Configuration Register (PSI5_CH0_DOBCR)* control the behavior of the Output Command path. *Figure 1601* also shows the various clock sources to the Internal Sync Pulse Generator and the Time Stamp counter.

53.4.3.5 Response to ECU-to-sensor frames



The response to an ECU-to-sensor frame can be optionally transmitted in two ways:

- Out-of range values of data frame (as fast response coded as normal PSI5 payload region)
- Serial messaging channel (verification of the response frames must be handled by the software)

53.4.4 Tx/Rx scenario

The diagram below shows the communication scenario in synchronous modes. For asynchronous mode, sync pulses are not generated and sensor transmits data asynchronously.

Figure 1602. Synchronous mode communication scenarios

53.4.5 Interrupt handling

Configurable interrupts based on events (for example, reception of valid message), errors, DMA transfers, and so on are implemented. The following types of event can generate an interrupt:

- Reception of a new PSI5 message
- Reception of a new SMC message
- Unread SMC message overwritten in the SMC buffer area (PSI5_SFR)
- Unread PSI5 message overwritten in the PSI5 buffer area (PSI5_PMRH, PSI5_PMRL)
- Dedicated interrupts for selectable errors, mentioned below:
  - Bit C is set
  - Bit E or EM, or both, are set
  - Bit T is set
  - No PSI5 frame was received in a defined frame slot (Bit F is set)
- ECU-to-sensor communication-related interrupts
  - The application tries to load new data into the data preparation register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case).
  - The application loads new data into the data buffer register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case).
  - The application loads new data into the data shift register before the register has signalized that it is ready for new data (Note that the new command will be ignored in this case)
- DMA related interrupts (transfer finished/FIFO_FULL/underflow)
- Apart from this a single one sum interrupt OR-ing all the above events.

Various interrupt signals that represent the above events are:

- PSI5 new message arrival interrupt (Status flags in PSI5_NDSR)This is asserted when any of the programmed storage PSI5 locations (max 32) receive a new PSI5 message

(error/error free). This interrupt also indicates that the PSI5 receive register (PMRRL/PMRRH) has been updated with a new PSI5 message.

- SMC message, ECU-to-sensor communication, and Time Stamp related interrupts (All Status flags in PSI5_GISR): This is asserted during following events:
  - When a new SMC message is received in its corresponding slot OR
  - When there is a CRC error in any SMC message OR
  - When an unread message in some corresponding SMC location (in PSI5_SFR) gets overwritten by a new SMC message OR
  - When DPR is ready for receiving a new data OR
  - When DBR is ready for receiving a new data OR
  - When DSR is ready for receiving a new data OR
  - When there is an attempt to write to DPR while it is NOT ready OR
  - When there is an attempt to write to DBR while it is NOT ready OR
  - When there is an attempt to write to DSR while it is NOT ready OR
  - When data time stamp register is updated with new time stamp value OR
  - When the sync time stamp read register is updated with a new time stamp.
- PSI5 Message Overwrite Interrupt (Status Flags in PSI5_OWSR): This is asserted when any of the programmed storage locations in the memory (max 32) have an unread PSI5 message that is overwritten by a new upcoming PSI5 message. Corresponds to OWSR.
- PSI5 Error interrupt (Status Flags in PSI5_EISR): This is asserted when any of the programmed storage locations in the memory (max32) have an error in the PSI5 message. It is used only for PSI5 messages.
- DMA Interrupt (Status Flags in PSI5_DSR):
  - When the DMA transfer corresponding to conf2, conf3 or conf4 finishes OR
  - When the DMA transfer corresponding to SMC message gets over OR
  - When there is an FIFO_FULL/Underflow in the PSI5 RAM register area OR
  - When there is an underflow in the SMC message area.
- Global Interrupt: Single interrupt OR-ing all above interrupt events.

53.4.5.1 Error conditions

- C: CRC/parity error on received data, evaluated after recalculating CRC on received data and comparing with received CRC or recalculating parity on received data and comparing with received parity.
- E: Electrical error during any Tbit period (excluding Messaging field M0M1) during frame reception (not applicable during Idle state); that is, if at least one bit is absent during its Tbit period.
- EM: Electrical error on M0M1 field.
- T: Timing error during frame reception violates the slot boundary. Here, all the corner cases and conditions are taken care of (for example, the isolation of correct slot to correct message if the message is too early or too late with respect to its expected position, the crossing of the slot boundary when one frame overlaps the other, and so on).
- F: No frame received during a particular slot time in case of sync mode.

53.4.6 DMA support

- The PSI5 module generates separate DMA transfer requests for PSI5 message/diagnostic status and SMC messages.
- A single DMA request is used for PSI5 messages and diagnostic data. The request is triggered based on the selected DMA configuration (either PSI5 message or diagnostic data or both). After choosing the configuration, data is available on respective DMA pop-up registers.
- DMA requests for PSI5 messages and diagnostic registers are based on the watermark level of message buffers (to be treated as FIFO for the DMA). PSI5 message buffer FIFOs get data from the PSI5 receiver in the order they are received.
- DMA requests for SMC messages are based on successful storage of each SMC frame to the message buffers. The SMC message buffers get data from SMC extraction logic in fixed round-robin arbitration sequence.
- Refer to *Section 53.4.6.1: Single DMA request for PSI5/diagnostic message buffers* for PSI5 DMA handling and to *Section 53.4.6.2: Single DMA request for SMC received messages* for SMC DMA handling.

53.4.6.1 Single DMA request for PSI5/diagnostic message buffers

A common DMA request (per PSI5 block) is generated for PSI5 message/diagnostic buffers. The depth (up to 32 in present context) of the message buffer is programmable via the MEM_DEPTH filled in the PCCR. The width of each location of the PSI5 message buffer is 64 bits. When reading PSI5 message through the DMA, the 32-bit DPMR is sequenced with the data from the PSI5 message buffer. When reading the diagnostic registers through the DMA, the 32-bit DDSR is sequenced as NDSR followed by EISR. The DMA operation will happen as follows:

- Based on the DMA configuration chosen, one of the three DMA transfer sequence is initiated:
  - PSI5 buffer followed by diagnostic data sequenced to DPMR
  - PSI5 data sequenced to DPMR
  - Diagnostic buffer data sequenced to DDSR
- The DMA request is asserted when the number of messages stored in the buffer crosses the configured watermark number of messages.
- DMA request is deasserted once the “watermark” number of messages have been read.
- If the number of unread messages is still greater than the watermark programmed, then the DMA request is reasserted.
- The received message data is read from a common memory-mapped 32-bit DMA PSI5 message register (DPMR). Thus, a single PSI5 message (64-bit wide) will require two IPS read operations. The diagnostic data is read either through the DPMR or through the DDSR (single 32-bit register) by the DMA controller via the IPS interface.
- It is assumed that the DMA Controller’s Transfer Control Descriptor (TCD) would be set to transfer bytes equal to the messages indicated by watermark level, as described in *DMA_PM _DS_WM* in *Section 53.3.2.3: DMA Control Register (PSI5_CH0_DCR)*. It is assumed that when responding to a DMA request, the DMA controller will read faster

than the rate at which messages are received and stored in the buffer/FIFO, which will cause the DMA request to deassert.

- The next received message will be updated on the common memory map register once the previous message is read by the DMA (by the DMA sequencer).
- The store signal from the synchronization logic will push the message into the memory-mapped RAM registers and in parallel also into the PSI5 receive register. *Figure 1597* shows the format in which the messages will be stored in any message buffer (RAM registers) and finally when being read from DMA access register.
- For more details about DMA programming refer to *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 53.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, *Section 53.3.2.4: DMA Status Register (PSI5_CH0_DSR)*, *Section 53.3.2.10: DMA PSI5 Message Register (PSI5_CH0_DPMR)* and *Section 53.3.2.12: DMA Diagnostic Status Register (PSI5_CH0_DDSR)*.

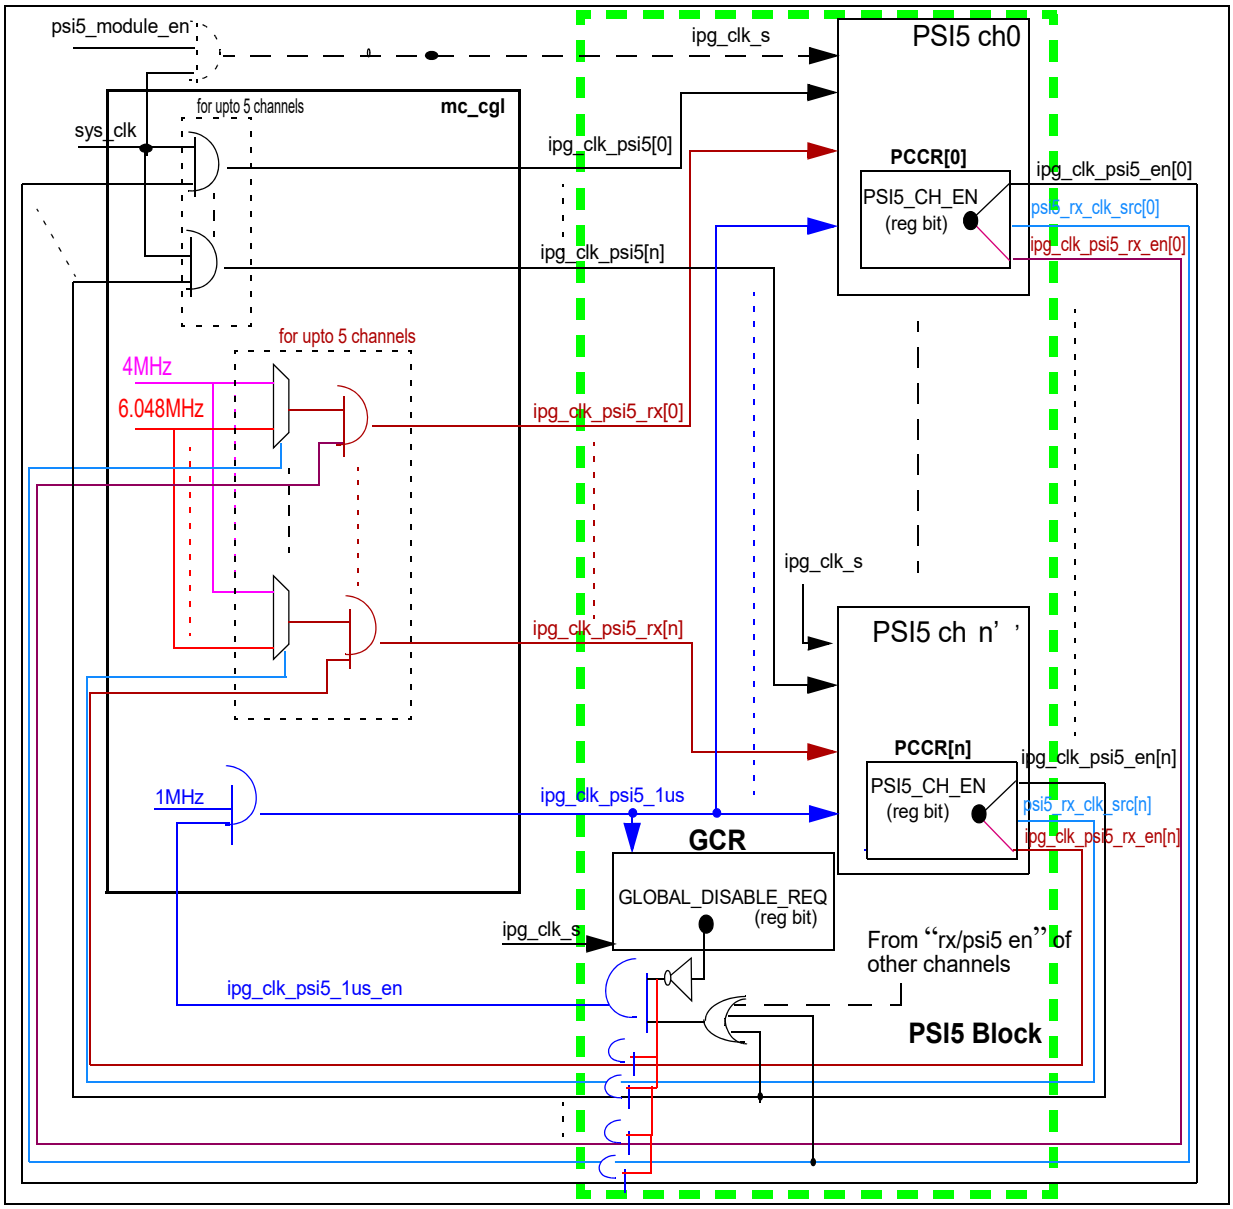
53.4.6.2 Single DMA request for SMC received messages

A separate DMA request (each channel) is generated for the SMC message buffer. Each SMC received message would be stored in the internal registers and read out by DMA controller via a common memory-mapped DMA SMC Frame Register (DSFR) (single 32-bit register for each message buffer). The data flow will happen as follows:

- A request is asserted when the system buffer successfully receives one complete SMC message, and remains asserted until all complete messages have been read. Data is read from the DMA PSI5 Message Register in the memory map.
- It is the job of an internal sequencing logic to provide the next complete received message. The internal sequencer works in a round-robin fashion checking for the slot-specific registers for each SMC message. Thus the sequence will be slot1— slot2—slot3—slot4—slot5—slot6—slot1 and so on. In whichever slot it encounters the first complete SMC message, the DMA request is asserted and the sequencer will wait for this data to be read before moving on to the next slot in its loop. If a particular slot message remains unread and a new SMC message for the same slot comes in, then the previous message would be overwritten and the OW bit would be set.
- The DMA controller should be programmed to read only one message in one DMA transfer. Otherwise, if it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur. User software should ensure there is no overflow.
- For more details about DMA programming refer to *Section 53.3.2.2: PSI5 Channel Control Register (PSI5_CH0_PCCR)*, *Section 53.3.2.3: DMA Control Register (PSI5_CH0_DCR)*, *Section 53.3.2.4: DMA Status Register (PSI5_CH0_DSR)* and to *Section 53.3.2.12: DMA Diagnostic Status Register (PSI5_CH0_DDSR)*.

53.4.7 Message read through interrupt generation

There is a separate interrupt request for received messages for each PSI5 channel. Each PSI5 channel can be configured individually to generate an interrupt on reception of messages. An interrupt is asserted when the corresponding PSI5 channel has received a complete message (PSI5 or SMC). Refer to *Section 53.4.5* for more details about interrupts. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing the corresponding PSI5 channel that is enabled to give out messages via interrupts through the IPS Interface. In response to these interrupts,



the CPU is expected to read interrupt status register for individual PSI5 Channel (depending on which interrupt was asserted) and store it in system memory.

53.5 Clock and reset

The proposed clock scheme of the PSI5 block is shown in *Figure 1603*. Global clock and clock divider are taken care of inside the CGM. Following is a brief description of these clocks with respect to the CGM:

- Global clock (refer to *Figure 1603*)
  - 1 Global clock generated from a single source but separately controllable for each PSI5 channel (“ipg_clk_psi5” for each channel that is generated from sys_clk).
  - It has a jitter of less than 5 ns at 1 MHz.
  - 1 global clock, which is enabled during any register read/write from IPS interface. (“ipg_clk_s”, which is common to all the PSI5 channels).
- Clock divider
  - Only one clock divider for all PSI5 interfaces (divider to generate 4 MHz/6.048 MHz from the system clock).
  - The clock divider generates all clocks that are needed for up to five interfaces.
  - The clock divider is configurable by software.
  - The output of the clock divider has a jitter of less than 5 ns at 1 MHz.

Figure 1603. PSI5 clock scheme

Note: Refer to the Device Configuration chapter for value of PSI5_NUM_CH.

53.5.1 Latency and Jitter related requirements

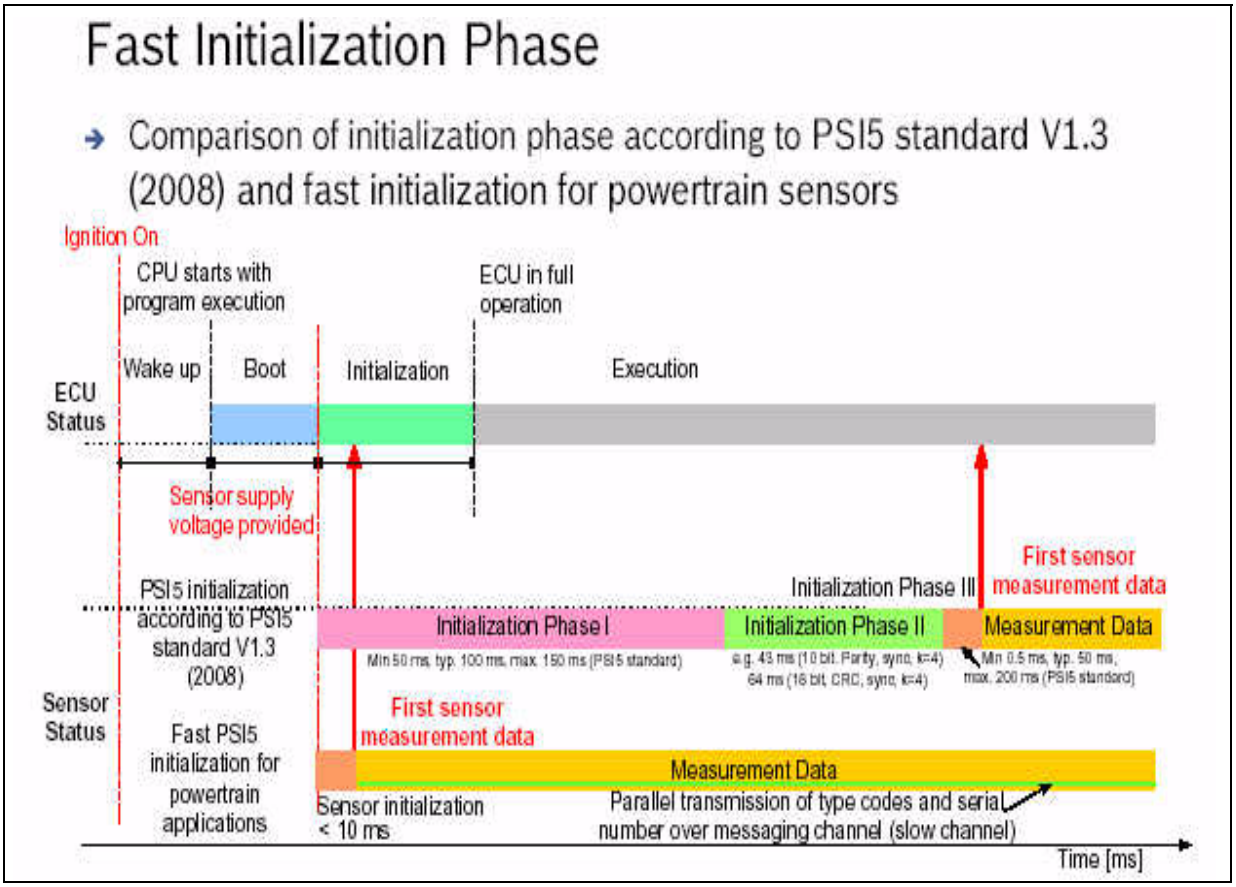
- Latency related
  - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): ≤ 3µs.
  - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: ≤ 2µs.
- Jitter related
  - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): <= $1T_{ipg_clk_psi5}$
  - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: <= 1 µs +$T_{ipg_clk_psi5}$

53.5.2 Reset

The device has a single global asynchronous reset input to the module that resets the whole module bringing it to an inactive state upon its assertion. The user software must program the module registers to bring up the receiver operations.

53.6 Initialization information

53.6.1 Initialization



53.6.1.1 Sensor startup and initialization

After each power-on or under-voltage reset, the sensor performs an internal initialization, which is divided into three phases:

- Initialization Phase1: No data transmission.
- Initialization Phase 2: Transmission of type code and serial number of sensor.
- Initialization Phase 3: Transmission of “Sensor Ready” or “Sensor Defect” or other sensor specific data.

As this PSI5 implementation is targeted towards powertrain devices/sensors the standard initialization phase is modified and tuned for those applications. The comparison of the original scheme and enhanced schemes are shown in *Figure 1604*. *Figure 1604* also describes that the initialization content is the same as defined in V1.3, and the only modification is that it is transmitted using the SMC channel when a fast startup is required. “Fast Initialization Phase” below means that the sending of first sensor data is fast, but the sending of sensor initialization data will actually be much slower.

Figure 1604. Fast initialization phase

53.7 Design assumptions and limitations

53.7.1 Assumptions

- Slot Configuration Register would always be programmed with valid number of bits for frame configuration.
- There will be no Timing error bits (T) in async mode. Also, in this mode the IP waits indefinitely for the detection of a valid start sequence, hence the F bit (NFR) is not set in Async mode. Rest all of the errors are available (E, EM, and C).

53.7.2 Limitations

As this is a PSI5 receiver, designed primarily to only receive the PSI5/SMC data and store as it is into the RAM buffer. So, it would not be responsible neither to recognize the content of the received messages nor do any decision making based on the content. Similarly, for Command it would not recognize the content of command and would transmit as it is writing into corresponding DSR and reception of PSI5 messages would not in any way depend on the content of command as far as PSI receiver is concerned. Its the responsibility of SW to sequence the issue of commands across the PSI5 channels and thereby recognize the content of received message and infer it.

53.8 Miscellaneous descriptions

53.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels

Each PSI5 channel has the Channel Target Pulse Registers (CTPR) and Channel Initialize Pulse Register (CIPR). The CTPR defines the period of the internal sync pulse generation and the CIPR defines the initial offset time with respect to the sync pulse trigger. The sync pulse trigger can be generated from either the PSI5_GCR[CTC_GED] global bit or the PSI5_PCCR[CTC_ED] channel specific bit.

When staggering of the channels is required then the PSI5_GCR[CTC_GED] global bit is used as a common trigger for all the PSI5 channels in which PSI5_PCCR[CTC_GED_SEL] bit is set to 1. Setting this bit to 1 triggers the internal sync pulse generators of all the PSI5 channels and the trigger of each channel is then automatically staggered with respect to the other channel, depending on the value of the CIPR.

When the specific PSI5 channel is not to be kept as a part of staggered channels, then the channel-specific PSI5_PCCR[CTC_GED_SEL] bit has to be kept as 0. The channel in this case, has to be triggered locally by writing a 1 to the PSI5_PCCR[CTC_ED] of that specific channel. This triggers the internal Sync Pulse Generator of that specific channel without affecting other channels.

Following is the procedure for starting the internal Sync Pulse Generators:

- If in Normal mode, then stop and reset all Channel Trigger Counters (CTCs) by setting the global PSI5_GCR[CTC_GED] bit to 0 or the channel specific PSI5_PCCR[CTC_ED] to 0.
- Enter Config mode.
- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a “0” to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, refer to *Section 53.3.2.34: Counter Target Pulse Register (PSI5_CH0_CTPR)*, *Section 53.3.2.35: Counter Initialize Pulse Register (PSI5_CH0_CIPR)* and to *Section 53.4.3.4.5: Sync Pulse Trigger Generation*.

Figure 1605. CIPR and CTPR

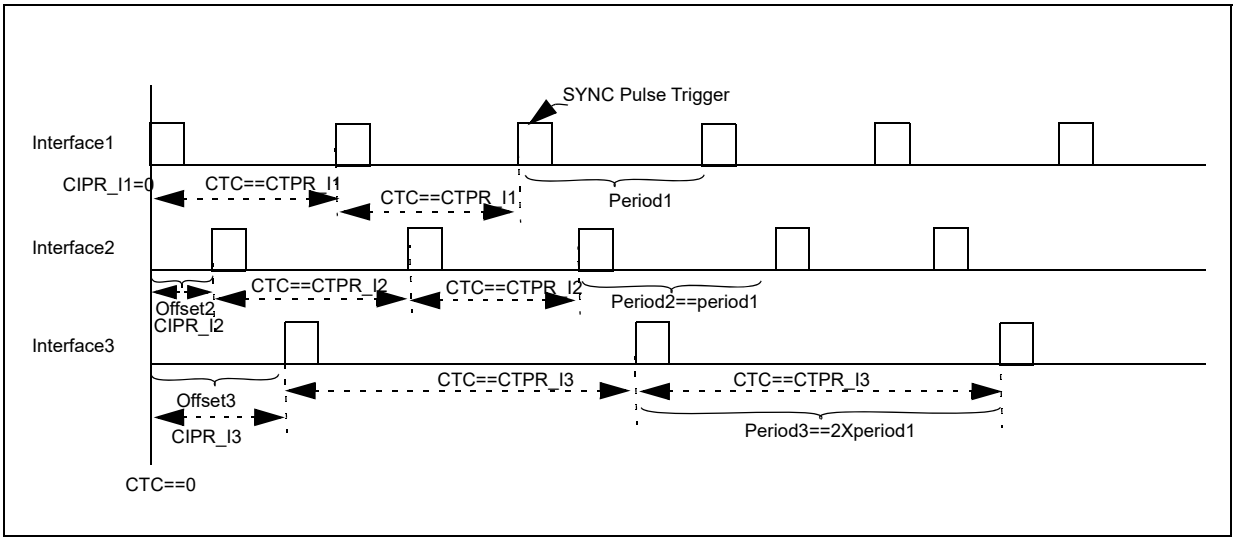


Figure 1605 shows the CIPR and the CTPR definition with respect to the staggering of the channels. *Figure 1606* is a more detailed representation of these parameters along with the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

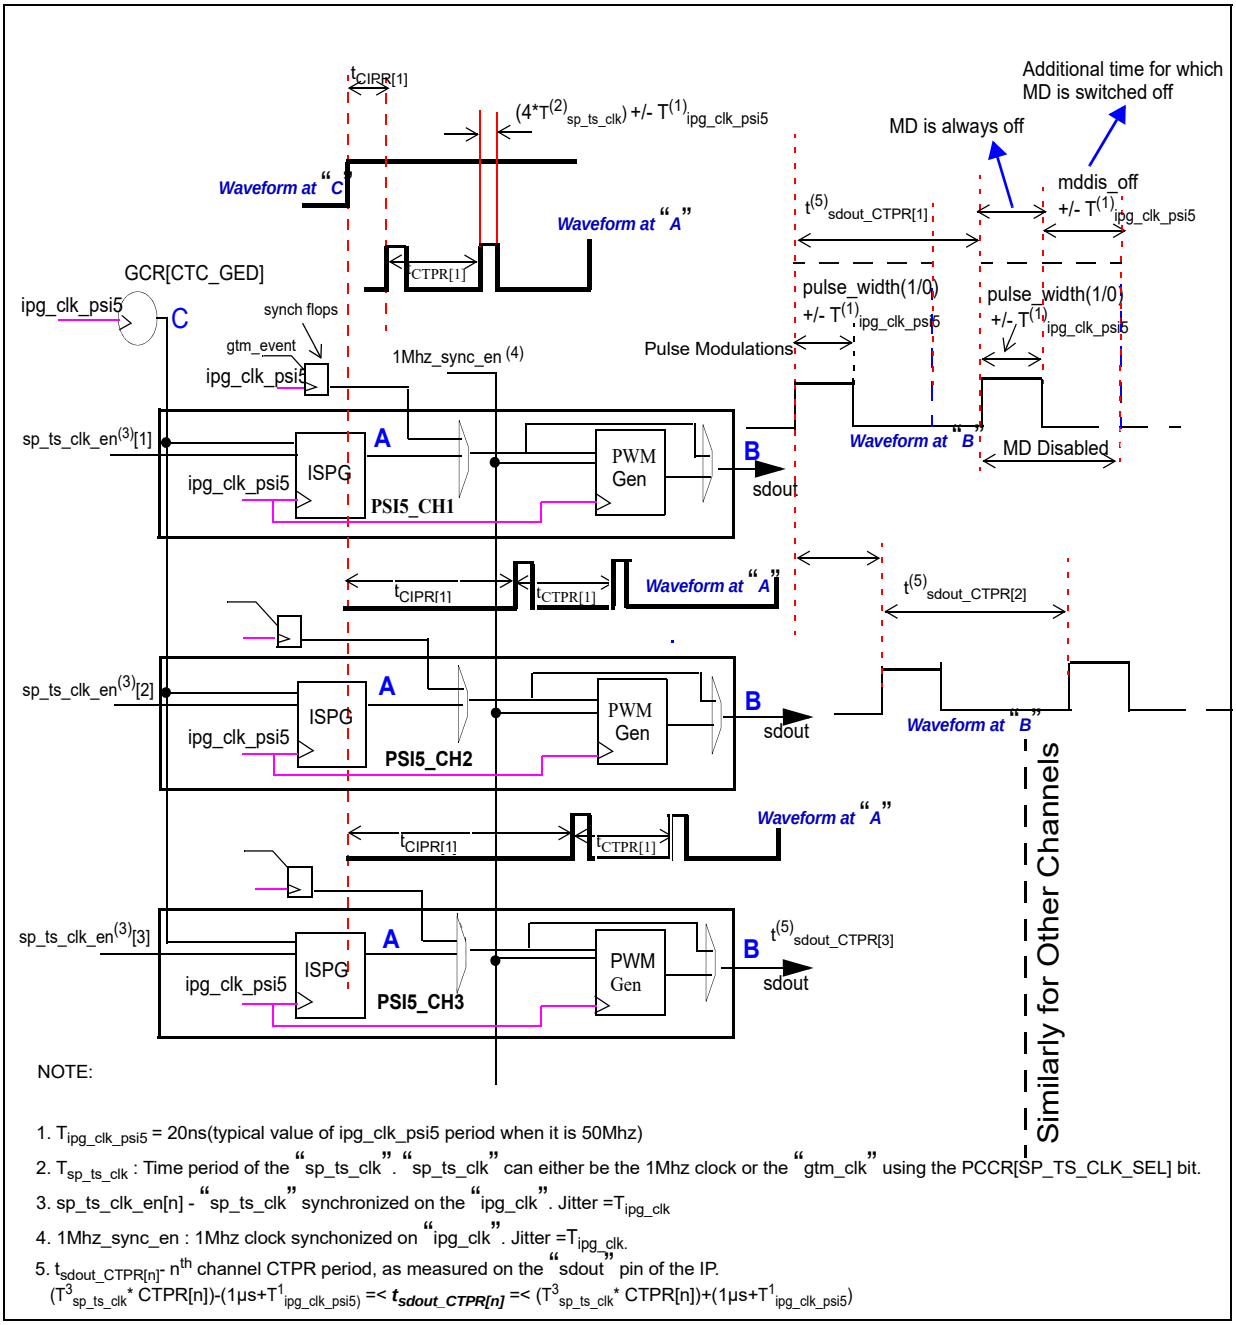
Figure 1606. Sync pulse generation parameters and Jitters



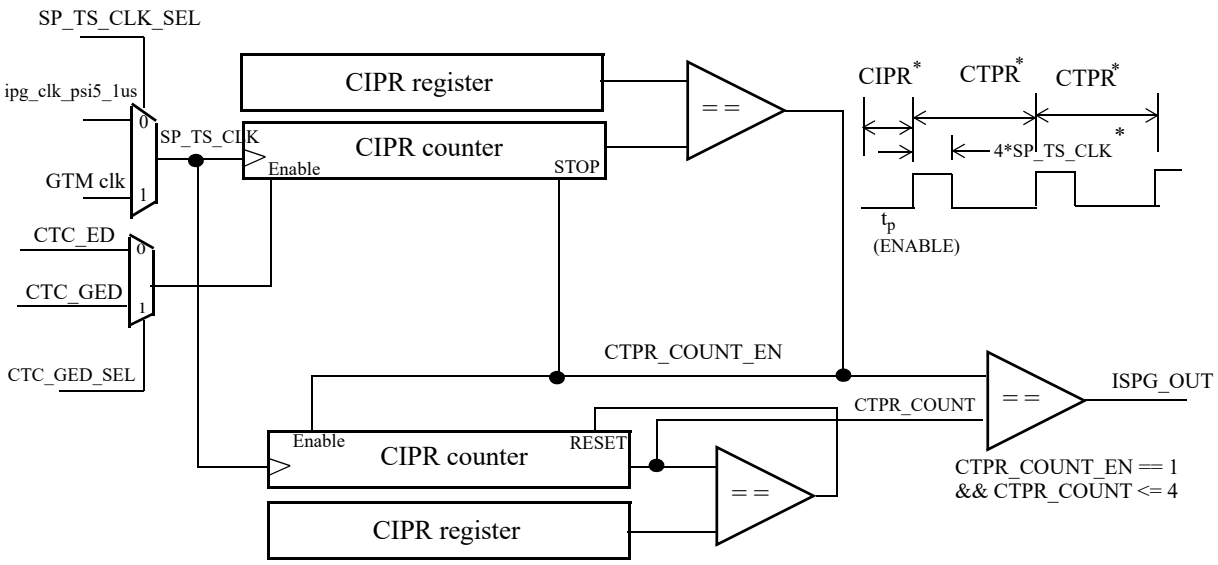


Figure 1606 shows the various jitters.

Figure 1607. ISPG (Internal Sync Pulse Generator) structure

* - For exact values and more details refer to *Figure 1606*

Note 1: All channels with CTC_GD selected will be enabled at the same time, enabling staggering of the ispg_out signals.
Note 2: This structure is replicated in each channel, with CTC_GED being a common signal to all channels.

54 Peripheral Sensor Interface-Support module (PSI5-S)

54.1 Introduction

The PSI5 Support IP (PSI5-S) module is used to interface directly to a UART compatible PSI5 transceiver over a high speed UART link. The transceiver is required to implement a compliant PSI5 module for all vehicle applications as is currently defined in the PSI5 protocol specification V2.0.

PSI5 messages from sensors received by the transceiver are decomposed into UART bytes and sent to the PSI5-S which in turn reconstructs the PSI5 messages from the UART packet, and makes them available for the application in system RAM.

ECU-to-sensor commands are sent from the PSI5-S module to the transceiver, which in turn generates the appropriate logical 1's and 0's in the SYNC pulses sent on the bus.
The PSI5-S supports all command formats of the PSI5 V2.0 including the "tooth gap" method and "variable length" pulses.

At the system level, the PSI5-S supports one transceiver with up to seven PSI5 channels. Apart from these seven channels, there is an eighth channel available for special purposes, including direct communication with the transceiver and storage of corrupt messages.

Note: For details on PSI5-S system, refer to Figure 1655.

54.1.1 Overview

PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make PSI5 also suitable for many other automotive sensor applications. The development goal of PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented license free.

The main features of PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications.

The main features of the PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s or optional 189 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module can be configured to support the following PSI5 features:

- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

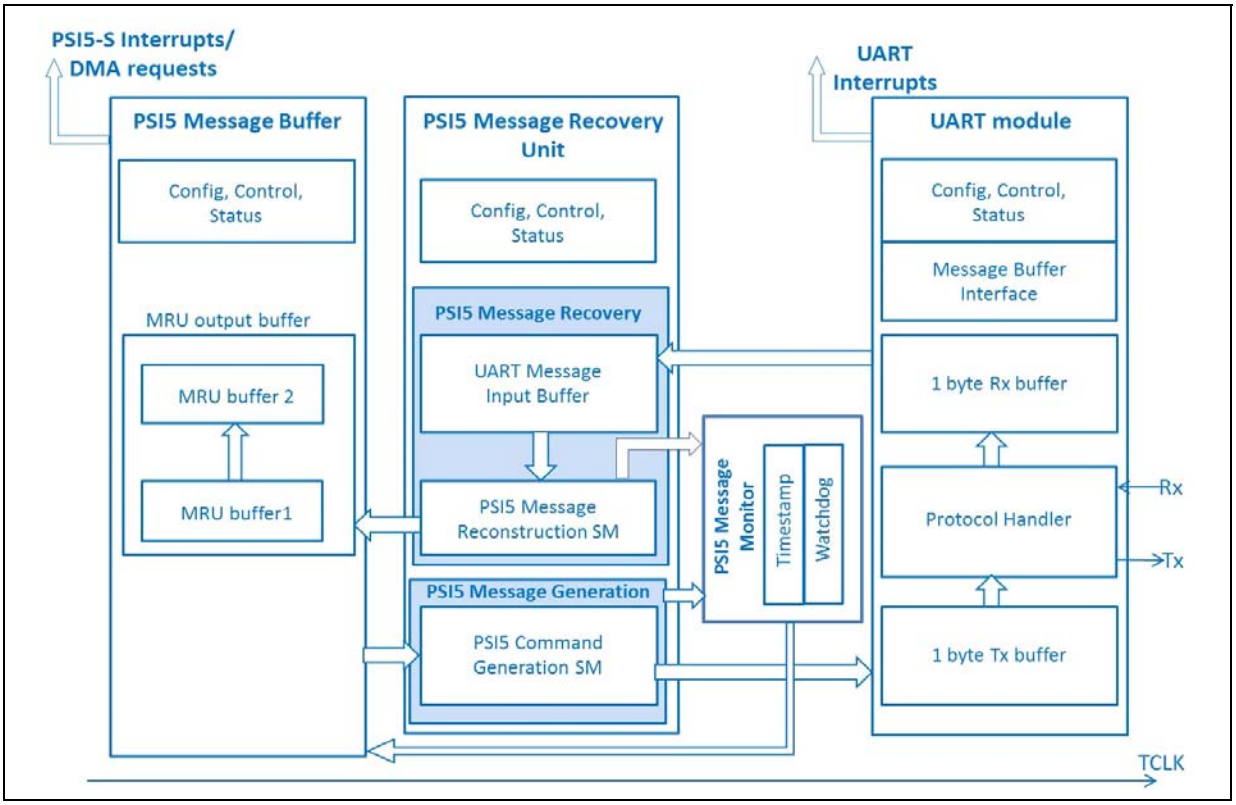
The PSI5-S module requires the physical and data link layer of the PSI5 to be implemented outside its interface. It also requires the PSI5 information to be embedded in the form of UART packet, from where it reconstructs the PSI5 message.

The module receives PSI5 message, from up to seven PSI5 channels each with up to six sequential frames. This is achieved via the external UART compliant transceiver. The PSI5 message in each of these frames are decomposed into three-to-six UART bytes (depending on PSI5 data payload) and streamed on a UART link at up to 6.25 Mbit/s to the PSI5-S module. In addition, via the PSI5-S interface, the application sends commands to the transceiver. The transceiver interprets them as either SYNC pulse commands (which will result in short, long or no SYNC pulses on the PSI5 bus), configuration commands (which will result in updates to the transceiver configuration) or diagnostic commands (which will result in the transceiver responding directly over the UART connection). In addition to the seven channels above there is an additional channel, known as Channel0, which is used for special purposes like storing the direct responses from the transceiver or storing the unrecoverable messages.

The PSI5-S consists of three main functional blocks.

1. UART front end: used as PSI5-S front end.
   When PSI5 functionality is not required then it is possible to use this as a standard UART (without LIN) also.
2. Message Recovery Unit: it consists of two state machines.
   – The first state machine interprets the input UART data stream and rebuilds the PSI5 message contained in the up to six UART bytes and also checks for the status of the correct reception of PSI5 message.
   – The second state machine sends SYNC pulse commands via the UART TxBuffer, to the external UART compliant transceiver, which in turn outputs SYNC pulses (short, long, or no SYNC pulse) on the PSI5 bus used to synchronize sensor responses in a bus configuration, and where required, also sends commands to sensors as defined in the PSI5 protocols V2.0.
3. PSI5 Message buffer & interface: It is composed of two MRU buffers, MRU buffer1 and MRU buffer2.
   Both buffers are collectively referred to as MRU output buffer. The MRU buffer1 is internal to the IP and not accessible from outside the IP. It is three word deep. MRU buffer2 is accessible to the application and is 4 word deep. MRU buffer2 can be read by the DMA interface, to transfer the stored PSI5 messages, to Channel specific mailboxes in system RAM directly.

Note: General description:



- *The location in system RAM where the messages are stored is referred to as the Mailbox. The mailbox is divided on the basis of channel and each channel is divided on the basis of slots on the PSI5 bus. Thus Mailbox1, location1 would mean Mailbox location for Channel1 and Slot No “1”. This is also denoted by MBOX1, LOC1 or $MBOX_1$, LOC_1. This terminology would be followed in the subsequent sections of the doc.*
- *Each “location” of each mailbox channel is made up of 3x32 bits. The maximum size of each mailbox can be 6 “locations”. There are 8 such mailboxes. For channels operating in asynchronous mode, the whole of the Mailbox would act like a ring buffer and all the 6 locations would be filled in that manner.*
- *Mailbox0 only has two locations MBOX0, LOC0 and MBOX0, LOC1. MBOX0, LOC0 is reserved for messages intended for Channel0 (used for transceiver specific messages) while*

MBOX0, LOC1 contain "unrecoverable" messages for any channel. Other 4 locations of the MBOX0 are reserved.

- *Also a "UART byte" would mean the "byte" that is received by the UART receiver. "UART packet" would mean the group of UART bytes from which the PSI5 message would be extracted. "PSI5 message" means the message contained in the MRU buffers which contains the actual PSI5 message along with the timestamp and the error status bits.*

Figure 1611 shows the block diagram of the PSI5-S module.

Figure 1611. PSI5-S digital interface block diagram

54.1.2 Features

- IPS interface for register read/write.
- Support for up to 7 PSI5 channels (Channel1 to Channel7) with each channel supporting up to 6 different Frame Streams (Slots). Each of the Frame Streams can be individually configured for Parity/CRC, payload Length, Synchronous/Asynchronous Operation, Timestamp Capture event, Timestamp A or Timestamp B selection.
- Additional Channel0 for special functions.
- Supports bidirectional full duplex operations, via the UART Rx and Tx links.
- Provision of Extended CRC (XCRC) to check the coherence of the UART packet that comprise the PSI5 message.
- Message Reconstruction Unit (MRU) buffer2 (consisting of 4, 32-bit words). Three of these words contain the PSI5 messages (PSI5 message payload, Message Status

flags, Time Stamp) and the fourth one contains the mailbox address to which the three PSI5 words need to be transferred.

- A 24-bit time stamp register, clocked with either the module clock or the trigger clock (trig). The time stamp appended to the PSI5 message in the MRU, can be configured to be, either the one that is captured when a new PSI5 message is detected, or the one that is captured when the Output ECU to Sensor command is transferred from the UART TX buffer to the UART Tx Shift register.
- IPS interface DMA support, for transferring the data in the MRU output buffer to system memory.
- Downstream Data Shift Register (DDSR) on per channel basis supporting the following:
  - Application can write the ECU to Sensor commands to the DDSR.
  - Supports automatic addition of the start bits/stuff bits /CRC calculation to the contents of DDSR.
  - Provision of resetting and rejecting the contents of DDSR at any stage of command transmission.
- Support for conversion of the logic levels contained in the DDSR, to UART commands to be sent to the transceiver.
- Provision of writing the Software calculated commands directly to the UART TX Buffer. This can be used for direct writing of the transceiver status or diagnostic commands, or both.
- Configurable UART message idle time counter, that indicates to the PSI5 MRU when an idle time at least as long as the configured length (number of bit times), has occurred on the Rx line.
- Provision of configuring the PSI5-S front-end as a standalone UART module, when the PSI5-S module is disabled. In this mode the module, does not have any relation with the PSI5 protocol.
- Support of up to 6.25 Mbit/s UART Rx Baud Rate.
- An output clock for the PSI5 transceiver UART interface.

54.1.3 PSI5-S global modes of operation

The PSI5-S module can be configured in 4 different global modes of operation. These are UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. These global modes can be entered by programming the PS_GLCR[GLOBAL_MODE] bits appropriately. *Figure 1612* shows the state transition diagram for these bits.

The PS_NORMAL, PS_CONFIG and PS_DISABLE are collectively referred to as the “PSI5-S” modes (refer to *Figure 1612*). Once the PS_GLCR[GLOBAL_MODE] bits are appropriately configured for the “PSI5-S” modes, the information that the intended mode of operation is fully achieved is reflected by the setting of the PS_GLSR[GL_MODETR_DONE] status bit. An interrupt can also be generated for this event, in case the PS_GLCR[GL_MODETR_DONE_EN] bit is set to “1”. Thus, only when PS_GLSR[GL_MODETR_DONE] goes to “1” it should be considered that the IP has entered the desired “PSI5-S” mode.

This bit is reset to “0” when the mode is changed from any of the PSI5-S modes to the UART_STDALONE mode and the corresponding interrupt is automatically deasserted.

Following are the descriptions of the different global modes.

54.1.3.1 Standalone UART mode (UART_STDALONE mode)

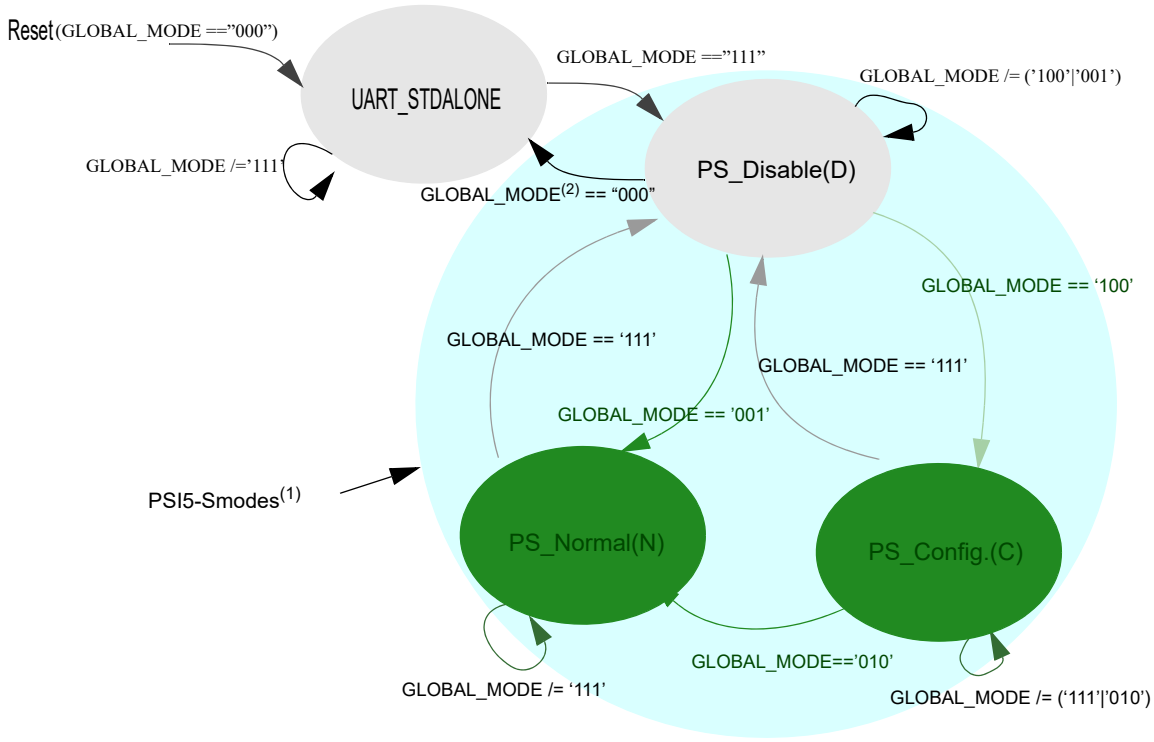
This is the default state after the module reset. In this mode, only the PS_GLCR[GLOBAL_MODE] register bits and the registers of the UART module are accessible for writing. This is the mode which is to be used when the PSI5-S front end has to be used as a standalone UART. This state indicates that the UART will now function as a standard UART and the PSI5-S core will be disabled.

54.1.3.2 Disable mode (PS_DISABLE)

PS_Disable mode in the PSI5-S reduces power consumption. In this mode the RX, TX and common time base counters are disabled for any operation. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1663*, for the details of these bits. Note that when entering PS_Disable mode from any other mode, the register contents are retained and are not changed. The timestamp counter is however reset when entering Disable mode.

In PS_Disable mode, only PS_GLCR[GLOBAL_MODE] register bits are accessible for read/write. Accessing any other register bits will generate transfer error.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of the PS_GLCR[GLOBAL_MODE] bits.



54.1.3.3 Configuration mode (PS_CONFIG mode)

In the configuration mode all PSI5-S global, channel specific configuration/control registers and UART registers can be written. The receiver and transmitter sub-blocks remain disabled in this mode. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1663*, for the details of these bits.

54.1.3.4 Normal mode (PS_NORMAL mode)

In PS_NORMAL mode, the receiver and the transmitter blocks become active, error handling is enabled, UART starts its operation and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5-S global and channel-specific configuration registers are locked for writing, although these registers can still be read. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Refer to *Table 1663* for the details of these bits. Note that there are still some register bits that can be written in this mode also (refer to the detailed register description).

Figure 1612. Operating modes

1. PSI5-S module can be configured in 4 different Global modes of operation. These are UART_STDALONE, PS_NORMAL, PS_CONFIG and PS_DISABLE. The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as “PSI5-S” modes.
2. PS_GLSR[GL_MODETR_DONE] status bit is reset to “0” when the transition occurs from PS_DISABLE to UART_STDALONE mode.

Table 1663. State transition

Present state	PS_GLCR (State Variables)			Next state
	PS_GLCR[GLOBAL_MODE(2)]	PS_GLCR[GLOBAL_MODE(1)]	PS_GLCR[GLOBAL_MODE(0)]	
UART_STDALONE	1	1	1	PS_Disable
PS_Disable	0	0	0	UART_STDALONE
PS_Disable	0	0	1	PS_Normal
PS_Disable	1	0	0	PS_Config
PS_Config	1	1	1	PS_Disable
PS_Config	0	1	0	PS_Normal
PS_Normal	1	1	1	PS_Disable

54.1.4 PSI5-S system modes of operation

54.1.4.1 Stop mode

For PSI5-S modes:

In this mode, upon the STOP request from the system level the IP generates a system level acknowledgment with the information that the clocks to the IP can be switched off. The process of the same is as described below.

At the PSI5-S Rx side, as soon as stop mode request is received by the IP then the current PSI5 message under construction (in the internal PSI5 message extraction logic) is immediately saved to the MRU output buffer1. Thus the assertion of the stop mode acts like a “forced” flushing for the current PSI5 message completion. Depending on the state of the PSI5 message under construction, the resultant PSI5 message might or might not have errors. Any byte that is being received by the UART is henceforth rejected. The internal PSI5 message extraction logic goes back to an “idle” state and remains so till the STOP mode request remains asserted.

At the PSI5-S Tx side, on the reception of the stop mode request, the internal sync pulse generation counters are stopped immediately (DDSR trigger counters) and no further command bits are shifted onto the UART Tx side. The UART Tx completes the current byte that is being transmitted and enters the idle state. No further transmissions take place. On deassertion of the stop mode, once the clock restarts, the transmission of the commands resumes from where they had halted.

Once both the above processes are completed the IP generates acknowledgment for switching of the clocks to the PSI5-S IP. Also, refer to *Section 54.4.2.2: PSI5 “recoverable and unrecoverable” messages*.

For UART STDALONE mode, refer to *Chapter 56: LINFlexD*.

54.1.4.2 Debug mode

The IP enters this mode on system request. Any register can be read or written to by the debugger. The IP can enter the debug mode in addition to it being in any of the other modes (UART Standalone/Disable/Normal/Config). In this mode the hardware clearing of the register PS_WDGTSSR remains disabled and any read of this register has no effect on the contents of this register. Apart from this there is no other difference as to whether the IP is in debug mode or not in the debug mode of operation.

54.2 External signal description

Table 1664. External signal description

S.No	Name	Function	I/O	Pull-up
Signals to/from pads				
1.	ipp_ind_linrx	LINUART receive pin. Used for Receiving UART packets from transceiver which contain information to enable the rebuilding of the PSI5 message within the packet of between three and six UART bytes	I	Active

Table 1664. External signal description (continued)

S.No	Name	Function	I/O	Pull-up
2.	ipp_do_lintx	LINUART transmit pin. Used for transmitting command bytes from TxFIFO to transceiver for generation of SYNC pulses (long, short or no) on the PSI5 bus or direct diagnostic/status commands for the transceiver itself	O	Passive
3.	ipp_port_en_tx	LINUART transmission port enable: Connected to the enable pin of the pad which is to be used for “LINTX” functionality. When “1” it indicates that the IP is doing transmit of data.	O	Passive
4.	ipp_psi5_uart_tclk	Transceiver clock output, which drives the UART interface on the transceiver. The clock output frequency is configurable between 4 and 8 x UART baud rate on the interface between PSI5-S and transceiver.Frequency can be controlled at the system level through the Clock Generator Module (MC_CGM). The duty cycle of the transceiver clock is between 40% and 60%	O	Passive

54.3 Memory map and register description

54.3.1 Memory map

Table 1665 shows the memory map.

1. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot wherein writing a 1 causes an effect on the register bit while writing a 0 has no effect; a read always returning a 0”, D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable.
2. Locations from 0x0000 to 0x005C are for UART registers.
3. PS_NOUSE_REG: Stands for register NOT REQUIRED in PSI5-S modes. It will be required in UART STANDALONE mode.
4. Register has significance in UART STANDALONE mode. This document would only mention the bit field names in the corresponding register description. For detailed bit description and the functioning of this register in UART modes (sleep, init and normal) belonging to UART STANDALONE mode, refer to *Chapter 56: LINFlexD*.
5. Not all register bits are of this type (refer to the register bit description for more details).
6. Register Bits are automatically hardware cleared on read of any bit of this register.

54.3.2 Transfer error generation

The IP generates transfer error cases in a number of scenarios as detailed below:

1. Trying to write to any register in the PS_DISABLE mode (apart from the PS_GLCR and PS_GLSR) will result in the generation of the transfer error.
2. Trying to write to any “Read Only” register (those which have “R,R,R” in all the D,C,N columns in *Table 1665*) will generate a transfer error in any of the PS_DISABLE, PS_NORMAL and PS_CONFIG modes. Apart from the above “Read Only” registers, trying to write to any register bits outside there intended mode of operation (Normal/Config) would be ignored without the generation of any transfer error. For bit level operation and mode access of each register, refer to *Section 54.3.3* and *Section 54.3.4*.
3. Trying to access (R/W) any register space which is declared as reserved in *Table 1665* or which is unimplemented will generate a transfer error.
4. Reading of any register in any mode and if that register is NOT in unimplemented/reserved space, then a transfer error will not be generated.
5. Trying to write to any PSI5-S register (starting from locations 0x00B4, but apart from PS_GLCR and PS_GLSR) in the UART_STDALONE mode will generate a transfer error.
6. In UART Standalone mode the UART behaves as a standalone IP and for detailed transfer error cases in this mode, refer to *Chapter 56: LINFlexD*.

54.3.3 UART register configuration

This section contains information of the UART registers that are specifically required for correct functioning of the IP in the “PSI5-S” modes.

In order to operate the PSI5-S module, the UART configuration registers need to be programmed with appropriate values. The values that are required for different register fields are defined in the following register descriptions. Some bits have to be programmed with definite values of “1” or “0” only. This configuration has to be strictly followed for a predictable operation of the PSI5-S core. All these bits should be programmed in the PS_CONFIG mode before enabling the UART RX or the TX paths.

In the following UART register description “PS_NOUSE_BIT” against a bit name and bit description, means that the specific register bit is present in the UART module but it is NOT REQUIRED in the PSI5-S modes of operation. For correct operation in the PSI5-S modes, the corresponding register bit might be required to be programmed as “1” or a “0”; the same would be mentioned in the bit description.

Note that a bit with “PS_NOUSE_BIT” against its description would still be required in the UART STDALONE mode. For detailed information of the UART register bit functioning in the UART STDLONE mode, refer to the separate document describing the standalone LINUART module. There are some other register bits which do not have a “PS_NOUSE_BIT” against them. These can be programmed as required. A bit mentioned as “Reserved” would mean that neither it is available in the UART STANDLONE mode nor in the PSI5-S modes.

54.3.3.1 PSI5-S LIN control register 1 (PS_LINCR1)

The PS_LINCR1 register contains control bits used to configure features of the PSI5-S UART Front end.

Figure 1613. PSI5-S LIN control register 1 (PS_LINCR1)

Table 1666. PS_LINCR1 field descriptions

Field	Description
19 AUTOWU	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
25 SLFM	Self test mode 0 Self test mode disabled 1 Self test mode enabled To be used along with the LBKM bit. When this bit is set then in addition to the Loop Back mode; the “ipp_do_lintx” is driven to “1”.
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Programmed in PS_CONFIG mode. When set then the “ipp_do_lintx” output is internally looped back and connected to “ipp_ind_linrx” pin.
29 RBLM	PS_NOUSE_BIT Always program as 0 in PSI5-S modes.
30 SLEEP	PS_NOUSE_BIT **Note:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standalone mode. This bit is read as “1” in PS_DISABLE mode but is read as “0” in PS_NORMAL and PS_CONFIG mode.
31 INIT	PS_NOUSE_BIT **Note:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standalone mode. This bit is read as “0” in PS_DISABLE and PS_NORMAL mode, and “1” in PS_CONFIG mode.

Figure 1614. PSI5-S LIN interrupt enable register (PS_LINIER)

Table 1667. PS_LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
17 OCIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **Note:** This bit is also writable in PS_NORMAL mode.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (FEF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
26 WUIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **Note:** This bit is also writable in PS_NORMAL mode.

Table 1667. PS_LINIER field descriptions (continued)

Field	Description
28 TOIE	Timeout Interrupt Enable 0 No interrupt 1 Interrupt generation enabled. An interrupt is generated if this bit is set and the Timeout Flag (TO) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Data Received Flag (DRF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in PS_UARTSR is set. This interrupt can be used by the Application for debugging when it wants to read the byte that is under transmission. This byte can be read from the PS_BDRL[DATA_TX[0]] location. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **Note:** This bit is also writable in PS_NORMAL mode.

54.3.3.3 PSI5-S LIN status register (PS_LINSR)

This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes

Figure 1616. PSI5-S UART mode control register (PS_UARTCR)

Table 1669. PS_UARTCR field descriptions

Field	Description
0 MIS	PS_NOUSE_BIT Always program as “1” in PSI5-S modes.
1:3 CSP	Configurable Sample Point These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: **OSR** / **CSP**: 4 / 2, 3; 5 / 2, 3, 4; 6 / 3, 4, 5; 8 / NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6 and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.

Table 1669. PS_UARTCR field descriptions (continued)

Field	Description
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
12 PCE_Tx/ DTU	In PSI5-S mode Parity Control Enable for Tx path (In UART STANDLONE mode used to disable UART timeout, refer to *Chapter 56: LINFlexD* for more details): 1 Parity generation for Tx path enabled. 0 Parity generation for Tx path disabled. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[31] == 1. When programmed as “1” then a 1 bit additional parity bit is added to the transmitted 8 bits of UART data, so a total of 9 bits including parity are present between a start and a stop bit, in the transmitted data. When programmed as “0” then total of 8bits data is present between a start and a stop bit in the transmitted data.
13:14 SBUR	PS_NOUSE_BIT Always program as “00” in PSI5-S modes.
15 WLS	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
16:18 TDFL/TFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
19:21 RDFL/RFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
22 RFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
23 TFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
24 WL1	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
25 PC1	Parity Control {PC1, PC0} 00 Parity is Even for both the Rx/Tx paths. 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths. 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed only in the PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
26 RxEn	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when PS_UARTCR[31] == 1.

Table 1669. PS_UARTCR field descriptions (continued)

Field	Description
27 TxEn	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when PS_UARTCR[UART] == 1
28 PC0	Parity Control {PC1, PC0} 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
29 PCE_Rx	Receive Parity check enable. 1 Enable the parity checking on the Rx path 0 Disable the parity checking on the Rx path Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1. When programmed as “1” then a 1 bit additional parity bit is expected along with the received 8 bits of UART data, so a total of 9 bits including parity are expected between a start and a stop bit, in the received data. When programmed as “0” then total of 8bits data is expected between a start and a stop bit in the received data.
30 WL0	PS_NOUSE_BIT Always program as “1” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
31 UART	PS_NOUSE_BIT Always program as “1” in PSI5-S modes. Can be programmed in PS_CONFIG mode only.

54.3.3.5 PSI5-S UART mode status register (PS_UARTSR)

Figure 1617. PSI5-S UART mode status register (PS_UARTSR)

Table 1670. PS_UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated on the UART interrupt lines if the SZIE bit in PS_LINIER is set.
17 OCF	PS_NOUSE_BIT Read Only Bit.
18:20 PE[3:1]	PS_NOUSE_BIT Read Only Bit.
21 PE0	Parity Error flag for Data0 byte These bits indicate if there is a Parity Error in the received byte. No interrupt is generated if this error occurs. 0 No parity error 1 Parity error in the corresponding received byte This flag is automatically cleared by hardware. The software can poll this flag for debugging purposes.
22 RMB	PS_NOUSE_BIT Read Only Bit.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). FEF is automatically cleared by hardware. An interrupt is generated if this bit is set and the FEIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and the previous byte has not yet been read from the UART Rx buffer due to some fault in PSI5-S core reading logic. It is automatically cleared by hardware. An interrupt is generated if this bit is set and the BOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	PS_NOUSE_BIT Read-only Bit.
27 RFNE	PS_NOUSE_BIT Read-only Bit.

Table 1670. PS_UARTSR field descriptions (continued)

Field	Description
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO is automatically cleared by hardware. An interrupt is generated if this bit is set and the TOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
29 DRF	Data Reception Completed Flag DRF is set by hardware in UART buffer mode and indicates that one byte has been received and is ready for being read. DRF is automatically cleared by hardware. An interrupt is generated if this bit is set and the DRIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
30 DTF	Data Transmission Completed Flag DTF is set by hardware in UART buffer mode and indicates that the current byte which was written to the PS_BDRL[0] location has been successfully transmitted by the UART. DTF is automatically cleared by hardware when a new byte transmission is started. An interrupt will be generated if the DTIE bit in PS_LINIER is set.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

54.3.3.6 PSI5-S LIN fractional baud rate register (PS_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Address: 0x0024 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

<tr><td>0xFFFFF</td><td>1048575</td></tr>
</table>
</td></tr>
</table>

Note: The UART baud rate is programmed in two registers: the LIN Integer Baud Rate register (PS_LINIBRR) and the LIN Fraction Baud Rate register (PS_LINFBRR). The baud rate registers can be programmed only during the PS_CONFIG mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Tx_{BR} = Rx_{BR} = ipg_baud_clk/(16 × LDIV) (when UARTCR[ROSE] == 0)

Tx_{BR} = Rx_{BR} = ipg_baud_clk/UARTCR[OSR] x LINIBRR (when UARTCR[ROSE] == 1)

LDIV is an unsigned fixed point number which comprises of the mantissa and the fraction. The mantissa is coded into 20 bits of LINIBRR, and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled (UARTCR[ROSE] ==1) then PS_LINFBRR is not used. Hence LDIV contains only the integer part programmed in LINIBRR. Following are 2 examples for two different baud rate calculations.

Example 1:

With UARTCR[ROSE] = 0.

LDIV = 1041.67, ipg_baud_clk = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Tx_{BR} = Rx_{BR} = 80 Mhz/ (16 x 1041,67) = 4.8 Kbit/s

Example 2:

When UARTCR[ROSE] = 1:

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, UARCR[OSR] = 4

Tx_{BR} = Rx_{BR} = ipg_baud_clk/ (UART[OSR] × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

54.3.3.8 PSI5-S LIN control register 2 (PS_LINCR2)

This register includes control status bits related to buffer operations.

Address: 0x0030 Access: User read/write

1. Register bit can be read in any mode, written only in PS_CONFIG mode.
2. Register bit can be written only by software in PS_CONFIG mode. Bit is always read 0 by software.

Figure 1623. PSI5-S global control register (PS_GCR)

Table 1676. PS_GCR field descriptions

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB: 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is the LSB bit (of DATA_TX in PS_BDRL register) 1 The first bit of transmitted data is MSB — in other words, first bit transmitted is the MSB bit (of DATA_TX in PS_BDRL register)
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB: 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (of DATA_RX in PS_BDRM register) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (of DATA_RX in PS_BDRM register)
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only). 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only). 0 Received data is not inverted 1 Received data is inverted
30 STOP	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
31 SR	Soft reset SR executes a soft reset of the UART controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0.

54.3.3.12 PSI5-S UART preset timeout register (PS_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed to monitor the idle state of the reception line. This register can be written by software any time.

Address: 0x0050 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1624. PSI5-S UART preset timeout register (PS_UARTPTO)

Table 1677. PS_UARTPTO field descriptions

Field	Description
20:31 PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. The register must be programmed to a value of “Idle Timeout required in terms of number of bits received” at that particular baud rate. The idle timeout is measured after the stop bit and measures the minimum amount of time (in terms of bits) for which the line stays high. Refer also to register UARTCTO.

54.3.3.13 PSI5-S UART current timeout register (PS_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (refer to *Section 54.3.3.12: PSI5-S UART preset timeout register (PS_UARTPTO)* to monitor the idle state of the reception line.

The timeout counter:

- Starts at zero and counts upward.
- Is clocked with baud clock frequency of Tx_{BR}/Rx_{BR}. Also refer to *Note: on page 2586*.
- Is automatically enabled when UARTCR[RXEN] = 1.

Note: Due to internal synchronization there is a delay between 4 to 6 clock cycles of “ipg_clk_ps”, for the internal counter’s value (which is clocked with baud frequency of Tx_{BR}/Rx_{BR}) to reflect on to UARTCTO.

UARTCTO is reset when:

- UARTCTO becomes equal to UARTPTO.
- Whenever UARTPTO is written.
- When the PSI5-S goes in PS_DISABLE mode.

31 DRE0	PS_NOUSE_BIT Always program with “0” in PSI5-S modes

54.3.3.16 PSI5-S UART Tx idle delay time (PS_PTD)

This register is used to add a programmable idle time between the data that is transmitted on the UART Tx line. The duration of this delay is programmable between 1 to 16 bit times. The programmable delay is such that when the normal ECU to Sensor communication (no direct command) is happening, then it comes into play between each byte of transmitted data. When the ECU to Sensor direct command is used then this delay comes into play between each direct command. The direct commands can be programmed as 1, 2 and 4 bytes depending on the PS_GLCR[DIRCMD_LEN] register. Refer to *Section 54.3.4.13: PSI5-S ECU to sensor direct command write register (PS_DIRCMD)* and *Section 54.3.4.1: PSI5-S global control register (PS_GLCR)*, for more details.

26:30 IFD	Interframe Delay The idle time added between the UART data on the TX line is IFD+1 bit times. The UART data can be sized to be of either one byte or 1, 2 and 4 bytes.
31 EN	IFD Enable 0 The IFD is active in the UART Tx path 1 The IFD is inactive

54.3.4 PSI5-S register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

PS_GLCR[GLOBAL_MODE] are the only register bits that can be written in the PS_DISABLE mode.

All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error.

54.3.4.1 PSI5-S global control register (PS_GLCR)

The Global Control Register (PS_GLCR) provides control functions for all the PSI5-S channels simultaneously.

Figure 1629. PSI5-S global control register (PS_GLCR)

Table 1682. PS_GLCR field descriptions

Field	Description
8:9 DIRCMD_LEN	Direct Command Length Register This defines the length of the Direct Command that is transferred to the UART Tx line. The Direct command is written to the PS_DIRCMD register in the format {DIRCMD_BYTE3, DIRCMD_BYTE2, DIRCMD_BYTE1, DIRCMD_BYTE0}.Following is the bit description: 00 1 byte command: 1 byte {DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx. Rest bytes of the PS_DIRCMD are ignored. 01 2 byte command: 2 bytes {DIRCMD_BYTE1, DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx without any idle time between DIRCMD_BYTE1 and DIRCMD_BYTE0. Rest bytes of the PS_DIRCMD are ignored. 10 4 byte command: 4 bytes 11 4 byte command: 4 bytes {DIRCMD_BYTE3, DIRCMD_BYTE2, DIRCMD_BYTE1, DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx line without any idle time between these bytes. The idle time between the commands is still governed by the PS_PTD register in the LINUART module. This register is also writable in the NORMAL mode.
11 IE_DIRCMD_RDY	Interrupt enable bit for DIRCMD_RDY 0 PS_GLCR[DIRCMD_RDY], when goes as “1”, does not generate any interrupt on the “ipi_ps_glbl” interrupt line. 1 PS_GLCR[DIRCMD_RDY], when goes as “1”, generates an interrupt on the “ipi_ps_glbl” interrupt line. **Note:** This bit is also writable in PS_NORMAL mode.
13 DEBUG_EN	Debug enable bit 0 The IP does not enter the debug mode when a request is made to the IP for entering into the debug mode. It continues its normal operation. 1 The IP enters the debug mode immediately, as soon as a request is made to the IP for entering into the debug mode. For debug mode operation, refer to *Section 54.1.4.2: Debug mode*.
14:15 TRIG_SEL	TRIG_SEL bits. These bits are used to select the trigger for the Timestamp counters as shown in *Figure 1672: Clock distribution in PSI5-S*. The trigger signals control the frequency of operation of the timestamp counters. In other words they control the clocking (clkA and clkB) of the timestamp counters A and B. 00 trig[0] is selected for clocking the timestamp counter. 01 trig[1] is selected for clocking the timestamp counter. 10 trig[2] is selected for clocking the timestamp counter. 11 trig[3] is selected for clocking the timestamp counter.
16 GL_DDSR_TRIG	This is the global shift trigger of all the DDSRs of each channel. When the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] == 1, only then is this bit effective, else this bit has no effect. 1 The shift triggers of all the DDSR’s start synchronously. 0 Shift triggers of all the DDSR registers are halted (default state). If bit is cleared during runtime, PS_DDTRIG_PERR and PS_DDTRIG_OFFR counters are reset. **Note:** If bit is subsequently set after being cleared, then the counters will restart and the offsets in PS_DDTRIG_PERR and PS_DDTRIG_OFFR registers will be applied again. This bit is also writable in PS_NORMAL mode

Table 1682. PS_GLCR field descriptions (continued)

Field	Description
17 GL_MODETR_ DONE_EN	Interrupt enable for PS_GLSR[GL_MODETR_DONE] bit 1 Generates the interrupt when PS_GLSR[GL_MODETR_DONE] bit is set. 0 No interrupt is generated on setting of the PS_GLSR[GL_MODETR_DONE] bit **Note:** This bit is also writable in all modes (PSI5-S and UART_NORMAL)
18 MRU_ERR_EN	Enables the interrupt for MRU overwrite when the unread contents of MRU Buffer1 are overwritten by a new message. 0 MRU overwrite error is not enabled. 1 MRU overwrite error is enabled. **Note:** This bit is also writable in ps_normal mode
19 TSCS_B	This bit controls the selection of clock input to timestamp counter B, either by the external periodic clock or by the Trigger module. 1 trig is selected as the clock. 0 External clock (ipg_clk_ps_ts) is selected.
20 TSCS_A	This bit controls the selection of clock input to timestamp counter A, either by the external periodic clock or by the Trigger module. 1 trig is selected as the clock. 0 External clock (ipg_clk_ps_ts) is selected.
21 CLR_CNTR_B	This bit will reset timestamp counter B when PS_GLCR[CLRTSCNT_G_L] is NOT set. 1 Timestamp counter B is reset. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode
22 CLR_CNTR_A	This bit will reset timestamp counter A when PS_GLCR[CLRTSCNT_G_L] is NOT set. 1 Timestamp counter A is reset. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode
23 CLRTSCNT_G	This bit controls the global clearing of the timestamp counters A and B when CLRTSCNT_G_L == 1. When CLRTSCNT_G_L == 0 then this bit has no effect. 1 Both timestamp counters are cleared at the same time. This bit is a one shot and is always read as 0. **Note:** This bit is also writable in ps_normal mode
24 CLRTSCNT_G_L	This bit control whether the timestamp counters counter A and B are cleared simultaneously or independently: 0 Timestamp counters A and B are cleared independently. When PS_GLCR[CLR_CNTR_A] == 1 timestamp counter A is cleared. When PS_GLCR[CLR_CNTR_B]== 1 timestamp counter B is cleared. 1 Both timestamp counters are cleared simultaneously as soon as CLRTSCNT_G == 1.
25 TSCNT_EN_B	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G_L] is not set. 0 Timestamp counter A not enabled 1 Timestamp counter B is enabled **Note:** This bit is also writable in ps_normal mode.

Table 1682. PS_GLCR field descriptions (continued)

Field	Description
26 TSCNT_EN_A	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G_L] is not set. 0 Timestamp counter A not enabled 1 Timestamp counter A is enabled **Note:** This bit is also writable in ps_normal mode.
27 TSCNTEN_G	This bit controls the global trigger of the timestamp counters A and B when TSCNTEN_G_L == 1. When TSCNTEN_G_L == 0 then this bit has no effect. 0 Both timestamp counters are disabled simultaneously. 1 Both timestamp counters start simultaneously. **Note:** This bit is also writable in ps_normal mode.
28 TSCNTEN_G_L	This bit control whether the timestamp counters counter A and B are started simultaneously or independently. 0 Timestamp counters A and B are started independently. When PS_GLCR[TSCNT_A_EN] == 1 timestamp counter A starts When PS_GLCR[TSCNT_B_EN] == 1 timestamp counter B starts. 1 Both timestamp counters are triggered simultaneously as soon as TSCNTEN_G == 1.
29:31 GLOBAL_MODE	These are the bits which decide Global Mode of the IP. There are 4 modes, UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. For details of modes related to GLOBAL_MODE bit setting, refer to *Table 1663: State transition*. **Note:** These bits are writable in all modes (PSI5-S and UART_STANDALONE).

54.3.4.2 PSI5-S global status register (PS_GLSR)

Address: 0x00B8 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	DIRCMD_RDY	0	0	0	0
W												w1c

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1630. PSI5-S global status register (PS_GLSR)

Table 1683. PS_GLSR field descriptions

Field	Description
11 DIRCMD_RDY	Bit used to indicate the “Ready for Direct Command write” status: 0 Direct Command that is written to the PS_DIRCMD register is currently under processing. Any further command written to the PS_DIRCMD register would be rejected without any information. 1 The PS_DIRCMD register is empty and the application can write the direct ECU to sensor transceiver command to the PS_DIRCMD register. Once the command is written to the PS_DIRCMD, then a “w1c” to this register should be done so that the command written to the PS_DIRCMD register is queued for UART transmission with the highest priority. When the command has been transferred from this register to the UART, then this bit goes as “1”. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1” then this event generates an interrupt on the ipi_ps_glbl line. **Note:** This bit is also writeable in the PS_NORMAL mode.
17 GL_MODETR_DONE	This bit indicates, as to when the global mode transitions, as programmed by PS_GLCR[GLOBAL_MODE] have actually been accomplished: 1 The global mode as programmed in the PS_GLCR[GLOBAL_MODE] have been accomplished 0 The intended global mode, as programmed in the PS_GLCR[GLOBAL_MODE] register bits, is under processing. **Note:** This bit is cleared by w1c. The bit is also writable in PS_NORMAL and PS_DISABLE mode. This bit is reset to “0” when the mode is changed from PS_DISABLE to the UART_STDALONE mode.
18 MRU_ERR	This bit shows whether unread MRU buffer1 contents have been overwritten by a new message: 1 overwrite occurred 0 no overwrite occurred **Note:** This bit is cleared by w1c. The bit is also writable in PS_NORMAL mode.
26:28 FID	Points to the frame whose data in MRU buffer 1 was overwritten
29:31 CHID	Points to the channel whose data in MRU buffer 1 was overwritten

54.3.4.3 PSI5-S channel base address register (PS_CH_BASE_ADDR)

Figure 1632. PSI5-S MRU output buffer 2 register 0 (PS_MRU_BUF2_REG0)

Table 1685. PS_MRU_BUF2_REG0 field descriptions

Field	Description
0:31 CHANNEL_SPECIFIC_MAILBOX_ADDR	This register will provide the channel specific mailbox address corresponding to channel and slot for which data has been received.This value is computed by the IP based on the PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] and FID, CID. Following is the formula used to calculate this address: – For messages with CID==0 in the header byte, destined for Channel0 location0, value is: PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] – For “unrecoverable” messages destined for Channel0,location1, value is: PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]+0xC – For other messages with CID = 1 to 7 the value can be calculated as: (PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] + (6*4*3(MSG_CH_ID)+(MSG_FRAME_ID)*4*3)) When using the DMA for reading the MRU buffer, this register forms the Access1 of the DMA transfer.

Figure 1633. PSI5-S MRU output buffer 2 register 1 (PS_MRU_BUF2_REG1)

Table 1686. PS_MRU_BUF2_REG1 field descriptions

Field	Description
0:3 DCI	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
5 R_UVL_ERR	Message underflow It is set when less than three UART bytes are received in the UART packet. In case of XCRC error the message is treated as unrecoverable and written in mail box location1 of channel 0 1 Error occurred 0 No error occurred Refer to *Section 54.4.2.1: PSI5 message extraction*, for more details.
6 N_ERR	Indicates that the number of UART bytes in the received UART packet does not match the number specified in Channel Configuration Register A indicated by CID and FID that is the number of UART bytes does not match the value programmed in PS_MSGA_CH_{CID}[F_{FID}_bytes]. Also, refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)*. 1 Error occurred 0 No error occurred Refer to *Section 54.4.2.1: PSI5 message extraction*, for more details.
7:9 CHID	Indicates Channel id of PSI5 message present in the UART header byte.
10:12 FID	Indicates Frame ID of PSI5 message present in the UART header byte.
13 R_OVL_ERR	Message overflow. It is set when more than six UART bytes are received in the UART packet. The message may be recoverable (XCRC_ERR == 0) or unrecoverable (XCRC_ERR==1). Refer to *Section 54.4.2.1: PSI5 message extraction*, for more details. 1 Error occurred 0 No error occurred

Table 1686. PS_MRU_BUF2_REG1 field descriptions (continued)

Field	Description
14 F_WD_ERR	Frame watchdog error in the received PSI5 message In case there is no XCRC error in the received message, then this bit will be the same as the PS_WDGTSSR[F_WD_ERR[CID]] bit, where CID is the channel ID of the received PSI5 message. In case the received PSI5 message has an XCRC error then this bit will be the logical OR of all the PS_WDGTSSR[F_WD_ERR[CHn]] bits that is in this case it will be "PS_WDGTSSR[F_WD_ERR[1]] OR PS_WDGTSSR[F_WD_ERR[2]] OR....PS_WDGTSSR[F_WD_ERR[7]]". Refer to *Section 54.4.5: PSI5-S watchdog operation*, *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* and *Section 54.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*, for more details. 1 Error occurred 0 No error occurred **Note:** Whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set, PS_WDGTSSR (which is a hardware clearing register) should always be read. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective "CID", whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID.This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit.
15 SCI_O_ERR	UART overrun error has occurred in at least one UART byte of the received UART packet, due to which some UART byte has been lost. 1 Error occurred 0 No error occurred
16 SCI_F_ERR	UART framing error has occurred in the current received UART packet. 1 Error occurred 0 No error occurred
17 SCI_P_ERR	UART message parity error has occurred in at least one UART byte of the received UART packet. 1 Error occurred 0 No error occurred
18 HD_ERR	This bit is set when any of the ERR[1:0] is "1" and indicates a transceiver error. 1 Error occurred 0 No error occurred
19:20 ERR	Transceiver error flags received in the Message header byte of the UART packet indicated by CID and FID
21 CRC_ERR/ P_ERR	Indicates whether "PSI5 message" crc_err or the parity error in the PSI5 message indicated by CID and FID has occurred. The Parity is taken as even for PSI5 calculation: 1 Indicates crc_error/Parity Error has occurred. 0 No crc_error/parity error has occurred. **Note:** This bit always remains "0" for messages having CID and FID both as "0".
22:24 CRC	Contains the received CRC or Parity Bits of the PSI5 message, of indicated by CID and FID

Table 1686. PS_MRU_BUF2_REG1 field descriptions (continued)

Field	Description
25 XCRC_ERR	Indicates xcrc_err in the received UART packet: 1 Indicates xcrc_error occurred 0 No xcrc_error occurred
26:31 XCRC	This is the value of XCRC received in the last six bits of the UART byte, which occurs just before the information of a “new UART packet received” has been generated. Refer to *Section 54.4.1: PSI5-S UART message structure* and *Section 54.4.2.5: PSI5-S XCRC handling*, for more details.

Figure 1636. PSI5-S mbox status IRQ (PS_MBOX_SR_IRQ)

Table 1689. PS_MBOX_SR_IRQ field descriptions

Field	Description
24 MBOX_CH7	When set it Indicates at least one message in mailbox 7 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH7[*F(0-5)_READ*] bits that is MBOX_CH7 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel7 are cleared.
25 MBOX_CH6	When set it Indicates at least one message in mailbox 6 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH6[*F(0-5)_READ*] bits that is MBOX_CH6 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel6 are cleared.
26 MBOX_CH5	When set it Indicates at least one message in mailbox 5 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH5[*F(0-5)_READ*] bits that is MBOX_CH5 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel5 are cleared.
27 MBOX_CH4	When set it Indicates at least one message in mailbox 4 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH4[*F(0-5)_READ*] bits that is MBOX_CH4 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel4 are cleared.
28 MBOX_CH3	When set it Indicates at least one message in mailbox 3 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH3[*F(0-5)_READ*] bits that is MBOX_CH3 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel3 are cleared.
29 MBOX_CH2	When set it Indicates at least one message in mailbox 2 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH2[*F(0-5)_READ*] bits that is MBOX_CH2 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel2 are cleared.

Table 1689. PS_MBOX_SR_IRQ field descriptions (continued)

Field	Description
30 MBOX_CH1	When set it Indicates at least one message in mailbox 1is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH1[*F(0-5)_READ*] bits that is MBOX_CH1 = F0_READ OR F1_READ OR...F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel1 are cleared.
31 MBOX_CH0	When set it Indicates at least one message in mailbox 0is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH0[*F(0-1)_READ*] bits that is MBOX_CH0 = F0_READ OR F1_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel0 are cleared.

Note: Also refer to Figure 1669: IRQ[n] interrupts, for bit fields details.

Figure 1637. PSI5-S error status IRQ (PS_ERR_SR_IRQ)

Table 1690. PS_ERR_SR_IRQ field descriptions

Field	Description
22 R_UVL_ERR	When set indicates that message underflow error (number of UART bytes received are less than 3) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_UVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_UVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
23 N_ERR	When set indicates that N_ERR (Number of UART bytes are not equal to PS_MSGA_CHn[Fn_byte]) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[N_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[N_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
24 R_OVL_ERR	When set indicates that message Overflow error (number of UART bytes received have exceeded 6) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_OVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_OVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
25 F_WD_ERR	When set indicates that Frame Watchdog error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[F_WD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[F_WD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
26 SCI_O_ERR	When set indicates that UART Overrun error (from the UART side) is present in the message currently present in MRU buf2. When “1”, then this bit indicates that some UART byte belonging to the concerned UART packet, has been overwritten by another UART byte and is lost. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_O_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_O_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.

Table 1690. PS_ERR_SR_IRQ field descriptions (continued)

Field	Description
27 SCI_F_ERR	When set indicates that UART Framing error is present in the message currently present in MRU buf2. If this bit is set then it indicates to the application that the synchronization of the UART module is lost and any subsequent UART bytes received will be error prone. In this case the application is required to reset the UART module by using the PS_GCR[SR] bit. Subsequently it should restart the transmission. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_F_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_F_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
28 SCI_P_ERR	When set indicates that UART parity error is present in the message currently present in MRU buf2. This bit will be set when there is a parity error in any UART byte using which the concerned UART packet was formed. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
29 HD_ERR	When set indicates that Header error (E0/E1) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[HD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[HD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.
30 CRC_ERR/P_ERR	When set indicates that PSI5 CRC/Parity error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **Note:** This bit always remains “0” for messages having CID and FID both as “0”.
31 XCRC_ERR	When set indicates that XCRC error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[XCRC_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[XCRC_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. **Note:** The bit is also writable in PS_NORMAL mode.

Note: Also refer to Figure 1669: IRQ[n] interrupts, for bit fields details.

If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message

Figure 1640. PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)

Table 1693. PS_WDGTSSR bit field details

Field	Description
0:6 F_WD_ERR_STATUS	F_WD_ERR_STATUS[7:1] These bits give the watchdog error status for the watchdog of each corresponding channel. Thus F_WD_ERR_STATUS[1] will give the watchdog error status for watchdog of channel1. Similarly F_WD_ERR_STATUS[2] will give the watchdog error status for watchdog of channel2 and so on till F_WD_ERR_STATUS[7], which gives the watchdog error status for watchdog of channel7. As soon as the watchdog of the corresponding channel has a watchdog overrun error, the error status is latched in the corresponding bits of this register. **Note:** PS_WDGTSSR is a hardware cleared register. These bits are automatically cleared by the hardware when PS_WDGTSSR is read by the application. This register should ALWAYS be read whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective “CID” whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID.This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit.
8:31 WDGTS_STATUS	Timestamp value of that specific channel, the timestamp of which is captured when the watchdog error of that specific channel has occurred. This register always contains the timestamp value corresponding to the last occurring Watch Dog error. If due to bad programming watchdog error of more than one channel happen simultaneously then this register contains the timestamp value of the highest channel. For each channel, whether Timestamp A or B is captured depends on the value of PS_MSGA_CHn[TIMESTAMP_A_B_SEL] register bit. **Note:** These bits are automatically cleared by the hardware when PS_WDGTSSR is read by the application.

Note: All bits of PS_WDGTSSR register are self clearing on read. This implies that in case this register is read by the application before the corresponding PS_WDGTSSR[F_WD_ERR_STATUS[CHn]] has had a chance to be sent in the next upcoming PSI5 message, then this bit would be sent as a "0" in this upcoming PSI5 message.

54.3.4.13 PSI5-S ECU to sensor direct command write register (PS_DIRCMD)

Address: 0x012C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	DIRCMD_BYTE1								DIRCMD_BYTE0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1641. PSI5-S ECU to sensor direct command write register (PS_DIRCMD)

Table 1694. PS_DIRCMD field descriptions

Field	Description
0:7 DIRCMD_BYTE3	Byte3 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1"
8:15 DIRCMD_BYTE2	Byte2 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1"
16:23 DIRCMD_BYTE1	Byte1 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1"
24:31 DIRCMD_BYTE0	Byte0 of the Direct Command The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **Note:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is "1"

Note: A "w1c" should be done on the PS_GLSR[DIRCMD_RDY] so that the command written on the PS_DIRCMD register is queued for transmission on the UART TX line. As soon as any ongoing transmission on the UART TX is finished, the PS_DIRCMD starts being transmitted

on the UART Tx line. When PS_GCR[TDFBM] = 0, then the bits on the UART Tx line are shifted in the following sequence "DIRCMD_BYTE0[0], DIRCMD_BYTE0[1]....DIRCMD_BYTE3[0]....DIRCMD_BYTE3[7]" with DIRCMD_BYTE0[0] being shifted first.

54.3.4.14 PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)

Figure 1642. PSI5-S channel 0 message configuration register A (PS_MSGA_CH0)

Table 1695. PS_MSGA_CH0 field descriptions

Field	Description
21:23 F0_BYTE	Number of UART bytes comprising one UART packet. Applicable only to special messages having CID = 0 in their Message Header. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled and a message with the corresponding frame ID is not expected to occur. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
26 TIME_STAMP_A_B_SEL	Whether the Timestamp corresponding to timestamp counter A or B, is appended to messages targeted for Channel0. 0 Timestamp counter A 1 Timestamp counter B
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 Timestamp buffer is cleared. This bit is one shot and is always read as "0". **Note:** This bit is also writable in PS_NORMAL mode.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value "0" or is refreshed on a timestamp "capture event" 0 Timestamp buffer maintains value "0". 1 Timestamp buffer responds to a "capture event" and captures the respective timestamp value.

54.3.4.15 PSI5-S channel 0 message configuration register B (PS_MSGB_CH0)

Figure 1644. PSI5-S mailbox status register channel 0 (PS_MBOX_SR_CH0)

Table 1697. PS_MBOX_SR_CH0 field descriptions

Field	Description
26 F1_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC1) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC1) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when an unrecoverable message (with the CID = 0 and FID=1) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
27 F1_OV	1 Indicates that there is an unread message stored in MBOX0, LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX0, LOC1 It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode.
28 F1_READ	MBOX0, LOC1 is reserved for any unrecoverable message (XCRC_ERR has occurred or it is an "illegal message"). It can correspond to any channel from 1 to 7. 1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX0, LOC1 by the DMA. 0 No unread message in MBOX0.LOC1 It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC1. This bit is also writable in ps_normal mode.
29 F0_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC0) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0, LOC0) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when a transceiver message (with the CID = 0 and FID=0) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.

Table 1697. PS_MBOX_SR_CH0 field descriptions (continued)

Field	Description
30 F0_OV	1 Indicates that there is an unread message stored in MBOX0, LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX0, LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode.
31 F0_READ	MBOX0, LOC0 is reserved for a transceiver message. 1 It indicates that the message that has just been read from PS_MRU_BUF2 will be stored in MBOX0, LOC0 by the DMA. 0 No unread message in MBOX0, LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0, LOC0. This bit is also writable in ps_normal mode.

54.3.4.17 PSI5-S channel message configuration register A (PS_MSGA_CHn)

Address: 0x0190 + [n-1]*0x3C (n=1 to 7) Access: User read/write

Figure 1645. PSI5-S channel message configuration register A (PS_MSGA_CHn)

Table 1698. PS_MSGA_CHn field descriptions

Field	Description
0 L_PC_EN	Selects whether the parity/CRC selection for a PSI5 message is to be controlled globally on a channel basis (through the G_PC bits) or locally on a per frame basis (through the L_PC[frame] bits). 0 Parity/CRC option controlled globally through the G_PC bit 1 Parity/CRC option controlled locally through the L_PC[frame] bits individually for message of each frame.
1:3 F5_BYTE	Number of bytes in UART packet for message corresponding to frame 5. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F5_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
4 L_PC5	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame5 1 CRC selected for PSI5 message for frame5
5:7 F4_BYTE	Number of bytes in UART packet for message corresponding to frame 4. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F4_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
8 L_PC4	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame4 1 CRC selected for PSI5 message for frame4
9:11 F3_BYTE	Number of bytes in UART packet for message corresponding to frame 3. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F3_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
12 L_PC3	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame3 1 CRC selected for PSI5 message for frame3.
13:15 F2_BYTE	Number of bytes in UART packet for message corresponding to frame 2. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F2_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
16L_PC2	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame2 1 CRC selected for PSI5 message for frame2.

Table 1698. PS_MSGA_CHn field descriptions (continued)

Field	Description
17:19 F1_BYTE	Number of bytes in UART packet for message corresponding to frame 1. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F1_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
20 L_PC1	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message. 0 Parity selected for message for frame1 1 CRC selected for PSI5 message for frame1
21:23 F0_BYTE	Number of bytes in UART packet for message corresponding to frame 0. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F0_payload] is immaterial. Refer to note in *Section 54.3.4.18: PSI5-S channel message configuration register B (PS_MSGB_CHn)* that explains the recalculation of Fn_bytes.
24 L_PC0	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message. 0 Parity selected for message for frame0 1 CRC selected for PSI5 message for frame0
25 MODE	This bit selects the operating modes between sync and async for the channel. 1 Asynchronous 0 Synchronous
26 TIME_STAMP_A_B_SEL	Decides whether timestamp counter A or B value is captured in the local timestamp buffer, whenever a “capture event” occurs. 0 Timestamp counter A 1 Timestamp counter B
27 TMSG_TCMD	Whether the timestamp is recorded when the message is received or when the channel command is moved from the TxFIFO to the UART Tx register (emulates a sync pulse) 1 Timestamp recorded based on message header byte received. 0 Timestamp recorded based on “emulated” sync pulse.
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 Timestamp buffer is cleared. This bit is one shot and is always read as “0”. **Note:** This bit is also writable in PS_NORMAL mode.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value “0” or is refreshed on a timestamp “capture event”. 0 Timestamp buffer maintains value “0”. 1 Timestamp buffer responds to a “capture event” and captures the respective timestamp value.

Table 1698. PS_MSGA_CHn field descriptions (continued)

Field	Description
30 G_PC	This bit globally selects the Parity or the CRC option for all the Frames of that particular channel provided L_PC_EN is set “0”. 0 Parity option selected globally for messages of all frames. 1 CRC option selected globally for messages of all frames.
31 CH_EN	PSI5 Channel Enable. This bit decides if the IP takes the data belonging to the specific channel as “legal” or “illegal”. 0 Concerned PSI5 channel is disabled. Any data occurring with a CID value of a disabled channel is treated as an “illegal message” and send to Channel 0 unrecoverable message area ($MBOX_0$, LOC_1). 1 Concerned PSI5 channel is enabled.Any data occurring with a CID value of an enabled channel can either be treated as “legal” or “illegal”. Refer to *Section 54.4.2.1: PSI5 message extraction* for the definition of legal and illegal messages. Legal messages are sent to $MBOX_{CID}$, LOC_{FID} while illegal messages are sent to $MBOX_0$, BOX_0, LOC_1.

54.3.4.18 PSI5-S channel message configuration register B (PS_MSGB_CHn)

Address: 0x0194 + [n-1]*0x3C (n=1 to 7) Access: User read/write

Figure 1646. PSI5-S channel message configuration register B (PS_MSGB_CHn)

Table 1699. PS_MSGB_CHn field descriptions

Field	Description
2:6 F5_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 5. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
7:11 F4_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 4. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Table 1699. PS_MSGB_CHn field descriptions (continued)

Field	Description
12;16 F3_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 3. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
17:21 F2_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 2. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
22:26 F1_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 1. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
27:31 F0_payload	Number of bits in the payload region of the PSI5 message corresponding to frame 0. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Note: The IP expects legal values to be programmed for Fn_byte field. If this is not followed then the IP reprogrammed the registers with default values. Whenever the value of "Fn_byte" field becomes 1 or 2 it is defaulted to 3 and value of 7 is defaulted to 6. This updation happens once the IP enters the PS_NORMAL mode.

In addition to the above, the following checks are also performed.

By default the IP will expect that there is coherence between the expected number of bytes calculated through the "minUARTbytes" and the number of bytes in the "Fn_byte" field. Refer to Figure 1656: PSI5-S packet structure for definition of "minUARTbytes". If there is no coherence (that is the above two calculations do not match) then the IP does the following recalculation:

When Programmed Fn_byte > "minUARTbytes", then the IP will expect that the additional extra bytes would be stuffed with 0s from the transceiver. Rest of the checking will be done as described in Section 54.4.2.2: PSI5 "recoverable and unrecoverable" messages.

When Fn_byte < "minUARTbytes" then the "Fn_bytes" is internally "increased" such that the expanded "Fn_bytes" is now equal to minUARTbytes". Refer to Figure 1656: PSI5-S packet structure for definition of "minUARTbytes". Using this expanded "Fn_bytes" value the message that would be arriving is analyzed. This would mean that no data bits are lost. Rest of the checking will be done as described in Section 54.4.2.2: PSI5 "recoverable and unrecoverable" messages.

The "recalculated" Fn_byte field is automatically updated by the IP once the IP enters the NORMAL mode of operation. For the subsequent occurrence in the document, all references to "Fn_byte" would mean the recalculated value of "Fn_byte".

54.3.4.19 PSI5-S mailbox status register channel (PS_MBOX_SR_CHn)

Address: 0x019C +[n-1]*0x3C (n= 1 to 7) Access: User read/write

Figure 1647. PSI5-S mailbox status register channel (PS_MBOX_SR_CHn)

Table 1700. PS_MBOX_SR_CHn field descriptions

Field	Description
14 F5_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC5) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC5) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=5) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writeable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
15 F5_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC5 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writable in ps_normal mode.
16 F5_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC5. 0 No unread message in MBOX[n], LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC5. This bit is also writable in ps_normal mode.

Table 1700. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
17 F4_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC4) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC4) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=4) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
18 F4_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC4 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode.
19 F4_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC4. 0 No unread message in MBOX[n], LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC4. This bit is also writable in ps_normal mode.
20 F3_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC3) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC3) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=3) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
21 F3_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC3 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode.
22 F3_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC3 by the DMA. 0 No unread message in MBOX[n], LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC3. This bit is also writable in ps_normal mode.

Table 1700. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
23 F2_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC2) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC2) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=2) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit fields details.
24 F2_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC2 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode.
25 F2_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC2. 0 No unread message in MBOX[n], LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC2. This bit is also writable in ps_normal mode.
26 F1_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC1) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC1) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=1) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
27 F1_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode.
28 F1_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC1. 0 No unread message in MBOX[n], LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC1. This bit is also writable in ps_normal mode.

Table 1700. PS_MBOX_SR_CHn field descriptions (continued)

Field	Description
29 F0_ERR	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC0) by the DMA, has one or more _ERR bits set. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n], LOC0) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message (with the CID = n and FID=0) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode. **Note:** Also refer to *Figure 1669: IRQ[n] interrupts*, for bit field details.
30 F0_OV	1 Indicates that there is an unread message stored in MBOX[n], LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n], LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode.
31 F0_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2, will be stored in MBOX[n], LOC0. 0 No unread message in MBOX[n], LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n], LOC0. This bit is also writable in ps_normal mode.

54.3.4.20 PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)

Address: 0x01A0 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	WDRST	WDCS	WDEN	0	WD_TO

Figure 1648. PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)

Table 1701. PS_WD_CFGR_CHn field descriptions

Field	Description
4 WDRST	Resets watchdog counter for the channel This bit will reset the watchdog counter and the counter will be reloaded with the value of WD_TO and automatically start counting again. **Note:** It is also writable in PS_NORMAL mode.
5 WDCS	This will select either Trigger or the module clock for watchdog counter of the channel. Refer to *Figure 1672: Clock distribution in PSI5-S*. 0 ipg_clk_ps_wd clock 1 trig is selected as the clock.
6 WDEN	The watchdog counter for each channel can be started, stopped. 1 watchdog counter started. 0 watchdog counter stopped. It maintains its value. **Note:** This bit is also writable in PS_NORMAL mode.
8:31 WD_TO	This indicates the watchdog time out value. The watchdog generates an overrun error, in case the watchdog is not refreshed before the watchdog counter reached the WD_TO value. The Watchdog is refreshed in a different manner depending on whether the PSI5-S channel is in asynchronous mode or synchronous mode as described below: In Asynchronous mode: As soon as the IP enters the PS_NORMAL mode the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled then the counter starts immediately. Whether the WD has to be “refreshed (re-loaded)” or “not to be refreshed” is analyzed when the XCRC is calculated. In case the XCRC is correct the watchdog is re-loaded (It is not STOPPED), else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In case of watchdog overrun error the counter is refreshed. In Synchronous Mode: As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled then the counter starts immediately. Thereby it is re-loaded, either on the occurrence of a sync pulse or the watchdog overrun error. In case the event for this load is the Sync Pulse then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured (enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FFID_byte] is not equal to “0”. The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured“, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered. In both the above modes, the watchdog can be always refreshed using a software reload. **Note:** The watchdog counter is enabled ONLY if the channel is enabled.

54.3.4.21 PSI5-S DDSR trigger offset register channel (PS_DDTRIG_OFFR_CHn)

Address: 0x01A4 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1649. PSI5-S DDSR trigger offset register channel (PS_DDTRIG_OFFR_CHn)

Table 1702. PS_DDTRIG_OFFR_CHn field descriptions

Field	Description
16:31 DDTRIG_OFFR	These bits configure the delay between the “shift trigger” of the various DDSRs across different channels. The value in this register governs the delay after which the specific DDSR would be triggered once the Global Shift trigger (PS_GLCR[GL_DDSR_TRIG]) is written to “1” and the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] is set to “1” for that channel. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register.

54.3.4.22 PSI5-S DDSR trigger period register channel (PS_DDTRIG_PERR_CHn)

Address: 0x01A8 + [n-1]*0x3C (n=1 to 7) Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1650. PSI5-S DDSR trigger period register channel (PS_DDTRIG_PERR_CHn)

Table 1703. PS_DDTRIG_PERR_CHn field descriptions

Field	Description
16:31 DDTRIG_PERR	These bits configure the “shift trigger” period for the DDSR of that specific channel. The value in this register governs the period with which the data for the DDSR of that particular channel would be shifted out. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register. **Note:** This register should be programmed to be greater than or equal to 2.

54.3.4.23 PSI5-S ECU to sensor control register (PS_E2SCR_CHn)

Address: 0x01AC + [n-1]*0x3C (n=1 to 7) Access: User read/write

Field	Description
1:5 CMD	Bits for the ECU-to-sensor “CMD” format. They refer to the command send to the UART Tx logic, when a “1” is shifted from the DDSR register.
7:11 ACMD	Bits for the ECU-to-sensor “ACMD” format. They refer to the command send to the UART Tx logic, when a “0” is shifted from the DDSR register.

Table 1704. PS_E2SCR_CHn field descriptions (continued)

Field	Description
14 CH_TRIG	This controls that the DDSR of the specific channel is triggered locally. This bit controls the shifting when PS_E2SCR_CHn[GL_TRIG_SEL] is 0. 1 Start the “shift trigger” of the DDSR. 0 Stop the DDSR from shifting the commands. The counters corresponding to DDTRIG_PERR and the DDTRIG_OFFR are reset. **Note:** This bit is also writable in PS_NORMAL mode.
15 GL_TRIG_SEL	This bit controls whether the DDSR shift trigger is a global trigger or a local channel trigger. 1 The DDSR shift trigger is a global trigger dependent on PS_GLCR[GL_DDSR_TRIG]. 0 The DDSR shift trigger is a local channel trigger dependent on the bit CH_TRIG.
16 DEFAULT_SYNC	Decides the value to which the DDSR should default to when PS_E2SSR_CHn[DDSR_RDY] == 1. When PS_E2SSR_CHn[DDSR_RDY] == 1 then the default shift (whether it is CMD or ACMD) is based on the value of this bit.
17 DDSR_SHIFT_SEL	DDSR Shift Selection This is used to select the shift trigger for the DDSR registers. 0 The shift trigger is from internal DDSR counters which are clocked from either the trig or the ipg_clk_ps_ddtrig. 1 The input signal trig directly acts as the shift trigger of the DDSR registers. Refer to *Figure 1672: Clock distribution in PSI5-S* for more details.
18 DDSR_CLR	Used for rejecting the contents of the DDSR register. As soon as this bit is written to “1” the contents of DDSR are immediately rejected and defaulted to “0” after the completion of the current ACMD or the CMD transmission. PS_E2SSR_CHn[DDSR_RDY] goes to 1 and value of PS_E2SCR_CHn[DEFAULT_SYNC] starts getting shifted. This bit is one shot (W1S). **Note:** This bit is also writable in PS_NORMAL mode.
19 DDSR_CLK_SEL	Selects which clock clocks shift logic of the DDSR, for shifting the bits for command transmission. 0 ipg_clk_ps_ddtrig clock 1 trig is selected as the clock.
20 CMDTR_SW_CTRL	This bit decides that once the command is ready for transmission (indicated by the setting PS_E2SSR_CHn[CMDPR_BZY] to 1), then when should the actual transmission start: 0 The actual transmission of command remains suspended, even though the command is ready in the DDSR. 1 The command transmission starts once the PS_E2SSR_CHn[CMDPR_BZY] becomes 1, and the internal shift logic is available. **Note:** This bit is also writable in PS_NORMAL mode.
22 SYNCHRO_OVF_IE	Synchro overflow interrupt enable 1 Generate an interrupt when PS_E2SSR_CHn[SYNCHRO_OVF] is set to “1” 0 No interrupt is generated when PS_E2SSR_CHn[SYNCHRO_OVF] is set to “1”

Figure 1652. PSI5-S ECU to sensor status register (PS_E2SSR_CHn)

Table 1705. PS_E2SSR_CHn field descriptions

Field	Description
22 SYNCHRO_OVF	This bit gets set whenever due to any reason (like too less DDTRIG period), sync pulse of a channel comes before the previous sync pulse of the same channel has actually shifted its data. It can be used to detect sync pulse overflow. If PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to “1” then this can also be used to generate an interrupt on the ipi_ps_e2s_ch[n] line where “n” is the specific channel number. 1 Synch Pulse overflow has occurred for the specific channel. 0 No synch pulse overflow has occurred in the specific channel.
24 CMDTR_NWRT	Status of Command written to the DDSR: 1 Command written to the DDSR is rejected as an attempt to write to it has been made when DDSR_RDY == 0. 0 Command written to the DDSR has been accepted for processing.

Table 1705. PS_E2SSR_CHn field descriptions (continued)

Field	Description
25 CMDPR_BZY	Command Processing Busy Status This bit along with the DDSR_RDY bit can be used to check the status of the command that is being processed in the DDSR. 1 DDSR is ready with the processed command complete with CRC/start bits/stuff bits.The transmission of the same would start if PS_E2SCR_CHn[CMDTR_SW_CTRL] == 1. For this status DDSR_RDY should also be read as “0”. 0 DDSR is busy with command processing. For this status DDSR_RDY should also be read as “0”. Note that when DDSR_RDY goes to “1” then this bit goes to “0”. So it represents the above status conditions ONLY when DDSR_RDY is “0”.
26 DDSR_RDY	Status for DDSR getting empty and ready for receiving new command. 1 DDSR is empty and ready for receiving a new command. 0 DDSR is not ready and is busy with either the command processing or the command transmission.

54.3.4.25 PSI5-S channel1 ECU to sensor downstream data shift register high (PS_DDSR_H_CHn)

Figure 1654. PSI5-S channel1 ECU to sensor downstream data shift register low (PS_DDSR_L_CHn)

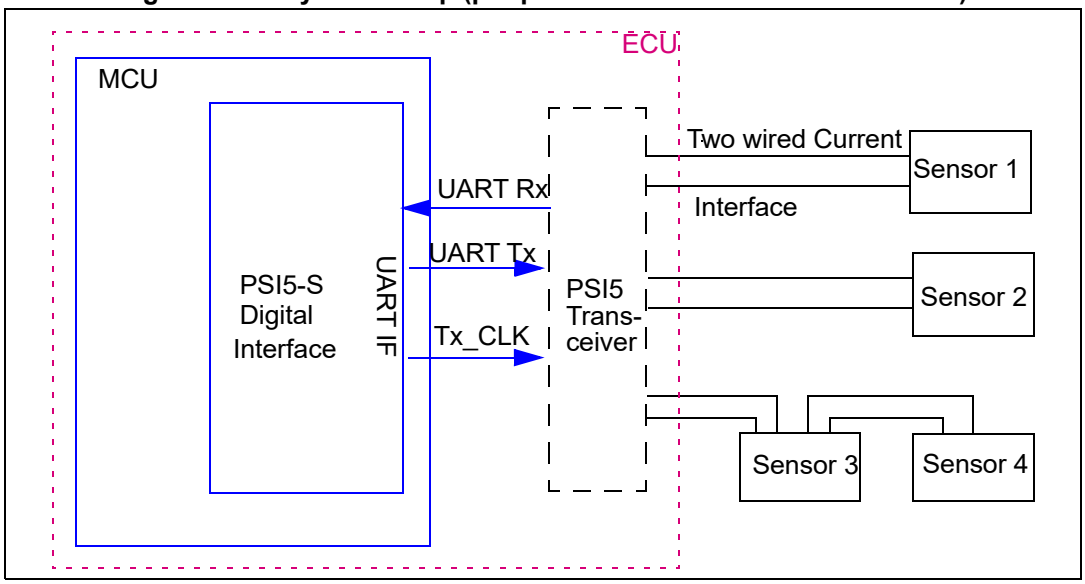

Table 1707. PS_DDSR_L_CHn field descriptions

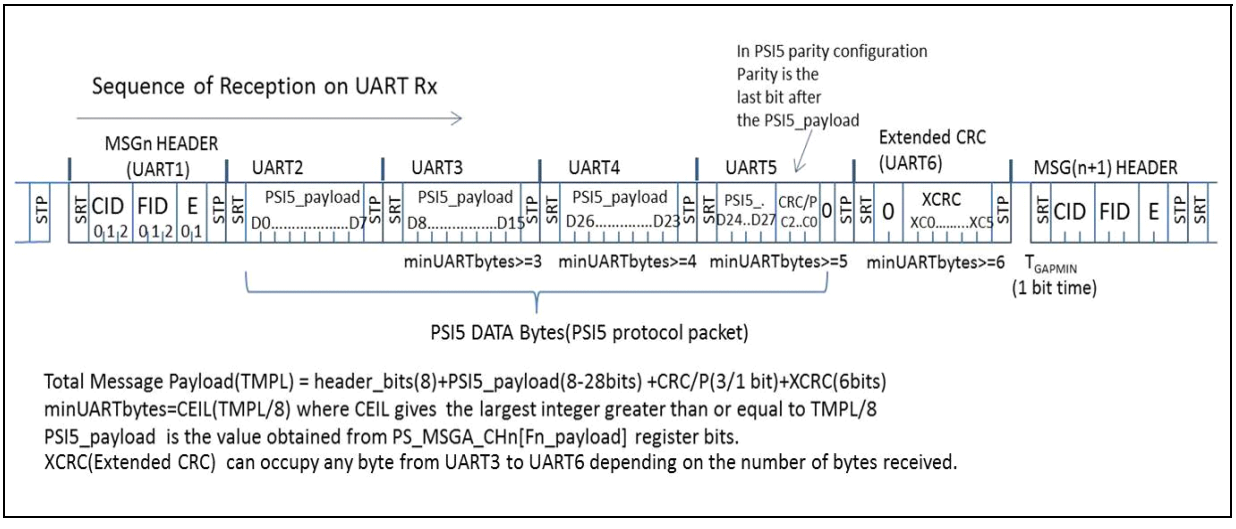
Field	Description
0:7 DDSR_L1	8 bits of the DDSR_L that can only be read by the Application. These 8 bits are automatically updated by the hardware. They can be read by the software to check for the processed command after the command is written to the DDSR by the application, the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to “1”.
8:31 DDSR_L0	Lower 24 bits of the DDSR register that are written by the Application as well as updated by the hardware once the command processing is over. Though all the 24 bits can be written by the software, yet only those number of bits as governed by PS_E2SCR_CHn[CMD_TYPE] are actually taken for processing. This register can be read by the software to check for the processed command, after the command is written to the DDSR by the application, the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to “1”. **Note:** These bits are also writable in the PS_NORMAL mode.

54.4 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The UART compatible transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. *Figure 1655* shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1655. System setup (peripheral sensor connected to device)



ECU (Electronic Control Unit) is comprised of PSI5-S digital interface and the UART compatible PSI5 transceiver (present externally). The PSI5-S digital interface communicates with the PSI5 Transceiver though the UART interface as shown in *Figure 1655*. When conducting the Sensor To ECU communication, the external transceiver converts the sensor data to the UART packet format before sending it to the PSI5-S module. The IP extracts the PSI5 Frames from the input UART Packet.

54.4.1 PSI5-S UART message structure

The transceiver sends a UART message packet consisting of between three to six UART bytes which contains information to allow rebuilding of the PSI5 message as well as the message itself and has a CRC which protects the complete packet (XCRC).

Each byte is made up of one start bit, eight data bits and one stop bit - no parity is included in the UART byte. *Figure 1656* shows the PSI5-S UART packet structure.

Figure 1656. PSI5-S packet structure

The UART packet is made up of the following:

- MSGnHEADER: This is the message header byte which includes the indication of which channel the PSI5 message was received on (3-bit CID), the slot on that channel in which the message was received (3-bit FID) and transceiver error indication bits (2-bit E).
- PSI5 DATA bytes - minimum one, maximum four, depending on the data payload region of the PSI5 message (8 - 28 bits) and whether parity (1-bit) or CRC (3-bit) is configured for the PSI5 message. In the above example shown in *Figure 1656* it is taken as 28 bits and 4 UART bytes are shown (UART2-UART5). Messages having CID and FID both as “0s” do not have the CRC/Parity field in them. Such messages only have the message header, payload and the XCRC fields.
- XCRC- 6-bits - This is the extended CRC which protects the UART packet. Note that any bits between the end of the PSI5 message payload and the XCRC are ‘stuffed’ with ‘0’s. This can also be seen in *Figure 1656*. For details about XCRC handling, refer to *Section 54.4.2.5*.
- Example to calculate the minUARTbytes (for messages NOT having CID and FID both as 0):
  - Fn_payload = 14
    with PSI5 CRC option: TMPL = 8+14+3+6=31, minUARTbytes=CEIL(3.8)=4
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:13], CRC[2:1]),
    UART4(CRC[0],0,XCRC[0:5])
  - Fn-payload = 13
    with PSI5 Parity option: TMPL = 8+13+1+6=28, minUARTbytes=CEIL(3.5)=4
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:12],Paritybit,00),
    UART4(00,XCRC[0:5]).

Note: The “0” stuffing between the parity bit and the XCRC. The XCRC is always in the last 6 bits of the last byte.

- Example to calculate the minUARTbytes (for messages having CID and FID both as 0):
  - F0_payload = 8
    TMPL = 8+8+0+6=22, minUARTbytes=CEIL(2.75)=3
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(00,XCRC[0:5]).
  - F0_payload = 10
    TMPL = 8+10+0+6=24, minUARTbytes=CEIL(3)=3
    These input data stream is interpreted as
    UART1(header), UART2(D[0:7]), UART3(D[8:9],XCRC[0:5])

54.4.2 PSI5 received message handling

The PSI5 message (UART Type) received from sensors (through the external UART Transceiver) is handled internally to the PSI5-S IP by three separated parts:

- PSI5 message extraction:

  This decides when a UART packet has been received with the correct header byte, and then how to extract the information from this UART packet form a complete PSI5 message.
- PSI5 “recoverable” and “unrecoverable messages”:

  This differentiates the PSI5 messages received above, into “recoverable” and “unrecoverable” messages.
- PSI5 message storage and Mailbox transfer:

  This ensures the transfer of the PSI5 message to the correct location in the system RAM, once the PSI5 message has been correctly differentiated into “recoverable” and “unrecoverable” messages.

Following sections detail the above 3 parts.

54.4.2.1 PSI5 message extraction

Once a UART start bit is detected after the idle timeout (the idle time between message packets on the UART interface, that is the number of bit times between message packets in the range of at least 1 to 16, configurable in the UART module through the PS_UARTPTO register) has occurred, the UART bytes are subsequently sampled. They are being received by an internal state machine in the MRU, which checks for the formation of a complete UART packet, its coherence and extraction of the PSI5 message from the UART packet. Also, refer to *Figure 1657* for further understanding of this section. Each UART packet that is received can be considered as “recoverable” or “unrecoverable”. Demarcation between the two is explained subsequently. Following are the sequence of steps performed as each UART byte is being received:

1. There is a 6 byte UART message input buffer into which the UART bytes from the UART Rx register are written as they are received. A 3-bit UART message counter is incremented on the reception of each byte in UART message packet that is each UART byte received between idle time counter indications.
2. All the subsequent UART bytes in the UART packet are stored internally till any of the following events occurs:
   - UART Timeout that is bus idle time is detected.
   - Framing Error from the UART.
   - Number of UART bytes that are received as reported through the UART message counter described in *1.* above exceed 6.
   - STOP mode request mode is asserted. Refer to *Section 54.1.4.1*, for further details.
3. As soon as any of the events described in *2.* above occur, it is assumed that a complete UART packet has been received. The XCRC is then calculated immediately on the received UART packet. Refer to *Section 54.4.2.5*, for details about XCRC. If there is an XCRC error the message is assumed to be “unrecoverable” and it is sent to

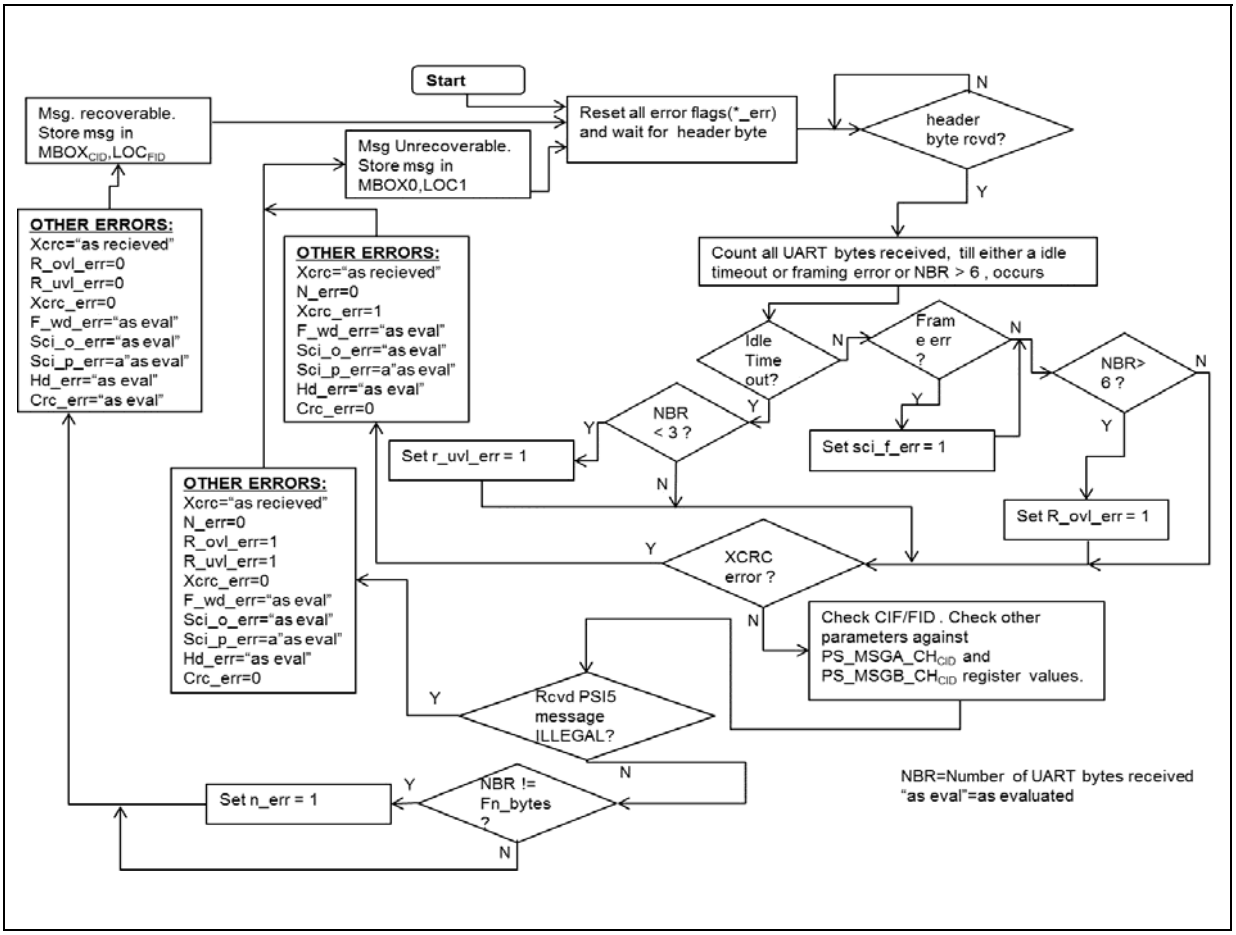
$MBOX_0$, LOC_1.The timestamp of the message is captured as is described in *Section 54.4.4*.The watchdog error is captured as is described in *Section 54.4.5*.

4. If there is NO XCRC error, then the CID and FID are extracted from the header byte, and the configured length of the message is determined from the configuration in PSI5 Channel*n* Message Configuration Register A. Following steps are performed.
   - The FID and the CID from the header byte is transferred directly to the PSI5 Frame status word.
   - The transceiver error flags (E0, E1) are transferred directly to the PSI5 Frame status word.
   - The message is then analyzed to see whether it is “LEGAL” or “ILLEGAL.
   - Following are the conditions for a “LEGAL” message:
     When the CID and the FID of the received message are both “0s” and PS_MSGA_CH0[F0_byte] is NOT “0” OR
     When the data of an Asynchronous Enabled channel is received with FID = 0 and $PS_MSGA_CH_{CID}$[F0_byte] is NOT “0” OR
     When the data of a Synchronous Enabled channel is received with legal FIDs (0 to 5) and if the received FID is such that the corresponding $PS_MSGA_CH_{CID}[F_{FID}_byte]$ is NOT 0.
   - Any received message that does not satisfy the above condition is considered as “ILLEGAL”. Illegal Messages are also treated as “unrecoverable” messages and are sent to $MBOX_0$, LOC_1.
     Example can be a message with CID as 0 but FID as 1(illegal because Channel0 is asynchronous and can only have FID equal to 0 messages) or a message received for an enabled synchronous channel but having an FID equal to 7 (illegal because FID as 7 is not a legal Frame ID).
   - The timestamp of a Legal/Illegal message is captured as is described in *Section 54.4.4*. The watchdog error is captured as is described in *Section 54.4.5*.
   - The number of UART bytes received in the UART message packet is compared with the number specified in Message Configuration Register A for the channel indicated by CID and FID in the header byte. If the number of bytes indicated by the message counter does not match $PS_MSGA_CH_{CID}[F_{FID}_byte]$ field, then the status bit N_Err within the PSI5 Frame status word is set. The above “number of bytes received” check is not carried out for an “illegal message”.
5. The PSI5 message payload is checked using the PSI5 CRC or parity as per the configuration. Whether the CRC or parity check is correct or not, the PSI5 message payload is written to the PSI5 Sensor Data word and the CRC or parity is written to the PSI5 Frame Status word. Note that the messages which have CID and FID both as “0”, are not checked for CRC or parity error. The CRC/Parity error status bits remain “0” for such messages.This above check is NOT done for “illegal messages”.

54.4.2.2 PSI5 “recoverable and unrecoverable” messages

Based on *Section 54.4.2.1: PSI5 message extraction*, a message is considered “unrecoverable”, if the XCRC is incorrect or it is an “illegal message”, else the message is considered “recoverable”. “Unrecoverable” message indicates that an error has been detected during the assembling phase of the UART packet that is during the formation of the UART packet from the individual UART bytes. “Unrecoverable” messages are always stored in PSI5 mailbox $MBOX_0$, LOC_1 in system RAM. “Recoverable” messages are always stored in the Mailbox location pointed out by the CIDn and the corresponding FID fields.

Figure 1657 describes the treatment of the “Recoverable” and “Unrecoverable” messages. It also details the setting of the various error flags. The various cases for a new PSI5 message reception are:



- Idle Timeout occurrence
- Framing Error Occurrence

  As soon as a framing error has occurred, all the UART packets sampled till that instance are assembled to form a PSI5 packet and are transferred to the MRU buffer. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.
- Number of UART bytes received exceed 6

  In this case any UART bytes received after the 6th byte, are totally rejected by the internal PSI5-S state machine. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.
- STOP mode entry

  Refer to *Section 54.1.4.1*. Stop mode entry causes the flushing of the internal PSI5 message buffer and this event is treated like new message completion. Exiting from the stop mode resets the state machine and it becomes ready to respond to the next UART packet. The next UART packet is taken as the header byte of a new PSI5 message. The stop mode, as an event for a new PSI5 message formation is not shown in *Figure 1657*.

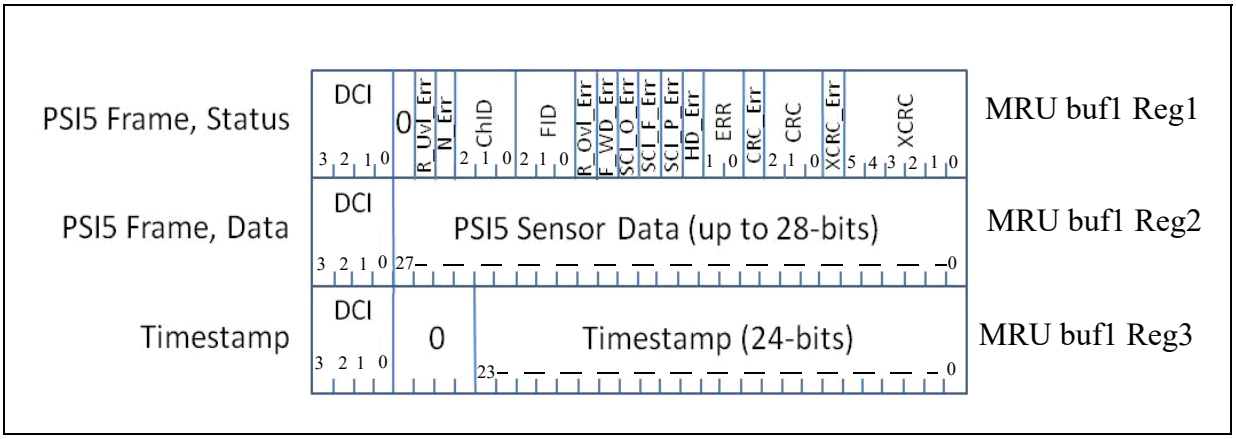
Figure 1657. PSI5-S message handling and error flags

Once the message has been correctly deciphered as “Recoverable” or “Unrecoverable” and the various error flags have been set then the Message is finally transferred to the MRU buf2. Once the corresponding message has been read from the MRU buf2 the bits in the “PS_MBOX_SR_CH[n]” register are set appropriately. This aids the application to correctly read the concerned message from the Mailbox. *Section 54.4.2.3* describes the PSI5 Message Storage and detection in detail.

54.4.2.3 PSI5 message storage and mailbox transfer

Once the message has been correctly deciphered as “recoverable” or “unrecoverable” and the various status bits are set, it is then transferred to the MRU output buffer. The MRU output buffer is a 2 stage buffer differentiated as MRU Buf1 and MRU Buf2. The MRU buf1 is composed of 3, 32-bit registers while the MRU buf2 is composed of 4, 32-bit registers. *Figure 1658* shows the structure of MRU buf1. It is composed of three internal registers. These registers are not in the addressable space of the IP. When the internal state machine has correctly decoded the PSI5 message, it is transferred to MRU buffer1. It serves to hold the PSI5 message until it is transferred to MRU buf2.

Figure 1658. MRU buf1 structure



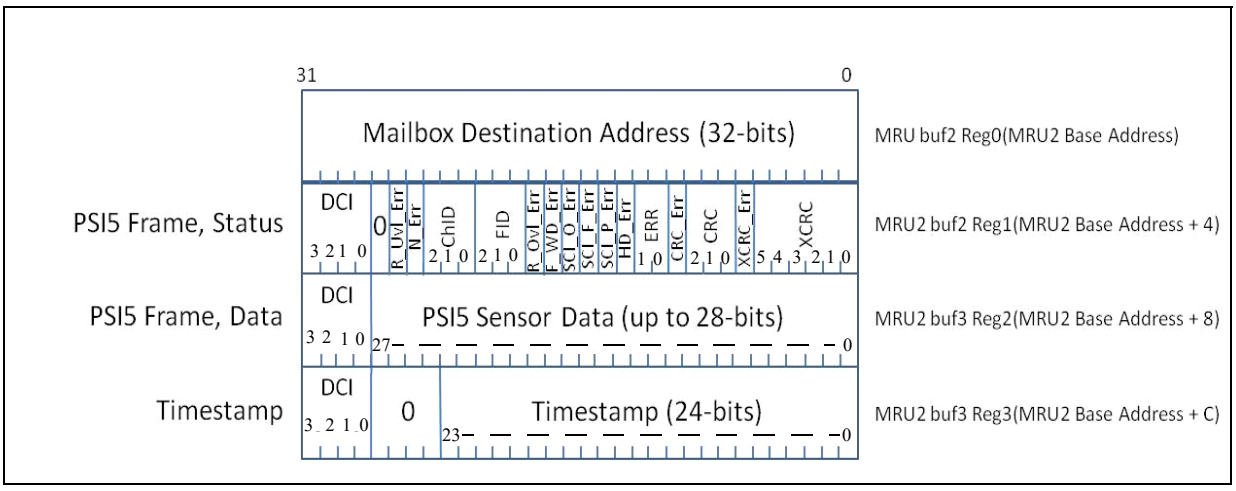


Figure 1659 shows the structure of MRU buf2. MRU buf2 has one extra location as compared to MRU buf1. This extra location (MRU buf2 Reg0) contains the address of the Mailbox location, where the message contained in the rest of the three locations of MRU buffer2 is to be placed. This specific MRU buf2 structure aids the DMA to perform linked scatter-gather data transfer from the IP. The extra location in the MRU buf2 is automatically updated by the hardware and provides the destination address for the message. This destination is the Mailbox Address at which the message (stored in MRU buf2 (Reg1-Reg3) is to be transferred by the DMA. This destination address is calculated by the IP based on ChID in the message header (or ChID0 in the case of an unrecoverable message), the FID in the message header and Base address of the mailbox in system RAM (provided by CH_BASE_ADDR) register.

Figure 1659. MRU buf2 structure

MRU buf2 is in the addressable space of the IP and is read by the DMA when the corresponding DMA request is asserted. The PSI5 message is transferred from the MRU buf1 to the MRU buf2 only when the MRU buf2 has been read completely by the DMA, that is all the 4 locations of the MRU buffer2 have been read by the DMA, for the corresponding PSI5 message.

Following are the sequence of operations that are performed, before the message in MRU buf2, gets ready to be accessed by the DMA:

1. The IP decodes the message as detailed in *Section 54.4.2.1: PSI5 message extraction* and *Section 54.4.2.2: PSI5 "recoverable and unrecoverable" messages*.
2. The corresponding message is available in MRU buf1 along with the various status bits latched internally in the IP. Externally, no interrupt is generated and neither are any status bit updated, when the message is transferred to MRU buf1.When the message is transferred to MRU buf1 a 3 bit DCI (data consistency indicator is added). The DCI is a 3-bit counter that is counted on a reception of each new message in MRU buf1.
3. The IP checks whether MRU buf2 is empty. If it is empty, then the MRU buf1 "Reg1 to Reg3" contents are transferred to the MRU buf2 "Reg1 to Reg3". The corresponding interrupts (except the Message Read from MRU) are also asserted based on the Interrupt Enable settings. Based on the PSI_CH_BASE_ADDR, the CID, FID values and whether an "unrecoverable message" has been received, the IP calculates the contents of MRU buf2 Reg0 register.
   - If CID == 0 then the "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0, LOC0.
   - If "unrecoverable message" is received then "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0, LOC1.
   - In all other cases "MRU buf2 Reg0" contains the Mailbox location corresponding to the $MBOX_{CID}$, LOC_{FID}.
4. Once the calculations in "*3.*" are done, the IP asserts the DMA request for Access 1. In DMA Access 1, the DMA reads the first location (MRU buf2 Reg0) of the MRU buf2. This single 32-bit access writes the content of MRU buf2 Reg0 into the destination address for the DMA channel performing the second access (Access 2). Access 2 is initiated by the DMA once the Access1 transfer is complete. Access 2 is composed of 3, 32-bit accesses of MRU buf2 and it writes the reconstructed PSI5 message along with its status and timestamp to the mailbox, starting at the destination address provided by Access 1.In Access2 the DMA reads the MRU buf2 Reg1, Reg2 and Reg3 in that order.
5. The application can read the PS_MBOX_SR_CH[n] register to get an indication to which mailbox location (or locations) the DMA would transfer the message. Note that "DMA transfer complete" bit/interrupt of the DMA indicates to the application, that the message read by the DMA from the IP has actually been written to the Mailbox.
6. The application should clear the corresponding "Fn_read" bits in the PS_MBOX_SR_CH[n] register once the application has read the corresponding message from the Mailbox. If a PSI5 message gets written to a Mailbox location, with "Fn_read" bit still set at the time at which the DMA has started the Acces1, then the corresponding "Fn_OV" bits are set in the PS_MBOX_SR_CH[n] register.
7. Reference to "*3.*" above, if the MRU buf2 has a pending message and the MRU buf1 also has a message that is ready to be transferred to the MRU buf2 and then a new message gets ready to be written to MRU buf1, then the previous message in MRU buf1 gets overwritten by the new message. The MRU overwrite interrupt is also generated with the setting of the corresponding register bit in the PS_GLSR register. PS_GLSR register contains the CID and the FID of the message that got overwritten by the new message in MRU buf1.
8. When writing an unrecoverable message to the PSI5 mailbox CID0, with the XCRC_ERR bit set, the timestamp that will be used will be the one which is captured at the time XCRC_ERR bit is set. When the unrecoverable message is due to an "illegal message", then the timestamp used would be the one which is captured on the

reception of any message that is always captured at the end of the header byte of every message.

9. In Asynchronous mode, FID will always be configured to be “0” and the module will use the PSI5 Mailbox for the channel (identified by CID in header) as a ring buffer, incrementing the destination address for each message received and saving up to the last six messages received. The bits of the PS_MBOX_SR_CH[n] register will still indicate the status of each location of the Ring Buffer. The software has to still clear the six bits of this register when it reads the Mailbox location else the overwrite bits would be set in the PS_MBOX_SR_CH[n] register. The message identification mechanism allows software to identify the latest message received.

54.4.2.4 PSI5-S data payload CRC recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1660. CRC calculation scheme

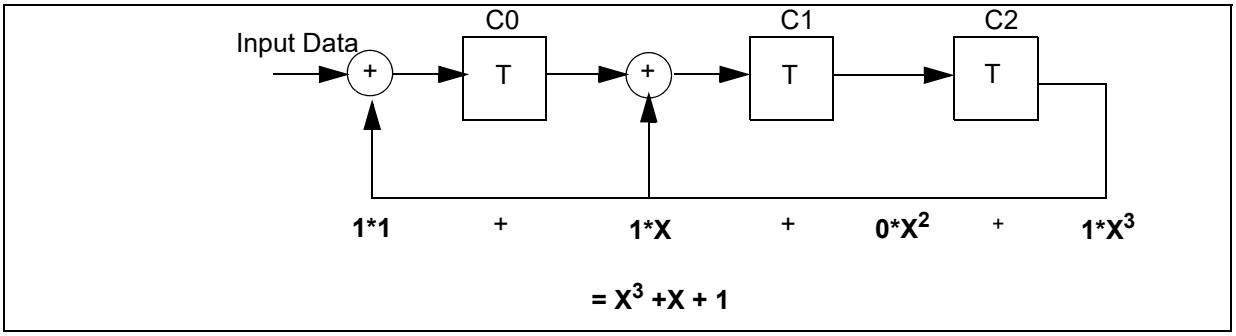

Table 1708. CRC calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1709. Transmitted and received sensor data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1709. Transmitted and received sensor data (continued)

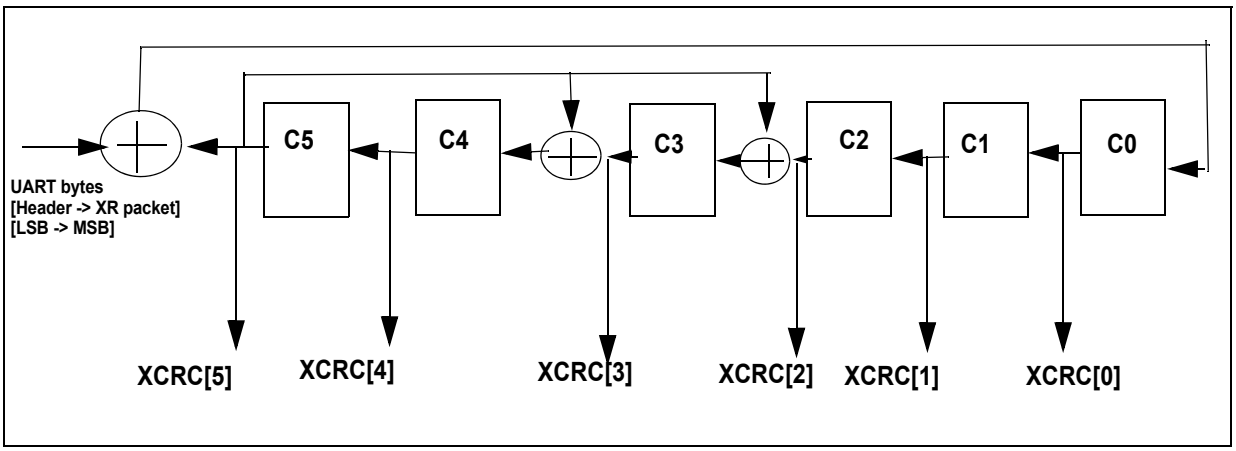
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1710. CRC re-calculation (at receiver side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.



54.4.2.5 PSI5-S XCRC handling

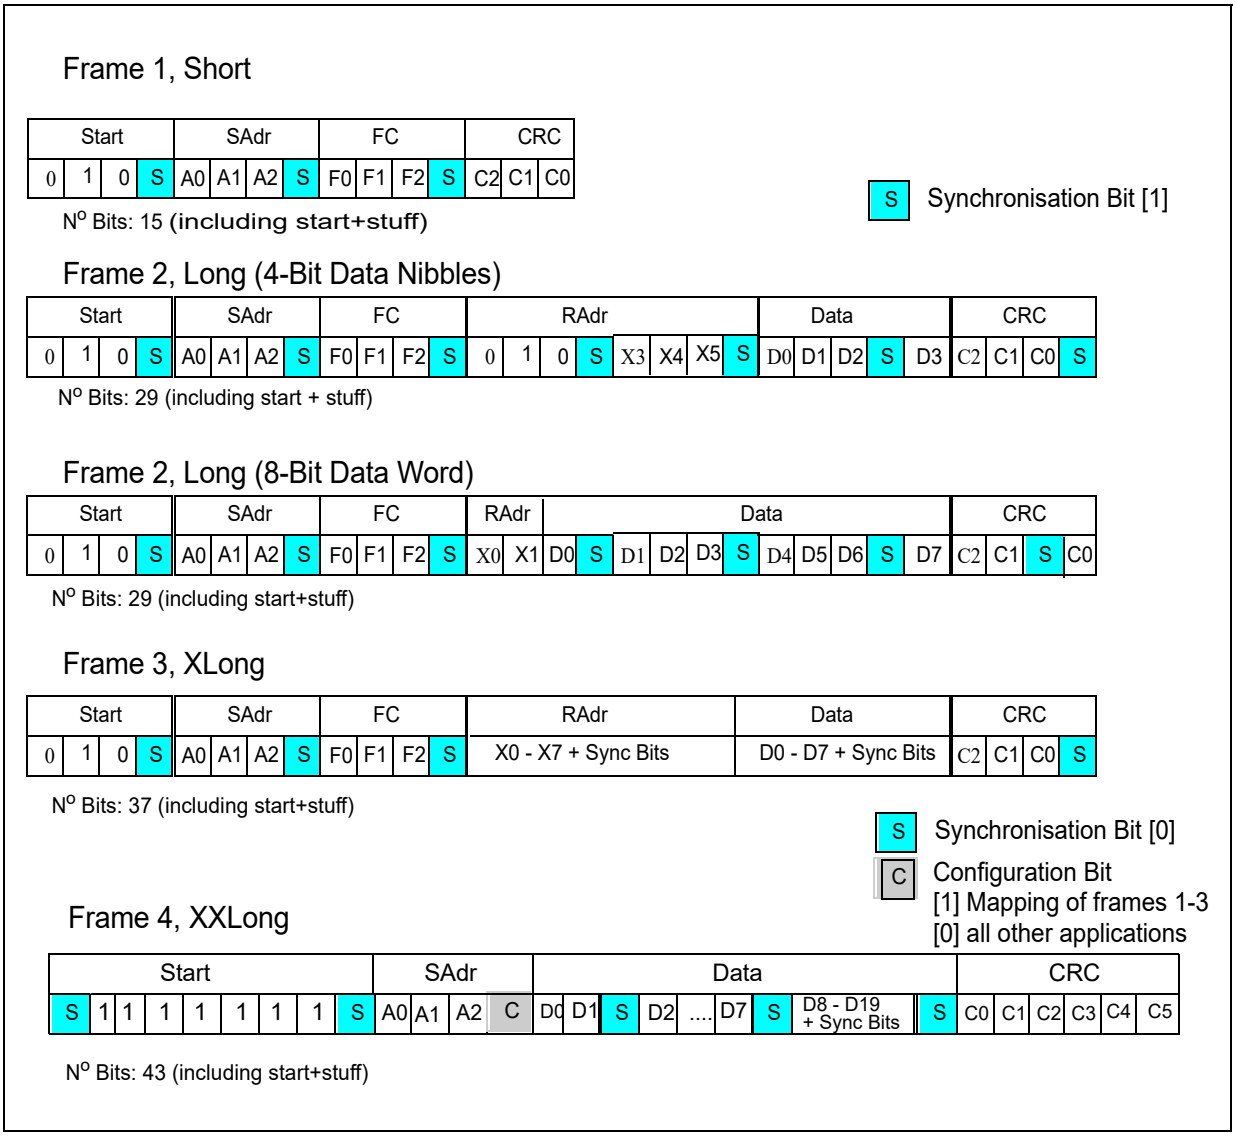
The XCRC calculation is triggered on any of the following events (which also indicate the reception of a new UART packet):

- UART idle timeout
- number of UART bytes exceed 6
- UART Framing error
- STOP mode assertion (refer to *Section 54.1.4.1*)

When any of the above events occur, the internal XCRC calculator becomes active. Each UART byte that is received, passes through the XCRC calculator on a bit by bit basis, starting from the header byte to the expected XCRC byte. The XCRC is assumed to be the last 6 bits of the last UART byte that is received before the occurence of any of the above events. *Figure 1661* shows the XCRC calculation algorithm.

Figure 1661. XCRC calculation

The UART bytes are shifted starting from the received header to data packets to the XCRC packet. Each of these UART bytes is shifted LSB first into this XCRC calculator. Once all the



bytes as denoted by the Fn bytes have been received and the Fnth packet (XCRC) has been shifted completely through this XCRC calculator and if XCRC[5:0] is equal to “0” then it denotes that the XCRC check has passed else there is an XCRC error and the XCRC_ERR bit is set.

The CRC polynomial used is “x6+x4+x3+1” with a binary initialization value of XCRC[5:0] = “010101”.

54.4.3 ECU-to-sensor communication

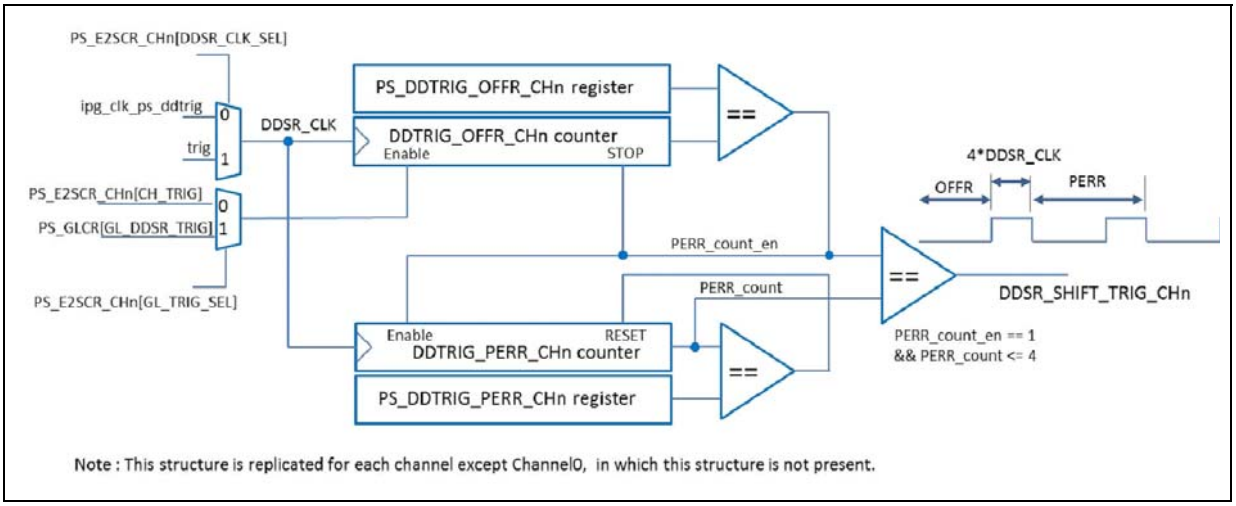
The IP send the commands for the ECU to Sensor communication in terms of UART bytes. It expects the external transceiver to correctly interpret the commands and then generate the appropriate logic 0 or logic 1 on the PSI5 bus. Following are the various PSI5-S ECU to Sensor commands supported by the IP, as shown in *Figure 1662*.

Figure 1662. Standard frame formats supported

- Short: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “C2,C1,C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes and “C2-C0” is the CRC. Refer to *Figure 1662* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, “000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]...PS_DDSR[5], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- Long (4bit Data Nibble): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,X2”, S, “X3,X4,X5, S, “D0,D1,D2”, S,“D3,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1662* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X5, D0...D3, “000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[15], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- Long (8bit Data Word): It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,D0”, S, “D1,D2,D3, S, “D4,D4,D6”, S,“D7,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X1” is the Range Address, “D0-D7” is the data and “C2-C0” is the CRC. Refer to *Figure 1662* for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X1, D0...D7, “000”] with “A0” being given first and “0” as

the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.

– When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[15], 000) with PS_DDSR[0] being fed first in the CRC calculator.



- X-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”, S, “A0,A1,A2”, S, “F0,F1,F2”, S, “X0,X1,X2”, S, “X3,X4,X5”, S, “X6,X7,D0”, S, “D1,D2,D3”, S, “D4,D5,D6”, S,“D7,C2,C1”, S, “C0” where “010” is the start sequence “S” is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, “X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Refer to *Figure 1662* for the frame structure.
  – The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
  – The transmitter extends the data bits by three zeros (as MSBs).
  – The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, F0...F2, X0...X7, D0...D7, “000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  – When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]...PS_DDSR[21], 000) with PS_DDSR[0] being fed first in the CRC calculator.
- XX-Long: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - “011111110”, “A0,A1,A2”, “C”, “D0,D1”, S, “D2,D3,D4” D5,D6,D7, S, “D8,D9,D10,D11,D12,D13”, S,“D14,D15,D16,D17,D18,D19”, S, “C0,C1,C2,C3,C4,C5” where “011111110” is the start sequence “S” is the stuff bit(0), A0-A2 is the sensor address, “C” is the configuration bit, “D0-D19” is the data and “C0-C5” is the CRC. Refer to *Figure 1662* for the frame structure.
  – The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0).
  – The transmitter extends the data bits by six zeros (as MSBs).
  – The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2, D0...D19, “000000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  – When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0], PS_DDSR[1]....PS_DDSR[23], 000000) with PS_DDSR[0] being fed first in the CRC calculator.

54.4.3.1 PSI5-S ECU to sensor command handling

The ECU-to-Sensor commands can be written to the PSI5 IP in two ways:

1. Direct writing for the special Transceiver commands: This can be used by the software to directly write the transceiver/diagnostic commands without using the internal sync pulse generators. Following procedure should be adopted for this:
   a) Application configures the PS_GLCR[DIRCMD_LEN] register for deciding the length of the direct command that is to be written. The length can be 1, 2 or 4 bytes.
   b) Application will check for the status flag PS_GLSR[DIRCMD_RDY]. A “1” here would mean that the PS_DIRCMD register is empty and ready to accept the Direct write command. Trying to write to PS_DIRCMD while DIRCMD_RDY is “0”, will be rejected without any information. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1” then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line, whenever the PS_GLSR[DIRCMD_RDY] bit goes to “1”.
   c) The application then writes the Direct Command to the PS_DIRCMD register. Depending on the PS_GLCR[DIRCMD_LEN] register, only the specific bytes are considered for transmission. Other bytes are ignored.
   d) A “w1c” to the PS_GLSR[DIRCMD_RDY] bit would queue the above direct command for UART transmission with the highest priority; and thereafter as soon as any pending current transmission is complete, the internal state machine would start the transfer of this direct command to the UART Tx line. All other channels would internally buffer their pending DDSR transmission and resume only once the above transmission is over.
   e) Once the Direct transmission is complete the PS_GLSR[DIRCMD_RDY] status bit would go to “1” and if the corresponding interrupt is enabled in the PS_GLCR register, then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line.
2. Writing to the DDSR (Downstream Data Shift Register): In this case the application writes the basic command to the DDSR_L and the IP will add the start bits/start condition/CRC/stuff bits before sending this command to the UART Tx FIFO. Following are the details:
   – There is one DDSR per channel. The default value of DDSR is dependent on the PS_E2SCR_CHn[CMD_TYPE] value. DDSR is composed of two sub registers DDSR_H (Higher) and DDSR_L (Lower). The application can only write to DDSR_L. The number of bits that can be written in the DDSR_L is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] bit values. Note that Channel0 does not have any DDSR, as it does not support any ECU-to-Sensor communication.
   – The “shift trigger” of the DDSR is governed by the values programmed in the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register and the frequency of ipg_clk_ps_ddtrig clock.
   – Once the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n are correctly programmed and each channel is programmed to respond to the selected shift trigger (local trigger or global trigger is decided via the bit PS_E2SCR_CHn[GL_TRIG_SEL]) the software has to write to the Global DDSR trigger bit, PS_GLCR[GL_DDSR_TRIG] or the PS_E2CR[CH_TRIG] bit, so as to synchronously start the DDSR triggers of each channel or locally start the DDSR shift triggers of each channel. The DDSR trigger logic gets the trigger signal immediately but it responds after a delay as programmed in the PS_DDTRIG_OFFR_CH[n] register. The shift trigger period is governed by the value programed in the PS_DDTRIG_PERR_CH[n] register. Refer to *Figure 1663* for the structure of the logic that generates the internal DDSR shift triggers.

Figure 1663. DDSR internal shift trigger generator

- The number of bits of DDSR_L that can be written by the application, is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] value.
- When PS_E2SSR_CHn[DDSR_RDY] == 1, then it indicates that the DDSR is empty and is ready to accept a new command. If the PS_E2SCR_CHn[DDSR_RDY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- Attempting to write to DDSR while PS_E2SSR_CHn[DDSR_RDY] == 0 results in the rejection of the new command and setting of the PS_E2SSR_CHn[CMD_NWRT] bit. If the PS_E2SCR_CHn[CMDTR_NWRT_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- The application then writes the command to the PS_DDSR_L and does a “w1c” to the PS_E2SCR_CHn[DDSR_RDY]. This indicates to the internal logic that the command is now ready for further processing.The clock that is used for shifting the contents of the DDSR can be configured through the PS_E2SCR_CHn[DDSR_CLK_SEL] register.
- Depending on the value of PS_E2SCR_CHn[CMD_TYPE], the internal logic adds the start bits/start condition/CRC/bit stuffing and updates the DDSR with the complete command, ready for transmission.
- Once this happens the PS_E2SSR_CHn[CMDPR_BZY] becomes “1”. If the PS_E2SCR_CHn[CMDPR_BZY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line. If PS_E2SCR_CHn[CMDTR_SW_CTRL] == 0 then the application can check the final value of the command in DDSR, that would actually be transmitted.Once the checking is complete it can put the PS_E2SCR_CHn[CMDTR_SW_CTRL] to “1”, to start the actual transmission. By default PS_E2SCR_CHn[CMDTR_SW_CTRL] is set to “1”. Note that the start condition is not a part of the DDSR and its transmission is dependent on the value of the PS_E2SCR_CHn[CMD_TYPE] and is automatically taken care by the IP.
- Each bit of the command in DDSR, if it is “1”, results in PS_E2SCR_CHn[CMD] being transferred to the UARTTX buffer or if it is “0” results in PS_E2SCR_CHn[ACMD] being transmitted to the UART-TX buffer. The “CMD” and the “ACMD” governs as to how the transceiver has to respond when it receives these values. These will specify to the transceiver whether it should send

a short or long SYNC pulse on the PSI5 bus when the application wishes to write to the sensors.

– Once the complete command has been transmitted, the PS_E2SSR_CHn[DDSR_RDY] goes to “1” while PS_E2SSR_CHn[CMDPR_BZY] goes to “0.

– Once the PS_E2SSR_CHn[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE].

– When PS_E2SSR_CHn[DDSR_RDY] == 1, then it is possible to abort the current transmission by doing a “W1C” of the PS_E2SCR_CHn[DDSR_CLR] bit. As soon as this is done the DDSR is reset to “0”, PS_E2SSR_CHn[DDSR_RDY] goes to “1” while PS_E2SSR_CHn[CMDPR_BZY] goes to “0”.Once the PS_E2SSR_CHn[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE]. Note that doing this “W1C” does not have any effect on the CMD/ACMD transmission that is already under progress in the UART.

Figure 1664. PS_DDSR sensor command (Ex: XXLong frame)

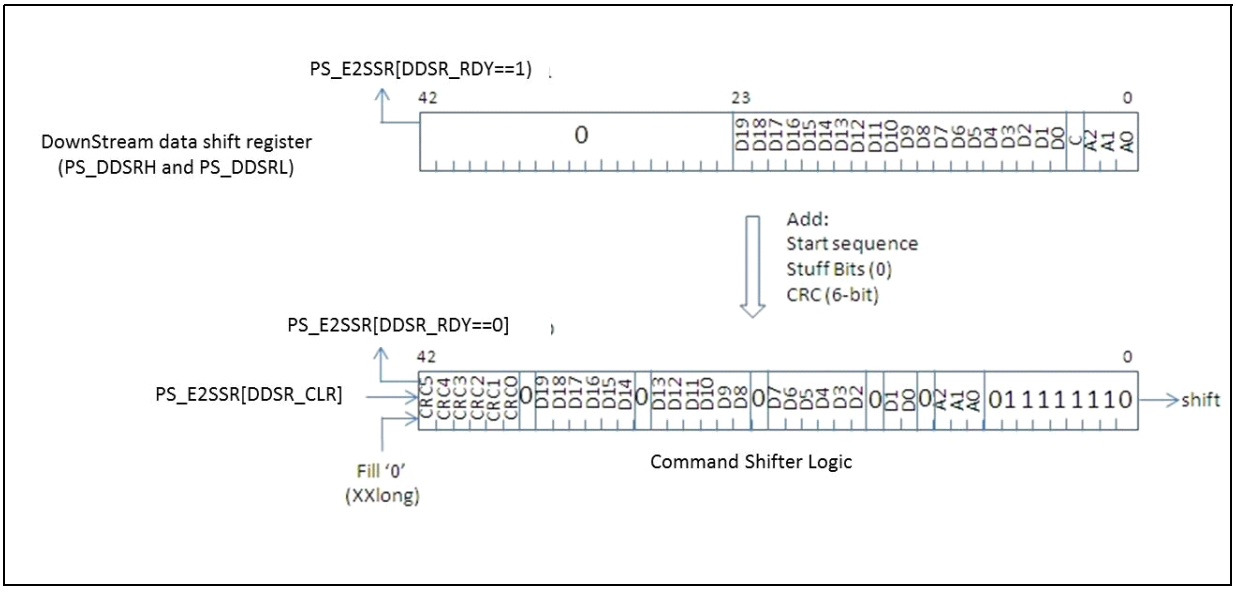


Figure 1665. PS_DDSR sensor command (Ex: PSI5 long format)

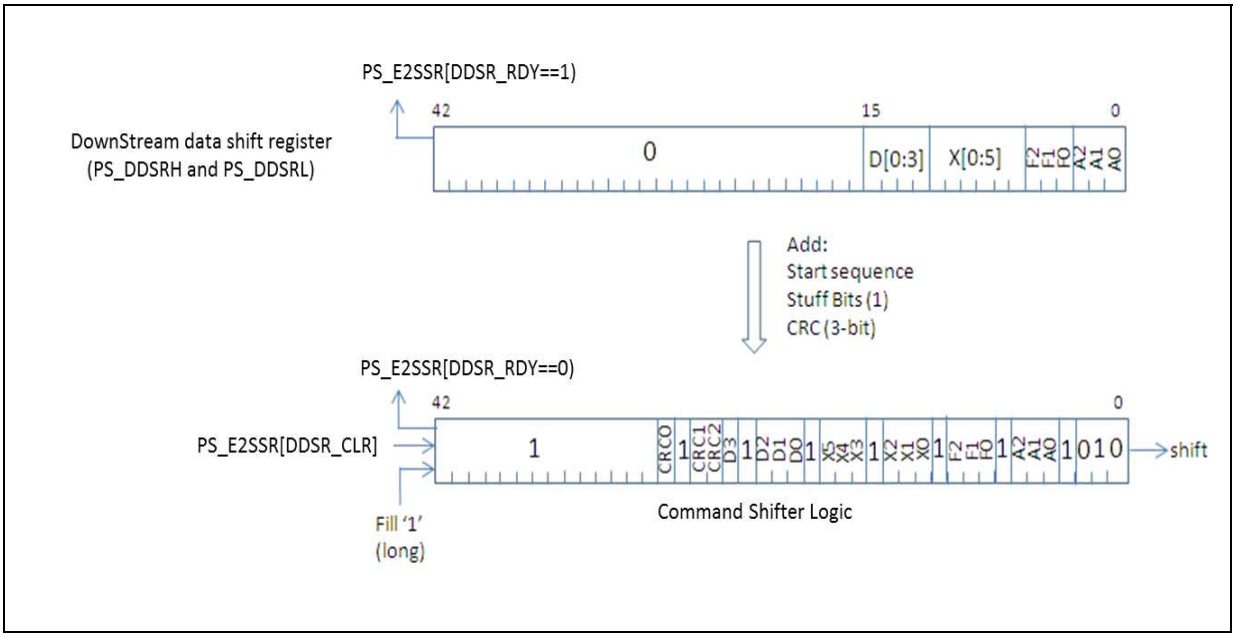

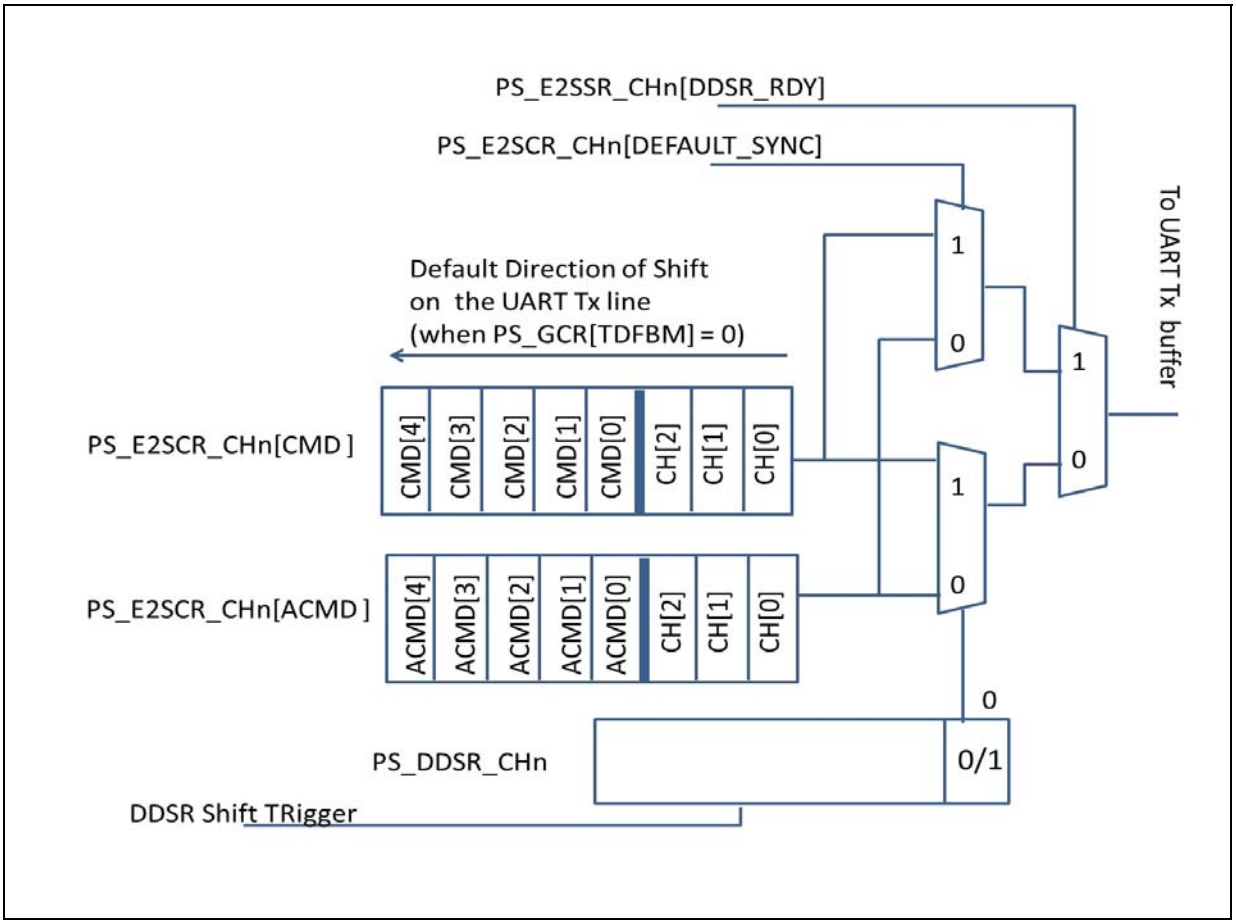

Figure 1666. CMD and ACMD

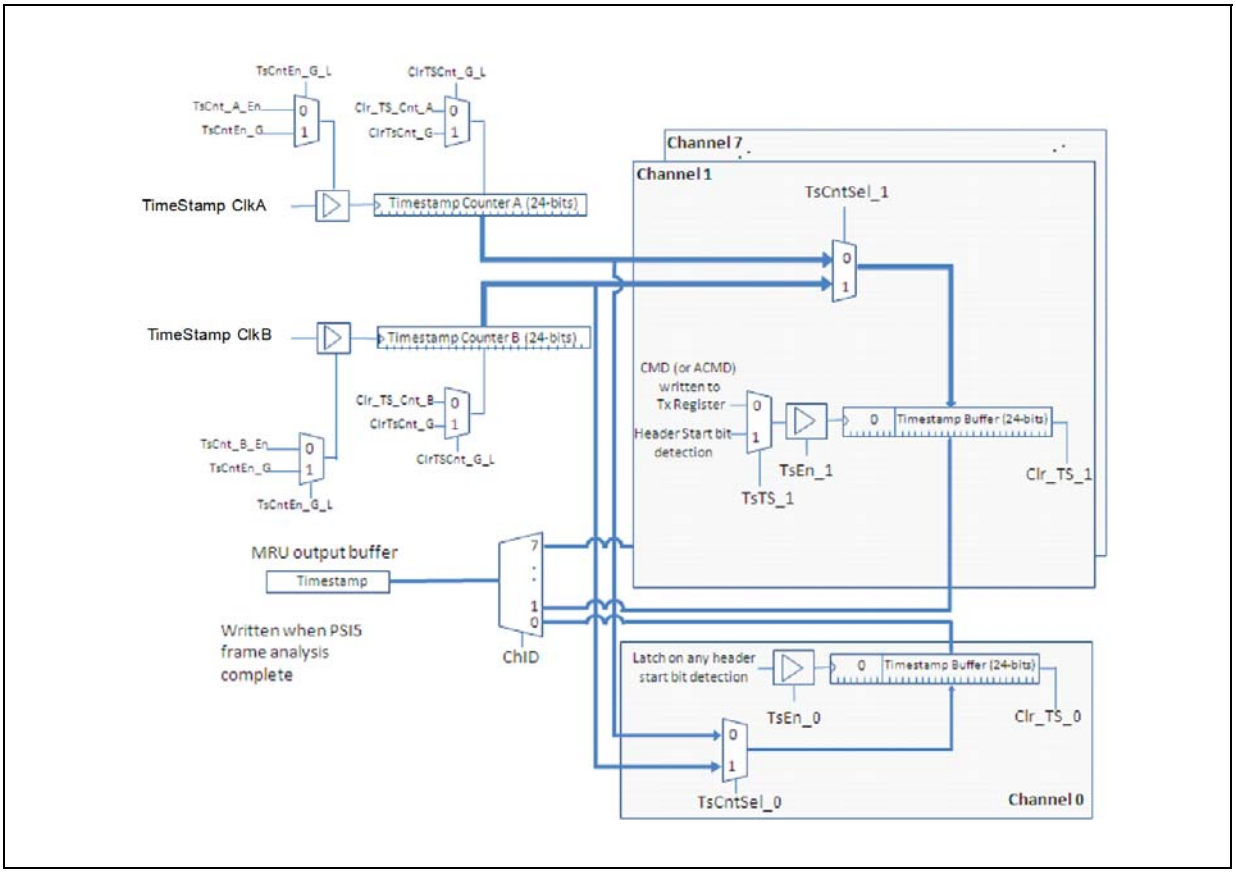
- The logic for processing the DDSR contents is shared among all the 7 channels. It has to be ensured by the software to correctly program the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register contents so that the none of the bits in the command get missed. Also since "*1.*" is possible, it is up to the application to ensure that the UART TX_BUFFER does not remain busy to the extent that some particular DDSR bit does not get the chance to be shifted out before it gets overwritten by some new DDSR bit.
- The approximate maximum time, beginning from when PS_E2SSR_CHn[DDSR_RDY] is made "0", to the time when the command is available for transmission is less than 1us, provided no other channel has an active command processing ongoing. If commands are written to multiple DDSR registers one after the other, then the time after which the particular channel will again get an access will increase. Note that the irrespective of the sequence in which the PS_E2SSR_CHn[DDSR_RDY] of the channels are cleared, the channels are always searched in a round robin fashion for the status of the respective DDSR_RDY bits. When the internal sequencer find the respective DDSR_RDY as "0" it starts the processing of the corresponding DDSR. The sequencer always goes as Channel1 -> Channel2 -> Channel3...Channel7 -> Channel1...
- The logic that shifts each bit of the DDSRs of each channel is shared among all the channels. When the shift trigger of a particular DDSR is received and if the UART TX Buffer is empty then the particular command bit is transmitted to the UART TX by the appropriate CMD/ACMD. It is possible that at one point of time, CMD/ACMD of more than one channel are pending to be transmitted to the UART TX. In this case the channel with a higher channel number will be given a priority. Thus if channel2 and channel1, both have a pending CMD/ACMD shift, then channel2 would be the first to get an access. Each pending channel would queue up for transmission. It can be ensured by the software that the internal shift triggers generated through the PS_DDTRIG_PERR_CHn and PS_DDTRIG_OFFR_CHn registers are correctly spaced so that all the channels get immediate access to transmit their DDSR bits.
- If a command bit that is desired to be shifted encounters more than one shift triggers (because it did not get shifted on the previous shift trigger) then the PS_E2SSR_CHn[SYNCHRO_OVF] bit gets set, to indicate synchronization overflow. An interrupt can also be generated if the PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to 1. In general, if the if PS_DDTRIG_PERR is programmed to be greater than 500us (which is a practical PSI5 sync pulse period) then it would be ensured that the bits are correctly transmitted even if all the channels simultaneously transmit their command bits.

54.4.4 Timestamp



The IP provides for two global 24-bit timestamp counters. Each can be clocked by either the module clock or the trigger The two timestamp counters are detailed as Timestamp Counter A and B (refer to *Figure 1667*). Following are the details:

1. Each channel has an internal Timestamp buffer that can be configured to capture either the TS counter A or B when it encounters the "capture event". Provided there is no XCRC error in the message, then this Timestamp buffer is appended to the message

when it is written to MRU buf1. When there is an XCRC error in the message, then Channel0 timestamp is appended (See "7.").

2. The "captured event" for the timestamp buffer of each channel can either be when a "a valid message header is detected" or when "a Command (or Alternate Command) is moved from the UART Tx Buffer to the UART Tx shift register" corresponding to the channel for which this command is being shifted to the UART
3. The Timestamp Buffer can be enabled or disabled through the PS_MSGA_CHn[TSBUF_EN] bit. When the Timestamp buffer is disabled then it no longer responds to "capture events" and always contains the value "0".
4. It is possible to reset each Timestamp buffer by using the PS_MSGA_CHn[TSBUF_CLR] bit. As soon as this bit is written to "1" the Timestamp buffer is reset to all "0s" and it remains in this state till it encounters a "capture event".
5. In the case when the reception of message is chosen as the trigger, the time stamp will be captured immediately after the header byte of the UART message packet has been received.
6. In the case when the move of CMD or ACMD from the internal UART Tx Buffer to the UART Tx shift register in the UART module is chosen as the trigger, the timestamp for the intended channel (indicated in the CIDn fields of CMD or ACMD) is valid for all frames received on a channel between moves of CMD or ACMD from the UART Tx Buffer to the UART Tx Register (that is for a PSI5 SYNC period).
7. When a XCRC error is detected in any message then the timestamp that is appended with the message is the Channel0 timestamp which is captured at the time when XCRC_ERR has been detected.
8. For "illegal messages", the timestamp value that is captured is the Channel0 Timestamp value, which is captured whenever "a valid message header for that illegal message is detected". Note that the definition of a "legal" or a "illegal" message applies to a PSI5 message only when the concerned UART packet has no XCRC error.
9. In addition to the timestamp buffers described in "1.", there is a separate timestamp capture that occurs in case of a watchdog error. This timestamp is captured in the PS_WDGTSSR[WDGTS_STATUS] bits. The Timestamp A or B (as programmed in the PS_MSGA_CHn[TIMESTAMP_A_B_SEL]) is captured as soon as the watchdog overrun error occurs for that channel. Refer to *Section 54.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*, for more details.

Figure 1667. Timestamp capture

54.4.5 PSI5-S watchdog operation

The IP provides a watchdog to keep track of a number of reception parameters. The watchdog counter is a 24 bit down counter. Each channel, except Channel0, contains a watchdog counter. The refresh event for the watchdog is automatically chosen depending on whether the channels mode is synchronous or asynchronous. The watchdog timeout value can be configured in the “WD_TO” bits in the PS_WD_CFGR_CH[n] register. The refresh event for the watchdog are different in the synchronous and asynchronous modes as mentioned below:

- In Asynchronous mode:

  As soon as the IP enters the PS_NORMAL mode the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled then the counter starts immediately. Whether the WD has to be “refreshed (re-loaded)” or “not to be refreshed” is analyzed when the XCRC is calculated. In case the XCRC is correct the watchdog is re-loaded (It is not STOPPED), else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In case of watchdog overrun error the counter is refreshed.

- In Synchronous mode:

  As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled then the counter starts immediately. Thereby it is re-loaded, either on the occurrence of a sync pulse or the watchdog overrun error. In case the event for this

load is the Sync Pulse then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured (enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FID_byte] is not equal to “0”. The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured“, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered.

In both the above modes, the watchdog is always refreshed on the occurrence of Watchdog overrun error (F_WD_ERR) or a software reload. Also refer to *Section 54.3.4.20: PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)*.

The watchdog can be started in the NORMAL mode by writing a “1” to the WDEN bit in the PSI5_WD_CFGR_CH[n]. If the watchdog counter is not refreshed by its event and the watchdog counter becomes equal to “0”; the F_WD_ERR flag is set in the PSI5_IRQ_ERR_SR register and the same is also reflected in the PS_MRU_BUF2_REG1 register. An interrupt can also be generated on any of the “ipi_ps_irq[irq_n]” lines depending on the configuration. Note that writing a “0” to WDEN bit disables the watchdog checking mechanism.*Figure 1668* shows the watchdog counter.

Figure 1668. Watchdog counter

As soon as the watchdog overrun error for a particular channel occurs, the status of the watchdog error is immediately latched in the register described in *Section 54.3.4.12: PSI5-S watchdog error status and watchdog timestamp status register (PS_WDGTSSR)*. This watchdog error status (PS_WDGTSSR[F_WD_ERR_STATUS[CHn]]) is also sent to the MRU registers (as F_WD_ERR) as shown in the PSI5 frame status word (shown in *Figure 1658* and *Figure 1659*). However this information is sent in the next upcoming PSI5 message packet that occurs for that particular channel, provided this upcoming PSI5 message has no XCRC error. In case the upcoming UART packet has an XCRC error then the Frame watchdog error field in this PSI5 message packet is the “OR” of the F_WD_ERR

status of all the channels that is OR of all the fields of PS_WDGTSSR[F_WD_ERR_STATUS] bits.

54.4.6 Interrupt handling

Following are the various interrupt signals that represent the various events:

1. PSI5-S general interrupt request (Status flags in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ)/ipi_ps_irq[irq_n] where irq_n = 0 to 7 and denotes the irq number.

   There are 8 such interrupts in the IP. Each of these “irq” lines can be configured to respond to any or all of the following events:

   – At least one message of the specific channel has been read by the DMA from the MRU buffer (The interrupt is configurable to respond to any channel through the corresponding PS_MBOX_SEL_IRQ[irq_n] register)
   – When there is a XCRC error in a new packet that is transferred to MRU buffer2 OR
   – When there is a CRC or parity error in a new packet that is transferred to MRU buffer2 OR
   – When the watchdog Error has been detected in the message just written to MRU buf2 OR
   – When the message header has been detected with transceiver error flags OR
   – When the PSI5 state machine detects in the UART, the message parity error, the overflow error or the framing error and the corresponding frame is transferred to MRU buffer 2
   – When the “R_OVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
   – When the “R_UVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
   – When the number of bytes received does not match the expected Fn bytes (N_ERR == 1)

   Each of the “ipi_ps_irq[irq_n]” lines can be configured to be asserted on any of the above events by correctly programming the registers PS_MBOX_SEL_IRQ[irq_n] and PS_ERR_SEL_IRQ[irq_n].

   This interrupt is cleared when the corresponding bits in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ are cleared. It is assumed that one event would not be mapped on more than one “irq” lines. If the same event is mapped on more than one “irq” lines then clearing the corresponding status bit in the PS_MBOX_SR_IRQ or PS_ERR_SR_IRQ will clear all the interrupt requests related to that same event.*Figure 1669* shows the interrupt structure for IRQ interrupts.

Figure 1669. IRQ[n] interrupts

2. PSI5-S ECU-to-Sensor interrupt (Status Flags in PSI5_E2SSR)/ipi_ps_e2s_ch[n] where n = 1 to 7.

   This interrupt is used for the ECU to Sensor Communications and is generated in the following cases:

   – When the DDSR is empty and is ready to accept a new command new from the application. In this case the PS_E2SSR_CHn[DDSR_RDY] bit is set to "1".

   – When the DDSR is still busy (PS_E2SSR_CHn[DDSR_RDY] bit is set to "0") and the application attempts to write a new command to the DDSR. The new command is rejected and the PS_E2SSR_CHn[CMD_NWRT] bit is set to "1".

   – When the command that is written to the DDSR has finished calculating the CRC/stuff bits/start bits and is ready for transmission the PS_E2SSR_CHn[CMDPR_BZY] goes to "1" leading to the generation of this interrupt.

   – When there is a synchronization overflow in a particular channel (the same data bit encounters 2 sync pulses without getting a chance to shift), then the bit PS_E2SSR_CHn[SYNCHRO_OVF] is set to "1".

Figure 1670. ECU to sensor interrupts

3. Global interrupt (Status Flags in PS_GLSR) /ipi_ps_glbl.

   This interrupt is a single interrupt for the whole IP and is generated in the following cases:

   – When the DMA has not completed reading the MRU buffer2; simultaneously there is a pending data in MRU buffer1 that needs to be offloaded to the MRU buffer2 and a new message comes, that overwrites the contents of MRU buffer 1. The channel ID and the Frame ID of the overwritten message can be read from the PS_GLSR registers.

   – When there is any change in the "PSI5-S" global modes of the IP. Thus it is asserted during the following transitions UART_STDALONE to PS_DISABLE, PS_DISABLE to PS_CONFIG, PS_DISABLE to PS_NORMAL and PS_CONFIG to PS_NORMAL. Assertion of this interrupt indicates that the desired mode has been accomplished by the IP.

   – When the "DIRCMD_RDY" bit in the PS_GLSR is set to "1", indicating that PS_DIRCMD register is ready to accept a new Direct Command write from the CPU.

Figure 1671. Global interrupts

54.5 PSI5-S clock and reset

Figure 1672. Clock distribution in PSI5-S

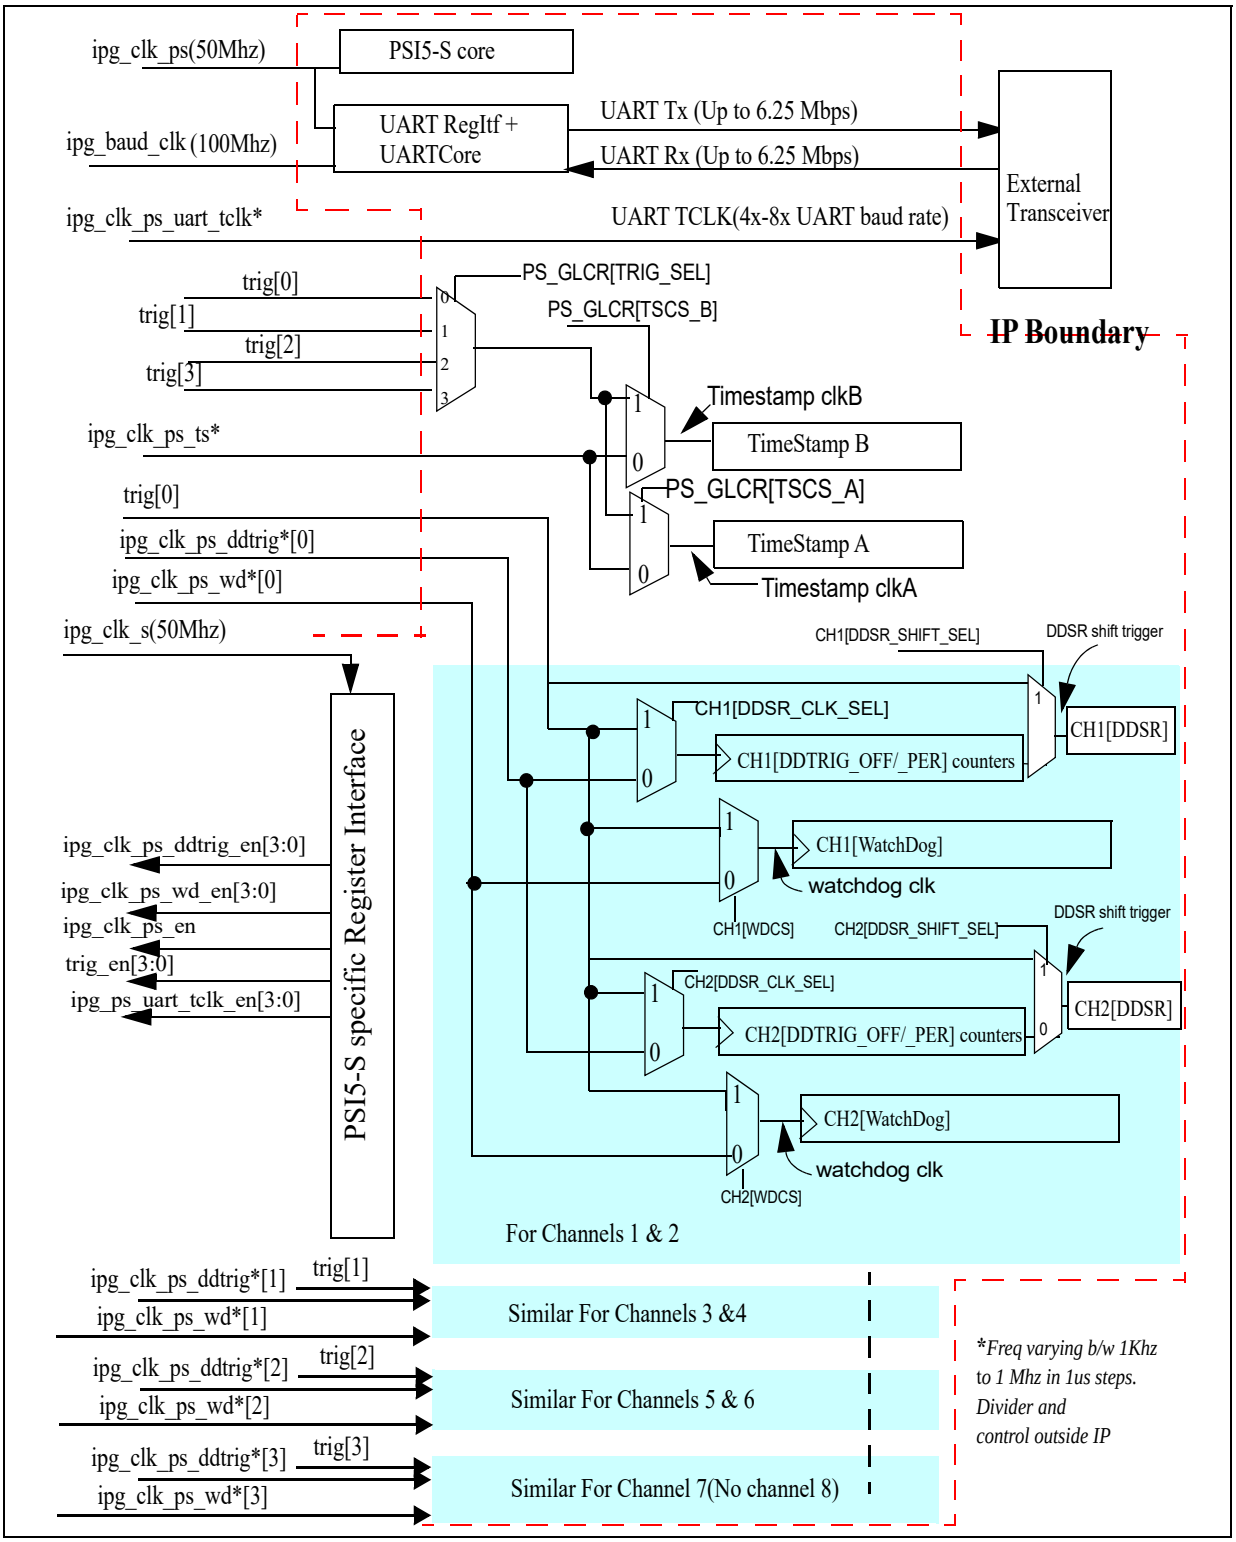


Figure 1672 shows the clocking scheme for the PSI5-S IP. It also shows the distribution of various clocks on the basis of channels.

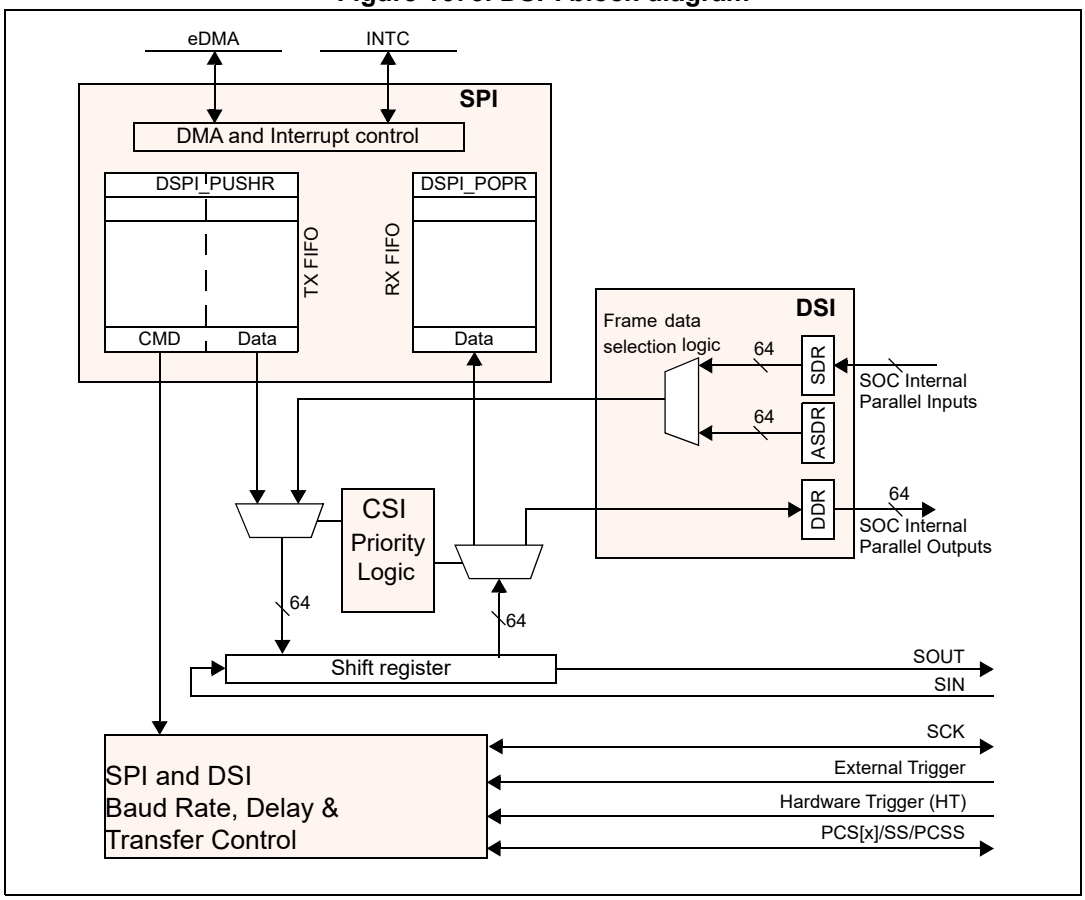
The divider and the control of clock “ipg_clk_ps_ts”, “ipg_clk_ps_wd” and “ipg_clk_ps_ddtrig” are outside the IP. The various clock enables are also controlled by the IP. When the IP enters the disable mode it deasserts all the clock enables from the IP. However the clock enables are deasserted only when once the PS_DISABLE mode entry interrupt has been received and the PS_GLSR[GL_MODETR_DONE_EN] bit has been cleared.

For the safe operation of the UART module, the following relation should be satisfied between “ipg_baud_clk” and “ipg_clk_ps”:

ipg_baud_clk > *ipg_clk_ps* > ipg_baud_clk/3

55 Deserial Serial Peripheral Interface (DSPI)

55.1 Introduction



The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note: For the chip-specific implementation details of the instances of this module, refer to the Device Configuration chapter.

55.1.1 Block diagram

Figure 1673 provides the block diagram of this module.

Figure 1673. DSPI block diagram

55.1.2 Features

The DSPI supports the following features:

- Full-duplex, four-wire synchronous transfers.
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection.
- Buffered transmit operation with 4-entry TX FIFO buffer.
- Buffered receive operation with 4-entry RX FIFO buffer.
- Asynchronous clocking scheme for Register and Protocol interfaces.
- Individual TX and RX FIFOs disabling for low-latency updates to SPI queues.
- Visibility inside TX and RX FIFOs for debugging.
- Programmable transfer attributes on a per-frame basis:
  - 8 transfer attribute registers along with 8 extended transfer attribute registers
  - Serial clock with programmable polarity and phase
  - Various programmable delays
  - programmable serial frame size of 4 to 64 bits, expandable by software control. SPI frames longer than 32 bits are supported using the continuous selection format
  - Continuously held chip select capability
  - Parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer.
- Deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer.
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End Of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame Complete (TCF)
  - Transfers due from current Command frame Complete (CMDTCF)
  - Transfer of current SPI frame Complete (SPITCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
  - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line.
- Modified SPI transfer formats for communication with slower peripheral devices.
- Power-saving architectural features: support for stop mode

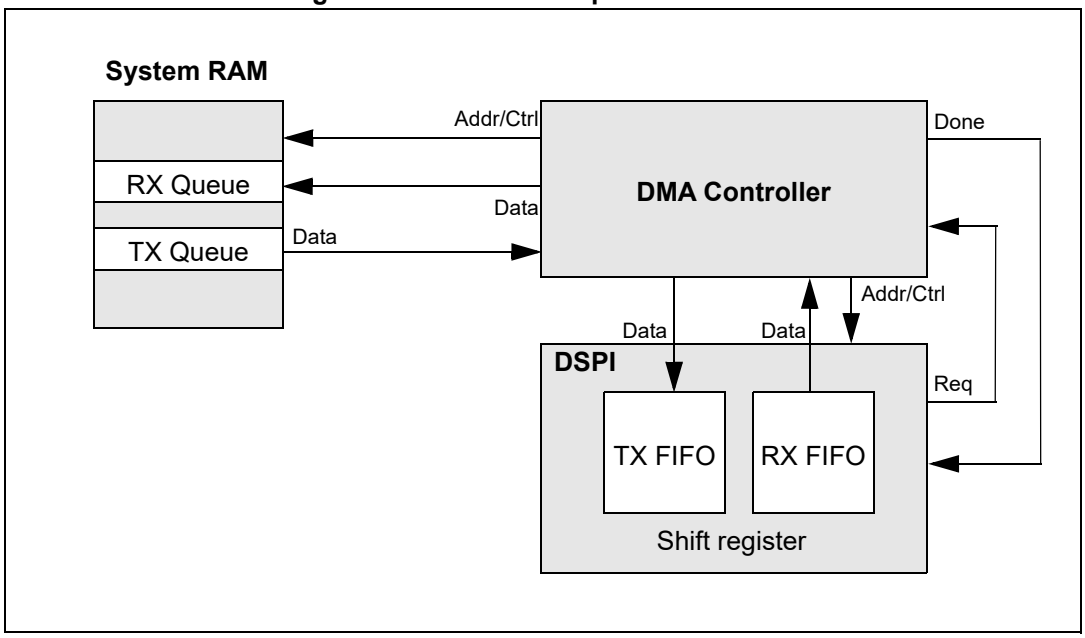
The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
  - DSPI memory-mapped register
  - Parallel input signals
  - Programmable selection of source data on bit basis.
- Deserialized data provided as:
  - Parallel output signals
  - Bits in a memory-mapped register
- Interrupt conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
  - Transfer of current DSI frame complete (DSITCF)
  - DSI parity error (DPEF)
- DMA request support for following conditions:
  - Deserialized data matches preprogrammed pattern (DDIF)
- Transfer initiation conditions:
  - Continuous
  - Edge sensitive hardware trigger
  - Change in data
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics.
- Continuous serial communications clock.

DSPI supports a combination of SPI and DSI modes of operation (Combined Serial Interface (CSI)) for the downstream Micro Second Channel in either Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration (configurable by software). Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is performed at frame boundaries.
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame.
- Separate interrupts for frame completion from SPI and DSI.

55.1.3 DSPI configurations



The DSPI module can operate in SPI configuration as well as in DSI, and CSI configuration. Refer to the relevant section in the “Communication interfaces” section of the “Device Configuration” chapter.

55.1.3.1 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. *Figure 1674* shows a system example with DMA, DSPI and external queues in system RAM.

Figure 1674. DSPI with queues and DMA

55.1.3.2 DSI configuration

In the DSI configuration the DSPI serializes up to 64 parallel input signals or register bits. The DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

TSB mode provides the Micro Second downstream Channel support (MSC), serializing from 4 to 64 parallel input signals or register bits. Refer to *Section 55.4.9: Timed Serial Bus (TSB)*.

55.1.3.3 CSI configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in *Section 55.4.10: Interleaved TSB (ITSB) Mode*.

55.1.4 Modes of operation

The DSPI modes of operation that can be divided into two categories:

- Module-specific modes
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes
  - External Stop mode
  - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

55.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

55.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI/DSI bus masters In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

55.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

55.1.4.4 External Stop mode

External Stop mode is used for MCU power management; the DSPI supports the Peripheral Bus Stop mode mechanism.

Upon a request to enter External Stop mode:

- In Master mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary, it signals that the protocol clock to the DSPI module may be shut off.
- In Slave mode, a request to enter External Stop mode must be run after the last clock cycle or Low-power mode is not entered.

55.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

55.2 DSPI signal description

This section provides the DSPI signals description.

Table 1711 lists the signals that may connect off chip depending on device implementation.

Table 1711. DSPI signal description

Signal	Description	I/O
PCS0/ SS	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[3:1]	Master mode: Peripheral Chip Select 1–3 Slave mode: Unused	O
PCS4	Master mode: Peripheral Chip Select 4	O
PCS5/ PCSS	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[7:6]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O
HT	Hardware Trigger	I

55.2.1 PCS0/$\overline{SS}$ — Peripheral Chip Select/Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low $\overline{SS}$ signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

55.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

55.2.3 PCS4 — Peripheral Chip Select 4

In master mode, PCS4 is a Peripheral Chip Select output signal.

55.2.4 PCS5/$\overline{PCSS}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

55.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

55.2.6 SIN — Serial Input

SIN is a serial data input signal.

55.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

55.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

55.2.9 HT — Hardware Trigger

In master mode while in DSI or CSI Configurations, the HT signal initiates a data transfer when the DSICR0[TRRE] bit is set and a rising or falling edge is detected on HT. Which edge to trigger on is determined by the DSICR0[TPOL] bit.

55.3 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPI_POPR also results in a transfer error.

Table 1712. DSPI memory map

Offset (hex)	Register name	Width (in bits)	Access	Reset value	Location
0000_0000	DSPI Module Configuration Register (DSPI_MCR)	32	R/W	0000_4001h	*Section 55.3.1*
0000_0004	Hardware Configuration Register (DSPI_HCR)	32	R	0133_3000h	*Section 55.3.2*
0000_0008	DSPI Transfer Count Register (DSPI_TCR)	32	R/W	0000_0000h	*Section 55.3.3*
0000_000C	DSPI Clock and Transfer Attributes Register 0 (In Master Mode) (DSPI_CTAR0)	32	R/W	7800_0000h	*Section 55.3.4*
0000_000C	DSPI Clock and Transfer Attributes Register 0 (In Slave Mode) (DSPI_CTAR0_SLAVE)	32	R/W	7800_0000h	*Section 55.3.5*
0000_0010	DSPI Clock and Transfer Attributes Register 1 (In Master Mode) (DSPI_CTAR1)	32	R/W	7800_0000h	*Section 55.3.4*

Table 1712. DSPI memory map (continued)

Offset (hex)	Register name	Width (in bits)	Access	Reset value	Location

55.3.1 DSPI Module Configuration Register (DSPI_MCR)

The DSPI_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Address: 0x0000 Access: User read/write

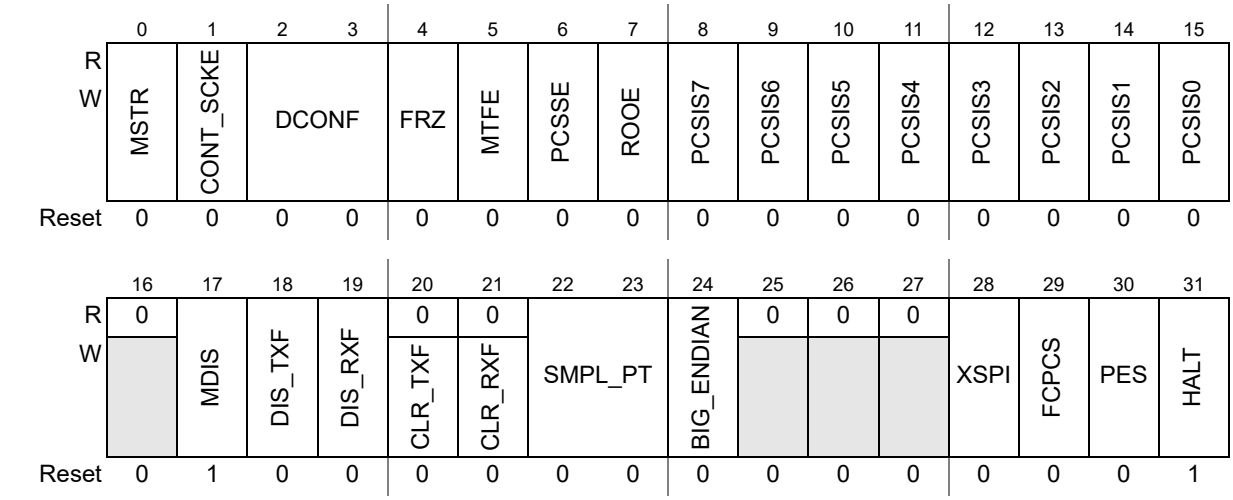

Figure 1675. DSPI Module Configuration Register (DSPI_MCR)

Table 1713. DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2:3 DCONF	DSPI Configuration Selects the DSPI configuration. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. MTFE should not be set in ITSB Mode as Microsecond Channel upstream operation is not supported. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.

Table 1713. DSPI_MCR field descriptions (continued)

Field	Description
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS[5]/PCSS is used as the Peripheral Chip Select[5] signal (PCS[5]). 1 PCS[5]/PCSS is used as an active-low PCS Strobe signal (PCSS).
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer generating the overflow is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8:15 PCSIS[7:0]	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCSx is low.(1) 1 The inactive state of PCSx is high.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI, putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is 1. MDIS should be set to ‘0’ in Slave Mode as a slave does not control master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes TX FIFO and CMD FIFO. Writing a ‘1’ to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.

Table 1713. DSPI_MCR field descriptions (continued)

Field	Description
21 CLR_RXF	Clear RX FIFO Flushes RX FIFO. Writing a '1' to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22:23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
24 BIG_ENDIAN	Big Endian Defines concatenation order of TxFIFO entries to form SPI frame 0 Little endian transfers 1 Big endian transfers This bit has impact only in XSPI mode for SPI frame size > 16 bits. In XSPI mode, if frame size > 16 , two data words are popped from TxFIFO to form the SPI frame. data16_1 is the first written 16 bit data and data16_2 is the next word written in TXPUSHR register. If this bit is '0', the first of the two popped entries forms the 16 LSB bits of the SPI frame, so SPI frame is extracted from {data16_2,data16_1}. If this bit is '1', the first of the two popped entries forms the 16 MSB bits of the SPI frame, so SPI frame is extracted from {data16_1,data16_2}. **Note:** In SPI Slave mode, for BIG_ENDIAN support, CTARE[0].FMSZE bit must also be set.
28 XSPI	Extended SPI Mode Enables use of CTARE (Command and Transfer Attribute Register Extended) registers, which allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled, allowing the user to send multiple Data Frames in a single Command Frame. When MCR[DIS_TXF] is asserted, Extended SPI Mode cannot be used to transmit SPI frames over 16 bits in size. 0 Normal SPI Mode. Up to 16-bit Frames. Command Cycling is not available. 1 Extended SPI Mode. Up to 32-bit SPI Frames. Command Cycling Enabled.
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of "After SCK (t_{ASC})" and "PCS to SCK (t_{CSC})" delays when operating in Continuous PCS mode. The individual delay masks are selected via PUSHR[PE_MASC] and PUSHR{PP_MCSC]. The firmware should select appropriate masks when providing continuous frames via the PUSHR. This masking is not available if Continuous SCK mode is enabled. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR.

Table 1713. DSPI_MCR field descriptions (continued)

Field	Description
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers. **Note:** HALT bit starts/stops the internal state machine. All the other MCR bits must be set to their expected value before releasing HALT bit. If one MCR bit needs to be changed in running state, HALT bit must be set first.

1. For DSPI_LP instance during SSWU operation, PCSIS* must be kept as '0' for correct SSWU operation.

55.3.2 Hardware Configuration Register (DSPI_HCR)

Hardware Configuration Register provides particular implementation details about the module, that is number of Receive and Transmit FIFO entries, number of CTAR registers and if DSI features are implemented in the module or not. It is read only register. A write to this register will generate a Transfer Error.

Note: The reset bits in the HCR are set by the configuration parameters.

Figure 1676. Hardware Configuration Register (DSPI_HCR)

Table 1714. DSPI_HCR field descriptions

Field	Description
0 DSI	DSI features are implemented for the module. 0 DSI features are not implemented, DSI registers do not exist. 1 DSI features are implemented
1 PISR	PISR0-3 and parallel inputs frame positions selection logic (DSI Muxing Logic) are implemented for the module. 0 PISR0-3 registers are not implemented. 1 PISR0-3 registers are implemented.
2 DSI64	DSI features in 64-bit mode are implemented for the module. 0 DSI features for 64-bit mode are not implemented; related registers do not exist. 1 DSI features for 64-bit mode are implemented
3 PISR_EX	PISR4-7 and parallel inputs frame positions selection logic (DSI 64-bit Muxing Logic) are implemented for the module. 0 PISR4-7 registers are not implemented. 1 PISR4-7 registers are implemented.
4 XSPI	Extended SPI Mode feature is implemented for the module. 0 Extended SPI Mode is not implemented. 1 Extended SPI Mode is implemented.
5:7 CTAR	Maximum implemented CTAR register number.
8:11 TXFR	Maximum implemented TXFR register number.
12:15 RXFR	Maximum implemented RXFR register number.
16:19 CMDFR	Maximum implemented command FIFO number.
20 MSTR_MODE	Master Mode implementation is enabled
21 SLV_MODE	Slave Mode implementation is enabled
22 TSB_EN	TSB Mode implementation is enabled
23 ITSB_EN	Interleaved TSB Mode implementation is enabled

55.3.3 DSPI Transfer Count Register (DSPI_TCR)

DSPI_TCR has an SPI transfer counter to assist in queue management.

Do not write the TCR when the DSPI is in the Running state.

Address: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1677. DSPI Transfer Count Register (DSPI_TCR)

Table 1715. DSPI_TCR field descriptions

Field	Description
0:15 SPI_TCNT	SPI Transfer Counter The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. A value written to SPI_TCNT presets the counter to that value. The Transfer Counter wraps around; incrementing past 65535 resets the counter to zero.

55.3.4 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTARs are used to define different transfer attributes:

- In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays.
- In slave mode, a subset of the bitfields in CTAR0 and CTAR1 set the slave transfer attributes.

Do not write to the CTARs while the DSPI is in the Running state.

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 1678. DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

Table 1716. DSPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate. (Master mode only) Doubles the baud rate of the Serial Communications Clock (SCK). It halves the Baud Rate division ratio, supporting faster frequencies and odd division ratios for the Serial Communications Clock (SCK). When DBR is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in *Table 1717*. Refer to the BR field description in this table for details on how to compute the baud rate. Refer to *Table 1717* for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid value for the number of bits to be transmitted for any mode is 4.There is a constraint on the minimum allowable Frame size, which depends on the register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. Min. Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol Clock Frequency f_r = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by (PBR x BR) / (1 + DBR) The minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'f_p' can be equal to, less than or greater than 'f_r' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is used in 64-bit mode, then DSICR0[FMSZ4] also comes into picture while switching PCS assertion control.
5 CPOL	Clock Polarity. (Master and Slave mode) Selects the inactive state of the Serial Communications Clock (SCK). Devices must have identical clock polarities for successful communication between serial devices. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.

Table 1716. DSPI_CTAR*n* field descriptions (continued)

Field	Description
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, this bit is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First. Specifies whether the LSB or MSB of the frame is transferred first. In TSB mode, this bit should comply with the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8:9 PCSSCK	PCS to SCK Delay Prescaler. Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. Refer to the CSSCK field description in this table for calculating the PCS to SCK Delay. Refer to *Section 55.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, PCSSCK has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10:11 PASC	After SCK Delay Prescaler. Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. Refer to the ASC field description in this table for calculating the After SCK Delay. Refer to *Section 55.4.5.3: After SCK delay (tASC)* for more details. In TSB mode, PASC has no effect. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12:13 PDT	Delay after Transfer Prescaler. (Master mode only) Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In TSB mode, the PDT field defines two MSB bits of the Delay after Transfer. Refer to the DT field description for calculating the Delay after Transfer. Refer to *Section 55.4.5.4: Delay after transfer (tDT)* for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.

Table 1716. DSPI_CTAR*n* field descriptions (continued)

Field	Description
14:15 PBR	Baud Rate Prescaler. (Master mode only) Selects the prescaler value for the baud rate. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. Refer to the BR field description in this table for calculating the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16:19 CSSCK	PCS to SCK Delay Scaler. (Master mode only) Selects the scaler value for the PCS to SCK delay. PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period calculated by: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$ *Table 1718* lists the delay scaler values. Refer to *Section 55.4.5.2: PCS to SCK delay (tCSC)* for more details. In TSB mode, the field has no effect.
20:23 ASC	After SCK Delay Scaler. (Master mode only) Selects the scaler value for the After SCK Delay. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period calculated by: $t_{ASC} = (1/f_P) \times PASC \times ASC$ *Table 1718* lists the delay scaler values. Refer to *Section 55.4.5.3: After SCK delay (tASC)* for more details.
24:27 DT	Delay After Transfer Scaler (Master mode only) Selects the Delay after Transfer Scaler. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period. The Delay after Transfer is a multiple of the protocol clock period calculated by: $t_{DT} = (1/f_P) \times PDT \times DT$ *Table 1718* lists the delay scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer to *Section 55.4.5.2: PCS to SCK delay (tCSC)* for more details.
28:31 BR	Baud Rate Scaler. (Master mode only) Selects the scaler value for the baud rate. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is calculated by: SCK baud rate = $(f_P/PBR) \times [(1+DBR)/BR]$ *Table 1719* lists the baud rate scaler values.

55.3.5 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Figure 1679. DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE)

Table 1720. DSPI_CTAR*n*_SLAVE field descriptions

Field	Description
0:4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ5	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTAR*n*_SLAVE[FMSZ5], CTAR*n*_SLAVE[FMSZ]} value plus 1.

55.3.6 DSPI Status Register (DSPI_SR)

The status register contains DSPI status bits and interrupt/DMA request event flag bits.

Software can clear most of the flag bits in the SR by writing a '1' to them (w1c). Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Figure 1680. DSPI Status Register (DSPI_SR)

Table 1721. DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag. Indicates that all bits in a frame have been shifted out. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status. Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2 SPITCF	SPI Frame Transfer Complete Flag. Similar to TCF but only asserted on SPI frame transmission completion in CSI Mode This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag. Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.

Table 1721. DSPI_SR field descriptions (continued)

Field	Description
4 TFUF	Transmit FIFO Underflow Flag. Indicates an underflow condition in the TX FIFO. Transmit underflow is detected only for DSPI blocks in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. Similar to TCF but only asserted on DSI frame transmission completion in CSI Mode. This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer to *Section 55.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*. This bit is valid only when DSPI_MCR[XSPI] is enabled. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9 DPEF	DSI Parity Error Flag. Indicates that a DSI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.

Table 1721. DSPI_SR field descriptions (continued)

Field	Description
10 SPEF	SPI Parity Error Flag. Indicates that a SPI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits. Indicates that a DSI frame has been received with bits selected by DIMR with active polarity, defined by the DPIR. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag. Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Transmit FIFO Invalid Write Flag. Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag. Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a ‘1’ to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16:19 TXCTR	TX FIFO Counter. Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20:23 TXNXTPTR	Transmit Next Pointer. Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.

Table 1721. DSPI_SR field descriptions (continued)

Field	Description
24:27 RXCTR	RX FIFO Counter. Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28:31 POPNXTPTR	Pop Next Pointer. Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

55.3.7 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

The DSPI_RSER controls DMA and interrupt requests.

Do not write to the RSER while the DSPI is in the Running state.

Field	Description
0 TCF_RE	Transmission Complete Request Enable. Enables TCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the Status register to generate a request. DSPI_RSER[CMDFFF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled. 1 Enabled.

Table 1722. DSPI_RSER field descriptions (continued)

Field	Description
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. Enables SPITCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. Enables DSITCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the status register to generate a request. DSPI_RSER[TFFF_DIRS] toggles between either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. DSPI_SR[TFFF] flag and DSPI_RSER[TFFF_RE] must be set. 0 Interrupt requests. 1 DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the status register to generate an interrupt requests. 0 Disabled. 1 Enabled.

Table 1722. DSPI_RSER field descriptions (continued)

Field	Description
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the status register to generate a request. DSPIRSER[RFDF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled 1 Enabled
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[RFDF] flag and DSPI_RSER[RFDF_RE] must be set. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO FIll DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[CMDFFF] flag and DSPI_RSER[CMDFFF_RE] must be set. 0 Interrupt request. 1 DMA request.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPI_SR[DDIF] flag and DSPI_RSER[DDIF_RE] must be set. 0 Interrupt request. 1 DMA request.

55.3.8 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.
- The CMD FIFO for writes to the Command field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

When Extended SPI Mode is not enabled (MCR[XSPI] = 0):

- TX FIFO and CMD FIFO must be filled simultaneously.
- Writes must be given to both Data and Command fields of PUSHR for every PUSHR operation.
- TX FIFO and CMD FIFO can be considered a single 32-bit FIFO.

When Extended SPI Mode is enabled (MCR[XSPI] = 1):

- TX FIFO and CMD FIFO can be written independently.
- A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register do not update the FIFO. Reads during Module disable mode return the last PUSHR write performed when Module was enabled.

Address: 0x0034 Access: User read/write

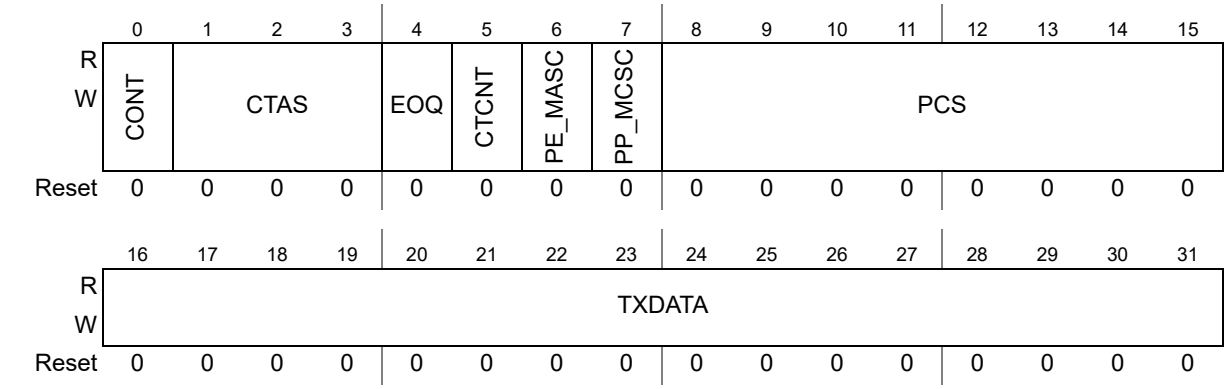

Figure 1682. DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

Table 1723. DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable. (SPI master mode) Continuous Selection Format enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame as EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1:3 CTAS	Clock and Transfer Attributes Select. Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI slave mode, CTAR0 is used. Refer to the Device Configuration chapter to determine how many CTARs this device has. Do not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7

Table 1723. DSPI_PUSHR field descriptions (continued)

Field	Description
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. DSPI_SR[EOQF] is set at the end of the transfer. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter. Clears the SPI_TCNT field in the Transfer Count register. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame causes this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE: This bit enables parity bit transmission and parity reception check for the SPI frame. MASC: The current frame has the “after SCK” delay masked if this bit is asserted. Refer to *Section 55.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE: No parity bit included/checked. MASC: t_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE: Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC: t_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP: controls the polarity of the parity bit transmitted and checked. MCSC: The next frame has the “PCS to SCK” delay masked if this bit is asserted. Refer to *Section 55.4.6.6: Fast Continuous Selection Format* for more details. This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP: Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC: t_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP: Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC: t_{CSC} delay is masked in the next frame.
8:15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16:31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command

55.3.9 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Figure 1684. DSPI POP FIFO Register (DSPI_POPR)

Table 1725. DSPI_POPR field descriptions

Field	Description
0:31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

55.3.11 DSPI Transmit FIFO Registers (DSPI_TXFR*n*)

TXFR*n* provide visibility into the TX FIFO for debugging purposes.

Each read-only register is an entry in the TX FIFO. Reading the TXFR*n* registers does not alter the state of the TX FIFO.

Reading DSPI_TXFR*n* registers is invalid for a DSPI Master when used in Extended SPI (XSPI) mode.

Address: 0x003C + *n**0x4 (*n* = 0 to 3) Access: User read-only

Figure 1687. DSPI DSI Configuration Register 0 (DSPI_DSICR0)

Table 1728. DSPI_DSICR0 field descriptions

Field	Description
0 MTOE	Multiple Transfer Operation Enable Enables multiple D SPIs to be connected in a parallel or serial configuration. The MTOE and TSB bits should not be set simultaneously. 0 Multiple transfer operation disabled. 1 Multiple transfer operation enabled.
1 FMSZ4	MSB of the frame size in master mode when DSI is used in 32-bit mode. If the bit is set, 16 is added to the frame size, as defined by the CTAR*n*[FMSZ] field. The CTAR*n* register is selected by the DSICTAS field.
2:7 MTOCNT[5:0]	Multiple Transfer Operation Count Selects the number of bits to be shifted out during a transfer in Multiple Transfer Operation. The field sets the number of SCK cycles that the bus master must generate to complete the transfer. The number of SCK cycles used is one more than the value in the MTOCNT field. The number of SCK cycles defined by MTOCNT must be equal to or greater than the frame size. When TSBC is set, MTOCNT has no effect.
8 FMSZ5	MSB of the frame size in master mode when DSI is used in 64-bit mode. If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ4], CTAR*n*[FMSZ]} fields. The CTAR*n* register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit is {DSICR0[FMSZ5], DSICR0[FMSZ4], CTAR*n*[FMSZ]}. This field is only valid when DSICR1[DSI64] is enabled.
9 TRG	Trigger Source for Interleaved TSB mode. This bit decides the source for trigger. It should be written only when MCR[HALT] bit is asserted, and is used when DSICR0[ITSB] bit is enabled. Refer to Interleaved TSB (ITSB) Mode for more details. 0 Internal Trigger: Trigger is generated internal to IP. Trigger period is given by DSICR1[TRGPRD]. 1 External Trigger: Trigger is generated external to IP at MCU level. Trigger period decided at MCU level.
10 ITSB	Interleaved TSB mode. Enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are sent when either the previous transmission was an SPI frame or the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. ITSB mode requires DSICR0[TSBC] set and should be written only when MCR[HALT] is asserted. If ITSB bit is set without setting DSICR0[TSBC], DSPI operates in Normal Mode depending on MCR[DCONF] bit. Refer to *Section 55.4.10: Interleaved TSB (ITSB) Mode* for more details. 0 Disabled. 1 Enabled.

Table 1728. DSPI_DSICR0 field descriptions (continued)

Field	Description
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows up to 64-bit data to be used. It also allows t_{DT} to be programmable. 0 Disabled. 1 Enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either: a) data from host software written to the DSPI DSI Alternate Serialization Data Register (ASDR1/0), or b) parallel input pin states latched into the DSPI DSI Serialization Data Register (SDR1/0). 0 SDR source. 1 ASDR source.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
14 TRRE	Trigger Reception Enable Enables the DSPI to initiate a DSI frames transfer with an external trigger signal. 0 Disabled. 1 Enabled.
15 CID	Change In Data Transfer Enable When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. Do not enable CID when DCONT is enabled. 0 Disabled. 1 Enabled.
16 DCONT	DSI Continuous Peripheral Chip Select Enable (DSI Master mode only) Enables the PCS signals to remain asserted between transfers. When the TSBC bit is set, DCONT has no effect. Do not enable DCONT when CID is enabled. 0 PCS signals return to inactive. 1 PCS signals remain asserted.
17:19 DSICTAS	DSI Clock and Transfer Attributes Select (DSI Master mode only) Selects the CTAR which provides transfer attributes for DSI frames. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop Stops DSI frame transmissions if DDIF flag is set in the status register. 0 Disabled. 1 Enabled.
21 PES	Parity Error Stop Stops DSI operation if a parity error occurred in the received DSI frame. 0 Disabled. 1 Enabled.

Table 1728. DSPI_DSICR0 field descriptions (continued)

Field	Description
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of '1' bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of '1' bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24:31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

55.3.14 DSPI DSI Serialization Data Register 0 (DSPI_SDR0)

Read-only SDR0 contains the states of the 32 LSB parallel input signals.

The states of these signals are latched into the SDR0 on the rising edge of every protocol clock.

When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

When DSICR1[DSI64E] is set, SDR1 is the MSB half and SDR0 is the LSB half of the 64-bit SDR.

Field	Description
0:31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals.

55.3.15 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized.

When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames.

Writes to the ASDR0 take effect on the next frame boundary.

When DSICR1[DSI64E] is set, ASDR1 is the MSB half and ASDR0 is the LSB half of the 64-bit ASDR.

Field	Description
0:31 ASER_DATA	Alternate Serialized Data Holds the alternate 32 LSB of data to be serialized.

55.3.16 DSPI DSI Transmit Comparison Register 0 (DSPI_COMPR0)

Read-only COMPR0 holds a copy of the 32 LSB of last transmitted DSI data.

DSI data is transferred to this register as it is loaded into the TX Shift Register.

When DSICR1[DSI64E] is set, COMPR1 is the MSB half and COMPR0 is the LSB half of the 64-bit COMPR.

Field	Description
0:31 COMP_DATA	Compare Data Holds the 32 LSB of last serialized DSI data.

55.3.17 DSPI DSI Deserialization Data Register 0 (DSPI_DDR0)

Read-only DDR0 holds the 32 LSB signal states for the parallel output signals.

Host software can read data from incoming DSI frames.

When DSICR1[DSI64E] is set, DDR1 is the MSB half and DDR0 is the LSB half of the 64-bit DDR.

Field	Description
0:31 DESER_DATA	Deserialized Data Holds 32 LSB of deserialized data presented as signal states to the parallel output signals.

55.3.18 DSPI DSI Configuration Register 1 (DSPI_DSICR1)

DSICR1 selects various attributes associated with TSB (and ITSB) Configuration.

Do not write to the DSICR1 while the DSPI is in the Running state.

Address: 0x00D0 Access: User read/write

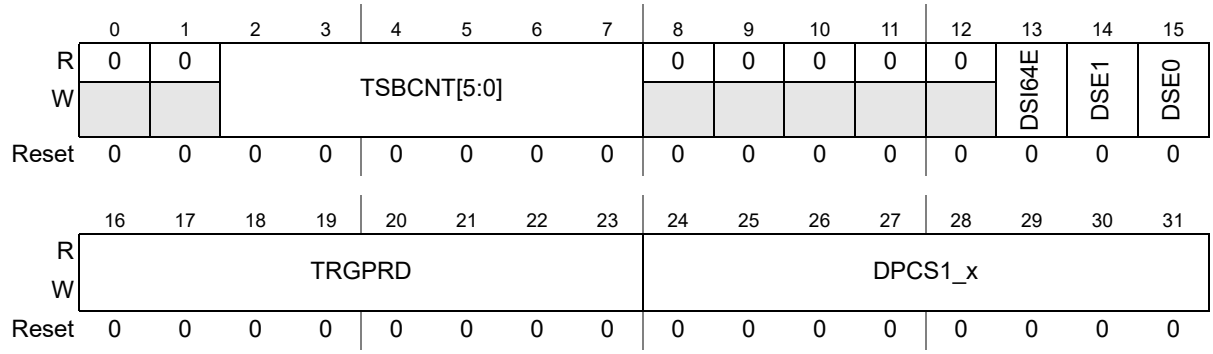

Figure 1692. DSPI DSI Configuration Register 1 (DSPI_DSICR1)

Table 1733. DSPI_DSICR1 field descriptions

Field	Description
2:7 TSBCNT[5:0]	Timed Serial Bus Operation Count TSBCNT defines the length of the data frame When TSBC is set. The TSBCNT field valid value is from 3 to 63. The TSBCNT field selects the number of data bits to be shifted out during a transfer in TSB mode. Number of data bits in data frame = TSBCNT + 1.
13 DSI64E	DSI 64-bit Mode Enable Allows serialization and deserialization of Data frames up to 64 bits in size. The extended registers DSPI_SDR1, DSPI_ASDR1, DSPI_COMPR1, DSPI_DDR1, DSPI_SSR1, DSPI_PISR4-7, DSPI_DIMR1, DSPI_DPIR1 are valid in this mode. 0 Disabled. DSI Mode operates in the default 32-bit configuration 1 Enabled. DSI Mode operates in 64-bit configuration
14 DSE1	Data Select Enable 1 When DSICR0[TBSC] bit is set, the DSE1 bit enables insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTAR*n* register, selected by the DSICR0[DSICTAS] field. If DSICR1[DSI64] is enabled, then the insertion bit position is defined by concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields. The TSBCNT field value must be greater than the FMSZ field value plus one for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When DSICR0[TSBC] bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the Data frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.

Table 1733. DSPI_DSICR1 field descriptions (continued)

Field	Description
16:23 TRGPRD	Internal Trigger Period for the ITSB mode. When DSICR0[TRG] bit is cleared and ITSB Mode is enabled, this field determines the trigger period for the internal trigger in number of baud rate clock cycles. The trigger period should be calculated as: Trigger Period = 64 bits (DSI frame maximum size) + 2 selection bits (maximum) + t_{PF} (passive frame time) When DSICR1[DSI64E] is disabled, DSI frame maximum size is 32. Refer CTAR[FMSZ] field for minimum frame size allowed. Refer to Interleaved TSB (ITSB) Mode for more details. 0 – 4 These values are invalid since minimum Command frame size is 5. (that is 1 selection bit + minimum frame size which is 4) 5 – 255 Number of baud rate clock cycles to be used as the trigger period. The trigger period implemented is equal to TRGPRD + 1.
24:31 DPCS1_x	DSI Peripheral Chip Select 0–7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

55.3.19 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0.

Each bit in the SSR0 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR0 register value has no effect.

When DSICR1[DSI64E] is set, SSR1 is the MSB half and SSR0 is the LSB half of the 64-bit SSR.

Address: 0x00D4 Access: User read/write

Figure 1693. DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

Table 1734. DSPI_SSR0 field descriptions

Field	Description
0:31 SS	Source Select Select the serialization source for the 32 LSB of DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR0 register

55.3.20 DSPI DSI Parallel Input Select Register 0 (DSPI_PISR0)

PISR0–3 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 if DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–3 only preselect the parallel input pins. The final selection to the transmitted frame is made with the DSPI_SSR1/0 register bits or the DSICR0[TXSS] bit.

When DSICR1[DSI64E] is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins).

28:31 IPS24	Input Pin Select 24 Selects the parallel input pin for transmitted frame bit 24.

55.3.24 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

DIMR0 selects bits in the 32 LSB of received DSI frame to be checked to generate the DDI interrupt.

When DSICR1[DSI64E] is set, DIMR1 is the MSB half and DIMR0 is the LSB half of the 64-bit DIMR.

Address: 0x00E8 Access: User read/write

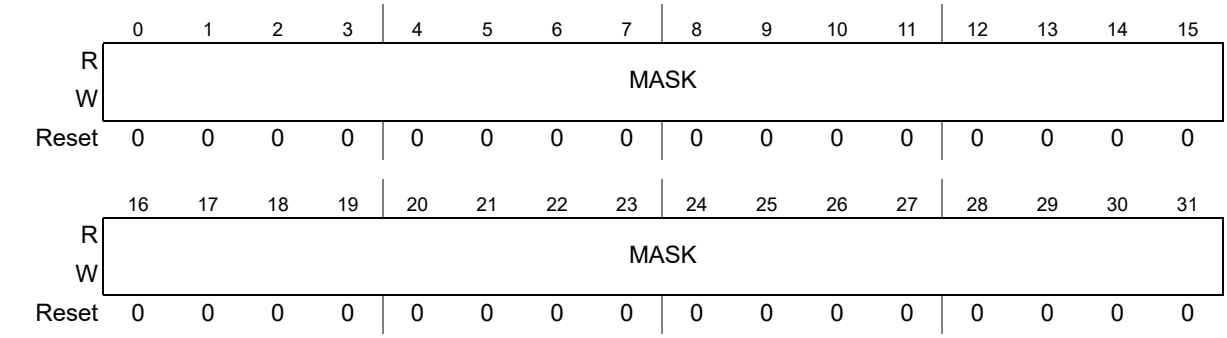

Figure 1698. DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0)

Table 1739. DSPI_DIMR0 field descriptions

Field	Description
0:31 MASK	Mask 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame produces a DDI interrupt if the data bit matches the configured polarity.

55.3.25 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

DPIR0 defines which data bit value in the 32 LSB of received DSI frame generates the DDI interrupt.

When DSICR1[DSI64E] is set, DPIR1 is the MSB half and DPIR0 is the LSB half of the 64-bit DPIR.

Address: 0x00EC Access: User read/write

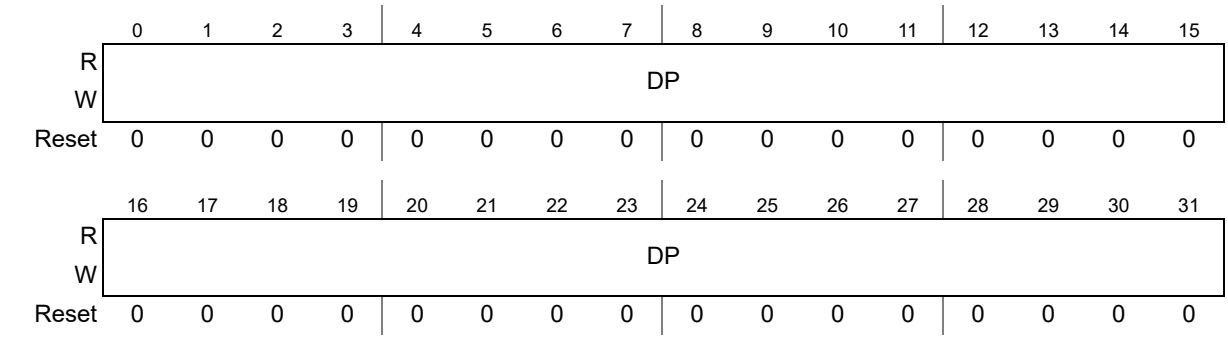

Figure 1699. DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

Table 1740. DSPI_DPIR0 field descriptions

Field	Description
0:31 DP	Data Polarity 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

55.3.26 DSPI DSI Serialization Data Register 1 (DSPI_SDR1)

Read-only SDR1 contains the states of the 32 MSB parallel input signals.

The states of these signals are latched into the SDR1 on the rising edge of every protocol clock.

When DSICR0[TXSS] is cleared, the data in SDR1 and SDR0 is the source of the DSI frames.

The concatenation of {DSPI_SDR1, DSPI_SDR0} provides the 64-bit data to be serialized.

This register is valid only when DSICR1[DSI64E] is set.

Address: 0x00F0 Access: User read-only

55.3.27 DSPI DSI Alternate Serialization Data Register 1 (DSPI_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized.

When DSICR0[TXSS] is set, the data in ASDR1 and ASDR0 is the source of the DSI frames.

Writes to the ASDR1 take effect on the next frame boundary.

The concatenation of {DSPI_ASDR1, DSPI_ASDR0} provides the 64-bit alternate serialization data.

This register is valid only when DSICR1[DSI64E] is enabled.

55.3.28 DSPI DSI Transmit Comparison Register 1 (DSPI_COMPR1)

Read-only COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data.

The upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift register.

The concatenation of {DSPI_COMPR1, DSPI_COMPR0} provides the 64-bit transmit comparison data.

This register is valid only when DSICR1[DSI64E] is enabled.

55.3.29 DSPI DSI Deserialization Data Register 1 (DSPI_DDR1)

Read-only DDR1 holds the 32 MSB signal states for the 64 parallel output signals.

Host software can read data from incoming DSI frames.

The concatenation of {DSPI_DDR1, DSPI_DDR0} provides the 64-bit Deserialized data.

This register is valid only when DSICR1[DSI64E] is enabled.

55.3.30 DSPI DSI Serialization Source Select Register 1 (DSPI_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and from SDR1.

Each bit in the SSR1 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR1 register value has no effect.

The concatenation of {DSPI_SSR1, DSPI_SSR0} provides the 64-bit Serialization Source Select value.

This register is valid only when DSICR1[DSI64E] is enabled.

Table 1745. DSPI_SSR field descriptions

Field	Description
0:31 SS	Source Select 0 The bit in the transmitted frame is taken from the parallel input pin. 1 The bit in the transmitted frame is taken from the ASDR1 register

55.3.31 DSPI DSI Parallel Input Select Register 4 (DSPI_PISR4)

PISR4–7 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 when DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–7 only preselect the parallel input pins. The final selection to the transmitted frame is made with the SSR0 and SSR1 register bits or the DSICR0[TXSS] bit.

When 64-bit DSI mode is enabled, PISR4-7 registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins). If DSICR1[DSI64E] is disabled, then DSPI_PISR4-7 registers are invalid.

55.3.37 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

CTARE registers are used to define the extended transfer attributes for an SPI frame.

These registers are valid only when DSPI_MCR[XSPI] is set.

When the DSPI is configured as:

- an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.
- an SPI bus slave, the CTARE0 register is used.

55.4 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations:

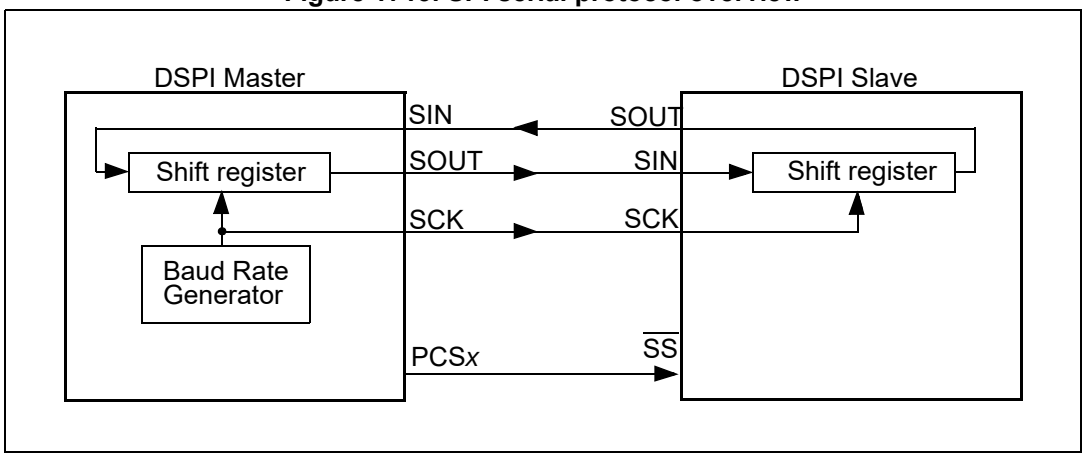
- SPI Configuration in which the DSPI operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes and deserializes parallel input/output signals or bits from memory-mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI Configuration. Refer to *Section 55.3.1: DSPI Module Configuration Register (DSPI_MCR)* for the DSPI configuration values.

The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows CTAR selection on a frame by frame basis by setting a field in the SPI command. Extended SPI Mode (DSPI_MCR[XSPI]) further allows the usage of CTARE*n* (CTAR*n* Extended) registers to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates which CTAR is used for the data transfer.

Refer to *Section 55.3.4: DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTARn)* for information on CTARs fields.



Refer to *Section 55.3.37: DSPI Clock and Transfer Attributes Register Extended (DSPI_CTAREn)* for information on CTAREs fields.

Typical master to slave connections are shown in *Figure 1713*.

When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave: the data that was in the master shift register is now in the shift register of the slave, and vice versa.

At the end of a transfer, the TCF bit in the Status register is set to indicate a completed transfer.

Figure 1713. SPI serial protocol overview

Generally, more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in *Section 55.4.6: Transfer formats*.

The transfer rate and delay settings are described in *Section 55.4.5: DSPI baud rate and clock delay generation*.

55.4.1 Start and Stop of DSPI transfers

The DSPI has two operating states that are independent of DSPI configuration:

- STOPPED is the default DSPI state: no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results.
- RUNNING is the state when serial transfers take place.

DSPI_SR[TXRXS] indicates what state the DSPI in (‘1’ = RUNNING state).

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

55.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The SPI frames can be 32-bit long.

The DSPI is in SPI Configuration when the DCONF field in the MCR is 0b00.

The host CPU or a DMA controller transfers the SPI data from memory external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer.

Received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI.

The FIFO buffers operation is described in:

- *Section 55.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*,
- *Section 55.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism*,
- *Section 55.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism*.

The interrupt and DMA request conditions are described in *Section 55.4.12: Interrupts/DMA requests*.

The SPI Configuration supports two block-specific modes:

- Master mode: the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry.
- Slave mode: the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

55.4.2.1 Master mode

In SPI Master mode, the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals.

The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields.

The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin.

In SPI Master mode, each SPI frame to be transmitted has a command associated with it for transfer attribute control on a frame-by-frame basis.

In Extended SPI Master mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. Extended SPI Mode allows for larger frame sizes of up to 32 bits.

55.4.2.2 Slave mode

In SPI slave mode, the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers.

Certain transfer attributes such as clock polarity, clock phase and frame size must be set in CTAR0 and CTARE0 for successful communication with an SPI master. The data is shifted out with MSB first; shifting out of LSB is not supported in this mode.

55.4.2.3 FIFO Disable operation

The FIFO Disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO.

The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled.

The Transmit and Receive side of the FIFOs are disabled separately:

- MCR[DIS_TXF] disables TX FIFO and CMD FIFO.
  - TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in the status register and the extended status register behave as if there is a one-entry FIFO.
  - The contents of the TXFR registers and TXNXTPTR and CMDNXTPTR are undefined.
- MCR[DIS_RXF] bit disables the RX FIFO.
  - The RFDF, RFOF and RXCTR fields in the status register behave as if there is a one-entry FIFO.
  - The contents of the RXFR registers and POPNXTPTR are undefined.

The FIFO Disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

55.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission.

The TX FIFO holds 4 words, each consisting of SPI data that is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR).

The number of entries in the TX FIFO is device-specific.

TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. This field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

55.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. When TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete, the TFFF bit is cleared. Writing a ‘1’ to the TFFF bit also clears it. The DSPI ignores attempts to push data to a full TX FIFO; the state of the TX FIFO does not change and no error condition is indicated.

The TFFF can generate a DMA request or an interrupt request. Refer to *Section 55.4.12.2: Transmit FIFO Fill interrupt or DMA request* for details.

55.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled and the frame size of SPI Data to be transmitted is more than 16 bits, then two Data entries are popped from TX FIFO simultaneously and transferred to the shift register. DSPI_MCR[BIG_ENDIAN] defines concatenation order of TxFIFO entries to form SPI frame. If DSPI_MCR[BIG_ENDIAN] is set, the first of the two popped entries forms the 16 most significant bits of the SPI frame, else it forms the 16 least significant bits of SPI frame to be transferred. Such an operation also causes TX FIFO Counter to decrement by two.

At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a ‘1’ to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave’s DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave’s SR is set. Refer to *Section 55.4.12.9: Transmit FIFO Underflow interrupt request* for details.

55.4.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific.

SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPI_MCR[XSPI]) is disabled:

- The TX FIFO and CMD FIFO must be filled together as every CMDFIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPI_MCR[XSPI]) is enabled:

- The TX FIFO and CMD FIFO can be filled independently as every CMDFIFO entry can have multiple TXFIFO entries attached to it.
- The CTARE[DTCP] field decides the number of SPI Data Frames of size {FMSZE, FMSZ} to be transmitted using the current Command Entry. FMSZ and FMSZE fields are given in the CTAR/CTARE registers respectively, pointed by the CTAS field in the Command frame.
- The amount of time a command entry is in use is known as a Command Cycle. The busy flag DSPI_SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO entry is used during the next command cycle. This field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFR*n* registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

55.4.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin.

The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific.

SPI data is added to the RX FIFO on completion of a transfer when the received data in the shift register is transferred into the RX FIFO.

SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the status register points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR = 2 means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

55.4.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register.

While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the status register is set to indicating an overflow condition. Consequently:

- If the DSPI_MCR[ROOE] bit is set, the incoming data is shifted in to the shift register.
- If the DSPI_MCR[ROOE] bit is cleared, the incoming data is ignored.

55.4.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one.

Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data read from the empty RX FIFO is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the status register is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete, or by writing a ‘1’ to it.

55.4.3 Deserial Serial Interface (DSI) configuration

The DSI Configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in *Section 55.4.6: Transfer formats*. The received serial frames are converted to a parallel form (deserialized) and placed on the parallel output signals or in the DSPI_DDR. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR1/0).

The DSI frames can be from 4 to 32 bits, or 64 bits when DSICR1[DSI64E] is enabled.

55.4.3.1 DSI master mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions (described in *Section 55.4.3.5: DSI transfer initiation control*) that can initiate a transfer:

- Continuous.
- Change in data.
- Trigger signal.
- Trigger signal combined with a change in data.

Transfer attributes are set during initialization. DSICR0[DSICTAS] field determines which of the DSPI_CTARs will control the transfer attributes.

55.4.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers.

Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1.

The data is shifted out with MSB first.

55.4.3.3 DSI serialization

The DSI configuration from 4 to 16 bits can be serialized using two different sources selected by DSICR0[TXSS]:

- DSPI DSI Serialization Data Register (DSPI_SDR1/0). The DSPI_SDR0 holds the latest 32 parallel input signal values which is sampled at every rising edge of the protocol clock.
  When DSICR1[DSI64E] is enabled, 64-bit DSI frames are supported and hence DSPI_SDR1 holds the 32 MSB parallel input signal values which is sampled at every rising edge of the protocol clock.
- DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0). The DSPI_ASDR1/0 registers are written by host software and used as an alternate source of serialized data. DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled.

The DSPI has to sample the (SDR/ASDR) inputs before it transmits a DSI frame. Due to the asynchronous clock structure within DSPI, the sampling of inputs come under Register Clock domain whereas DSI frame transmission logic lies in Protocol Clock domain. Hence the sampled data (from ASDR1/0 or SDR1/0) must be synchronized into the Protocol Domain before being loaded into the Shift register for transmission.

To prevent Clock Domain clocking issues, SDR/ASDR inputs should not change while they are being sampled into the Protocol Domain. This is assured in the following manner:

- For the ASDR0 and ASDR1 inputs:
  - The initial write performed on ASDR register causes the 32-bit ASDR input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain.
  - Once synchronized, the lock is removed and the next ASDR write triggers this process again. If a write is performed on ASDR while the lock is asserted, this is processed as soon as the previous synchronization process completes and the lock is de-asserted. If multiple writes are performed on ASDR when lock is asserted after the first write, only the last value is considered for synchronization once the lock is de-asserted.
- For the SDR0 and SDR1 inputs:
  - The process is the same as ASDR with the only difference being that SDR inputs are delayed internally by a single clock to detect a change in the SDR input pins.

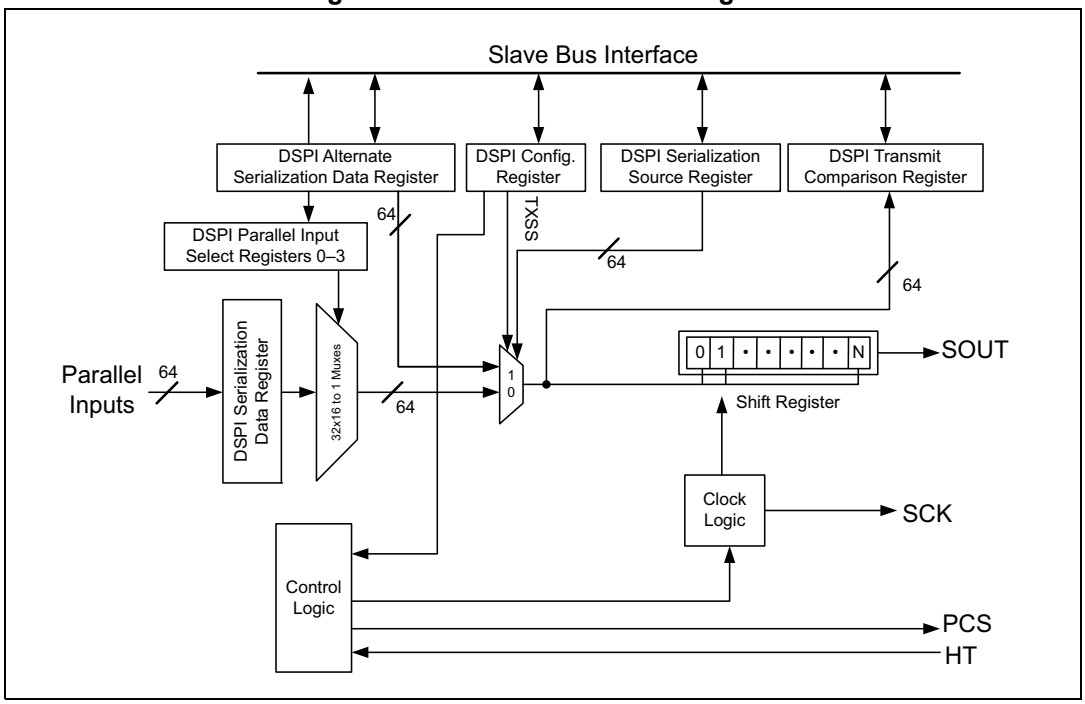
Note: If SDR0 and SDR1 inputs are both changed at the same time instant, then the synchronization logic ensures that both SDR0 and SDR1 contribute to the same DSI frame.

Once the synchronization process for a particular Deserial input begins, it takes up to five Register clock periods and five Protocol clock periods before the synchronization process for the next Deserial input can begin. Hence the writes performed on ASDR0/1 and SDR0/1 are constrained with this timing.

The DSPI_PISR0–3 registers (DSPI_PISR0–7 registers if DSICR1[DSI64E] is enabled) allow changing of the relative position of the parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent parallel inputs by writing IPS*n* fields. The IPS*n* field is treated as a 4-bit integer number, representing numbers from -8 to 7. The parallel input pin number, selected by IPS*n* field is defined by the sum of the IPS*n* field number (*n*) and the IPS*n* field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result. When DSICR1[DSI64E] is enabled, if the above operation result is negative, the number 64 should be added. If the result is higher than 64, 64 should be subtracted from the result.

For example, IPS0, set to minus 1 (binary 1111), preselects parallel input 31 to 0 position in the transmitted frame. (This preselects parallel input 63 to 0 position in the transmitted frame when DSICR1[DSI64E] is set).

IPS6, set to 3 (binary 0011), preselects parallel input 9 to be bit number 6 in the transmitted frame, while the value minus 2 (1110) preselects parallel input 4.



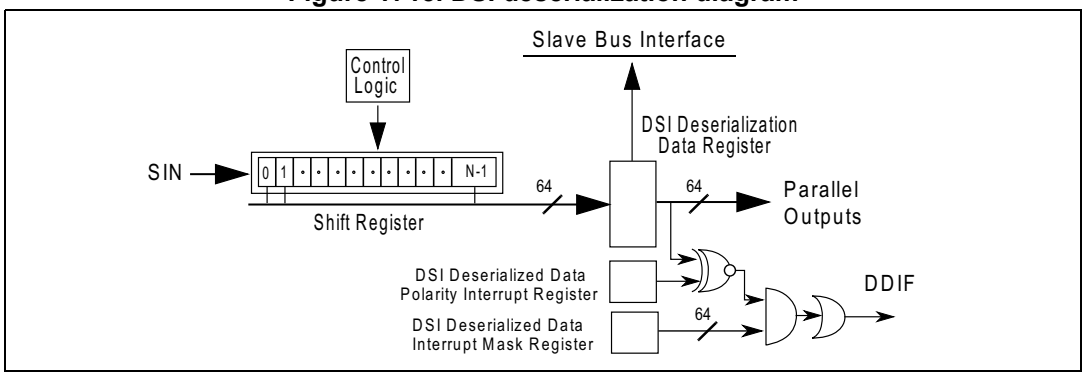
IPS31, set to minus 8 (binary 1000), preselects parallel input 23 to be bit number 31 in the transmitted frame.

The parallel input pin state to be transmitted should be selected by TXSS or DSPI_SSR1/0 registers and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR1/0 registers provide additional way of creating the frame for transmission. Each bit from this register is ORed with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR1/0 and DSPI_ASDR1/0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. The control field may come from DSPI_ASDR1/0 registers set by the CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMPR1/0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. *Figure 1714* shows the DSI serialization logic.

Figure 1714. DSI serialization diagram



55.4.3.4 DSI deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR1/0). This register presents the deserialized data as parallel output signal values. The DSPI_DDR1/0 is memory-mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR1/0), bit-wise ANDed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR1/0) and the results ORed to produce DDIF flag in the DSPI_SR. Which in turn can cause DDIF interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] and/or stop DSI frame transmissions if DSICR0[DMS] bit is set. *Figure 1715* shows the DSI Deserialization logic.

Figure 1715. DSI deserialization diagram

55.4.3.5 DSI transfer initiation control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0 register. *Table 1754* lists the four transfer initiation conditions.

Table 1754. DSI data transfer initiation control

DSPI_DSICR0 bits		Transfer initiation control
TRRE	CID	
0	0	Continuous
0	1	Change in Data
1	0	Triggered
1	1	Triggered or Change in Data

55.4.3.5.1 Continuous control

For continuous control, a new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

55.4.3.5.2 Change in data control

For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_COMPR1/0. When the data selected for the transfer from the DSPI_SDR1/0 and DSPI_ASDR1/0 registers is different from the data in the DSPI_COMPR1/0 a new DSI frame is transmitted.

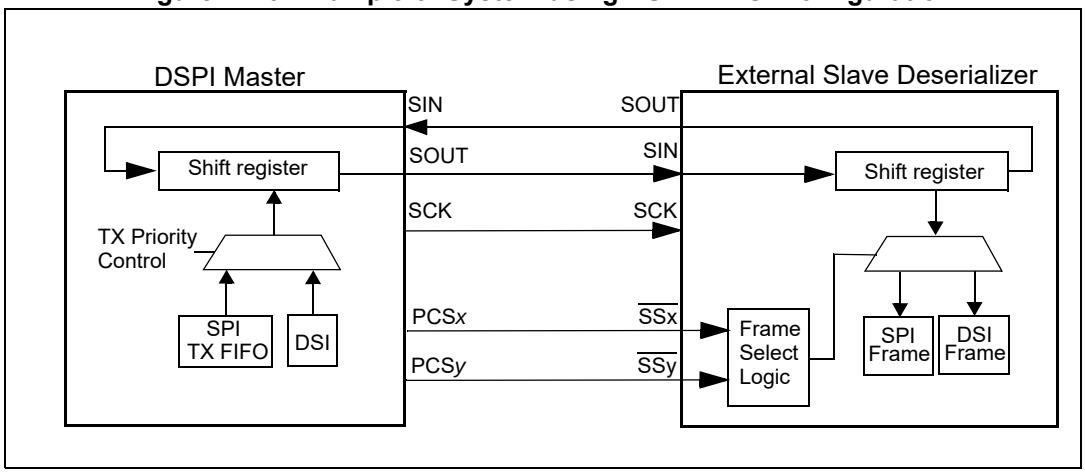
55.4.3.5.3 Triggered control

For Triggered Control, initiation of a transfer is controlled by the Hardware Trigger signal (HT). DSICR0[TPOL] bit selects the active edge of HT. For HT to have any affect, DSICR0[TRRE] bit must be set.

55.4.3.5.4 Change in data or triggered control

For change in data or triggered control, initiation of a transfer is controlled by the detection of a change in data to be serialized or by the HT signal.

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1; since the following statement then holds true:



> Once slave select is asserted, there is a very small window (of up to three module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occurs, the next frame to be transmitted would be loaded into the shift register. Since it is not feasible that such a write is initiated and completed within this short span of time, the data transmitted by DSPI slave would lag by one data frame.

55.4.4 Combined Serial Interface (CSI) configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis.

CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the parallel output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. *Figure 1716* shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

Figure 1716. Example of System using DSPI in CSI Configuration

In CSI Configuration, the DSPI transfers DSI data based on *Section 55.4.3.5: DSI transfer initiation control*. When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTARs associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy.

The CSI Configuration is only supported in master mode.

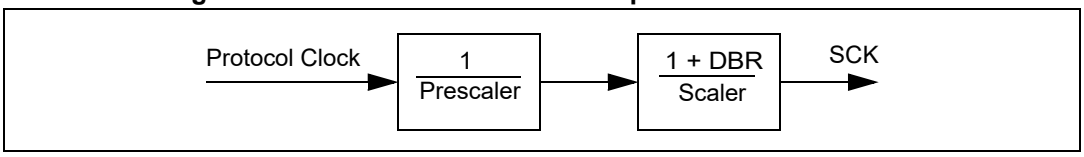
Data returned from the external slave while a DSI frame is transferred is placed on the parallel output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

55.4.4.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR selected by the DSICR0[DSICTAS] field.

The parallel inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR) on the rising edge of every protocol clock and serialized based on the transfer initiation control settings in the DSPI_DSICR1/0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty), they have priority over DSI data and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR1/0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.



55.4.4.2 CSI deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR1/0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred, the returned frames are deserialized and latched into the DSPI_DDR1/0. When SPI frames are transferred, the returned frames are deserialized and written to the RX FIFO.

55.4.5 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. *Figure 1717* shows conceptually how the SCK signal is generated.

Figure 1717. Communications clock prescalers and scalers

55.4.5.1 Baud rate generator

The baud rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. *Table 1755* shows an example of how to compute the baud rate.

Table 1755. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note: The clock frequencies mentioned in Table 1755 are given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

55.4.5.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. The PCSSCK and CSSCK fields in the CTAR*n* registers select the PCS to SCK delay by the formula in the CSSCK field description. *Table 1756* shows an example of how to compute the PCS to SCK delay.

Table 1756. PCS to SCK delay computation example

f_P	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1756 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

55.4.5.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. The PASC and ASC fields in the CTAR*n* registers select the After SCK delay by the formula in the ASC field description. *Table 1757* shows an example of how to compute the After SCK delay.

Table 1757. After SCK delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

Note: The clock frequency mentioned in Table 1757 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

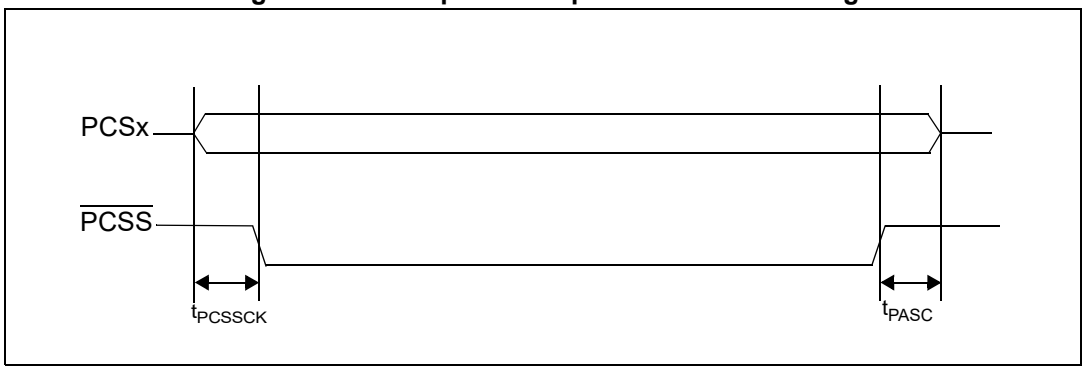
55.4.5.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. The PDT and DT fields in the CTAR*n* registers select the Delay after Transfer by the formula in the DT field description. *Table 1758* shows an example of how to compute the delay after transfer.

Table 1758. Delay after transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

Note: The clock frequency mentioned in Table 1758 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.



When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode, the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. Refer to detailed information on *Section 55.4.9: Timed Serial Bus (TSB)*.

55.4.5.5 Peripheral Chip Select Strobe Enable ($\overline{PCSS}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs, thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, $\overline{PCSS}$ provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4]and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. *Figure 1718* shows the timing of the $\overline{PCSS}$ signal relative to PCS signals.

Figure 1718. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

Equation 78

$$t_{PCSSCK} = \frac{1}{f_P} \times PCSSCK$$

At the end of the transfer the delay between $\overline{PCSS}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

Equation 79

$$t_{PASC} = \frac{1}{f_P} \times PASC$$

Table 1759 shows an example of how to compute the t_{PCSSCK} delay.

Table 1759. Peripheral Chip Select Strobe Assert Computation Example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

Table 1760 shows an example of how to compute the t_{PASC} delay.

Table 1760. Peripheral Chip Select Strobe Negate Computation Example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK or TSB mode are enabled.

Note: The clock frequency mentioned in the preceding Table 1759 and Table 1760 is given as an example. Refer to the Clocking chapter for the frequency used to drive this module in the device.

55.4.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTAR*n*) select the polarity and phase of the serial clock, SCK.

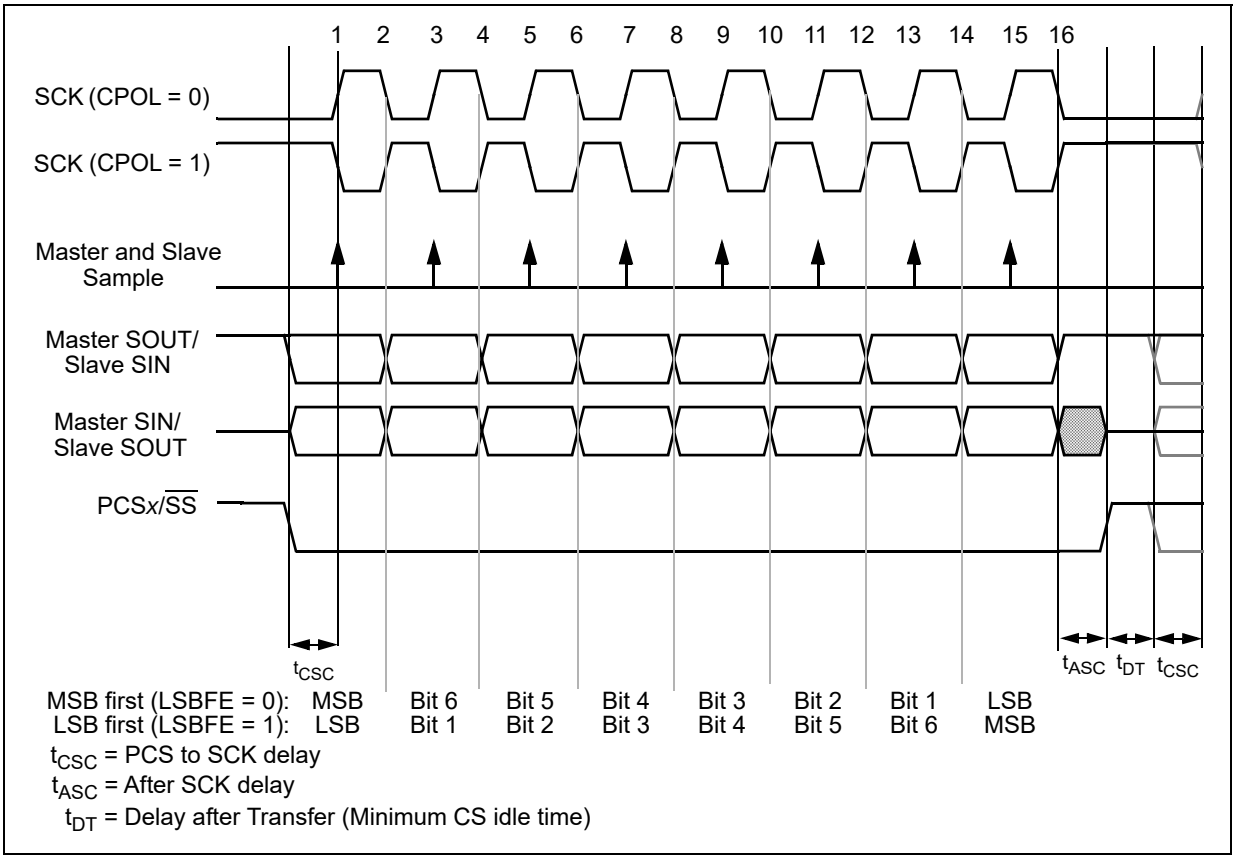
- CPOL: selects the idle state polarity of the SCK.
- CPHA: selects if the data on SOUT is valid before or on the first SCK edge.

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

In DSI slave mode, only CTAR1 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0.
- Classic SPI with CPHA = 1.
- Modified Transfer format with CPHA = 0.
- Modified Transfer format with CPHA = 1.



A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. Refer to *Section 55.4.6.5: Continuous Selection Format* for details.

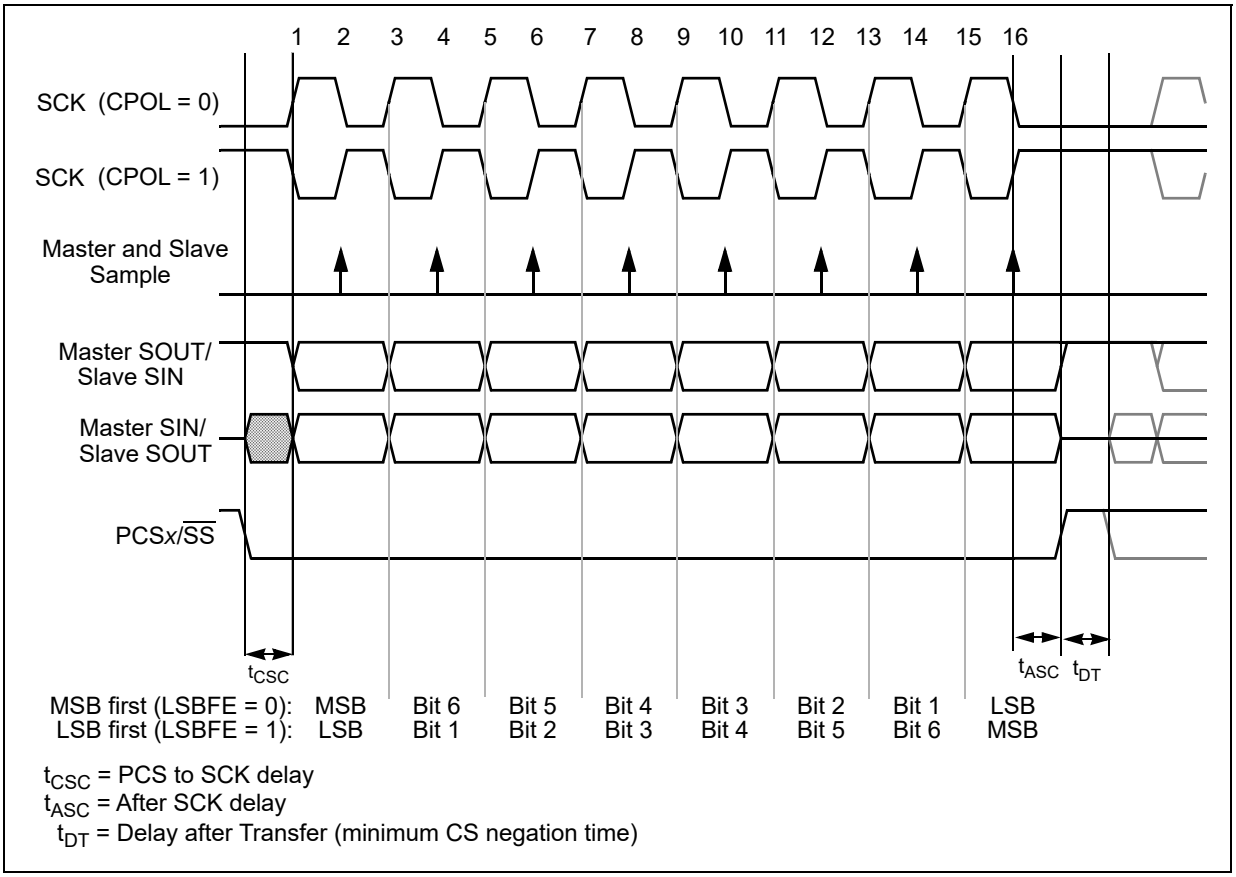
55.4.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in *Figure 1719* is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 1719. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals.

At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals.



For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

55.4.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in *Figure 1720* is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

Figure 1720. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave.

After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins.

For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

55.4.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave

mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_sl} – data hold time on slave data input
- t_p – protocol clock period

Figure 1721 shows the modified transfer format for CPHA = 0 and f_p/f_{sck} = 4{s}. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked “SOUT of Ext Slave”, presents regular SPI slave serial output.
- Signal, marked “SOUT of DSPI Slave”, presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according to DSPI master CPHA programming.

Note: In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

Note: When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

Figure 1721. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)

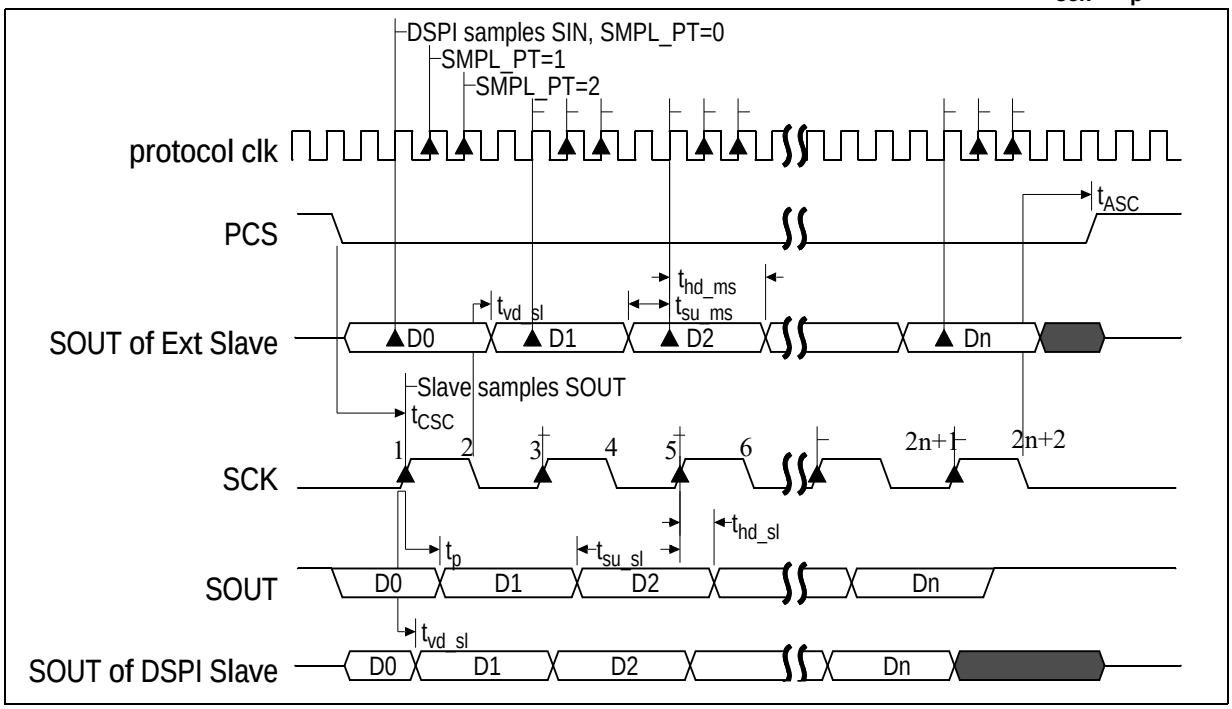


Figure 1722. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

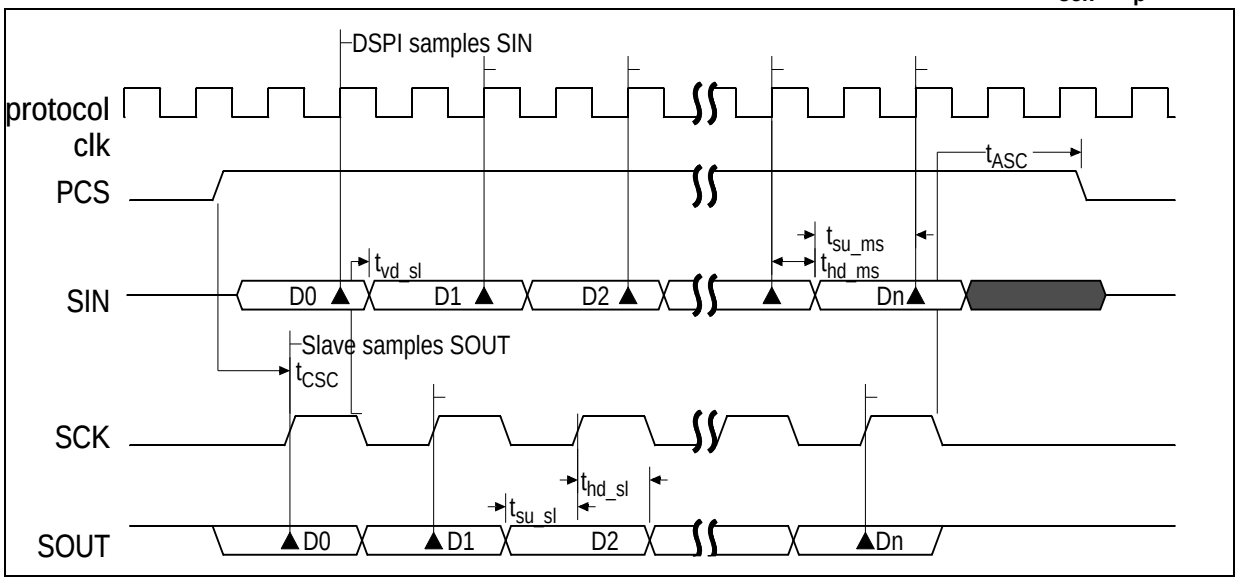

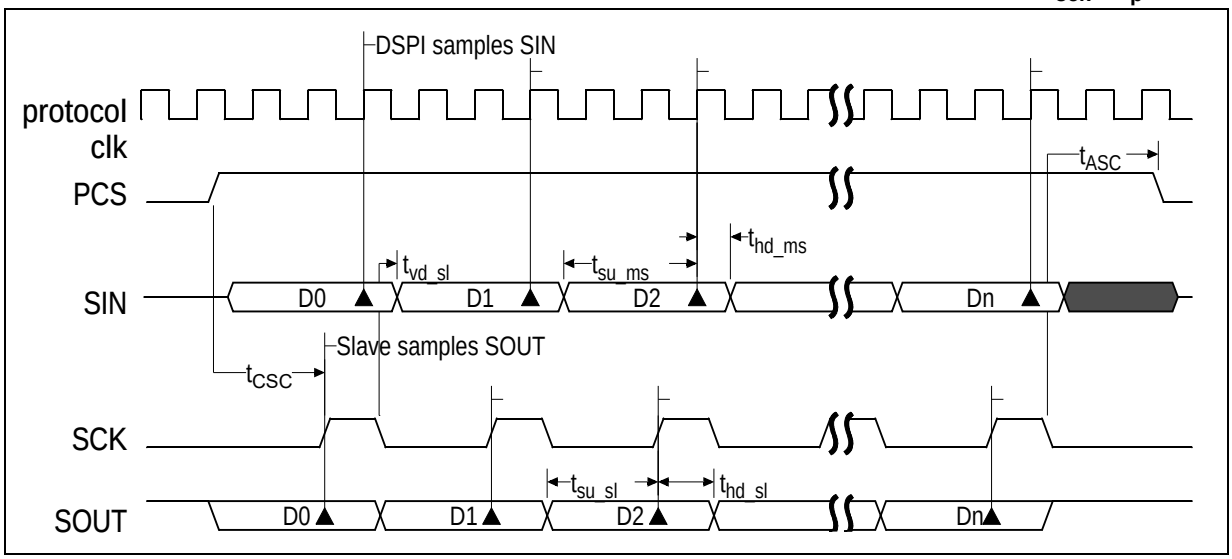

Figure 1723. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

55.4.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. The SCK to PCS delay must be greater than or equal to half of the SCK period.

Figure 1724. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)

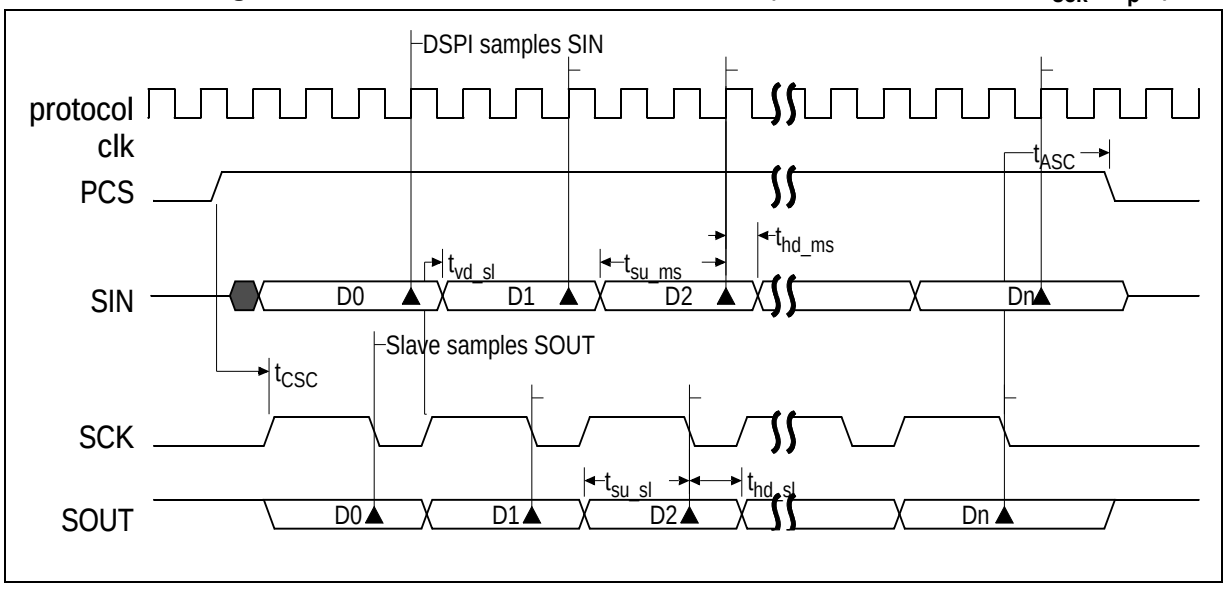

Figure 1725. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

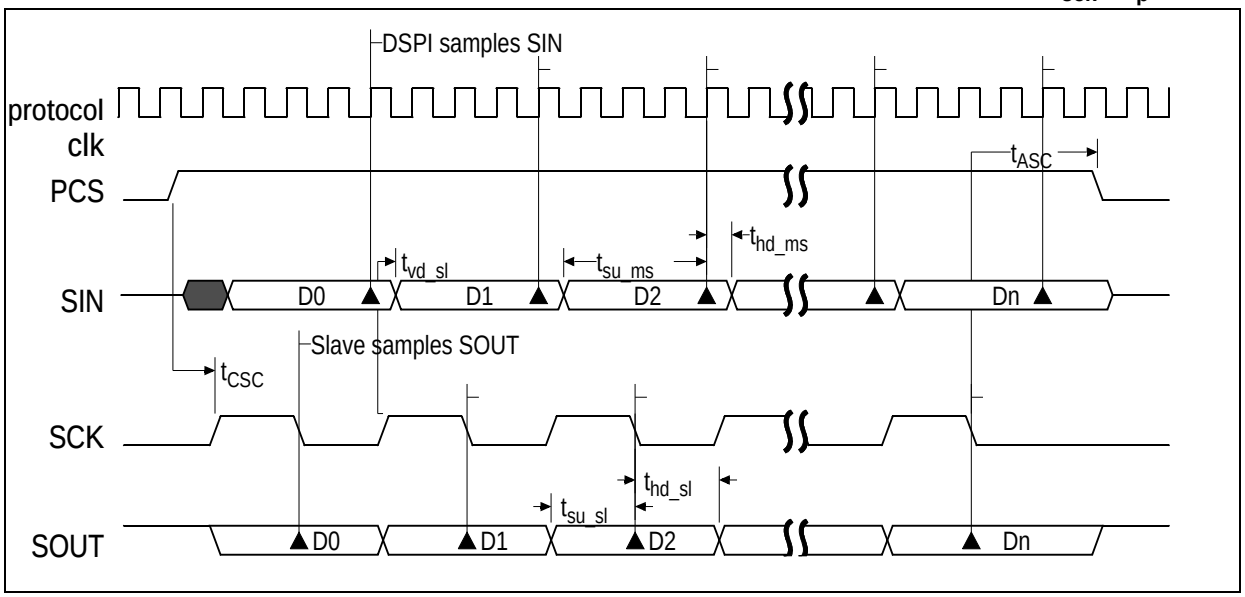

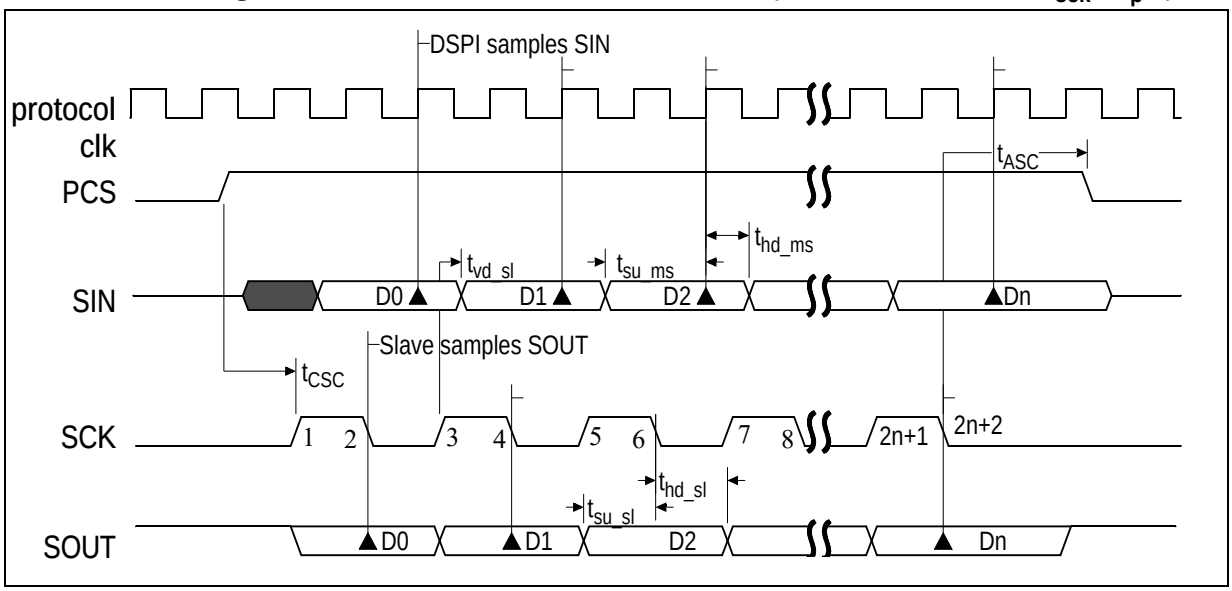

Figure 1726. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

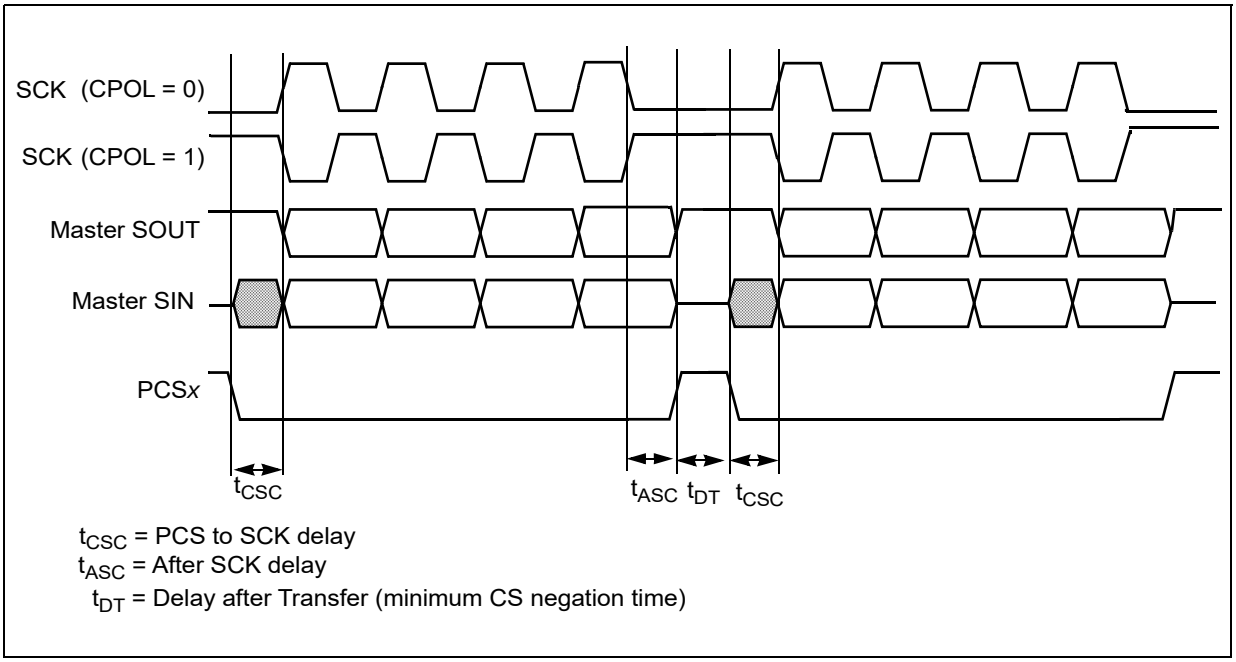
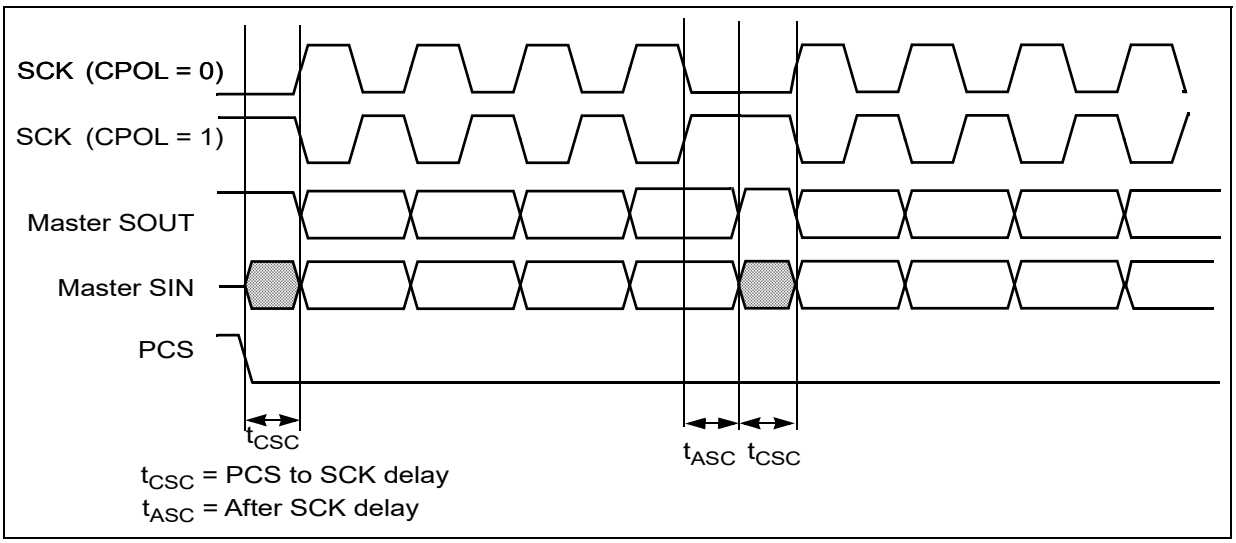


55.4.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI Configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.

The behavior of the PCS signals in the two configurations is identical so only SPI Configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select



signals are selected by the PCSIS*n* bits in the MCR. The timing diagram in *Figure 1727* is for two four-bit transfers with CPHA = 1 and CONT = 0.

Figure 1727. Example of non-continuous format (CPHA = 1, CONT = 0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. *Figure 1728* shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

Figure 1728. Example of continuous transfer (CPHA = 1, CONT = 1)

When using DSPI with continuous selection follow these rules:

- All transmit commands must have the same PCS*n* bits programming.
- The CTARs selected by transmit commands must be programed with the same transfer attributes. Only FMSZ field can be programed differently in these CTARs.
- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit de-asserted (in master mode) and the user software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCS*n* at end of transmission of last frame.
- The PUSHR[CONT]/DSICR0[DCONT] bits must be de-asserted before asserting MCR[HALT] bit (in master mode). This ensures that the PCS*n* signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCS*n* signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

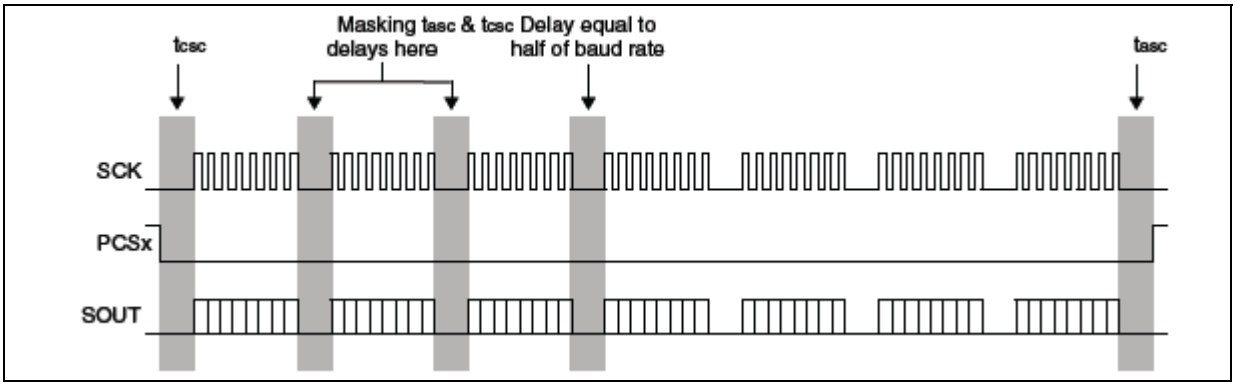
Note: You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

Note: When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

55.4.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

Note: The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.



The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR. When this bit is asserted, MASC and MCSC bits of the PUSHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

Figure 1729 shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

Figure 1729. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

55.4.7 Continuous Serial Communications Clock

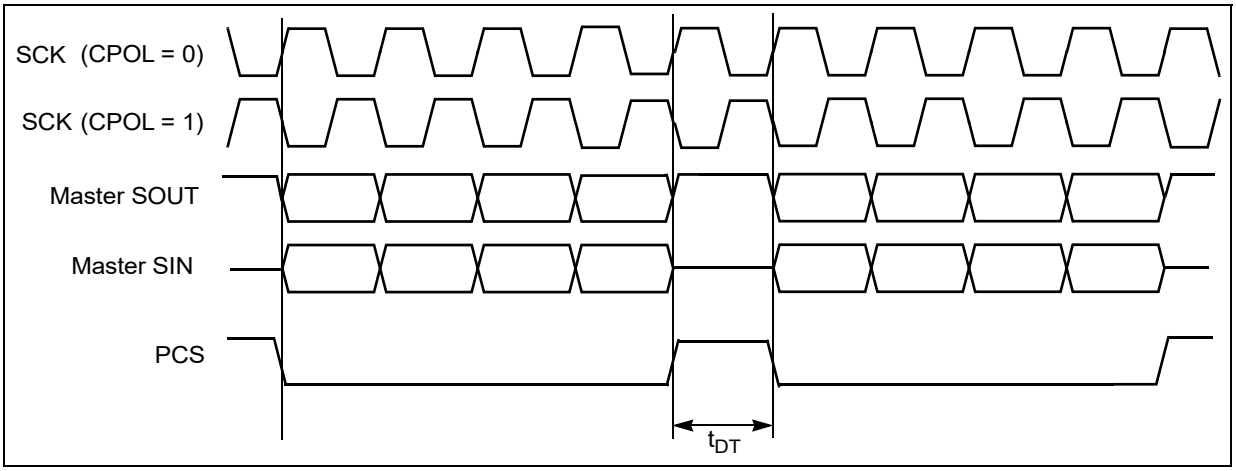
The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
  - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
  - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.



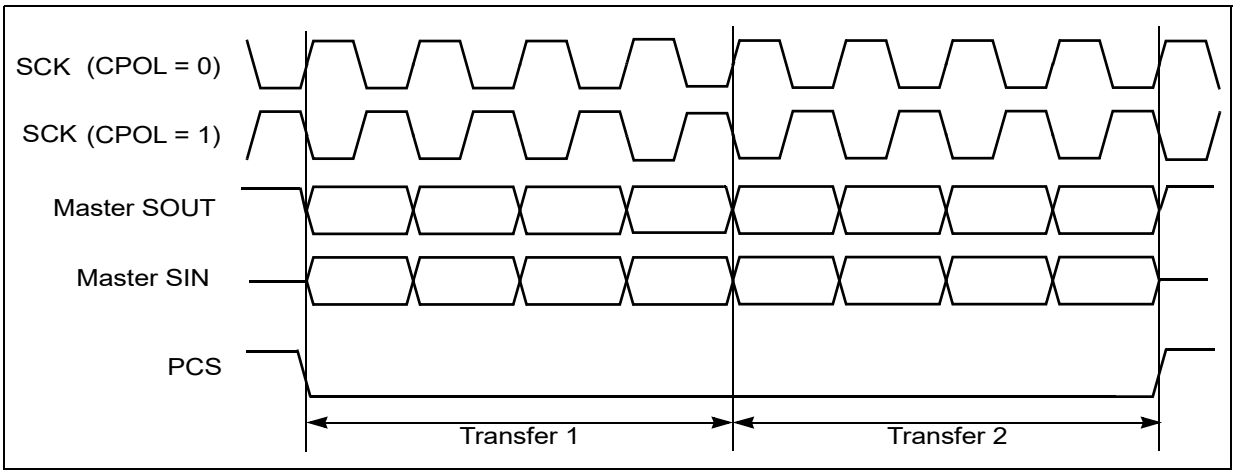
It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles.

Figure 1730 is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note: When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 1730. Continuous SCK timing diagram (CONT = 0)



If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with

PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to *Section 55.4.1: Start and Stop of DSPI transfers*).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

Figure 1731 shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 1731. Continuous SCK Timing Diagram (CONT = 1)

55.4.8 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

55.4.9 Timed Serial Bus (TSB)

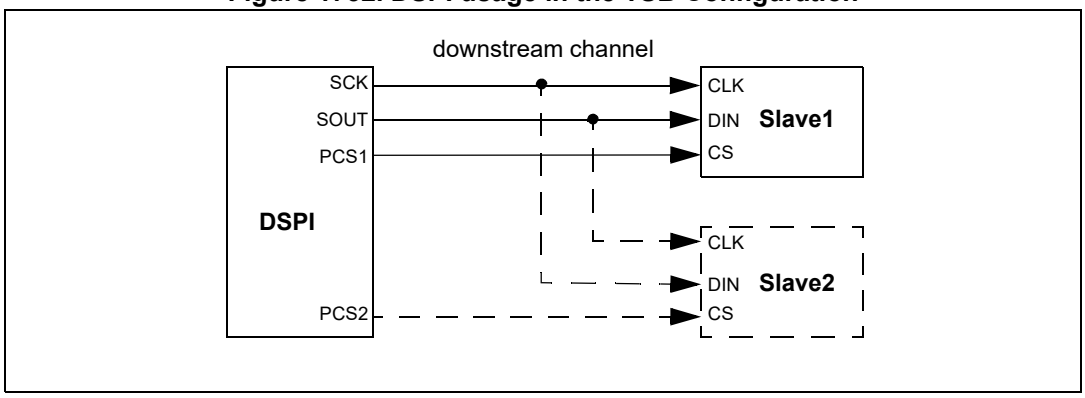
The DSPI can be programed in Timed Serial Bus configuration by setting DSICR0[TSBC] bit. Refer to *Section 55.3.13: DSPI DSI Configuration Register 0 (DSPI_DSICR0)* for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the device.

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

Figure 1732 shows the signals used in the TSB interface.



In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0), written by the host software,
- parallel input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR1/0).

DSICR0[TXSS] bit or DSPI_SSR1/0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

Figure 1732. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTAR*n* PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

Figure 1733. TSB Downstream Frames

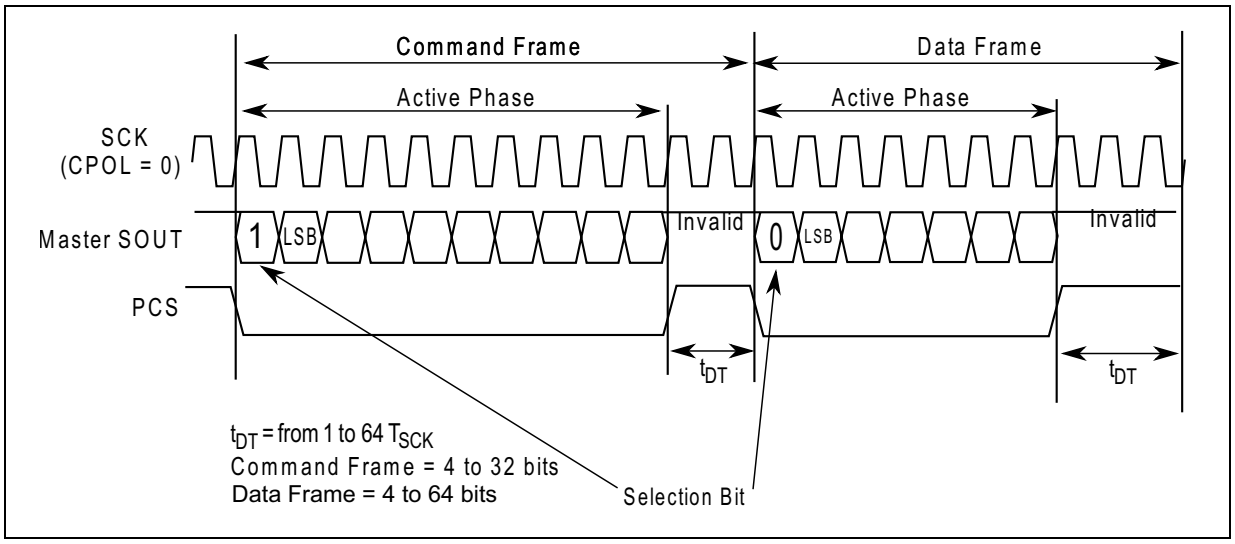


Figure 1733 shows two types of MSC downstream frames: command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit '0' indicates a data frame
- The selection bit '1' indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR1/0 or ASDR1/0 registers and up to two zero selection bits. Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSE*n* bit set increases the data frame size by one bit.

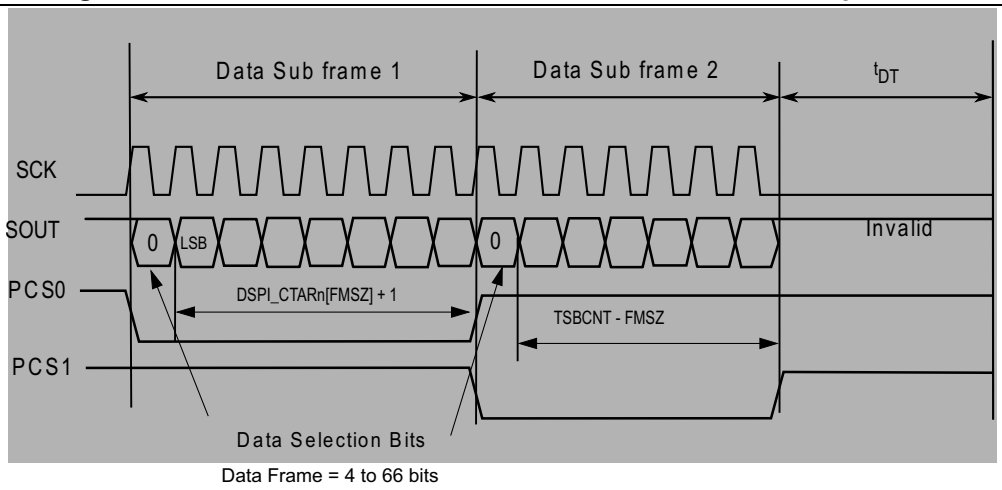
To comply with MSC specification, set DSPI_CTAR*n*[LSBFE] to transmit least significant bit first.

Regardless of the LSBFE bit setting, the data frame selection bits, if enabled, are always transmitted first, before the corresponding data subframes.

55.4.9.1 MSC Dual Receiver Support with PCS Switchover

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switchover occurs, is defined by FMSZ field of the DSPI_CTAR*n* register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Note: When using Dual receiver support, it must be ensured that the number of bits to be transmitted to each slave must be at least 4.



Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switchover occurs at the driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switchover if enabled.

The Data Frame with PCS switchover is shown in *Figure 1734*.

Figure 1734. TSB Data Frame Format for MSC Dual Receiver Operation

55.4.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB in all aspects except for the differences mentioned in *Table 1761*. In the Interleaved TSB or ITSB mode, frame transmission is governed by the following rules:

- Transmission of frames is executed on a periodic trigger that is generated internally to the DSPI. The trigger period is calculated as follows:
  - Trigger Period = 64 bits (maximum data frame size) + 2 selection bits (maximum bits in data frame) + t_{PT}

    t_{PT} is the passive frame time or dead time inserted to have constant trigger period.
  - The user software shall configure the trigger period and trigger source.
- If the previously transmitted frame was a SPI frame or the TX FIFO (or CMD FIFO) is empty, the frame transmitted on subsequent trigger will always be a DSI frame.
- If the previously transmitted frame was not a SPI frame and the TX_FIFO (and CMD FIFO) is not empty, the frame transmitted on subsequent trigger will always be a SPI frame.

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) in such a way to prevent back to back SPI frames. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits cannot be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

Table 1761 lists the differences between the TSB and ITSB modes.

Table 1761. Differences between TSB and ITSB modes

Mode attribute	TSB mode	ITSB mode
Frame priority	Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Frame selection bit	Selection bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Frame transmission	Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Periodically triggered transmission (that is frames are transmitted continuously on every trigger).
Frame gap	Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is inserted automatically as the whole operation is based on a periodic trigger. If a frame has less than 64-bits to be transmitted, dead or passive time is automatically inserted by waiting for the next trigger pulse. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In TSB and ITSB mode, separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI. MSC dual receiver support with PCS switchover is also supported in ITSB mode. Refer to *Section 55.4.9.1: MSC Dual Receiver Support with PCS Switchover* for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the ITSB mode features listed in the table above.

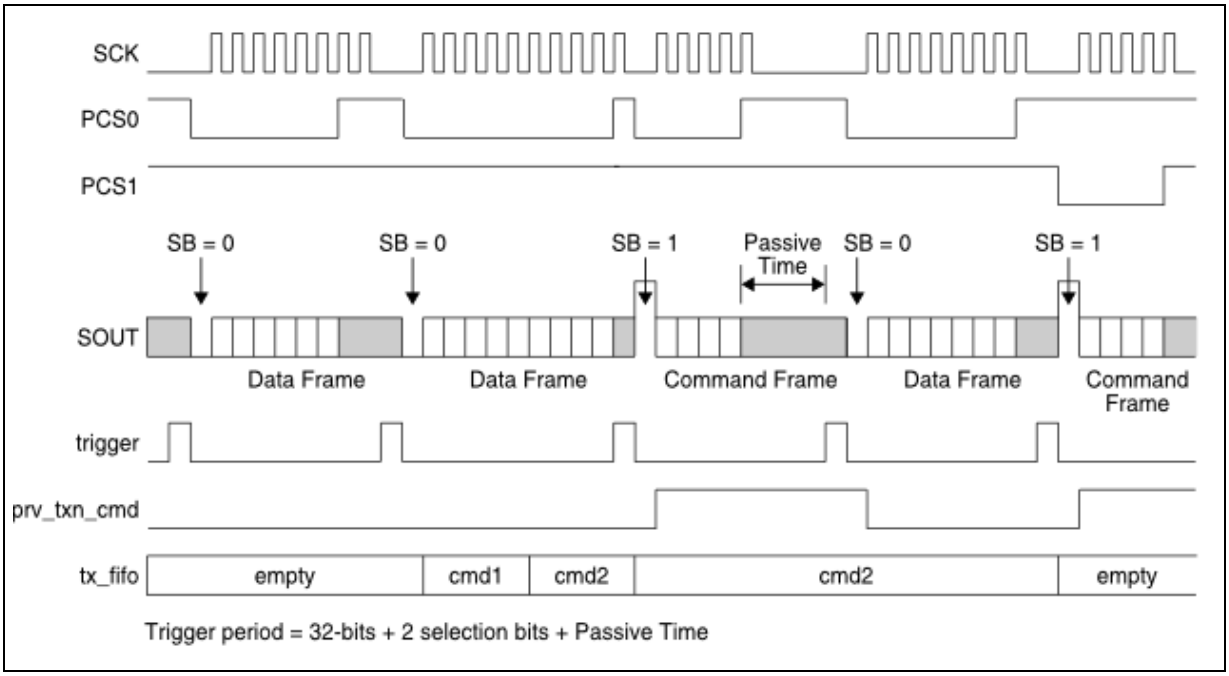
55.4.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame completion (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in *Section 55.4.10: Interleaved TSB (ITSB) Mode*.

55.4.10.2 Using ITSB mode for MSC downstream channel



MSC Downstream Channel uses two types of frames: command frames and data frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- If command frame has less bits than data frame, a gap is inserted to ensure next data frame starts at known reference time.
- In dual MSC ASIC, some bits of the data frame (which can be up to 64 bits) goes to first ASIC and remainder bits to second ASIC.
- In dual MSC ASIC, if a command frame is sent to one ASIC, it must not change the timing of the next data frame.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (Refer to *Section 55.4.10.1: Configuring DSPI for ITSB mode*), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in *Section 55.4.4: Combined Serial Interface (CSI) configuration*.

Figure 1735 shows a sample MSC Downstream transmission using the ITSB mode.

Figure 1735. Sample MSC downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, since there are no command frames, a data frame is transmitted: to send a command frame at the start of operation, the user software must program a command frame in the TX_FIFO before enabling DSPI (MCR[HALT] = 0).
- The second trigger sets off the transmission of another data frame.
- Between the second and third trigger, two command frames are pushed into the TX_FIFO.
- At third trigger, a command frame is transmitted as the TX_FIFO is not empty: since only 16 bits or less are transmitted, no transmission happens till next trigger. This is marked as the “Passive Time”. The passive time is added in all frames after frame transmission completes and until next trigger pulse is detected.
- At fourth trigger, since the previous transmission was a command frame, a data frame is transmitted.
- At fifth trigger, since one command frame is pending in TX_FIFO and last transmitted frame was not a command frame, a command frame is transmitted.
- At sixth trigger (not shown), the process continues.

55.4.11 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

55.4.11.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines the polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

55.4.11.2 Parity for DSI frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode, the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation, clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

55.4.12 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. *Table 1762* lists these conditions.

Table 1762. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
DSI Transfer Complete	DSITCF	Yes	—
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—
DSI Parity Error	DPEF	Yes	—
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

55.4.12.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note: This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

55.4.12.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[TFFF] flag clears automatically when DMA is used to fill TXFIFO.

Note: To clear SR[TFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

Wait until SR[TFFF] = 1

Write data to PUSHR using CPU.

Clear SR[TFFF] by writing a '1' to its location. If TXFIFO is not full, this flag will not clear.

55.4.12.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note: SR[CMDFFF] flag clears automatically when DMA is used to fill CMD FIFO.

Note: To clear SR[CMDFFF] when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

Wait until SR[CMDFFF] = 1

Write data to Command field of PUSHR using CPU.

Clear SR[CMDFFF] by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.

55.4.12.4 Transmit FIFO Invalid Write interrupt request

The Transfer Fifo Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered

invalid until a Command Entry becomes available. The Transfer Fifo Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

55.4.12.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

55.4.12.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

55.4.12.7 SPI Transfer Complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

55.4.12.8 DSI Transfer Complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

55.4.12.9 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

55.4.12.10 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: SR[RFDF] flag clears automatically when DMA is used to fill RXFIFO.

Note: To clear SR[RFDF] when not using DMA, follow these steps for every POP performed using CPU to drain RXFIFO:

Wait until SR[RFDF] = 1

Read data from POPR using CPU.

Clear SR[RFDF] by writing a ‘1’ to its location. If RXFIFO is not empty, this flag will not clear.

Note: Clearing SR[RFDF] by writing a ‘1’ to its location after performing MCR[CLR_RXF], will not happen if RXFIFO is not empty because the data from shift register can be transfered just after clear operation is performed.

55.4.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

55.4.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

55.4.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

55.4.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR1/0 data, masked with DSPI_DIMR1/0, has been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

55.4.13 Power saving features

The DSPI supports the following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

Note: When in Slave Mode, the module can only be put in Low Power Modes (such as STOP and HALT) once the Master module has transitioned to the Low Power Mode as well.

55.4.13.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter External Stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

If a DSPI block is configured in Slave mode, External Stop mode requests must be run after the last clock cycle or Low-power mode is not entered.

55.4.13.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting the MDIS bit in the MCR. The module disable mode can also be initiated by hardware.

When the MDIS bit is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.

If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible.

Certain read or write operations have a different effect when the DSPI is in the module disable mode:

- Reading the RX FIFO Pop register does not change the state of the RX FIFO.
- Writing to the FIFO Push register does not change the state of the TX FIFO or CMD FIFO.
- Clearing of the FIFOs has no effect.
- Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect.
- All status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect.
- Writing to the TCR during module disable mode has no effect.
- Interrupt and DMA request signals cannot be cleared.

55.5 Initialization/application information

This section describes how to initialize the DSPI module.

55.5.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI Configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a ‘1’ to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a ‘1’ to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

55.5.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a ‘1’ to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

55.5.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

55.5.4 Baud rate settings

Table 1763 shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

Table 1763. Baud rate values (bps)

Baud Rate scaler values (DSPI*n*_CTAR[BR])	Baud rate divider prescaler values (DSPI*n*_CTAR[PBR])			
	2	**3**	**5**	**7**
2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
64	781 kHz	521 kHz	312 kHz	223 kHz
128	391 kHz	260 kHz	156 kHz	112 kHz
256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

55.5.5 Delay settings

Table 1764 shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

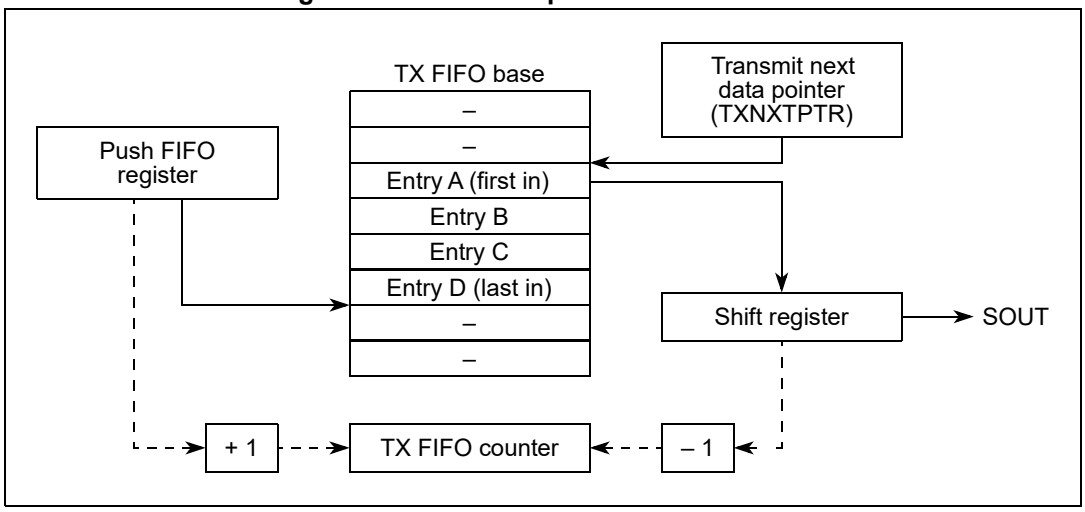
Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the Clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 1764. Delay values

		Delay prescaler values (DSPI*n*_CTAR[PBR])			
		1	**3**	**5**	**7**
Delay scaler values	**2**	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

55.5.6 Calculation of FIFO pointer addresses



Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped.

- For TX FIFO, the first-in pointer is the Transmit Next Pointer (TXNXTPTR).
- For CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR).
- For RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR).

Figure 1736 illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts are applicable to the CMD FIFO and RX FIFO.

Refer to *Section 55.4.2.4: Transmit First In First Out (TX FIFO) buffering mechanism*, *Section 55.4.2.5: Command First In First Out (CMD FIFO) buffering mechanism* and *Section 55.4.2.6: Receive First In First Out (RX FIFO) Buffering Mechanism* for details on the FIFO operation.

Figure 1736. TX FIFO pointers and counter

55.5.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

Equation 80

$$First-inEntryAddress = TXFIFOBase + (4 \times TXNXTPTR)$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

Equation 81

$$Last-inEntryAddress = TXFIFOBase + 4 \times (TXCTR + TXNXTPTR - 1) \bmod (TXFIFOdepth)$$

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXTPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

55.5.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

Equation 82

$$First-inEntryAddress = CMDFIFOBase + (4 \times CMDNXTPTR)$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

Equation 83

$$Last-inEntryAddress = CMDFIFOBase + 4 \times (CMDCTR + CMDNXTPTR - 1) mod (CMDFIFOdepth)$$

CMD FIFO Base – Base address of CMD FIFO
CMDCTR – CMD FIFO Counter
CMDNXTPTR – Command Next Pointer
CMD FIFO Depth – Command FIFO depth, implementation specific

55.5.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

Equation 84

$$First-inEntryAddress = RXFIFOBase + (4 \times POPNXTPTR)$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

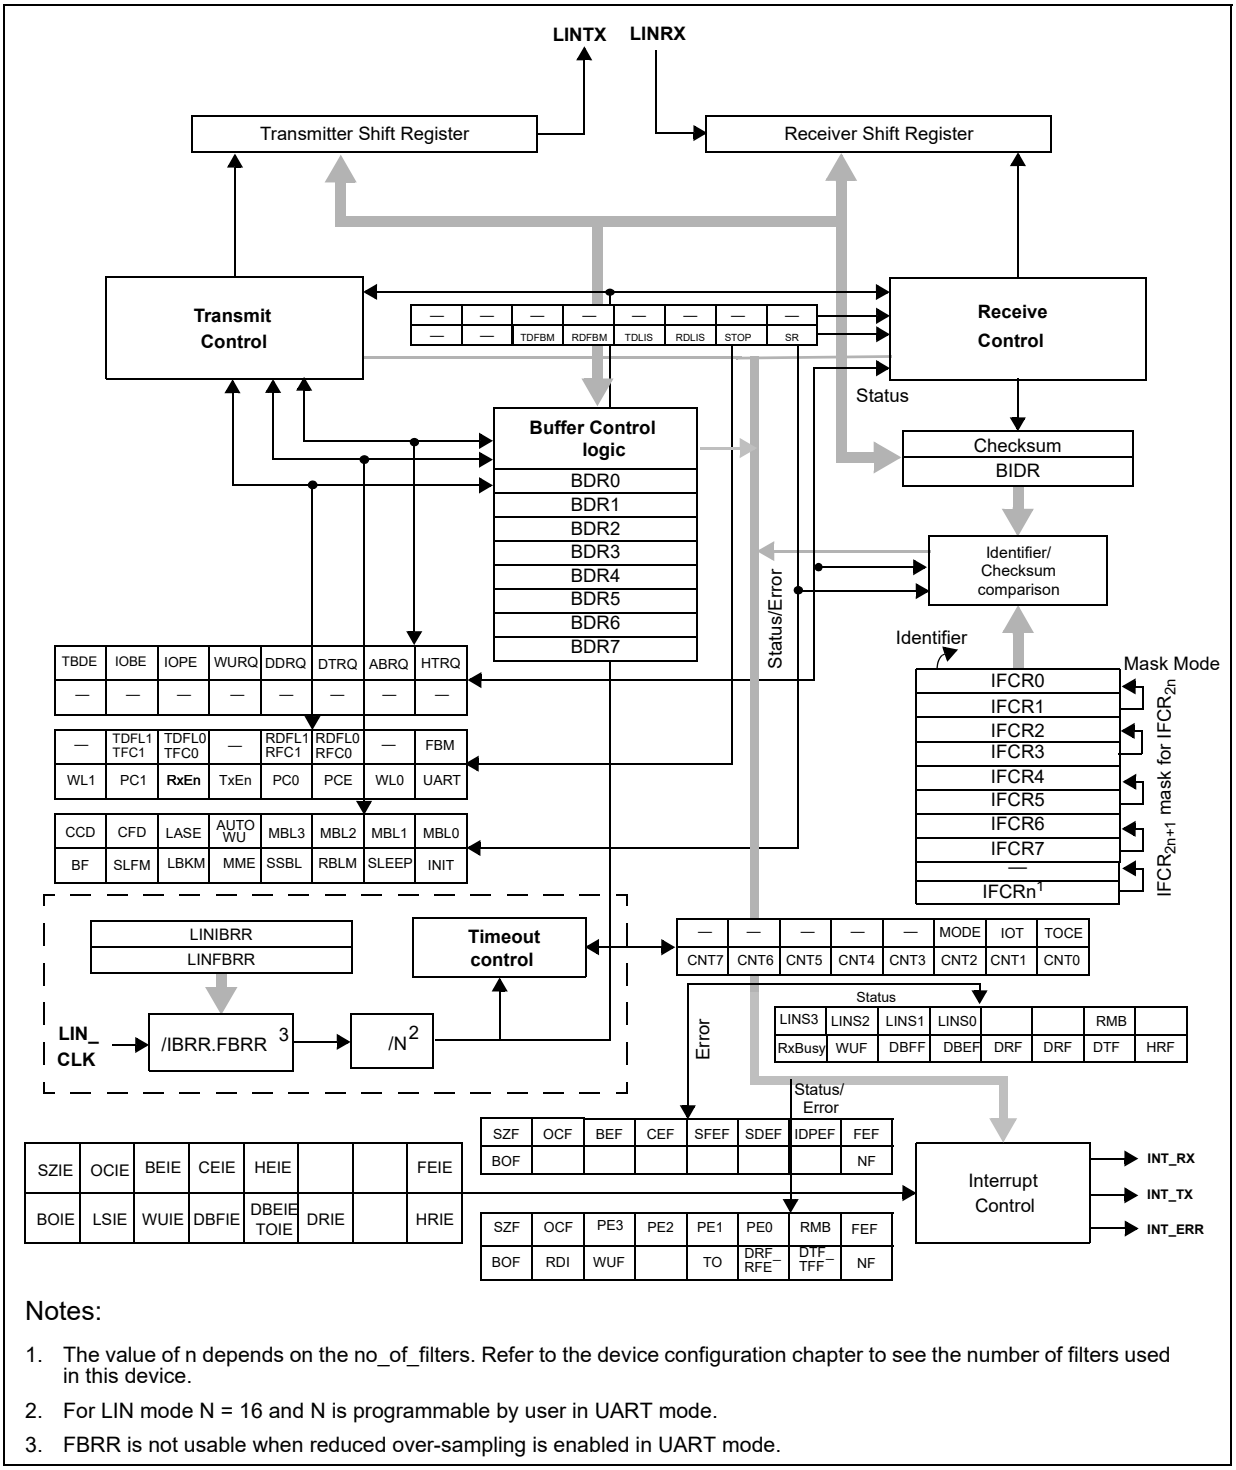
Equation 85

$$Last-inEntryAddress = RXFIFOBase + 4 \times (RXCTR + POPNXTPTR - 1) mod (RXFIFOdepth)$$

RX FIFO Base – Base address of RX FIFO
RXCTR – RX FIFO counter
POPNXTPTR – Pop Next Pointer
RX FIFO Depth – Receive FIFO depth, implementation specific

56 LINFlexD

56.1 Introduction



The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 1737. Block diagram

Notes:

1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.
2. For LIN mode N = 16 and N is programmable by user in UART mode.
3. FBRR is not usable when reduced over-sampling is enabled in UART mode.

56.2 Main features

LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

56.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK $\geq$ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)

56.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers (refer to *Section 56.3.2.8: Baud rate generation*)
- Separate clock for baud rate calculation (The relationship “(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate (BR) <= LIN_CLK/16
  - 16 times oversampling
  - 3:1 majority voting
- For LIN_CLK/16 < BR <= LIN_CLK/8
  - OSR = 8
  - 3:1 majority voting
- For LIN_CLK/8 < BR <= LIN_CLK/4
  - OSR = 4,5,6
  - 1:1 voting

56.2.3 Standard features

DMA2x bus interface.

56.3 Functional description

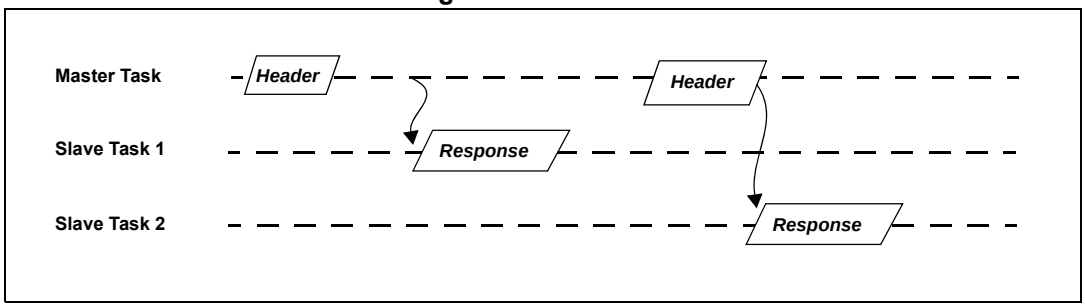
56.3.1 LIN protocol

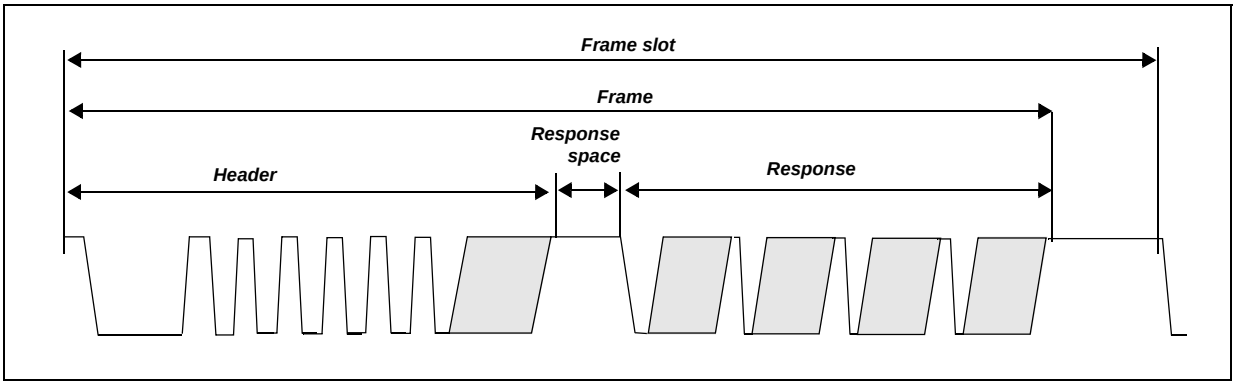
The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task - all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

56.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 1738. Frames





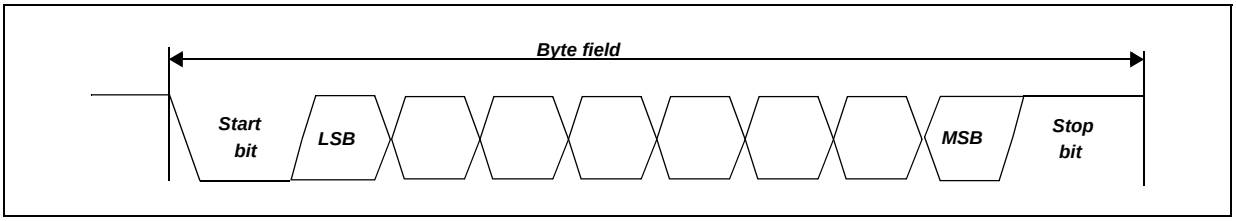


Figure 1739. Structure of LIN frame

56.3.1.2 Data field

Each byte is transmitted as shown in *Figure 1740*. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

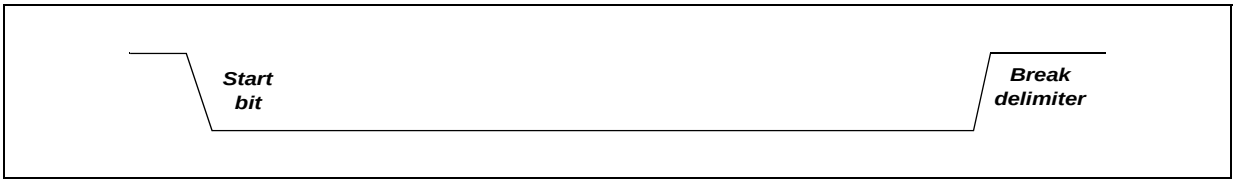

Figure 1740. Structure of byte field

56.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in *Figure 1741*. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

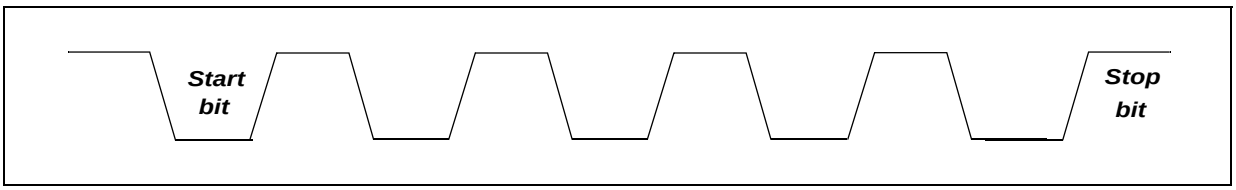

Figure 1741. Break field

56.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

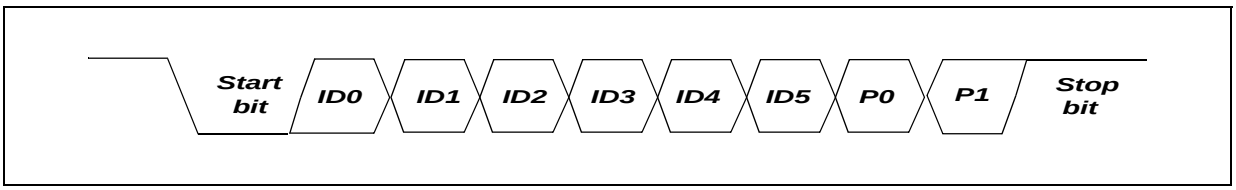

Figure 1742. Sync byte field

56.3.1.5 Identifier

The Identifier field consists of two sub fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 1743. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

56.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it used for communication with LIN 2.0 slaves.

56.3.2 LINFlexD features

56.3.2.1 Operating modes

The LINFlexD has three operating modes: Initialization, Normal, and Sleep modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

56.3.2.1.1 Initialization mode (INIT)

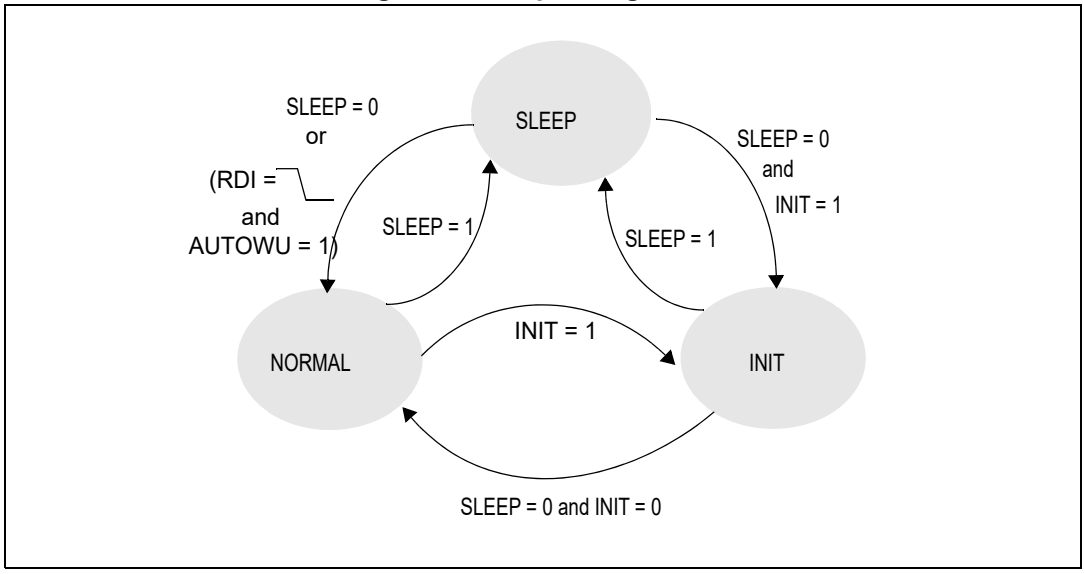
To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. Set up the baud rate registers
2. Reset the UART bit
3. Select the mode (Master or Slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

56.3.2.1.2 Normal mode (NM)



Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

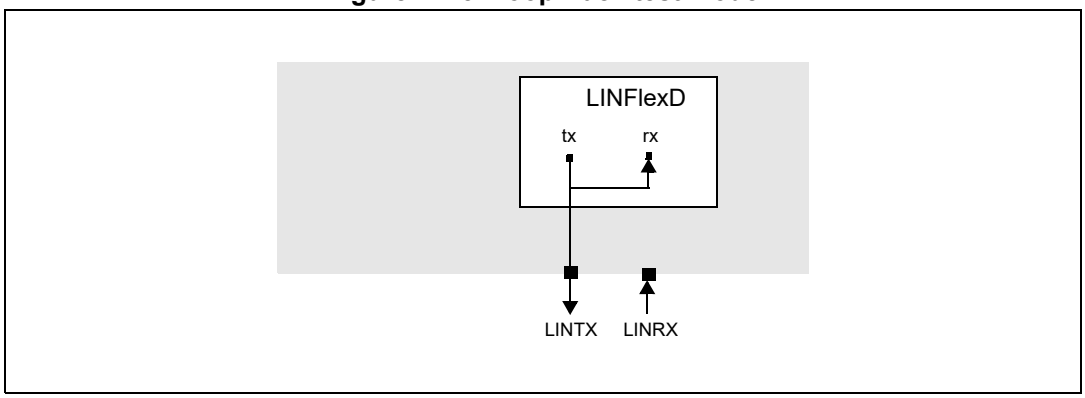
56.3.2.1.3 Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to *Section 56.3.2.10: Wakeup management*.

Figure 1744. Operating modes

56.3.2.2 Test mode



56.3.2.2.1 Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and

Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

Figure 1745. Loop Back test mode

56.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

56.3.2.3.1 Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

56.3.2.3.2 Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

56.3.2.3.3 Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

56.3.2.3.4 Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

56.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

56.3.2.4.1 Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

56.3.2.4.2 Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

56.3.2.5 Errors

56.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- That the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,

  or

- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field, referring to this period deviation as D.

   If there is an inconsistent Sync Field error, it means that:

   D > 14.0625%

   If there is no error, it means that:

   D < 14.84375%

   If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 0)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

1. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

56.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles. Bit error is not checked during break field transmission.

Example 1

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In

this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

56.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

56.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINIER.

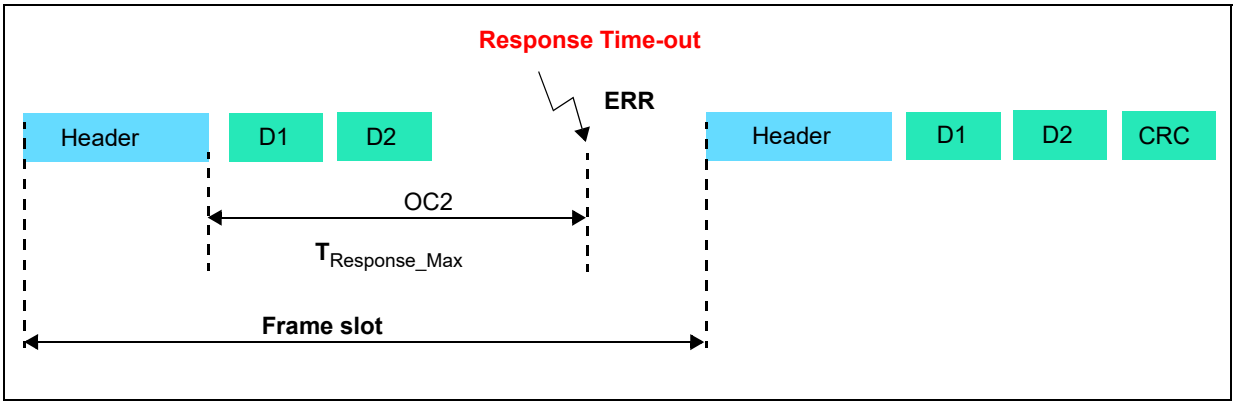
56.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

56.3.2.5.6 Timeout error

Figure 1746. Incomplete response (for example, missing checksum)



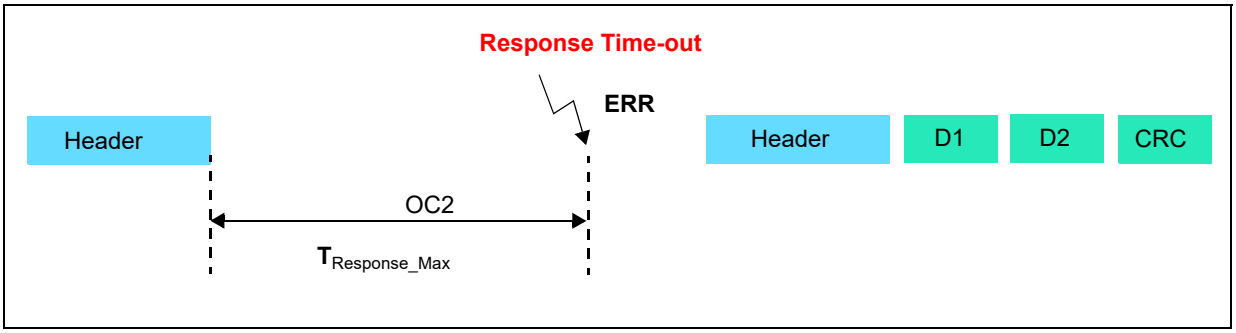


Figure 1747. No response

Header timeout mechanism

- Master mode
  - ocr_2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further ocr_2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the ocr_2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the ocr_2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, ocr_2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = 1.4 × (9 × 10 bit time) and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:

    At the end of the ID, ocr_2 is loaded with 36 (maximum possible response space)

    At the end of the first_data_byte it is reloaded again according to DFL

    Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length).
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

    Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit.
  - If the counter starts after 11 Tbit, the HTO value is 56 – 11 = 45 Tbit

    The reset value of HTO is 45 and this register can only be programmed in slave mode.

    As response space is now included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

    The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

56.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th, and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (refer to *Section 56.4.2.4: LIN Error Status Register (LINESR)*).

56.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a

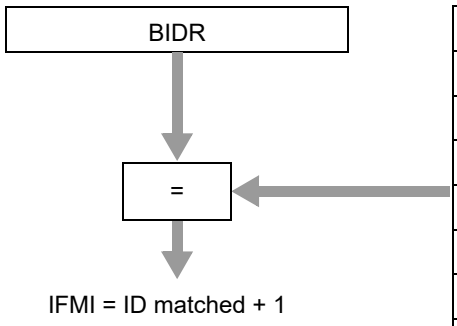
filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

56.3.2.6.1 Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2*n* and 2*n*+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2*n* or IFCR2*n*+1 (if the corresponding FACT bit is set).

56.3.2.6.2 Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2*n* is the filter and 2*n*+1 acts as a mask for it. The FACT bit for filter 2*n*+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.



If there is a match of identifier with the *m*th filter in any mode, then *m*+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note: If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.

56.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 1765. 10-bit-shift-register sample register

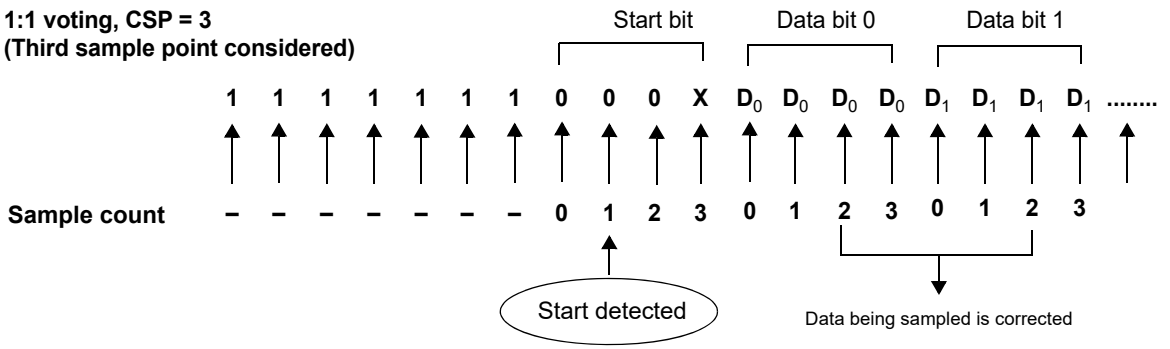
Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x(1)	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: due to sampling during transition of the bit, the bit value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. So ‘x’ refers to an indeterministic value.

56.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to *Table 1765* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘0’ (2 or more), then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.



56.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to *Table 1765* for the status of the sample register (shift register) when count = 6.
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority of these 3 samples are equal to ‘1’ (2 or more), then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

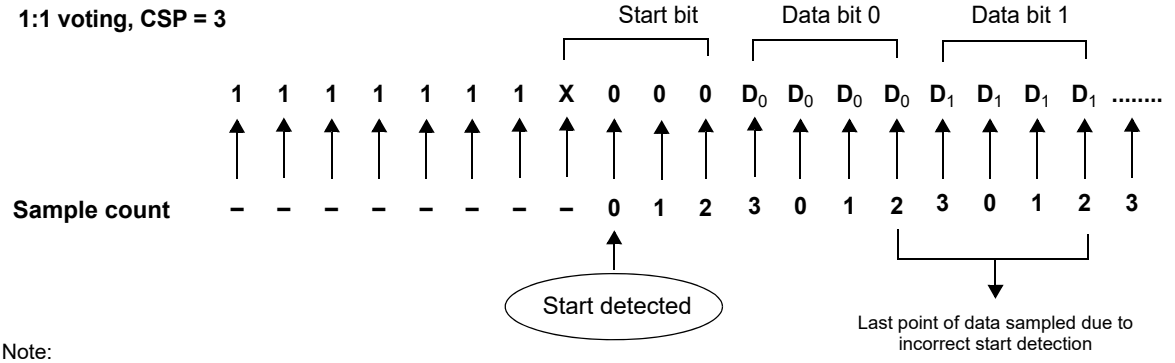


Figure 1750. Start detection and sampling for over sampling rate = 4 (Case 1)

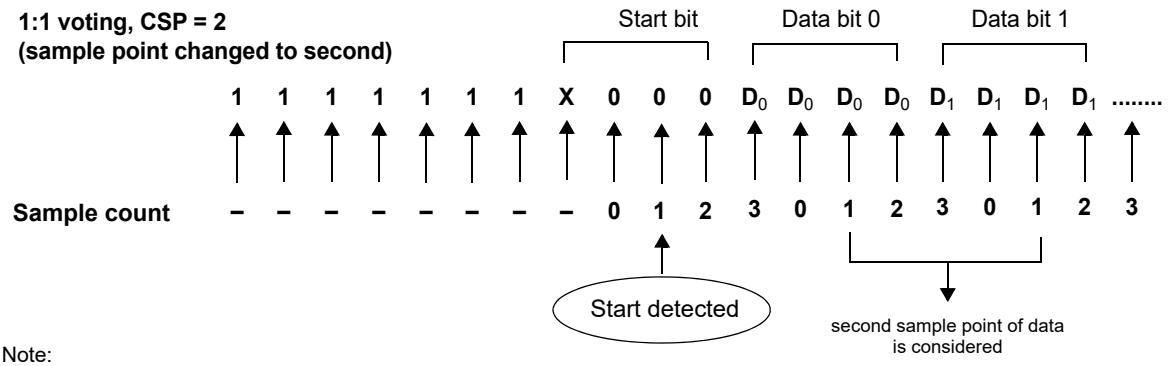
Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

Figure 1751. Start detection and sampling for over sampling rate = 4 (Case 2a)



Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two resulting in the following situation:

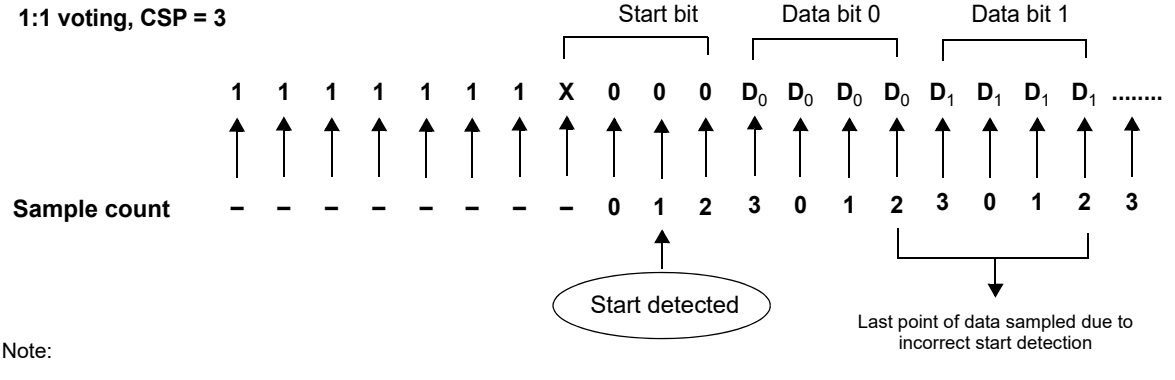


Figure 1752. Start detection and sampling for over sampling rate = 4 (Case 2b)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

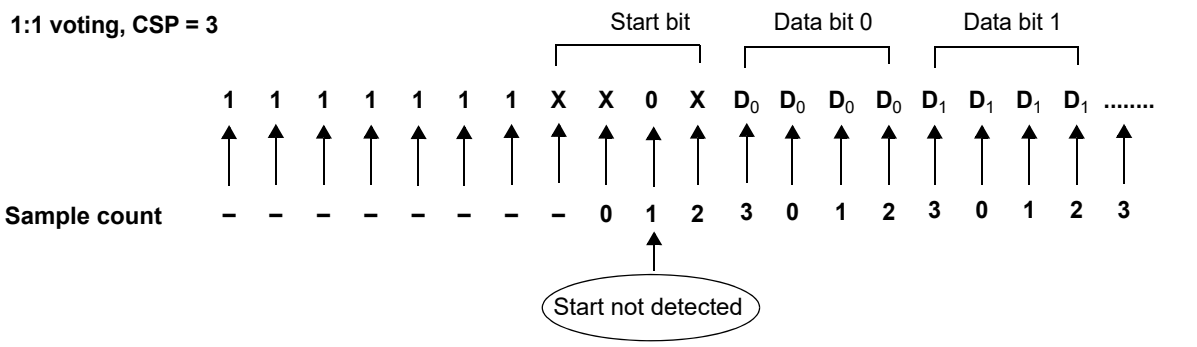

Figure 1753. Start detection and sampling for over sampling rate = 4 (Case 3)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

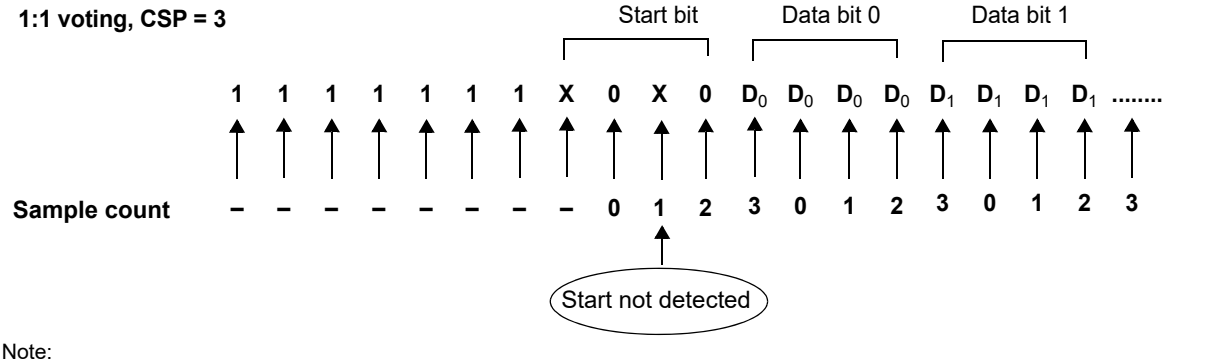

Figure 1754. Start detection and sampling for over sampling rate = 4 (Case 4)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

Figure 1755. Start detection and sampling for over sampling rate = 4 (Case 5)

Note:

1. D_0, D_1: Databits
2. X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a non deterministic value.

56.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Equation 86 Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled LINFBRR is not used and LDIV contains only the integer part of LINIBRR.

Example 2

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Baud rate = 80 MHz/(16 x 1041,67) = 4.8 Kbit/s

Example 3

When ROSE = 1 (Only for UART mode):

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, OSR = 4

Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

Note: Due to design constraints the maximum baud rate achievable is 25 Mbit/s.

The relationship "(2/3)* LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK" should be maintained)

56.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

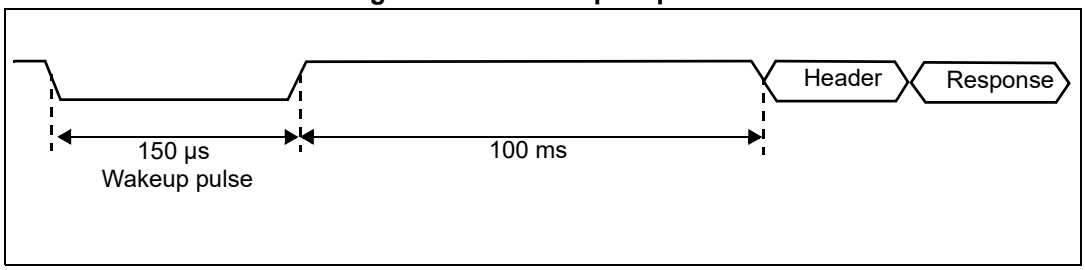
When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

56.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.



1. AUTOWU = 1

   On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.

2. AUTOWU = 0

   On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 1756. Wakeup sequence

56.3.2.11 Use case and limitations

In LIN mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

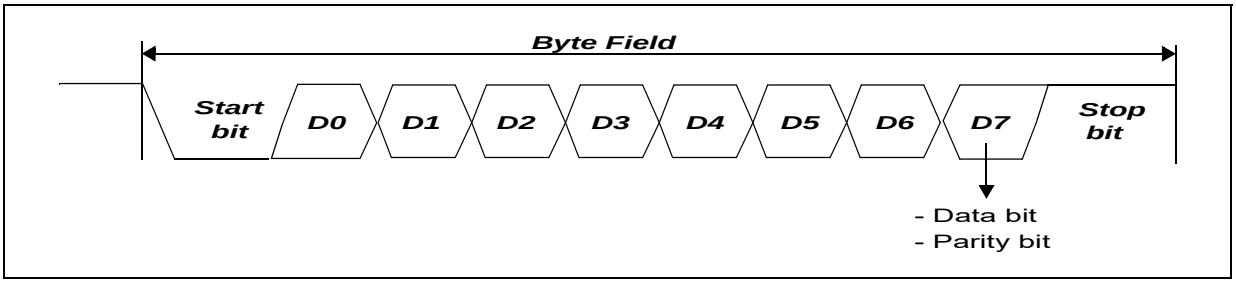
56.3.3 Timer

There is an 8-bit counter which has different behavior in different modes.

In Output Compare Mode (LINTCSR[MODE]= 1) : This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has soft reset the LIN IP through GCR [SR] bit to get reset the output compare flag (LINESR[OCF]).

In LIN Mode : The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

56.3.4 UART mode



The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames,16-bit frames,17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

56.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

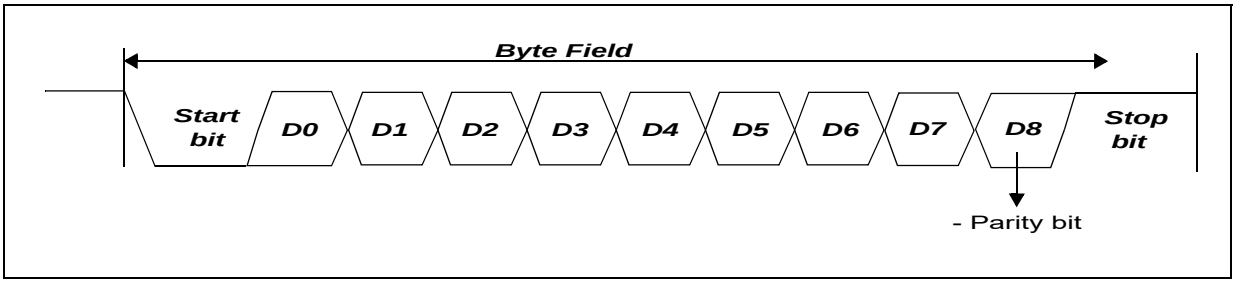


Figure 1757. UART mode 8-bit data frame

56.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

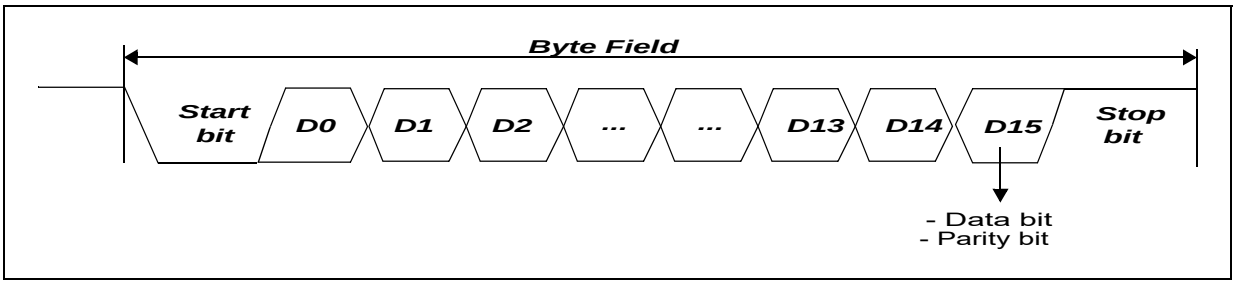

Figure 1758. UART mode 9-bit data frame

56.3.4.3 16-bit data frames

The 16th bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

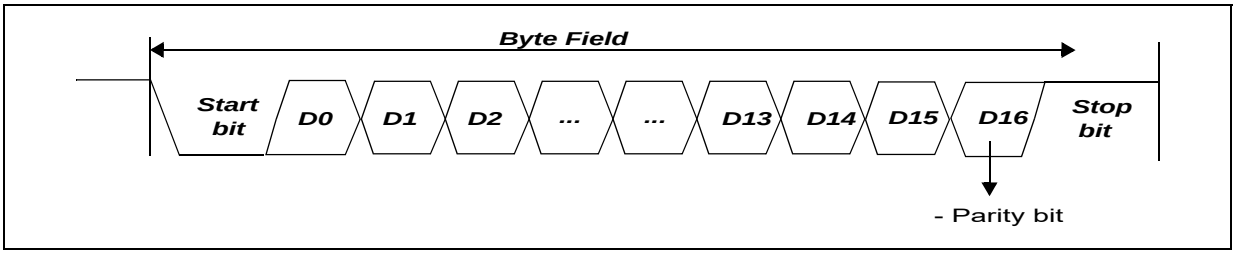

Figure 1759. UART mode 16-bit data frame

56.3.4.4 17-bit frames

The 17th bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

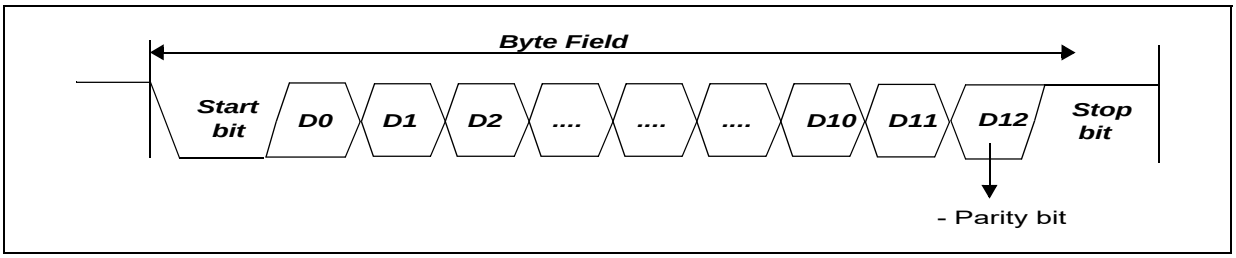

Figure 1760. UART mode 17-bit data frame

56.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

Figure 1761. UART mode 13-bit data frame

56.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in *Figure 1762*.

Figure 1762. Structure of 8-byte buffer

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1.

The same applies for reception.

56.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Invalid writes to BDRL which generates IPS transfer error, also triggers data transmission at the same time.

When the FIFO is full, a read to DATA0 of BDRM reflects the content of DATA3 in BDRL. Proper functionality of the IP is not affected by this.

Table 1766. BDRL access in UART mode

IPS operation(1)	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

56.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 1767. BDRM access in UART mode

IPS operation(1)	Register (2)	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.
   Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.
2. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.

Note: If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the

reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.

If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.

If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.

If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.

If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.

When WLS bit = 1, BDRM access depends on WL bit setting.

When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.

In UART FIFO mode, when IP is requested to enter STOP mode, the SW has to first set the INIT bit to send the receiver to IDLE. This ensures that the IP acknowledges STOP request.

56.3.5 DMA interface

56.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

56.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in *Table 1768* and *Table 1769*.

Table 1768. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: 1 8 bytes: normal frames 1 64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full

Table 1768. LINFlexD control/status fields description (continued)

Register	Field	Level	Description

DMATXE[2**TX_CH_NUM](1)		High	DMA Tx channel enable (read/write)
			In UART or LIN master mode only channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1.
			DMATXE[x] = 0b → TX channel x disabled
			DMATXE[x] = 1b → TX channel x enabled

DMARXE[2**RX_CH_NUM](1)		High	DMA Rx channel enable (read/write)
			In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1.
			DMARXE[x] = 0b → RX channel x disabled
			DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation

Table 1769. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the Transfer Control Descriptors (TCDs) referred to in this document are described in *Table 1770*.

Table 1770. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.

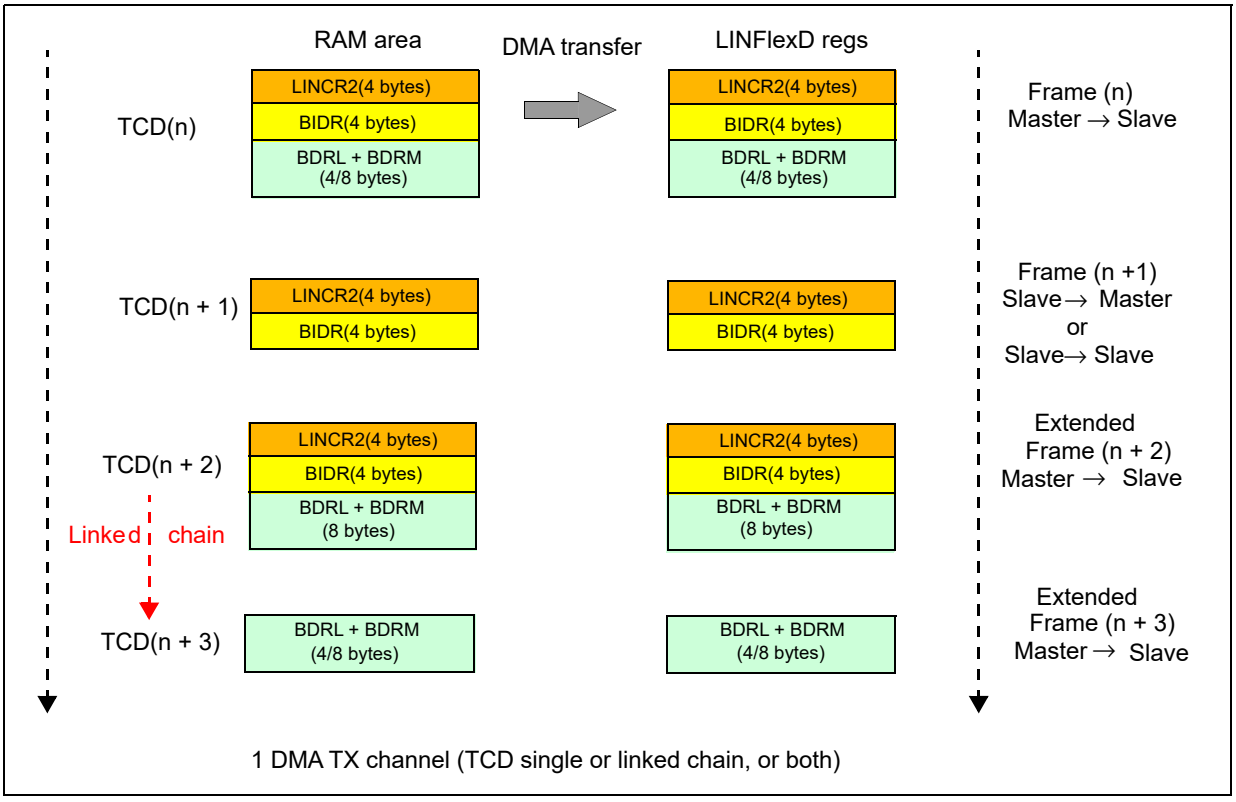

Table 1770. TCD control fields description (continued)

TCD field	Level	Description
SSIZE[2:0]	—	Source data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 8-bit 001 16-bit 010 32-bit 011 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

56.3.5.3 Master node: TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1763*.

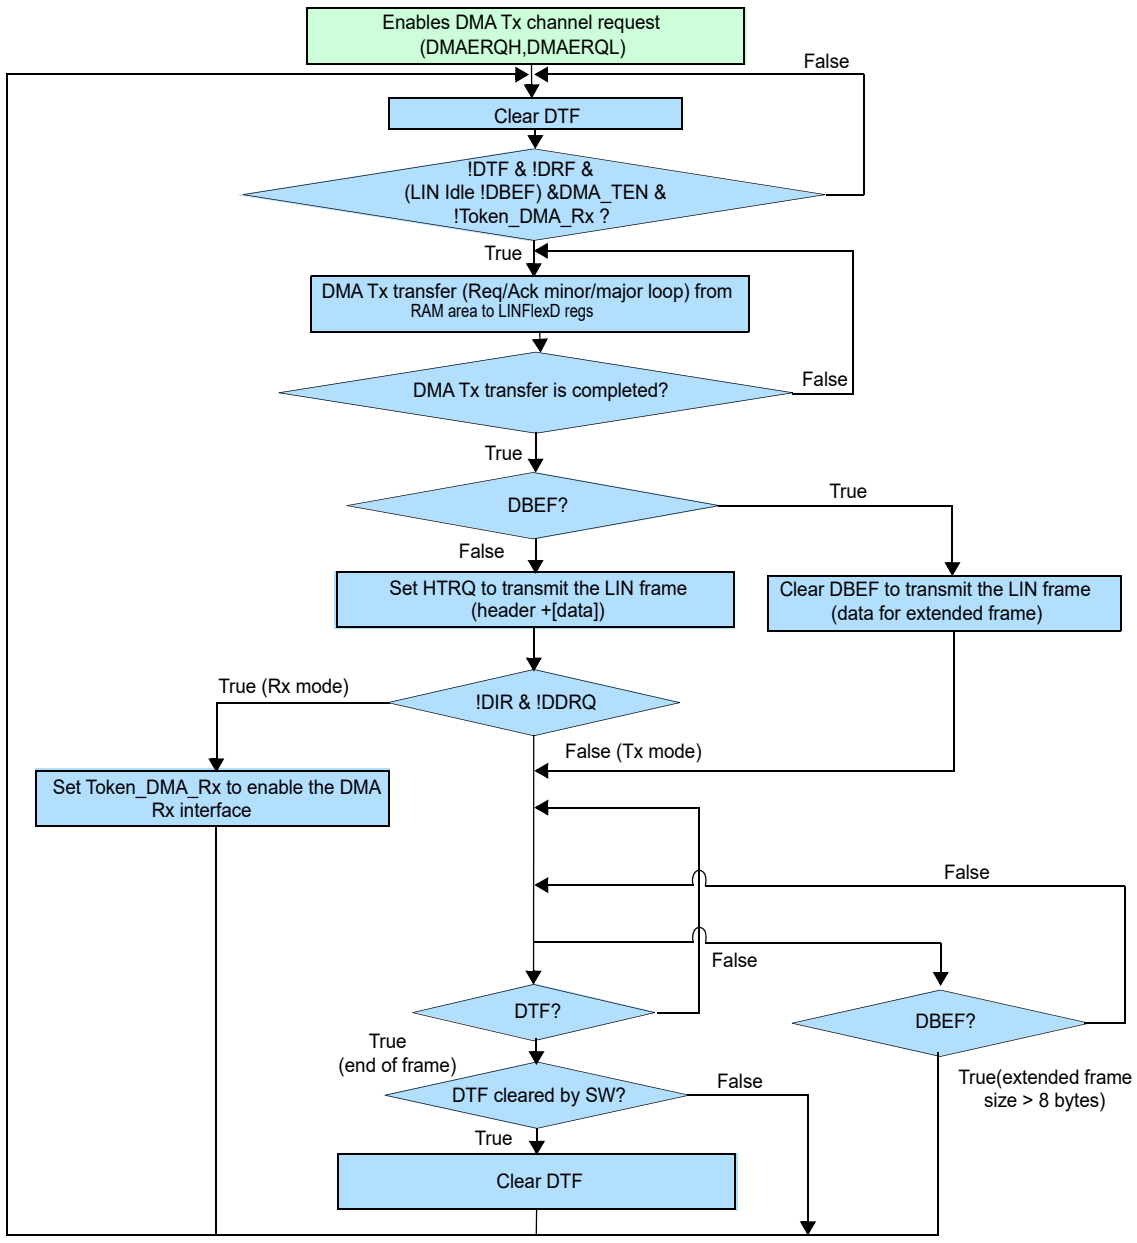
Figure 1763. Master node: TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

Table 1771 provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 1771. Master node: Tx mode - Register setting



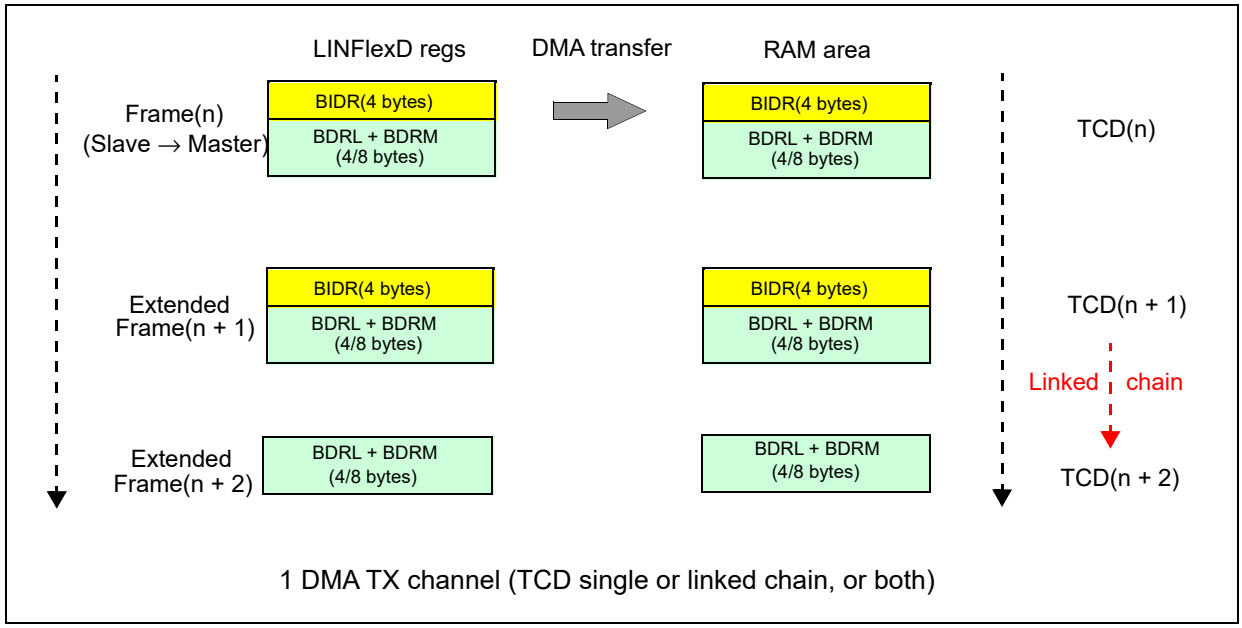
LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in *Figure 1764*. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in *Table 1772*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1772. TCD setting: Master node -Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1764. Master node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

56.3.5.4 Master node: RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1765*.

Figure 1765. Master node: RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in *Figure 1766*. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in *Table 1773*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

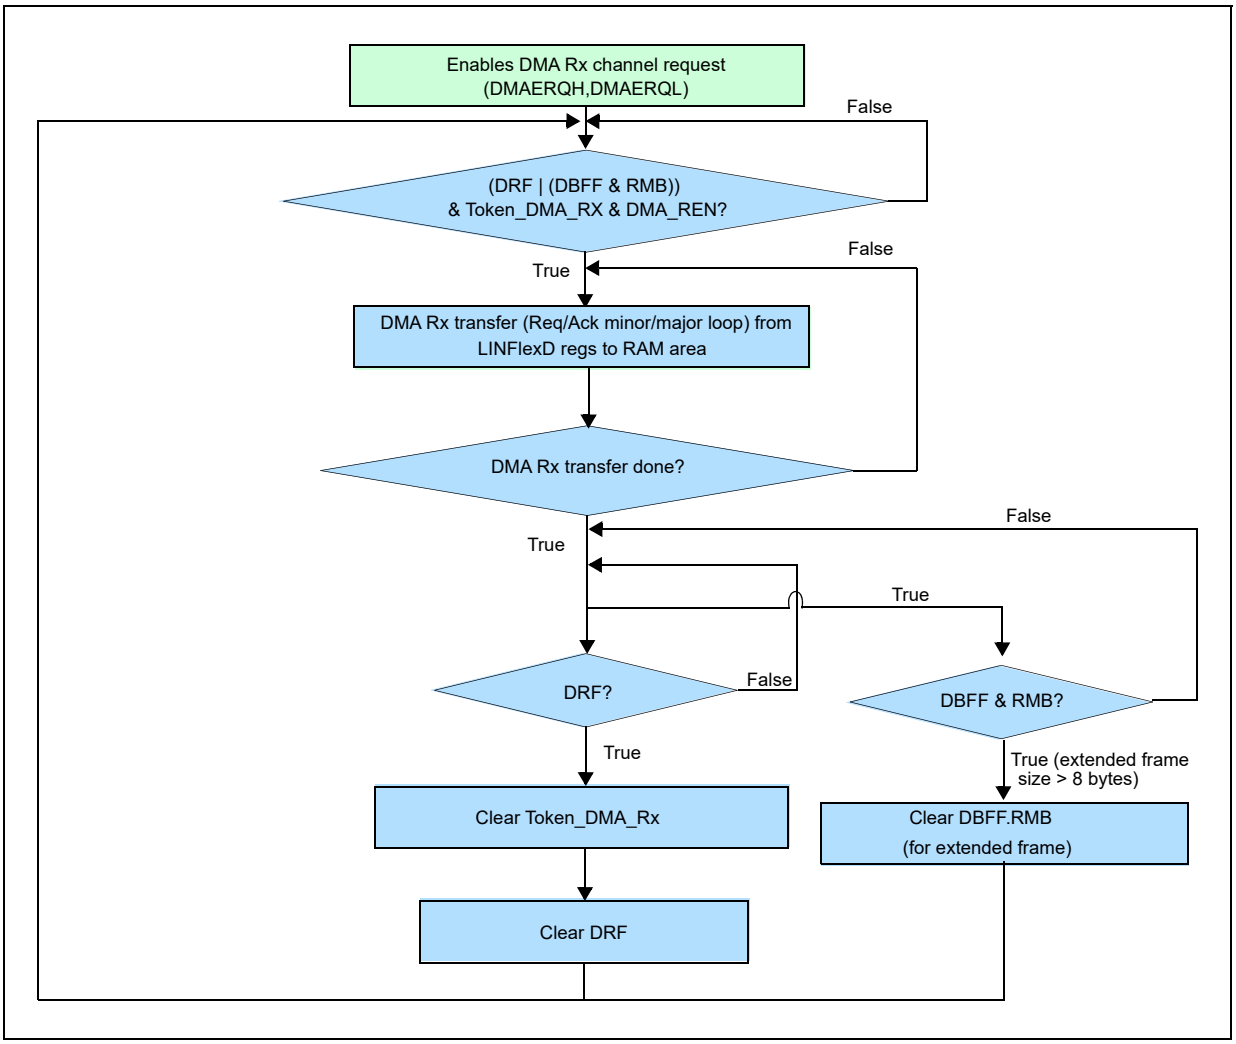


Table 1773. TCD setting: Master node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 1773. TCD setting: Master node - Rx mode (continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

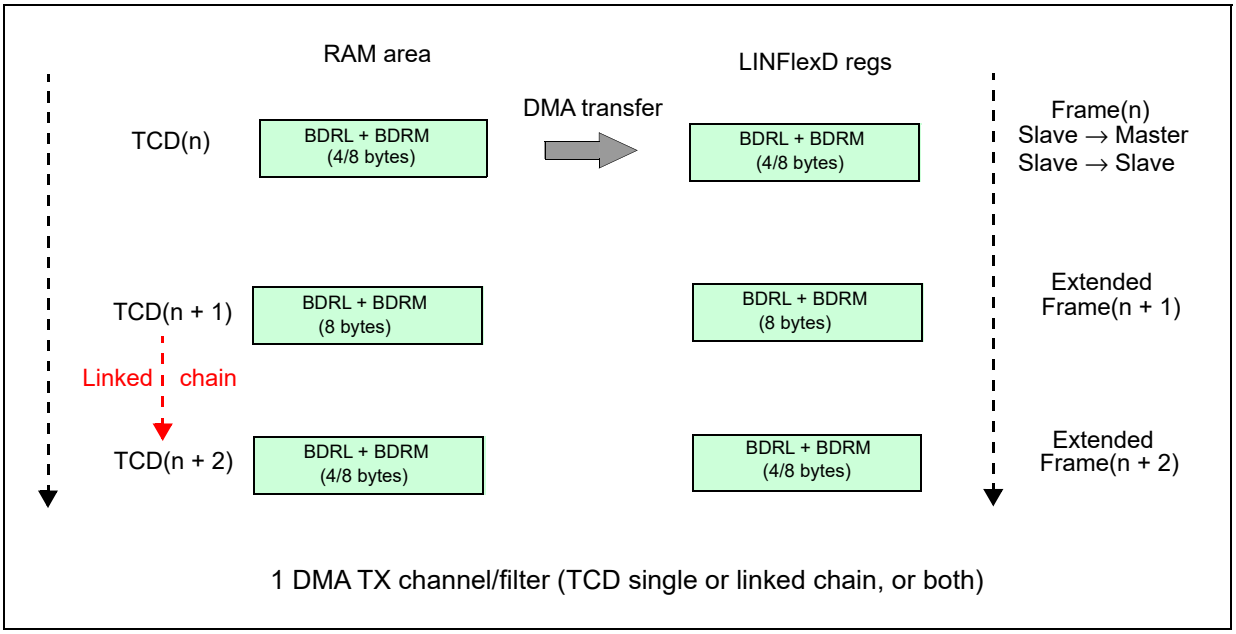

Figure 1766. Master node — DMA Rx FSM (concept scheme)

56.3.5.5 Slave node: TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1767*.

Figure 1767. Slave node — TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1774*.

Table 1774. Slave node: Tx mode - Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in *Figure 1768*. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1775*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

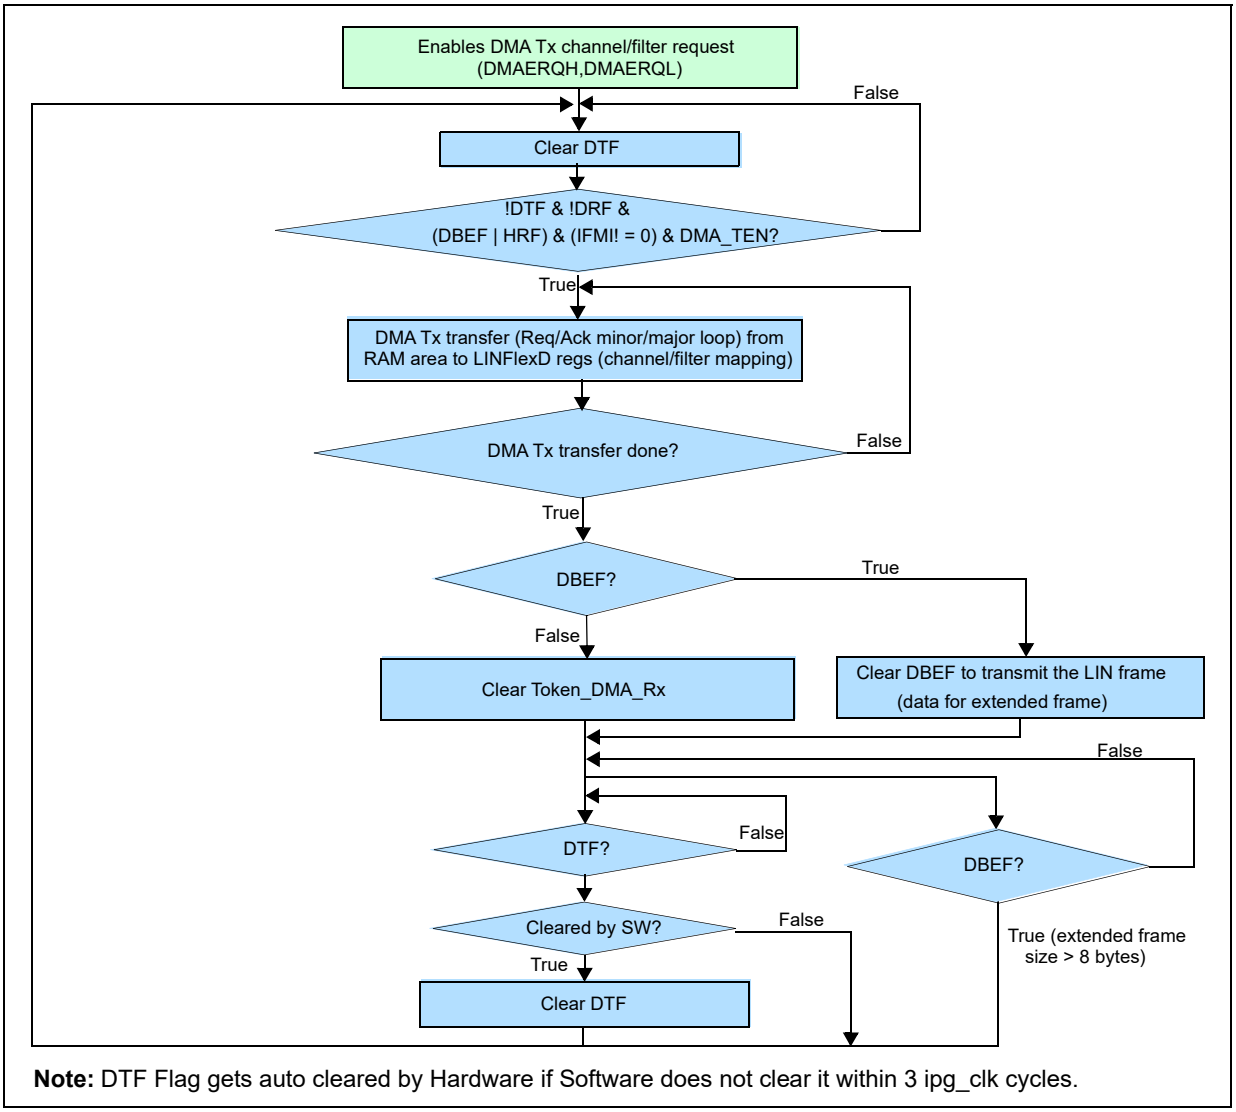

Table 1775. TCD setting: Slave node - Tx mode

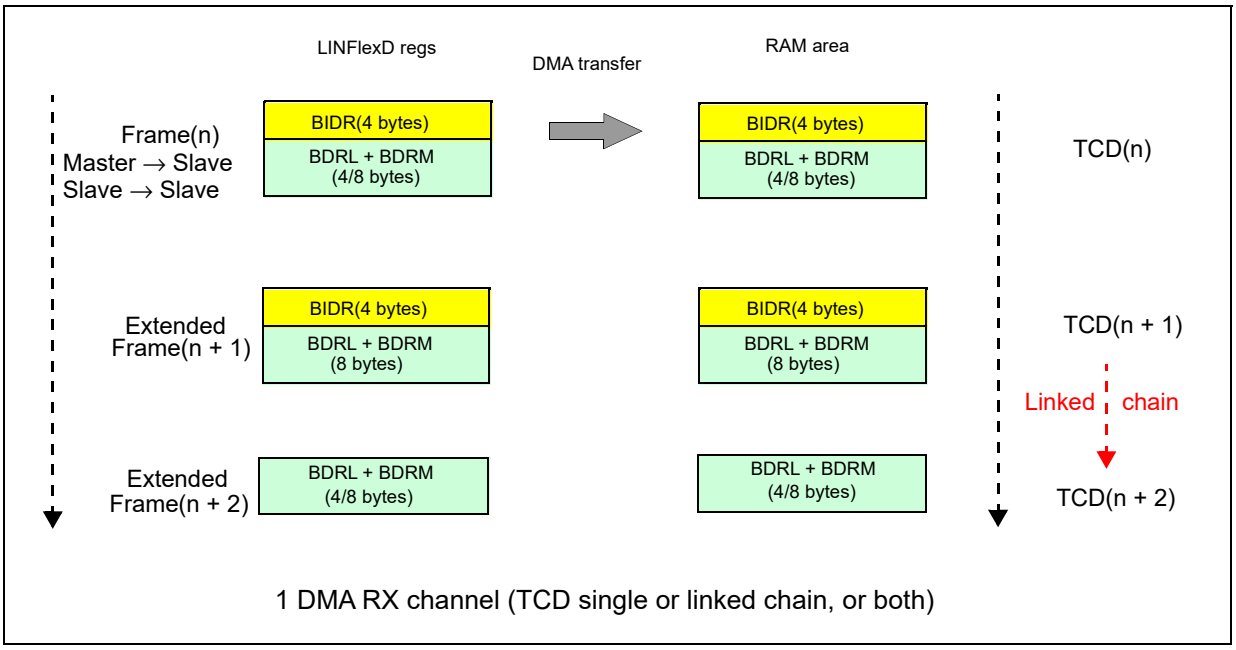
TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 1775. TCD setting: Slave node - Tx mode (continued)

TCD field	Value	Description
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	-N	—
DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1768. Slave node: DMA Tx FSM (concept scheme)



Note: DTF Flag gets auto cleared by Hardware if Software does not clear it within 3 ipg_clk cycles.

56.3.5.6 Slave node: RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1769*.

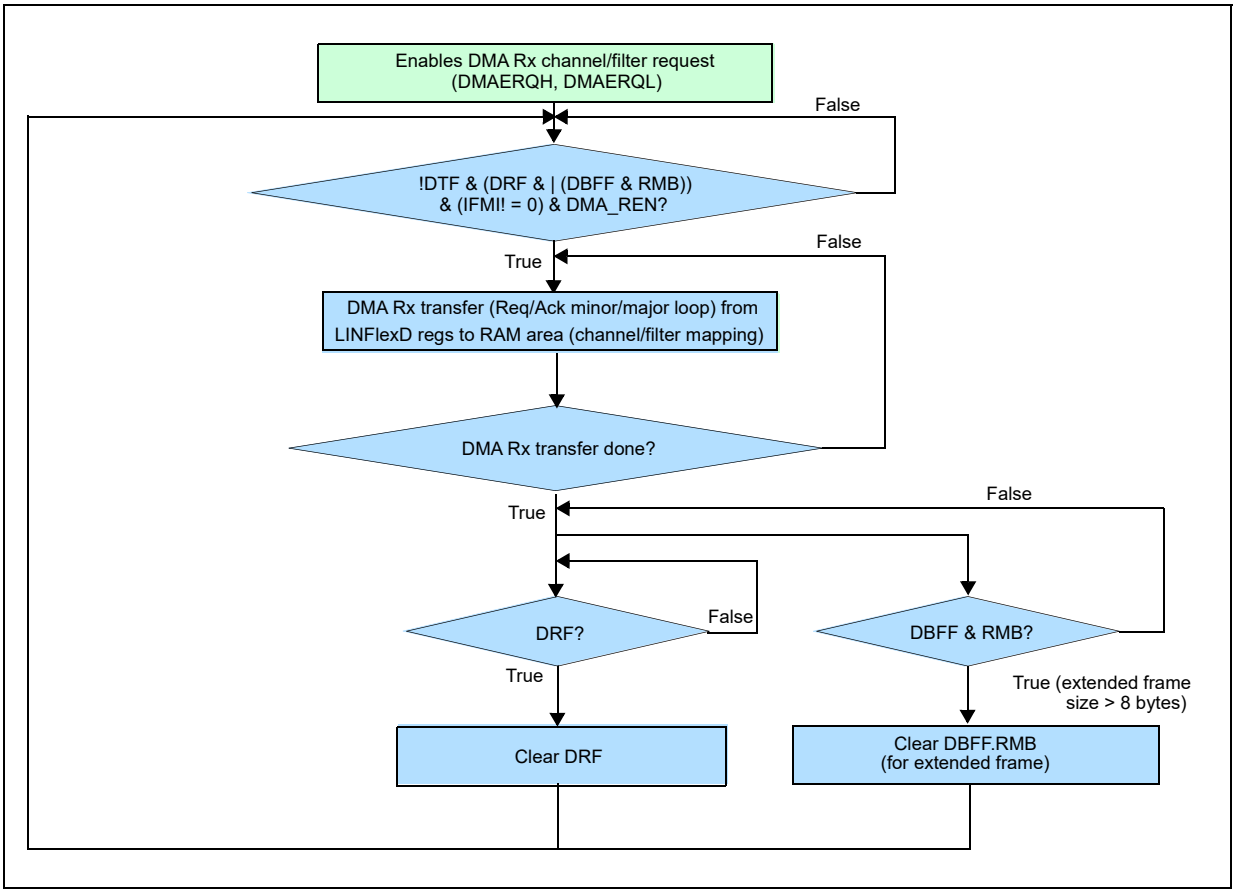
Figure 1769. Slave node: RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1776*.

Table 1776. Slave node: Rx mode - Register setting



LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in *Figure 1770*. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1777*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1777. TCD setting: Slave node - Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address

SLAST[31:0]	-N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	-N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

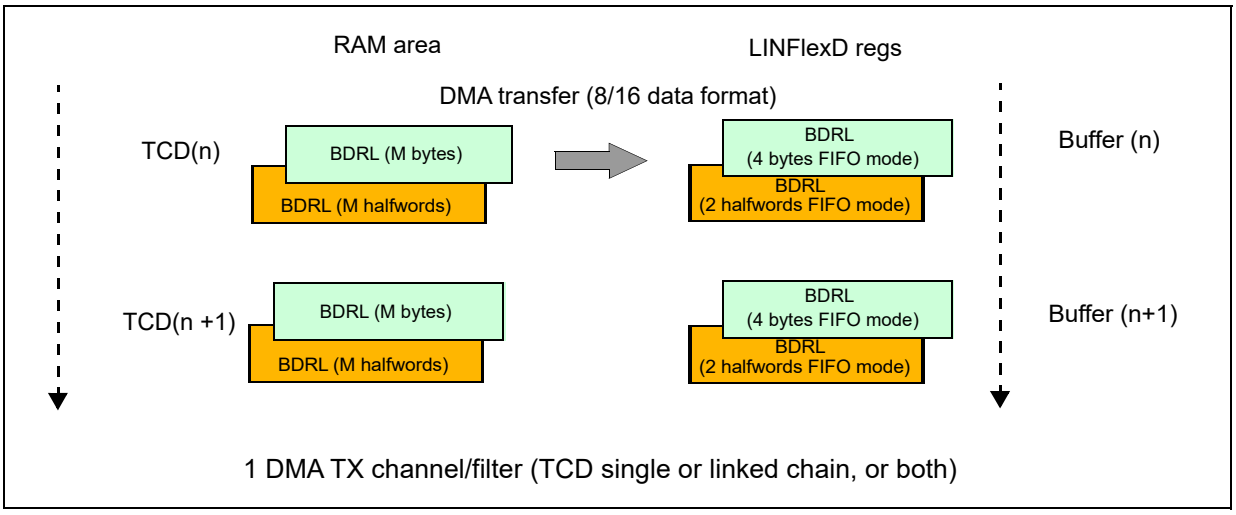

Figure 1770. Slave node — DMA Rx FSM (concept scheme)

56.3.5.7 UART: TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1771*.

Figure 1771. UART: TX memory map

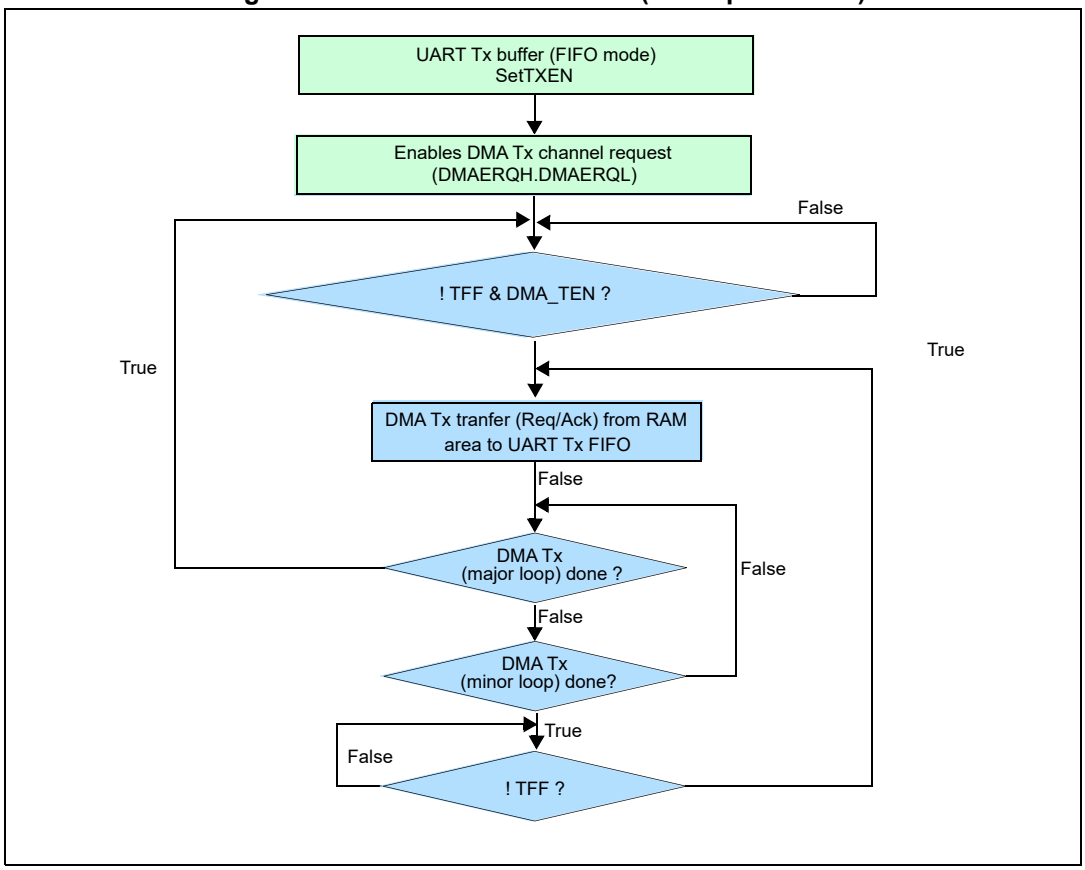
The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.



The concept FSM to control the DMA Tx interface is given in *Figure 1772*. DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in *Table 1778*. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 1778. TCD setting: UART - Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	-M	-M × 2	—
DADDR[31:0](1)	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

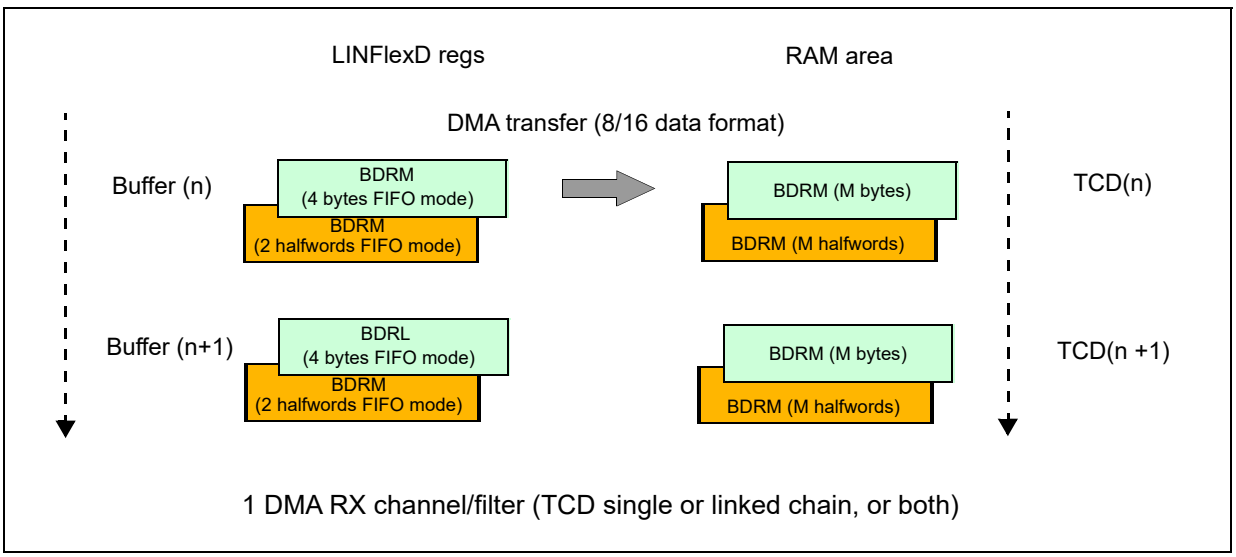


Figure 1772. UART: DMA Tx FSM (concept scheme)

56.3.5.8 UART: RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Table 1779*.

Figure 1773. UART: RX memory map

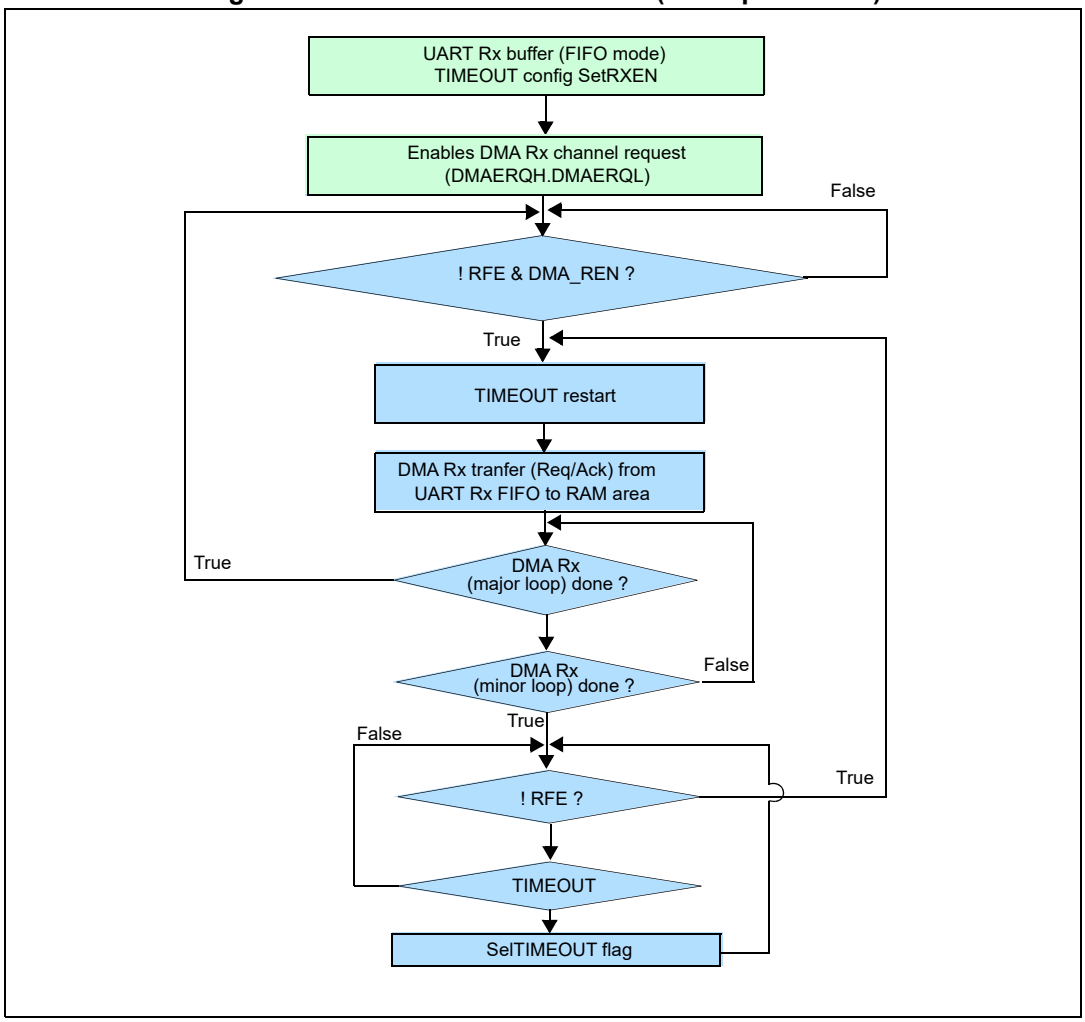
The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.



The concept FSM to control the DMA Rx interface is given in *Figure 1774*. DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 1779. TCD setting: UART - Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0](1)	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	-M	-M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 1774. UART — DMA Rx FSM (concept scheme)

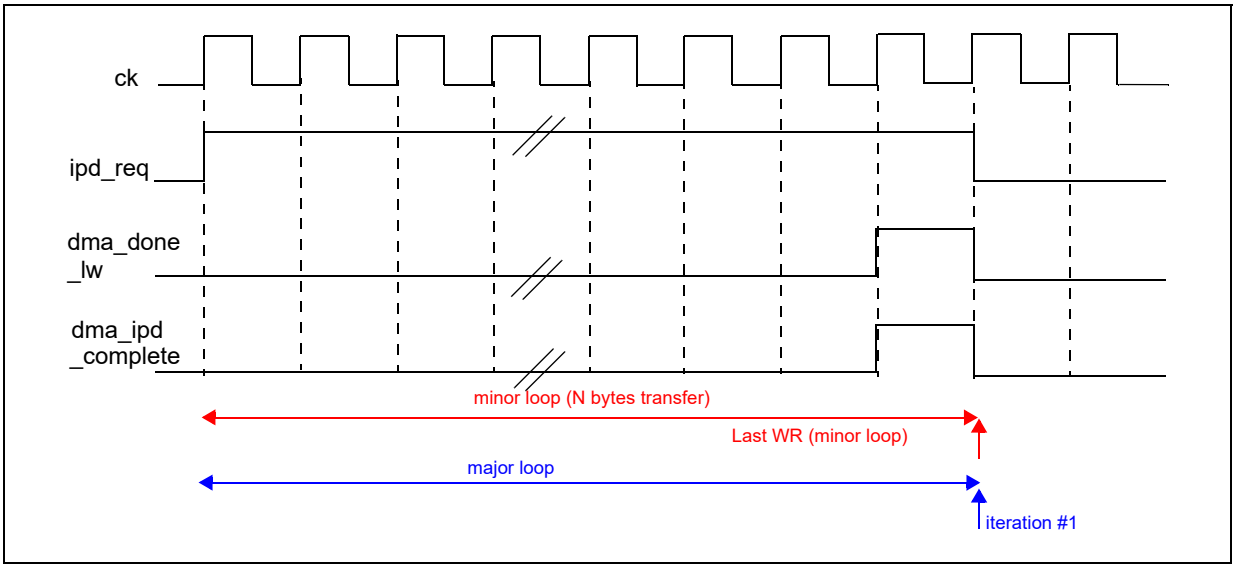
56.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- ipd_req
  - DMA peripheral request, asserted until the DMA transfer has been completed.
- dma_done_lw
  - DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected.
- dma_ipd_complete
  - DMA major loop finished. It is asserted for one cycle after the data phase of the last write.
- dma_ipd_ack, dma_ipd_done
  - Unused in this implementation.

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 1775. DMA interface (major loop — single iteration)



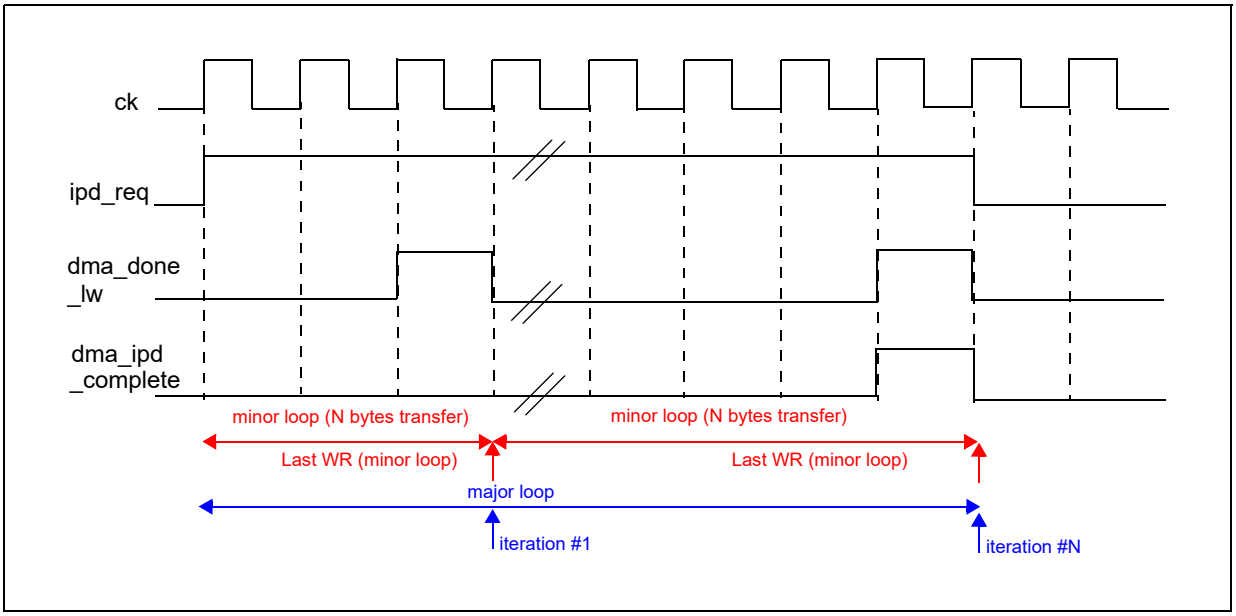


Figure 1776. DMA interface (major loop — N iteration)

56.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA

channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

56.4 Memory map and register description

Note: Refer to the LINFlexD configuration section of the Device Configuration chapter for registers implementation per LINFlexD instance.

56.4.1 Memory map

Table 1780 shows the LINFlexD memory map.

Note: In Master mode, the registers IFCR0–IFCR15 are not present.

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in bus transfer error.

56.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format.
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

56.4.2.1 LIN Control Register 1 (LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

Address: 0x0000 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

R	CCD(1)	CFD(1)	LASE(1)	AUTOWU(1)	MBL(1)				BF(1)	0	LBKM(1)	MME(1)	SSBL(1)	RBLM(1)	SLEEP	INIT
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1(2)	0	0	1	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When slave = 0, this field reads '1' and cannot be programmed.

Figure 1777. LIN Control Register 1 (LINCR1)

Table 1781. LINCR1 field descriptions

Field	Description
16 CCD	Calculation disable 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read-only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).

Table 1781. LINCR1 field descriptions (continued)

Field	Description
19 AUTOWU	Auto Wakeup 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.
20:23 MBL[3:0]	Master Break Length These bits choose the length of the Sync break to be generated by the master. 0x0 10-bit break length 0x1 11-bit break length 0x2 12-bit break length 0x3 13-bit break length 0x4 14-bit break length 0x5 15-bit break length 0x6 16-bit break length 0x7 17-bit break length 0x8 18-bit break length 0x9 19-bit break length 0xA 20-bit break length 0xB 21-bit break length 0xC 22-bit break length 0xD 23-bit break length 0xE 36-bit (cooling) break length 0xF 50-bit break length These bits can be programmed in Initialization mode only. They are read-only in Normal mode.
24 BF	By-pass filter 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter This bit can be programmed during Initialization mode only. Note: If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.
25	Reserved
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to *Section 56.3.2.2*. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. If generic *slave* = 0, then this bit will read a ‘1’ always, and cannot be programmed.

Table 1781. LINCR1 field descriptions (continued)

Field	Description
28 SSBL	Slave Mode Sync Break Length 0 11-bit break length 1 10-bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

56.4.2.2 LIN Interrupt enable register (LINIER)

Address: 0x0004 Access: User read/write

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1778. LIN Interrupt enable register (LINIER)

Table 1782. LINIER field descriptions

Field	Description
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **Note:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.

Table 1782. LINIER field descriptions (continued)

Field	Description
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE_TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

56.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0x0008 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Figure 1779. LIN Status Register (LINSR)

Table 1783. LINSR field descriptions

Field	Description
12 AUTOSYNC_COMP	Autosynchronization Completed This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers should be read in autosynchronization mode.
13:15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 1783. LINSR field descriptions (continued)

Field	Description
16:19 LINS	LIN state 0x0 Sleep mode LINFlexD is in Sleep mode to save power consumption. 0x1 Init 0x2 Idle This mode is entered when: SLEEP bit and INIT bit are reset by software, Wakeup pulse has been received on RX pin (AUTOWU set), Previous frame transmission/reception has been completed/aborted. 0x3 Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0x4 Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0x5 Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0x6 Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0x7 Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 0x8 Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 0x9 Checksum Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXBUSY	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.

Table 1783. LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **Note:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin and when: The slave is in Sleep mode The master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next eight bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: All filters are inactive and Bypass filter (BF) bit is set No match in any filter and Bypass filter (BF) bit is set TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

56.4.2.4 LIN Error Status Register (LINESR)

Address: 0x000C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1780. LIN error status register (LINESR)

Refer to *Section 56.3.2.5: Errors* for detailed description of all errors.

Table 1784. LINESR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

Table 1784. LINESR field descriptions (continued)

Field	Description
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **Note:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

56.4.2.5 UART Mode Control Register (UARTCR)

Address: 0x0010 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS(1)	CSP(1)			OSR(1)				ROSE(1)	NEF(1)(2)			DTU_PCETX(1)	SBUR(1)		WLS(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TDFL_TFC(2)			RDFL_RFC(3)			RFBM(1)	TFBM(1)	WL1(1)	PC1(1)	RXEN	TXEN	PC0(1)	PCE(1)	WL0(1)	UART(1)
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. When TFBM = 0, the field is read/write; when TFBM = 1, the field is read-only.
3. When RFBM = 0, the field is read/write; when RFBM = 1, the field is read-only.

Figure 1781. UART Mode Control Register (UARTCR)

Table 1785. UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 1 UARTCTO monitors the idle state of the reception line. 0 UARTCTO monitors the number of bits to be received. The default value of this bit is 0.
1:3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: – OSR 4: CSP 2, 3 – OSR 5: CSP 2, 3, 4 – OSR 6: CSP 3, 4, 5 – OSR 8: CSP NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4:7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9:11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received (num_of_frames). When num_of_frames equals NEF, Disable Timeout is set and num_of_frames gets reset to zero, restarting the timer and enabling the timeout again.
13:14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.

Table 1785. UARTCR field descriptions (continued)

Field	Description
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.
16:18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL_TFC defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL_TFC is a read/write field. TDFL_TFC[2] is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL_TFC = x01 or TDFL_TFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes TDFL_TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TDFL_TFCx is a read-only field available for debug purposes. 000 empty 001 1-byte 010 2-bytes 011 3-bytes 100 4-bytes Others: Reserved **Note:** TDFL_TFC can be programmed and are significative only when the UART bit is set.
19:21 RDFL_RFC	Reception Data Field Length/RX FIFO Counter RDFL_RFC defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL_RFC is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL_RFC = x01 or RDFL_RFC = x11 are allowed. x00 1-byte x01 2-bytes x10 3-bytes x11 4-bytes RDFL_RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RDFL_RFCx is a read-only field available for debug purposes. 000 Empty 001 1-byte 010 2-bytes/1.5 byte in case of WLS bit setting 011 3-bytes 100 4-bytes/2×1.5 byte in case of WLS bit setting Others: Reserved RDFL_RFC can be programmed and are significative only when the UART bit is set. **Note:** In buffer mode, RDFL_RFC should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.

Table 1785. UARTCR field descriptions (continued)

Field	Description
22 RFBM	RFBM Rx FIFO/Buffer mode 0 Rx Buffer mode enabled 1 Rx FIFO mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx FIFO/Buffer mode 0 Tx Buffer mode enabled 1 Tx FIFO mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
26 RXEN	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TXEN	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
29 PCE	Parity Control Enable 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.

Table 1785. UARTCR field descriptions (continued)

Field	Description
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

56.4.2.6 UART Mode Status Register (UARTSR)

Address: 0x0014 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SZF	OCF	PE				RMB	FEF	BOF	RDI	WUF	RFNE	TO	DRF_RFE(1)	DTF_TFF(2)	NF
W	w1c	w1c	w1c				w1c	w1c	w1c	w1c	w1c		w1c			w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. When RFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when RFBM = 1, the field is read-only.
2. When TFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when TFBM = 1, the field is read-only.

Figure 1782. UART Mode Status Register (UARTSR)

Table 1786. UARTSR field descriptions

Field	Description
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. For Baud rate above 1 Mbit/s, this flag is not usable.
18:21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. PE[i] (where i = 0,1,2 or 3) can be equal to: 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **Note:** Parity is checked only after a complete frame is received. When WL bits = 10 or 11, either PE[0] or PE[2] is only set. – When PE[0] is set, it indicates Parity error in either first or second byte received. – When PE[2] is set, it indicates Parity error in either third or fourth byte received.
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table 1786. UARTSR field descriptions (continued)

Field	Description
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF_RFE	Data Reception Completed Flag/Rx FIFO Empty Flag DRF_RFE is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF_RFE should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF_RFE bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF_RFE is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DRF_RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. DRF_RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF_TFF	Data Transmission Completed Flag/TX FIFO Full Flag DTF_TFF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF_TFF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. DTF_TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. DTF_TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

56.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Address: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	MODE(1)	IOT(1)	TOCE	CNT							
W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.

Figure 1783. LIN Time-Out Control Status Register (LINTCSR)

Table 1787. LINTCSR field descriptions

Field	Description
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event This feature is applicable only when MODE bit in LINTCSR is cleared.
23 TOCE	Time-out counter enable 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24:31 CNT	Counter Value These bits reflect the value of a free-running counter used for timeout. **Note:** For proper functionality of this counter, LINIBRR should be greater than or equal to 5. This counter increments once in every bit duration, as per the programmed bit rate. The counter starts as soon as the IP comes out of reset and increments based on the slowest baud rate possible (LINIBRR = FFFFFh), until the user programs LINIBRR and LINFBRR with the desired values.

56.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the count value in LINTOCR register. This register is writable by software only in Output Compare Mode.

Address: 0x001C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	1	1	1	0	0	0	0(1)/1	1(1)/0	1	1	0	0

1. This reset value is valid only in Master mode (slave = 0).

Figure 1785. LIN Time-Out Control Register (LINTOCR)

Table 1789. LINTOCR field descriptions

Field	Description
20:23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0xE = 14, corresponding to $T_{Response_Maximum} = 1.4 * T_{Response_Nominal}$
25:31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is 0x2C = 45, corresponding to $T_{Header_Maximum}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 0x1C = 28 (1.4 × 10 bits of sync + 1.4 × 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

56.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0x0024 Access: User read/write

1. This field can be read in any modes and written only in Initialization mode.
2. This field can be read/set by software.
3. When slave = 0, reset value is '0' and the this field cannot be programmed.

Figure 1789. LIN Control Register 2 (LINCR2)

Table 1793. LINCR2 field descriptions

Field	Description
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. **Note:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **Note:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.

56.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0x0034 Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1790. Buffer Identifier Register (BIDR)

Table 1794. BIDR field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1 **Note:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copies them in the BDRs 1 LINFlexD transmits the data from the BDRs
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = ‘1’).

56.4.2.15 Buffer Data Register Least Significant (BDRL)

This register is a part of an 8-byte data buffer.

Address: 0x0038 Access: User read/write

1. This field can be read in any modes and written only in *Initialization* mode.
2. Refer to the Device Configuration chapter to see the number of filters used in this device.

Figure 1797. Identifier Filter Control Register (IFCR2n+1)

Table 1801. IFCR2*n*+1 field descriptions

Field	Description
16:21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
26:31 ID	Identifier Identifier part of the identifier field without the identifier parity.

56.4.2.22 Global Control Register (GCR)

This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

Address: 0x8C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field can be read in any modes and written only in *Initialization* mode.
2. This field is read 0 by software.

Figure 1798. Global Control Register (GCR)

Table 1802. GCR field descriptions

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. 0 The first bit of received data is LSB – in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB – in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. 0 Received data is not inverted 1 Received data is inverted

Table 1802. GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. The following register fields are reset by SR: LINSR: All fields except RXbusy and AUTOSYNC_COMP LINESR: All fields LINTCSR: Only CNT[0:7] UARTSR: All fields except RFE & TFFt UARTCR: Only TFC & RFC UARTCTO: All fields

56.4.2.23 UART Preset Timeout Register (UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

Address: 0x8C + 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	PTO											
W																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

Figure 1799. UART Preset Timeout Register (UARTPTO)

Table 1803. UARTPTO field descriptions

Field	Description
20:31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A value of 0, 1 or 2 is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer to the UARTCTO register.

56.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (refer to *Section 56.4.2.23*) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

*Note: Due to this synchronisation, UARTCTO reflects the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) which was present on it, before 4 to 6 clock cycles of PBRIDGEx_CLK.*

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO-1
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

Address: 0x8C + 0x08 Access: User read

Field	Description
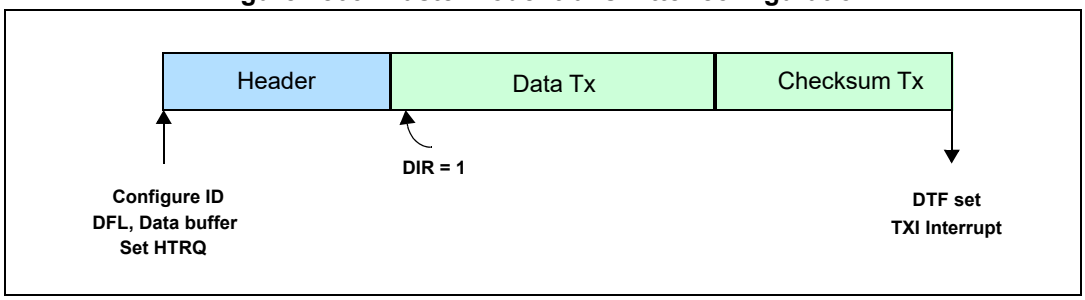
(32–2^RX_CH_NUM):31 DRE[(2^RX_CH_NUM-1):0]	DMA Rx channel Y enable 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled **Note:** The actual size of the register DMARXE depends on the value of the static parameter RX_CH_NUM. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. Refer to the device configuration chapter for the value of RX_CH_NUM used in this device.

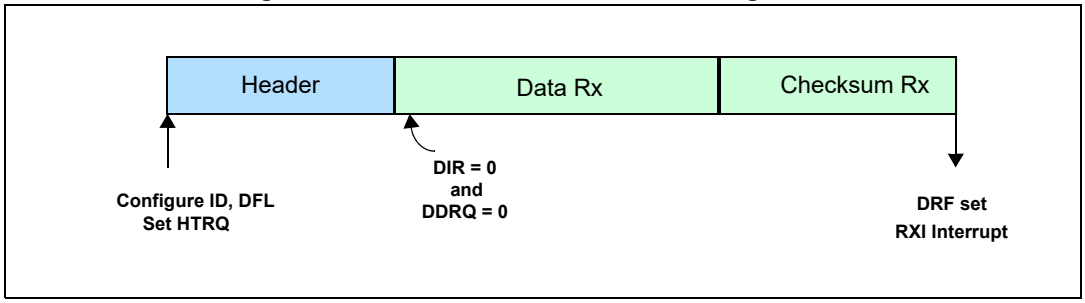
56.5 Programming considerations



The next subsections describe the various configurations in which the LINFlexD module can be used.

56.5.1 Master node

LINFlexD acts as Master when the MME bit is set.



56.5.1.1 Transmitter

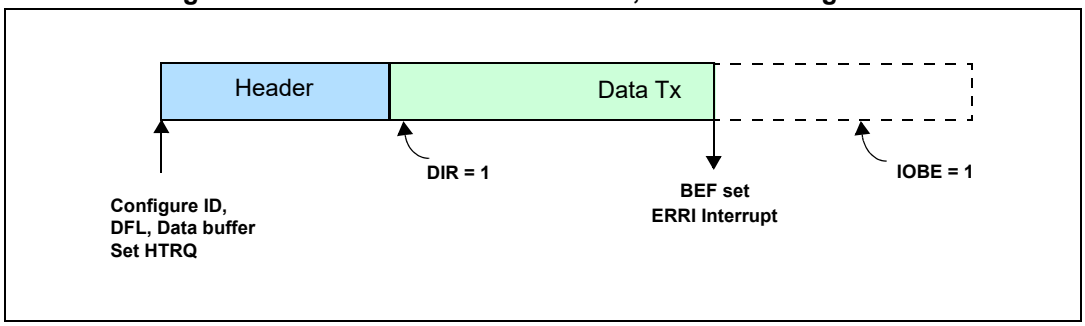
Figure 1803. Master node: transmitter configuration

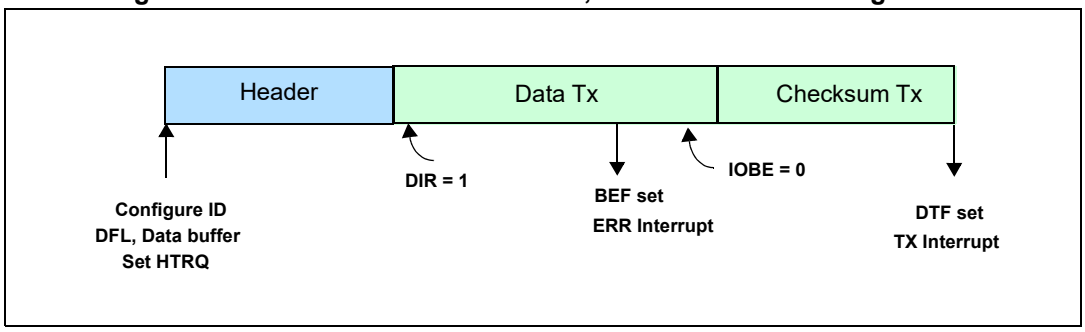
56.5.1.2 Receiver

Figure 1804. Master node: receiver configuration

56.5.1.3 Transmitter, Bit Error

Figure 1805. Master node: transmitter, bit error configuration





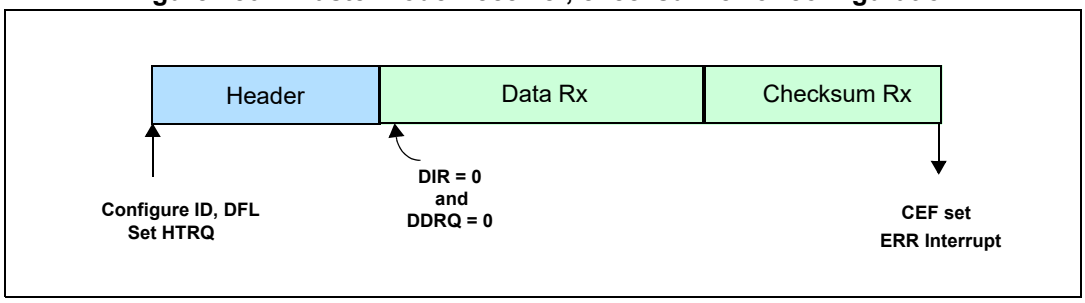


Figure 1806. Master node: transmitter, checksum error configuration

56.5.1.4 Receiver, Checksum Error

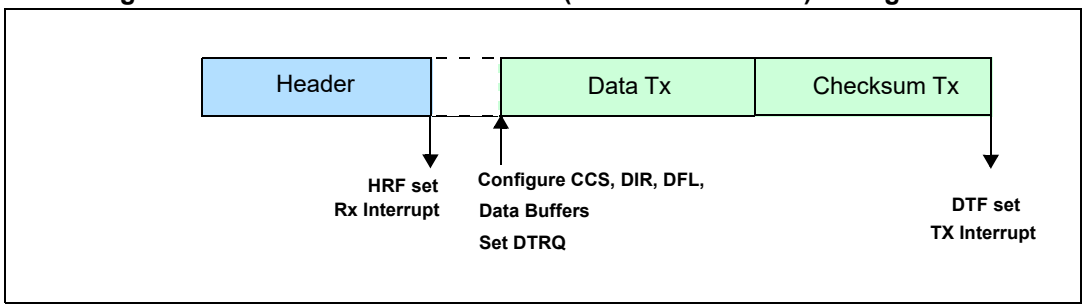

Figure 1807. Master node: receiver, checksum error configuration

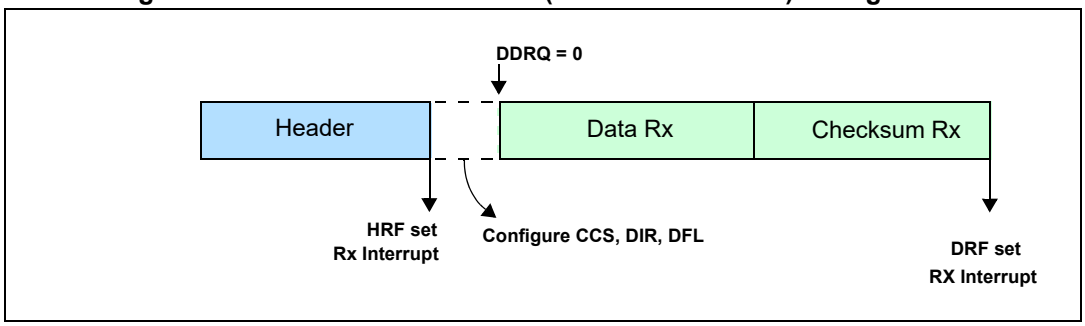
56.5.2 Slave node

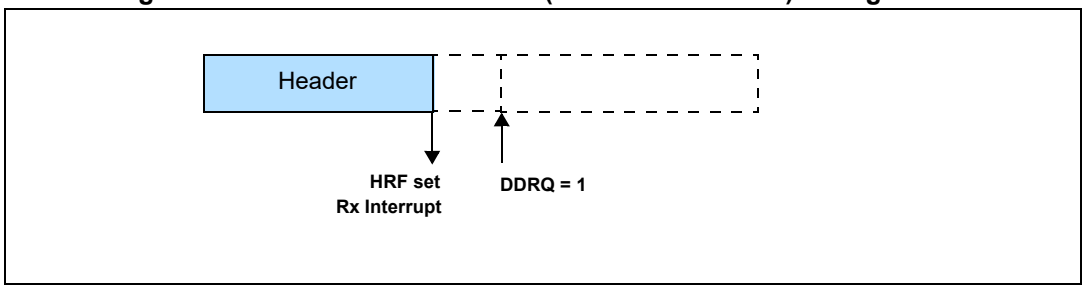
56.5.2.1 Transmitter (no identifier filters)

Figure 1808. Slave node: transmitter (no identifier filters) configuration

56.5.2.2 Receiver (no identifier filters)

Figure 1809. Slave node: receiver (no identifier filters) configuration





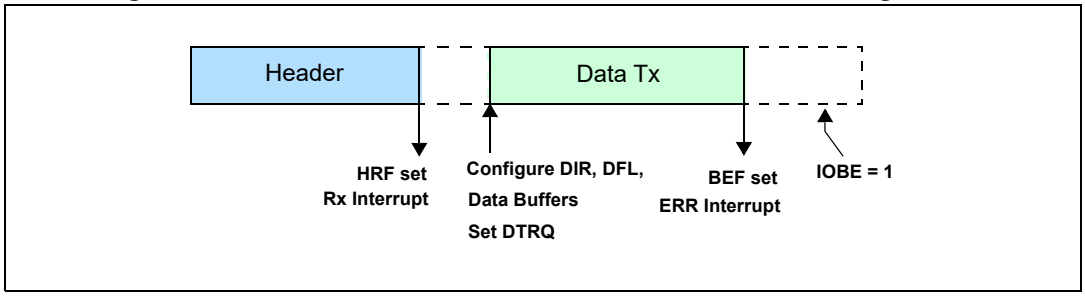


Figure 1810. Slave node: receiver (no identifier filters) configuration

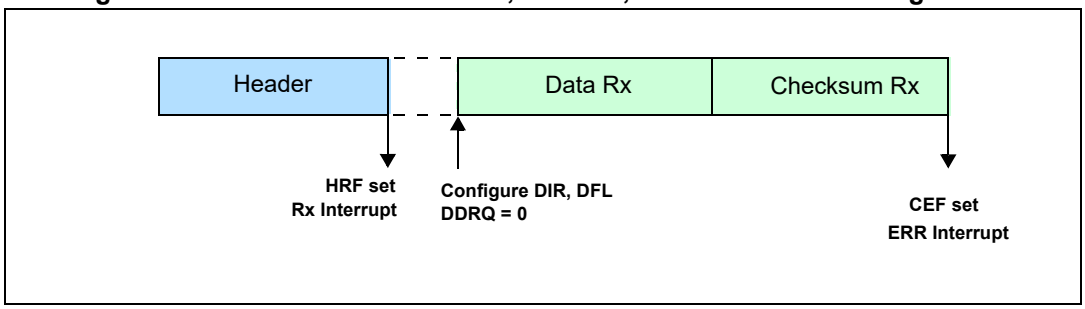

56.5.2.3 No filters, transmitter, bit error

Figure 1811. Slave node: No filters, transmitter, bit error configuration

56.5.2.4 No filters, receiver, checksum error

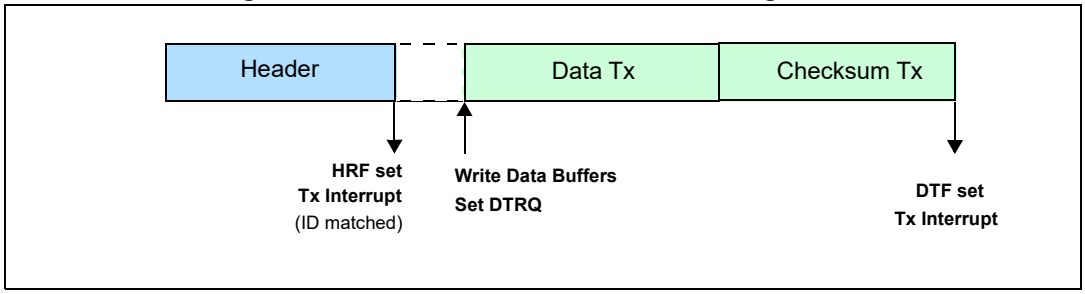

Figure 1812. Slave node: No filters, receiver, checksum error configuration

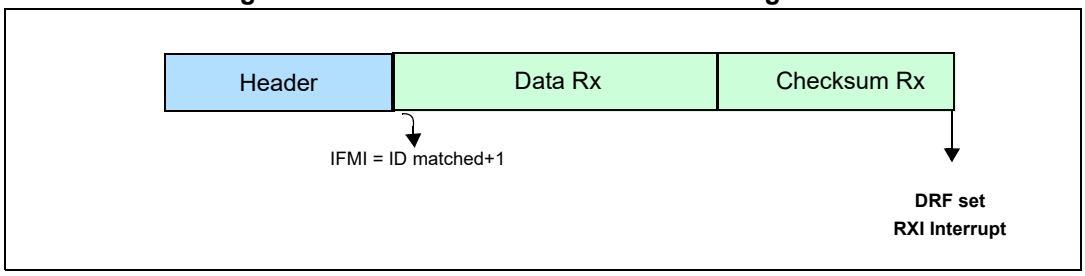
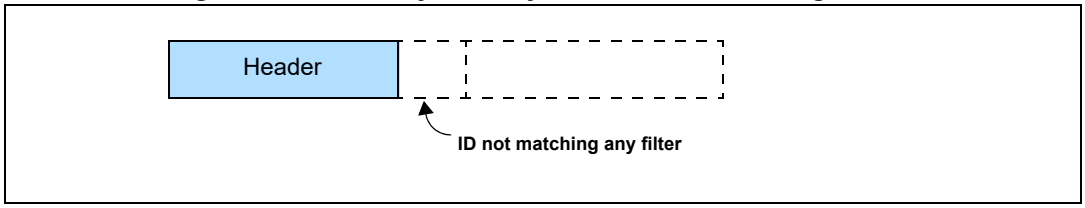
56.5.2.5 At least one TX filter, BF is reset, ID matches filter



This configuration can be used in case slave never receives data, for example, sensor.

Figure 1813. Slave node: one TX filter configuration



56.5.2.6 At least one RX filter, BF reset, ID matches filter

Figure 1814. Slave node: one RX filter configuration

56.5.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

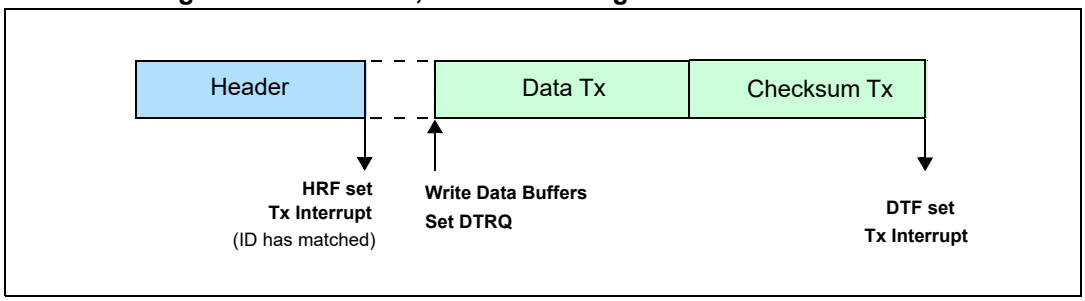
Figure 1815. RX only, TX only, RX & TX filters configuration

56.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

Figure 1816. TX filter, BF is set configuration: ID has matched



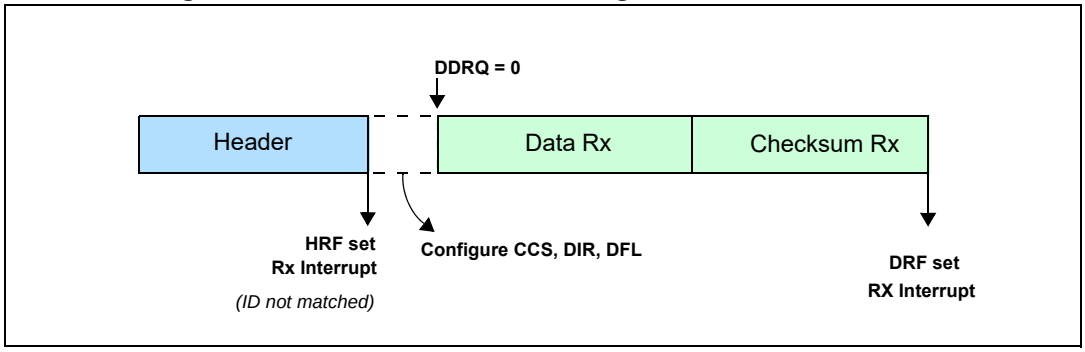


Figure 1817. TX filter, BF is set configuration: ID not matched

56.5.2.9 RX filter, BF is set

Figure 1818. RX filter, BF is set configuration: ID matched

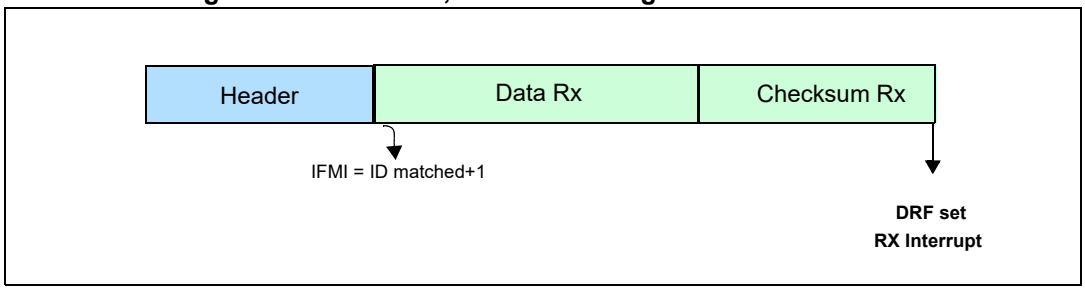

Figure 1819. RX filter, BF is set configuration: ID not matched (ID is Rx)

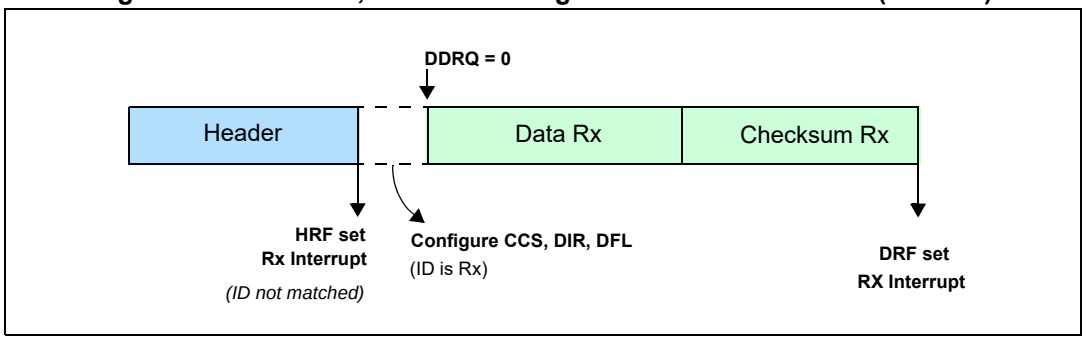

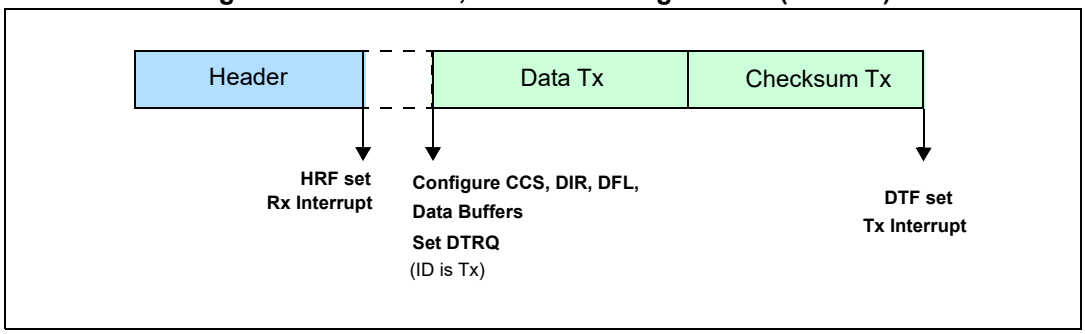

Figure 1820. RX filter, BF is set configuration: (ID is Tx)

56.5.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

Figure 1821. TX filter, RX filter, BF set configuration: (ID matched)

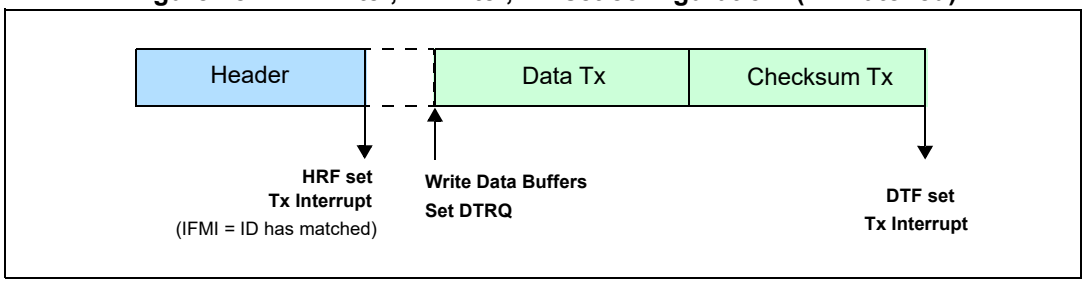

Figure 1822. TX filter, RX filter, BF set configuration: (ID matched + 1)

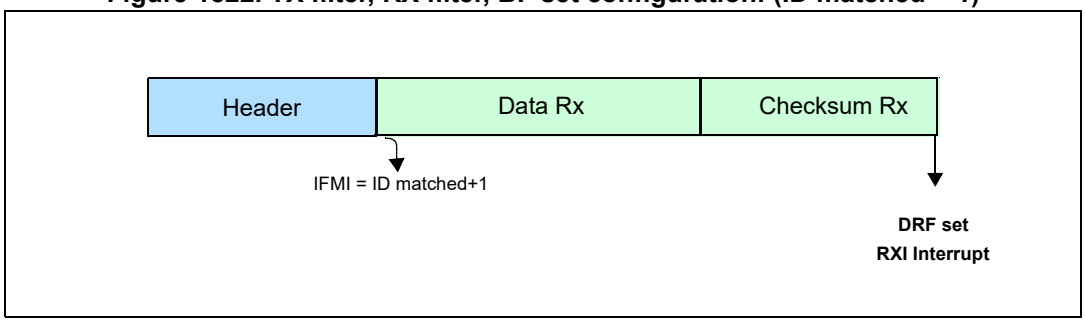

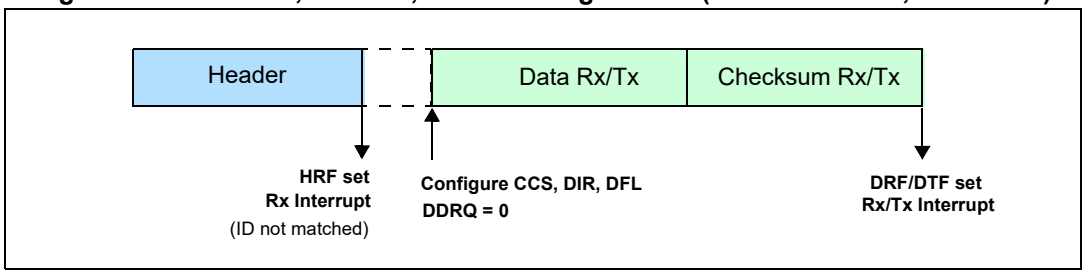

Figure 1823. TX filter, RX filter, BF set configuration: (ID not matched, RX/TX Int.)

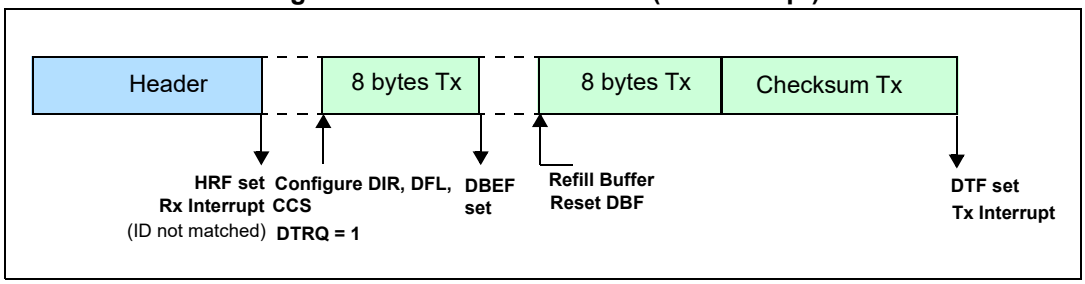
56.5.3 Extended frames

Figure 1824. Extended frames (TX Interrupt)



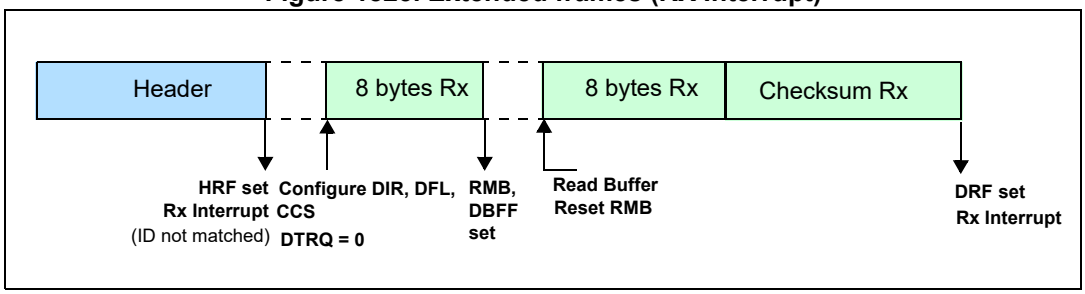


Figure 1825. Extended frames (RX Interrupt)

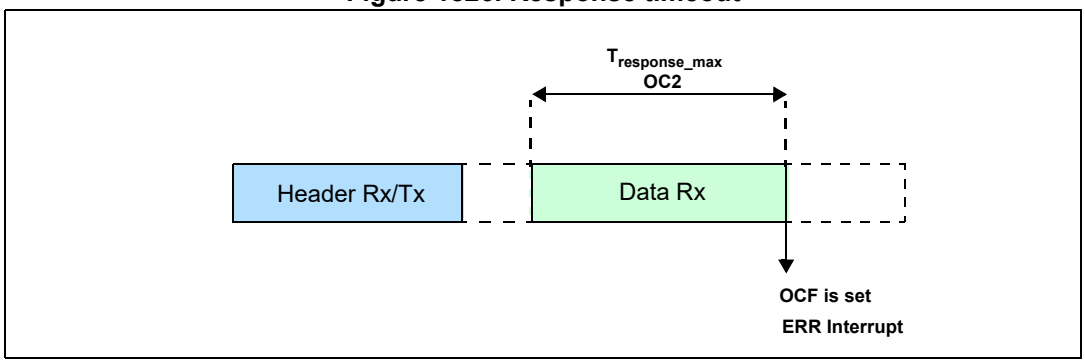
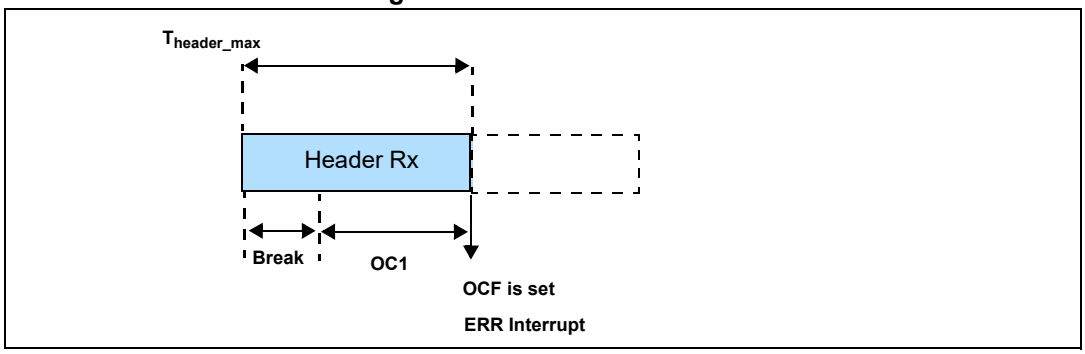
56.5.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

Figure 1826. Response timeout





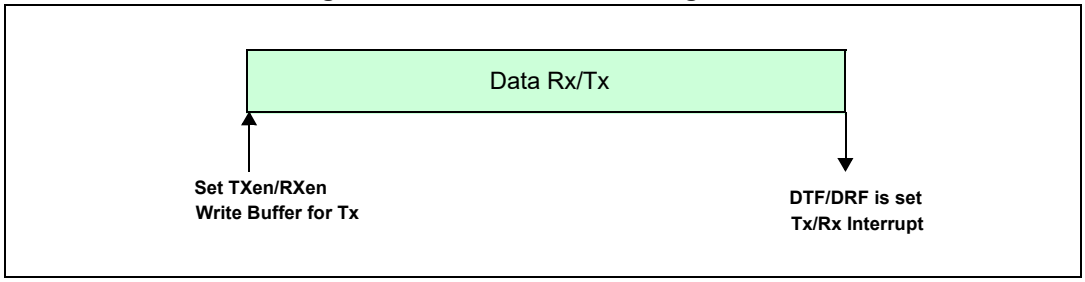


Figure 1827. Header timeout

57 Secure Digital and MultiMediaCard controller (SDMMC)

57.1 Features

57.1.1 General description

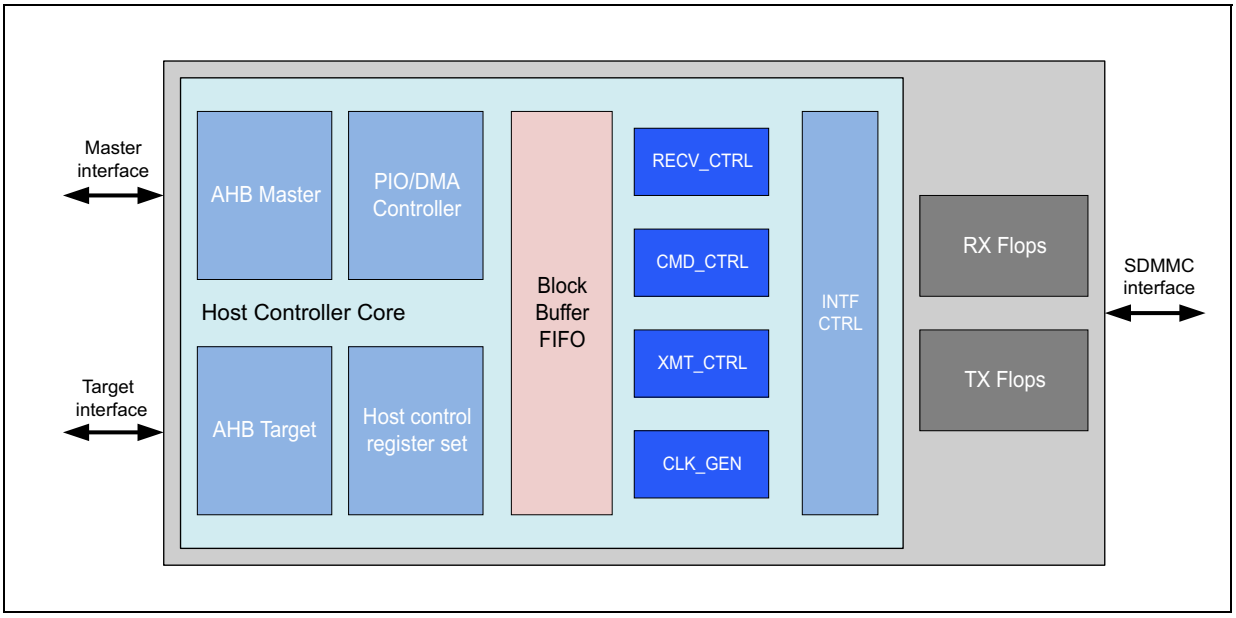
The 3MCR (multi card reader) controller is an advanced host controller compliant with MMC specification version 4.51 and SD Host Controller standard specification version 3.0.

The 3MCR controller handles MMC/SD/SDIO protocols at transmission level, packing data, adding cyclic redundancy check (CRC), start/end bit, and checking for transaction format correctness.

The 3MCR controller provides programmed IO method and DMA data transfer method. In programmed IO method, the host processor transfers data using the Buffer data port register. Host controller supports both SDMA and ADMA2. ADMA2 is enabled by user using programming bit. DMA allows a peripheral to read or write memory without intervention from the CPU. The 3MCR host controller's host controller System address register points to the first data address, and data is then accessed sequentially from that address.

57.1.2 Key features

- Compliance
  - MMC specification version 4.51
  - SD Host Controller standard specification version 3.00
  - SDIO Card specification version 3.0
  - SD Memory Card specification version 3.01
  - SD Memory Card Security specification version 1.01
- System/Host interface
  - Data transfer using PIO mode on the host bus slave interface, using DMA mode on the host bus master interface
  - System/Host interface clock frequency is 100 MHz (max)
- MMC card interface
  - EMMC card clock frequency is 50 MHz
  - Up to 400 Mbits (50 Mbytes) per second data rate using 8 bit parallel data lines (mmc8 bit SDR mode)
  - Up to 800 Mbits (100 Mbytes) per second data rate using 8 bit parallel data lines (mmc8 bit DDR mode)
  - Transfers the data in 1 bit, 4 bit and 8 bit modes and SPI mode
  - Cyclic redundancy check CRC7 for command and CRC16 for data integrity
  - Supports MMC plus and MMC mobile
- SD/ SDIO card interface
  - Host clock rate variable between 0 and 50 MHz
  - Transfers the data in 1 bit and 4 bit SD modes and SPI mode
  - Transfers the data in High and Default speed modes
  - Up to 200 Mbits (25 Mbytes) per second data rate in High speed mode
  - Cyclic Redundancy Check CRC7 for command and CRC16 for data integrity
  - Variable-length data transfers
  - Performs Read Wait control, Suspend/Resume operation SDIO CARD
  - Designed to work with I/O cards, Read Only cards and Read/Write cards
  - Supports Read Wait control, Suspend/Resume operation
- Miscellaneous
  - Handle the FIFO overrun and underrun condition by stopping eMMC card clock



57.2 Architecture

This chapter describes the architecture and block diagram of 3MCR controller.

57.2.1 Block diagram

The block diagram of 3MCR controller is shown in *Figure 1830*.

Figure 1830. 3MCR controller

57.2.2 Host controller core block description

The 3MCR host controller contains the major part of the design under 3MCR host controller core which contains the following blocks.

57.2.2.1 Host interface (master/target)

The 3MCR host controller interfaces to the system bus using AHB master and AHB target interface.

The target bus is used to access the registers inside the host controller. Also when operating in PIO mode, the driver can access the Data port register through this interface. This is the PIO method in which the host driver transfers data using the Buffer data port register. The target bus supports only single transfer access (no burst support) and only one outstanding read/write transaction.

The master bus is used by the DMA controller (when using SDMA or ADMA2 modes). The DMA controller uses the master DMA interfaces to transfer data between the internal block buffer and the system memory and vice-versa. The DMA controller also uses the master interface to fetch the descriptors while operating in ADMA2 mode.

57.2.2.2 Host controller register set

The host controller registers are dword accessible from the target interface. The host controller register set also implements the Data port register for the PIO mode transfers. The register set provides the control signals to rest of the blocks in design and monitors the status signals from the blocks to set interrupt status bits and eventually generate interrupt signal to the host bus.

The host controller register set acts as the bridge between host CPU and host controller.

The 3MCR controller registers are programmed by the host processor through host target interface. Interrupts are generated to the host processor based on the values set in the Interrupt status and Interrupt enable registers.

SDMMC IP does not provide error response for the accesses to reserved addresses. Also, it does not provide error response for the write accesses to read only registers or vice versa.

57.2.2.3 PIO/DMA controller

The PIO/DMA controller module implements the SDMA and ADMA2 engines as defined in the host controller specification and maintains the block transfer counts for PIO operation. It interacts with the registers set and starts the DMA engine when a command with data transfer is involved.

The DMA controller interfaces to the host master module to generate transfers and on the other side it interfaces with the block buffer to store/fetch block data. The DMA controller implements a separate DMA for SDMA operation and separate DMA for the ADMA2 operation. In addition, it implements host transaction generator that generates controls for the host master interface module.

57.2.2.4 Block buffer

The host controller uses a dual port block buffer (read/write on both ports) that is used to store the block data during data transfers. The size of the block buffer is 1 Kbyte, so that it can accommodate up to two 512B blocks. The block buffer uses circular buffer architecture. One side of the block buffer is interfaced with the DMA controller and operates on the host clock. The other side of the block buffer interfaces with control logic and operates on SDMMC card clock.

During a write transaction (data transferred from system processor to SDMMC card), the data is fetched from the system memory and is stored in the block buffer. When a block of data is available, the control logic will transfer it onto the SDMMC interface. The DMA controller continues to fetch additional block of data when the block buffer has space.

During a read transaction (data transferred from SDMMC card to system processor), the data from SDMMC card will be written in to block buffer and at the end when the CRC of the block is valid, the data is committed. When a block of data is available, then the DMA controller transfers this data to the system memory. The control logic meanwhile receives the next block of data provided there is space in the block buffer. If the host controller cannot accept any data from SDMMC card, then it will stop the data transfer from card by stopping the clock.

Note: As the block buffer size is twice that of the block size, the block buffer behaves like a ping-pong buffer.

57.2.2.5 Clock generator

The clock generator module generates interface clock from the reference clock, based on the controls programmed in the Clock control register. These includes clock divider value and clock enable. The outputs from this module are the SDMMCCTRL_CLK and the SDMMCCARD_CLK. The SDMMCCTRL_CLK is used by the control logic and the SDMMCCARD_CLK connected to the output clock pin of SDMMC interface. This module also generates system resets to various clock domains.

57.2.2.6 Timeout control

The timeout control logic implements the timeout check between block transfers. It uses the contents of the Timeout control register to implement timeout between blocks. This module operates under the control of the transmit control and receive control modules (based on

direction). When the timeout is detected the event is reported to transmit control or receive control module.

57.2.2.7 Command control

The command control module generates the command sequence on the CMD line of the SDMMC interface for every new command programmed by the software.

The command control module also implements the response reception and checking the validity of the response. It uses the response type field to determine the length of the response and the presence of CRC7 field. The response is received on the receive clock (which is the looped back clock). Once the response is received the contents of the response (start bit, command index, CRC7, end bit) are verified and response status is forwarded to the register set module for setting various status bits. It also implements the timeout check on the response reception to make sure that the response is received with in the defined time (5 or 64 clocks based on command type). The received response is then stored into appropriate bit position in the Response register.

The command control module generates controls to the transmit control and receive control based on the transfer direction.

The command control module also generates auto command (AutoCMD12 or AutoCMD23) when enabled.

57.2.2.8 Transmit control

The transmit control module is used for write transfers for transferring data to the card. Once the command is issued, this module waits for the block of data to be available in the block buffer and transfers this onto the DAT lines. Based on the configuration of data lines, the (1-bit, 4-bit or 8-bits or SPI), the data from block buffer is appropriately routed. The CRC16 is individually calculated on per lane basis and is attached at the end of block transfer before the end bit. In case of DDR operation, it implements separate CRC16 for each edge of the clock.

At the end of block transfer, it waits for the CRC response on DAT0 line and reports the result of the CRC check to the register set.

Also this module checks for the write busy indication (DAT0 line) before transferring next block of data. The timeout check is implemented to make sure that the write busy is asserted no more than the required limit.

57.2.2.9 Receive control

The receive control module is used for read transfers for receiving data from the card. Once the command is issued, this module waits for the block of data to be received from the card. Based on the configuration of data lines, the (1-bit, 4-bit or 8-bits or SPI), the data from SDMMC interface is assembled into byte and eventually into 32-bit word before it is being written into block buffer. The CRC16 is individually calculated on per lane basis and is checked against the received CRC16 at the end of block transfer before the end bit. In case of DDR operation, it implements separate CRC16 checker for each edge of the clock.

The data is received on the receive clock. This receive clock is the looped back clock (SDMMCCARD_CLK from the IO_BUF).

The timeout check is implemented to make sure that the gap between the block no more than the required limit.

57.2.2.10 Interface control

The interface control block maps the internal signals to the external SDMMC interface and vice versa. Based on the bus width (1/4/8) the internal signals are driven out appropriately.

The inputs from Rx flops module are latched on the rx_clk (looped back clock) and is output to the receive control module for further processing.

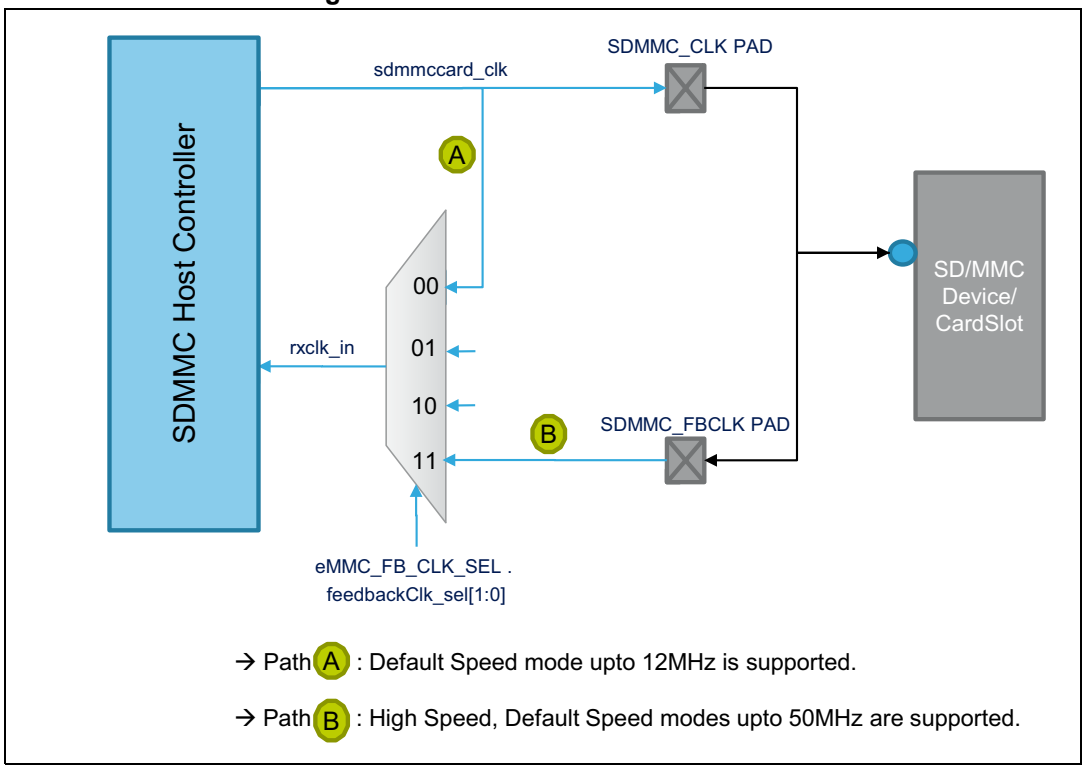
57.2.3 Clocks

SDMMC_CLK: This is the main clock provided by CGM. It is used for the SDMMC interface side of the host controller. This clock input is used to generate sdmmcctrl_clk and sdmmccard_clk clocks based on the divisor value programmed by the host driver.

ahb_clk (commonly called as host_clk): host bus clock. The host bus interface modules, the register set and the DMA controller operate on this clock.

sdmmcctrl_clk: This clock is derived from SDMMC_CLK based on the Clock control register value programmed by the driver. This clock is used by the most of the control logic (command control, transmit control and sdmmc interface side of the block buffer).

sdmmccard_clk: same as sdmmcctrl_clk, except that this is available only when clock enable is set by the driver. This is the clock supplied to the card.



The host controller supports both Full speed and High speed card. For High speed card, the host controller should clock out the data at rising edge of sdmmcctrl_clk and for Full speed card, the host controller should clock out the data at falling edge of sdmmcctrl_clk.

During read transaction when the read FIFOs are full, there is no space to accept one block of data from card, host controller will stop the clock to card so overrun condition will not occur at host controller side.

rxclk_in: This is the looped back clock either from the sdmmccard_clk or from the clk PAD of external memory device mounted on application board. This will account for the delay on the CLK being driven onto the SDMMC interface through the chip and the IO PAD. Refer to figure below for feedback clock selection.

Note: To select the looped back clock software driver should program FEEDBACKCLK_SEL field of Feedback clock selection register (FB_CLK_SEL).

Figure 1831. Feedback clock selection

57.2.4 Resets

The host controller uses asynchronous reset to reset the FF's, even though the reset itself is synchronous to the corresponding clock domain. ahb_reset_n is the primary reset input and is synchronized with corresponding clock domain. Internally an independent reset signal is generated for each of the clock domain from ahb_reset_n.

57.2.5 Frequency range

The host_clk frequency is 100 MHz. For selection of clock frequency refer to Clocking chapter.

The sdmmcctrl_clk frequency range is 400 KHz to 50 MHz.

57.2.6 FIFO overrun and underrun conditions in DMA and non-DMA transfers

57.2.6.1 Write

During write transaction the host controller will transmit data to card only when a block of data is ready to transmit and also the card is not driving busy. So underrun condition will not occur on SDMMC host controller side.

In DMA mode host controller initiates DMA READ from host memory only if space is available to accept a block of data.

In non-DMA mode host controller will assert buffer write ready interrupt only if space is available to accept a block of data.

57.2.6.2 Read

During read transaction, when the internal block buffer is full it can not accept any more data from the card. In these circumstances, host controller will stop the clock to card in order to avoid buffer overrun condition.

In DMA mode host controller initiates DMA WRITE to host memory only on reception of block of data from card.

In non-DMA mode host controller will assert buffer read ready interrupt only on reception of block of data from card.

57.3 Registers

57.3.1 Registers memory map

Base addresses are given in the Memory map chapter.

Note: Reserved fields are read only.

57.3.2 Registers description

The SDMMC host controller registers are described in this section.

The registers to generate SDMMC command are listed in the following table.

Table 1809. Registers to generate SDMMC command

	SDMA command	ADMA command	CPU data transfer	Non-DAT transfer
SDMA system No/AutoCMD23 Address/Argument 2	Yes/No	No/Auto CMD23	No/Auto CMD23	No/No
Block size	Yes	Yes	Yes	No (Protected)
Block count	Yes	Yes	Yes	No (Protected)
Argument 2	Yes	Yes	Yes	No (Protected)
Transfer mode	Yes	Yes	Yes	No (Protected)
Command	Yes	Yes	Yes	Yes

The table above shows register settings for three transactions: SDMA generated transactions, ADMA generated transactions and CPU data transfers and non-DAT transfers. When initiating a transaction, the host driver should program these registers sequentially from 0x000 to 0x00F. The beginning register offset may be calculated based on the type of transaction. The last written offset is always 0x00F because writing to the upper byte of the Command register triggers issuance of the command.

57.3.2.1 Register access method

SDMMC registers are defined in little endian address space.

To access these registers, using a big endian processor, byte locations in word and halfword addressed registers should be swapped.

Dedicated hardware is provided for this. The hardware will be enabled using EMMC_SLV_EN_BYTE_SWAP (bit 26) of PCM REG3 SoC Configuration register.

Reset value of EMMC_SLV_EN_BYTE_SWAP (bit 26) is set that is by default swapping is enabled.

57.3.2.2 SDMA System address / Argument 2 register (SDMASYSADDR)

This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	SDMA_SYSADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SDMA_SYSADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1832. SDMA System address / Argument 2 register (SDMASYSADDR)

Table 1810. SDMASYSADDR field descriptions

Field	Description
0:31 SDMA_SYSADDRESS	SDMA system address (Low) / Argument 2 (Low) (1) SDMA system address This register contains the system memory address for a SDMA transfer. When the host controller stops a SDMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (after a transaction has stopped). Read operations during transfers may return an invalid value. The host driver initializes this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the host SDMA buffer boundary in the Block size register. The host controller generates DMA Interrupt to request the host driver to update this register. The host driver sets the next system address of the next data position to this register. When the most upper byte of this register (0x003) is written, the host controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue request in the Block gap control register, the host controller starts at the next contiguous address stored here in the SDMA System address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block count register. 65535 blocks is the maximum value in this case.

57.3.2.3 Block size register (BLOCKSIZE)

The block size register is described below.

Offset: 0x0004 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	SDMA_ BUFBOUNDARY			XFER_BLOCKSIZE											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1833. Block size register (BLOCKSIZE)

Table 1811. BLOCKSIZE field descriptions

Field	Description
1:3 SDMA_ BUFBOUNDARY	Host SDMA buffer size To perform long DMA transfer, System address register is updated at every system boundary during DMA transfer. These bits specify the size of contiguous buffer in the system memory. The DMA transfer waits at the every boundary specified by these fields and the HC generates the DMA Interrupt to request the HD to update the System address register. These bits support when the DMA support in the Capabilities register is set to 1 and this function is active when the DMA enable in the Transfer mode register is set to 1. 000 4 Kbytes (Detects A11 Carry out) 001 8 Kbytes (Detects A12 Carry out) 010 16 Kbytes (Detects A13 Carry out) 011 32 Kbytes (Detects A14 Carry out) 100 64 Kbytes (Detects A15 Carry out) 101 128 Kbytes (Detects A16 Carry out) 110 256 Kbytes (Detects A17 Carry out) 111 512 Kbytes (Detects A18 Carry out)
4:15 XFER_BLOCKSIZE	Transfer block size This register field specifies the block size for block data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. It can be accessed only if no transaction is executing (that is after a transaction has stopped). Read operations during transfer return an invalid value and Write operations are ignored. 0x0000 No data transfer 0x0001 1 Byte 0x0002 2 Bytes 0x0003 3 Bytes 0x0004 4 Bytes ... 0x01FF 511 Bytes 0x0200 512 Bytes

57.3.2.4 Block count register (BLOCKCOUNT)

The block count register is described below.

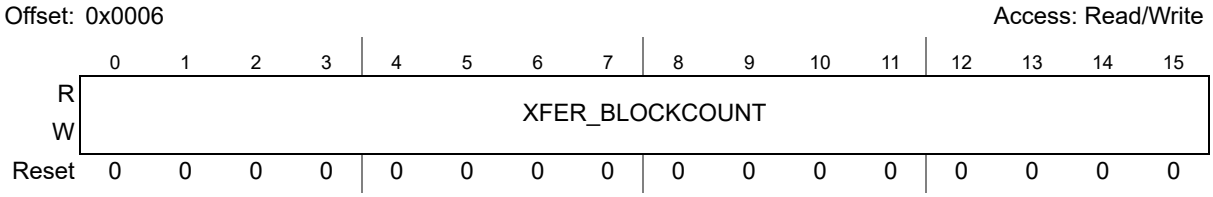

Figure 1834. Block count register (BLOCKCOUNT)

Table 1812. BLOCKCOUNT field descriptions

Field	Description
0:15 XFER_BLOCKCOUNT	Block count for current transfer This register is enabled when Block count enable in the Transfer mode register is set to 1 and is valid only for multiple block transfers. The HC decrements the block count after each block transfer and stops when the count reaches zero. It can be accessed only if no transaction is executing (that is after a transaction has stopped). Read operations during transfer return an invalid value and Write operations are ignored. When saving transfer context as a result of Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the HD restores the previously save block count. 0x0000 Stop count 0x0001 1 block 0x0002 2 blocks ... 0xFFFF 65535 blocks

57.3.2.5 Argument 1 register (ARGUMENT1)

The argument 1 register is described below.

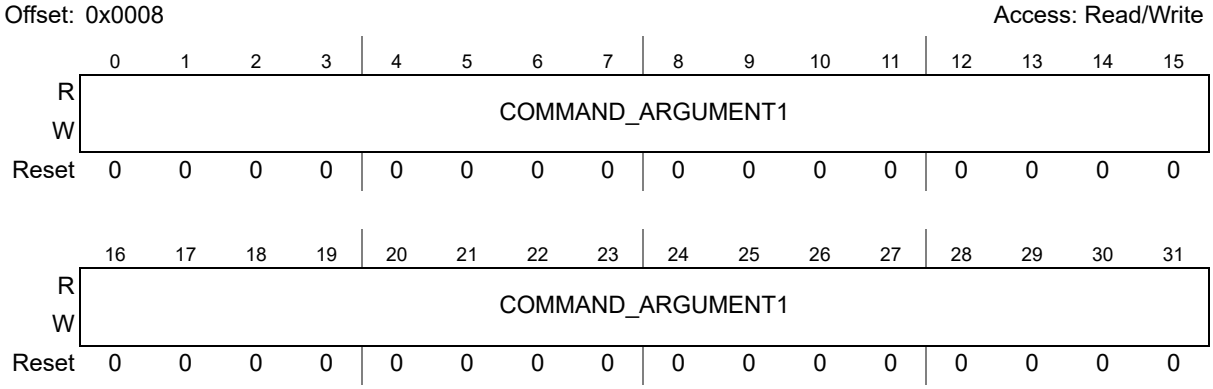

Figure 1835. Argument 1 register (ARGUMENT1)

Table 1813. ARGUMENT1 field descriptions

Field	Description
0:31 COMMAND_ARGUMENT1	Command argument 1 The MMC command argument is specified as bit39-8 of Command-Format.

57.3.2.6 Transfer mode register (TRANSFERMODE)

The transfer mode register is described below.

Offset: 0x000C Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	XFERMODE_MULTIBLKSEL	XFERMODE_DATAXFERDIR	XFERMODE_AUTOCMDENA		XFERMODE_BLKCNTENA	XFERMODE_DMAENABLE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1836. Transfer mode register (TRANSFERMODE)

Table 1814. TRANSFERMODE field descriptions

Field	Description
10 XFERMODE_ MULTIBLKSEL	Multi/Single block select This bit enables multiple block data transfers. 0 Single block 1 Multiple block
11 XFERMODE_ DATAXFERDIR	Data transfer direction select This bit defines the direction of data transfers. 0 Write (host to card) 1 Read (card to host)

Table 1814. TRANSFERMODE field descriptions (continued)

Field	Description
12:13 XFERMODE_ AUTOCMDENA	Auto CMD enable This field determines use of auto command functions. 00 Auto command disabled 01 Auto CMD12 enable 10 Auto CMD23 enable 11 Reserved There are two methods to stop multiple-block read and write operation. (1) Auto CMD12 enable Multiple-block read and write commands for memory require CMD12 to stop the operation. When this field is set to 01b, the host controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error status register. The host driver does not set this bit if the command does not require CMD12. (2) Auto CMD23 enable When this bit field is set to 10b, the host controller issues a CMD23 automatically before issuing a command specified in the Command register. The following conditions are required to use the Auto CMD23: A memory card that supports CMD23 (SCR[33]=1). If DMA is used, it is ADMA. Only when CMD18 or CMD25 is issued. By writing the Command register, the host controller issues a CMD23 first and then issues a command specified by the command index in Command register 32-bit block count value for CMD23 is set to SDMA System address / Argument 2 register.
14 XFERMODE_ BLKCNTENA	Block count enable This bit is used to enable the Block count register, which is only relevant for multiple block transfers. When this bit is 0, the Block count register is disabled, which is useful in executing an infinite transfer. 0 Disable 1 Enable
15 XFERMODE_ DMAENABLE	DMA enable DMA can be enabled only if DMA support bit in the Capabilities register is set. If this bit is set to 1, a DMA operation begins when the HD writes to the upper byte of Command register (0x00F). 0 Disable 1 Enable

Table 1815. Determination of transfer type

Multi / Single block	Block count enable	Block count	Function
0	Don’t care	Don’t care	Single Transfer
1	0	Don’t care	Infinite Transfer
1	1	Not Zero	Multiple Transfer
1	1	Zero	Stop Multiple Transfer

57.3.2.7 Command register (COMMAND)

The command register is described below.

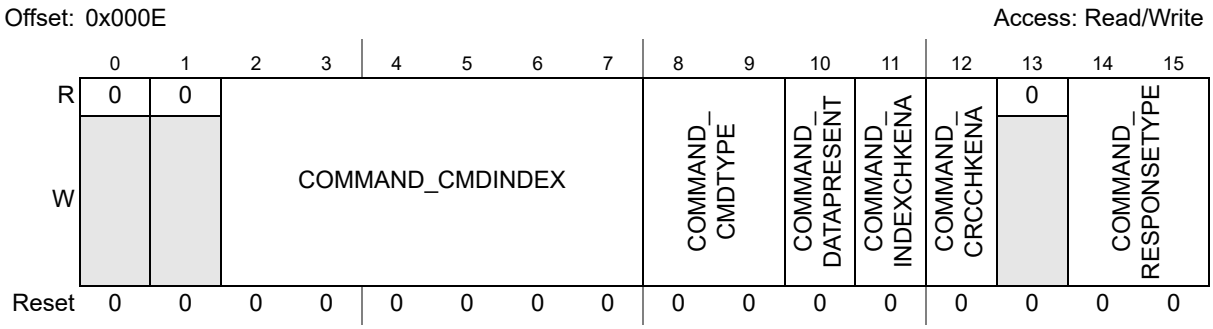

Figure 1837. Command register (COMMAND)

Table 1816. COMMAND field descriptions

Field	Description
2:7 COMMAND_ CMDINDEX	Command index This bit is set to the command number (CMD0–63, ACMD0–63).
8:9 COMMAND_ CMDTYPE	Command type There are three types of special commands: suspend, resume and abort. These bits are set to 00b for all other commands. *Suspend command* If the Suspend command succeeds, the HC assumes the eMMC Bus has been released and that it is possible to issue the next command which uses the DAT line. The HC de-asserts Read Wait for read transactions and stop checking busy for write transactions. The interrupt cycle starts, in 4-bit mode. If the Suspend command fails, the HC maintains its current state and the HD restarts the transfer by setting Continue request in the Block gap control register. *Resume command* The HD re-starts the data transfer by restoring the registers in the range of 0x000–0x00D. The HC checks for busy before starting write transfers. *Abort command* If this command is set when executing a read transfer, the HC stops Reads to the buffer. If this command is set when executing a write transfer, the HC stops driving the DAT line. After issuing the Abort command, the HD issues a software reset. 00 Normal 01 Suspend 10 Resume 11 Abort

Table 1816. COMMAND field descriptions (continued)

Field	Description
10 COMMAND_ DATAPRESENT	Data present select This bit is set to 1 to indicate that data is present and is transferred using the DAT line. It is set to 0 for the following: Commands using only CMD line (ex. CMD52) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) Resume command 0 No data present 1 Data present
11 COMMAND_ INDEXCHKENA	Command index check enable If this bit is set to 1, the HC checks the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the index field is not checked. 0 Disable 1 Enable
12 COMMAND_ CRCCHKENA	Command CRC check enable If this bit is set to 1, the HC checks the CRC field in the response. If an error is detected, it is reported as a command CRC error. If this bit is set to 0, the CRC field is not checked. 0 Disable 1 Enable
14:15 COMMAND_ RESPONSETYPE	Response type select 00 No Response 01 Response length 136 10 Response length 48 11 Response length 48 check. Busy after response.

57.3.2.8 Response n register (RESPONSEn)

The response n register is described below.

Offset: 0x0010 + n*0x2 (n=0 to 7) Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	COMMAND_RESPONSE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1838. Response n register (RESPONSEn)

Table 1817. RESPONSEn field descriptions

Field	Description
0:15 COMMAND_RESPONSE	Command response R[ ] refers to a bit range within the response data as transmitted on the SDMMC bus, REP[ ] refers to a bit range within the Response register. **Note:** These bits are read only bits and initialized to zero at reset.

Table 1818 defines the relation between the parameter and name of response type.

Table 1818. Determination of transfer type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R6, R5, R7
11	1	1	R1b, R5b

Table 1819 describes the mapping of command responses from the SDMMC bus to this register for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SDMMC bus, REP[ ] refers to a bit range within the Response register.

Table 1819. Response bit definition for each response type

Kind of response	Meaning of response	Response field	Response register
R1, R1b (normal response)	Card status	R[39:8]	REP[31:0]
R1b (Auto CMD12 response)	Card status for Auto CMD12	R[39:8]	REP[127:96]
R1 (Auto CMD23 response)	Card status for Auto CMD23	R[39:8]	REP[127:96]
R2 (CID, CSD, register)	CID or CSD reg. incl.	R[127:8]	REP[119:0]
R3 (OCR register)	OCR register for memory	R[39:8]	REP[31:0]

57.3.2.9 Data port register (DATAPORT)

The buffer data port register is described below.

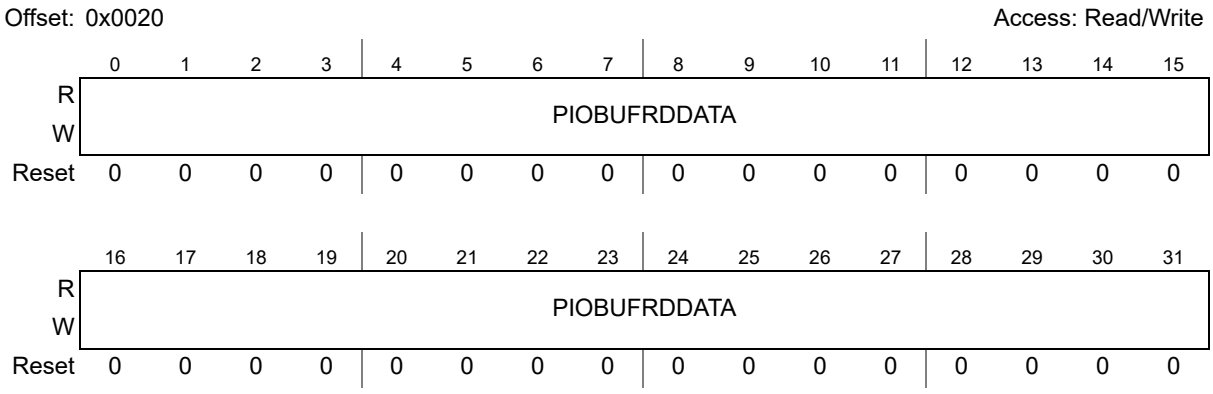

Figure 1839. Data port register (DATAPORT)

Table 1820. DATAPORT field descriptions

Field	Description
0:31 PIOBUFRDDATA	Buffer data The host controller buffer can be accessed through this 32-bit Data port register.

57.3.2.10 Present state register (PRESENTSTATE)

Each bit of this register indicates whether one of the DAT line on SDMMC bus is in use.

Offset: 0x0024 Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
				SDMMC_DAT7	SDMMC_DAT6	SDMMC_DAT5	SDMMC_DAT4	SDMMC_CMD	SDMMC_DAT3	SDMMC_DAT2	SDMMC_DAT1	SDMMC_DAT0	SDMMC_WP	SDMMC_CD_N	CARDDET_STATESTABLE	CARDDET_INSERTED
R	0	0	0													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
					DMACTRL_PIOBUFRDENA	DMACTRL_PIOBUFWRENA	DMACTRL_RDXFERACTIVE	DMACTRL_WRXFERACTIVE						DMACTRL_DATALINEACTIVE	PRESENTSTATE_INHIBITDAT	PRESENTSTATE_INHIBITCMD
R	0	0	0	0					0	0	0	0	0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1840. Present state register (PRESENTSTATE)

Table 1821. PRESENTSTATE field descriptions

Field	Description
3:6 SDMMC_DAT[7:4]	DAT[7:4] line signal level This status is used to check DAT line level to recover from errors, and for debugging.
7 SDMMC_CMD	CMD line signal level This status is used to check CMD line level to recover from errors, and for debugging.
8:11 SDMMC_DAT[3:0]	DAT[3:0] line signal level This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0].

Table 1821. PRESENTSTATE field descriptions (continued)

Field	Description
12 SDMMC_WP	Write protect switch pin level The write protect switch is supported for memory and combo cards. 0 Write protected 1 Write enabled **Note:** No write protection is provided. This bit will always read as 1. Ignore this bit because cards are always enabled for writing.
13 SDMMC_CD_N	Cart detect pin level 0 No card present 1 Card present
14 CARDDET_ STATESTABLE	Card state stable This bit is used for testing. If it is 0, the card detect pin level is not stable. If this bit is set to 1, it means the card detect pin level is stable. The software reset for all in the Software reset register does not affect this bit. 0 Reset of debouncing 1 No card or inserted
15 CARDDET_ INSERTED	Card inserted This bit indicates whether a card has been inserted. Changing from 0 to 1 generates a Card Insertion Interrupt in the Normal interrupt status register and changing from 1 to 0 generates a Card Removal Interrupt in the Normal interrupt status register. The software reset for all in the Software reset register does not affect this bit. 0 Reset or debouncing or no card 1 Card inserted
20 DMACTRL_ PIOBUFRDENA	Buffer read enable This status is used for non-DMA read transfers. This read only flag indicates that valid data exists in the host side buffer status. If this bit is 1, read-able data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when all the block data is ready in the buffer and generates the Buffer Read Ready Interrupt. 0 Read disable 1 Read enable **Note:** This bit is read only bit and initialized to zero at reset.
21 DMACTRL_ PIOBUFWRENA	Buffer write enable This status is used for non-DMA write transfers. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the buffer write ready interrupt. 0 Write disable 1 Write enable. **Note:** This bit is read only bit and initialized to zero at reset.

Table 1821. PRESENTSTATE field descriptions (continued)

Field	Description
22 DMACTRL_ RDXFERACTIVE	Read transfer active This status is used for detecting completion of a read transfer. This bit is set to 1 for either of the following conditions: – After the end bit of the read command. – When writing a 1 to Continue request in the Block gap control register to restart a read transfer. This bit is cleared to 0 for either of the following conditions: – When the last data block as specified by block length is transferred to the system. – When all valid data blocks have been transferred to the system and no current block transfers are being sent as a result of the Stop at block gap request set to 1. A Transfer Complete Interrupt is generated when this bit changes to 0. 1 Transferring data 0 No valid data **Note:** This bit is read only bit and initialized to zero at reset.
23 DMACTRL_ WRXFERACTIVE	Write transfer active This status indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the HC. This bit is set in either of the following cases: – After the end bit of the write command. – When writing a 1 to Continue request in the Block gap control register to restart a write transfer. This bit is cleared in either of the following cases: – After getting the CRC status of the last data block as specified by the transfer count (single or multiple). – After getting a CRC status of any block where data transmission is about to be stopped by a Stop at block gap request. During a write transaction, a block gap event interrupt is generated when this bit is changed to 0, as a result of the Stop at block gap request being set. This status is useful for the HD in determining when to issue commands during write busy. 1 Transferring data 0 No valid data **Note:** This bit is read only bit and initialized to zero at reset.
29 DMACTRL_ DATALINEACTIVE	DAT line active This bit indicates whether one of the DAT line on SDMMC bus is in use. 1 DAT line active 0 DAT line inactive **Note:** This bit is read only bit and initialized to zero at reset.

Table 1821. PRESENTSTATE field descriptions (continued)

Field	Description
30 PRESENTSTATE_ INHIBITDAT	Command inhibit (DAT) This status bit is generated if either the DAT line active or the read transfer active is set to 1. If this bit is 0, it indicates the HC can issue the next command. Commands with busy signal belong to Command inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete Interrupt in the Normal interrupt status register. **Note:** The host driver can save registers in the range of 0x000-0x00D for a Suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line **Note:** This bit is read only bit and initialized to zero at reset.
31 PRESENTSTATE_ INHIBITCMD	Command inhibit (CMD) If this bit is 0, it indicates the CMD line is not in use and the HC can issue a command using the CMD line. This bit is set immediately after the Command register (0x00F) is written. This bit is cleared when the command response is received. Even if the Command inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal interrupt status register. If the HC cannot issue the command because of a command conflict error or because of command not issued by Auto CMD12 error, this bit remains 1 and the Command Complete is not set. Status issuing Auto CMD12 is not read from this bit. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, host controller manages to issue two commands: CMD12 and a command set by Command register. **Note:** This bit is read only bit and initialized to zero at reset.

Note: DAT line active indicates whether one of the DAT line is on SDMMC bus is in use.

In the case of Read transactions:
This status indicates whether a read transfer is executing on the SDMMC bus. Changing this value from 1 to 0 generates a Block Gap Event Interrupt in the Normal interrupt status register, as the result of the Stop at block gap request being set.

This bit is set in either of the following cases:

1. After the end bit of the Read command.
2. When writing a 1 to Continue request in the Block gap control register to restart a read transfer.

This bit is cleared in either of the following cases:

1. When the end bit of the last data block is sent from the SDMMC bus to the host controller. In case of ADMA2, the last block is designated by the last transfer of descriptor table.
2. When a read transfer is stopped at the block gap initiated by a Stop at block gap request.

The host controller stops read operation at the start of the interrupt cycle of the next block gap by stopping SDMMC clock.

In the case of Write transactions:
This status indicates that a write transfer is executing on the SDMMC bus. Changing this value from 1 to 0 generate a Transfer Complete Interrupt in the Normal interrupt status register.

This bit is set in either of the following cases:

1. After the end bit of the Write command.
2. When writing to 1 to Continue request in the Block gap control register to continue a write transfer.

This bit is cleared in either of the following cases:

1. When the SDMMC card releases write busy of the last data block. If SDMMC card does not drive busy signal for 8 SDMMC clocks, the host controller considers the card drive “not busy”. In case of ADMA2, the last block is designated by the last transfer of descriptor table.
2. When the SDMMC card releases write busy prior to waiting for write transfer as a result of a Stop at block gap request.

Command with busy:
This status indicates whether a command indicates busy (for example erase command for memory) is executing on the SDMMC bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete Interrupt in the Normal interrupt status register.

Note: The HD can issue cmd0, cmd12, cmd13 (for memory) when the DAT lines are busy during data transfer. These commands can be issued when command inhibit (CMD) is set to zero. Other commands are issued when command inhibit (DAT) is set to zero.

57.3.2.11 Host control 1 register (HOSTCONTROL1)

The following table describes the Host control 1 register.

Offset: 0x0028 Access: Read/Write

	0	1	2	3	4	5	6	7
R	HOSTCTRL1_CDSIGSELECT	HOSTCTRL1_CDTESTLEVEL	HOSTCTRL1_EXTDATAWIDTH	HOSTCTRL1_DMASELECT		HOSTCTRL1_HIGHSPEEDENA	HOSTCTRL1_DATAWIDTH	0
W								
Reset	0	0	0	0	0	0	0	0

Figure 1841. Host control 1 register (HOSTCONTROL1)

Table 1822. HOSTCONTROL1 field descriptions

Field	Description
0 HOSTCTRL1_ CDSIGSELECT	Card detect signal detection This bit selects source for card detection. 1 The card detect test level is selected 0 Card detection pin is selected (for normal use) **Note:** Card detect signal is tied to always available state
1 HOSTCTRL1_ CDTESTLEVEL	Card detect test level This bit is enabled while the card detect signal selection is set to 1 and it indicates card inserted or not. Generates (card ins or card removal) interrupt when the normal int sts enable bit is set. 1 Card inserted 0 No card
2 HOSTCTRL1_ EXTDATAWIDTH	Extended data transfer width This bit controls 8-bit bus width mode for embedded device. Support of this function is indicated in 8-bit support for embedded device in the Capabilities register. If a device supports 8-bit bus mode, this bit may be set to 1. If this bit is 0, bus width is controlled by data transfer width in the Host control 1 register. 1 8-bit bus width 0 Bus width is selected by data transfer width
3:4 HOSTCTRL1_ DMASELECT	DMA select One of supported DMA modes can be selected. The host driver checks support of DMA modes by referring the Capabilities register. 00 SDMA is selected 01 32-bit address ADMA1 is selected 10 32-bit address ADMA2 is selected 11 Reserved
5 HOSTCTRL1_ HIGHSPEEDENA	High speed enable This bit is optional. Before setting this bit, the HD checks the High speed support in the Capabilities register. If this bit is set to 0 (default), the HC outputs CMD line and DAT lines at the falling edge of the SDMMC clock (up to 25 MHz/ 20 MHz). If this bit is set to 1, the HC outputs CMD line and DAT lines at the rising edge of the SDMMC clock (up to 50 MHz) If preset value enable in the Host control 2 register is set to 1, host driver needs to reset SDMMC clock enable before changing this field to avoid generating clock glitches. After setting this field, the host driver sets SDMMC clock enable again. 1 High speed mode 0 Normal speed mode
6 HOSTCTRL1_ DATAWIDTH	Data transfer width This bit selects the data width of the HC. The HD selects it to match the data width of the SDMMC card. 8 bit mode is selected using Extended data transfer width field of Host control 1 register. 1 4 bit mode 0 1 bit mode

57.3.2.12 Power control register (POWERCONTROL)

The following table describes the power control register.

Offset: 0x0029 Access: Read/Write

	0	1	2	3	4	5	6	7
R	0	0	0	0	PWRCTRL_SDBUSVOLTAGE			SD_BUS_POWER
W								
Reset	0	0	0	0	0	0	0	0

Figure 1842. Power control register (POWERCONTROL)

Table 1823. POWERCONTROL field descriptions

Field	Description
4:6 PWRCTRL_ SDBUSVOLTAGE	eMMC bus voltage select By setting these bits, the HD selects the voltage level. Before setting this register, the HD checks the voltage support bits in the Capabilities register. 111 3.3 Flattop 110 Reserved ... 000 Reserved **Note:** only 3.3V is supported
7 SD_BUS_ POWER	Before setting this bit, the SD host driver set SD Bus voltage select. If the HC detects the No card state, this bit is cleared. 1 Power on 0 Power off

57.3.2.13 Block gap control register (BLOCKGAPCONTROL)

The following table describes the block gap control register.

Offset: 0x002A Access: Read/Write

	0	1	2	3	4	5	6	7
R	BLKGAPCTRL_BOOTACKENA	BLKGAPCTRL_ALTBOOTMODE	BLKGAPCTRL_BOOTENABLE	BLKGAPCTRL_SPIMODE	BLKGAPCTRL_INTERRUPT	BLKGAPCTRL_RDWAITCTRL	0	BLKGAPCTRL_STOPATBLKGAP
W							BLKGAPCTRL_CONTINUE	
Reset	1	0	0	0	0	0	0	0

Figure 1843. Block gap control register (BLOCKGAPCONTROL)

Table 1824. BLOCKGAPCONTROL field descriptions

Field	Description
0 BLKGAPCTRL_ BOOTACKENA	To check for the boot acknowledge in boot operation. 1 Wait for boot ack from eMMC card 0 Will not wait for boot ack from eMMC card
1 BLKGAPCTRL_ ALTBOOTMODE	To start boot code access in alternative mode. 1 To start alternate boot mode access 0 To stop alternate boot mode access

Table 1824. BLOCKGAPCONTROL field descriptions (continued)

Field	Description
2 BLKGAPCTRL_ BOOTENABLE	To start boot code access. 1 To start boot code access 0 To stop boot code access
3 BLKGAPCTRL_ SPIMODE	SPI mode enable bit. 1 SPI mode 0 SDMMC mode
4 BLKGAPCTRL_ INTERRUPT	This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the HD detects an SD card insertion, this bit is set according to the CCCR of the SDIO card.
5 BLKGAPCTRL_ RDWAITCTRL	The Read Wait function is optional for SDIO cards. If the card supports Read Wait, set this bit to enable use of the Read Wait protocol to stop read data using DAT[2] line. Otherwise the HC has to stop the SD clock to hold read data, which restricts commands generation. When the HD detects an SD card insertion, this bit is set according to the CCCR of the SDIO card. If the card does not support Read Wait, this bit is never set to 1 otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported 1 Enable Read Wait control 0 Disable Read Wait control
6 BLKGAPCTRL_ CONTINUE	Continue request This bit is used to restart a transaction which was stopped using the Stop at block gap request. To cancel stop at the block gap, set Stop at block gap request to 0 and set this bit to restart the transfer. The HC automatically clears this bit in either of the following cases: 1) In the case of a Read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts. 2) In the case of a Write transaction, the Write transfer active changes from 0 to 1 as the write transaction restarts. Therefore it is not necessary for host driver to set this bit to 0. If Stop at block gap request is set to 1, any write to this bit is ignored. 1 Restart 0 Ignored **Note:** The host driver requests a host controller operation by setting the bit. The host controller clears the bit automatically when the operation is completed. Writing a 0 has no effect.
7 BLKGAPCTRL_ STOPATBLKGAP	Stop at block gap request This bit is used to stop executing a transaction at the next block gap for non-DMA,SDMA and ADMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the HD leaves this bit set to 1. Clearing both the Stop at block gap request and Continue request do not cause the transaction to restart. In case of write transfers in which the HD writes data to the Buffer data port register, the HD set this bit after all block data is written. If this bit is set to 1, the HD does not write data to Buffer data port register. This bit affects Read transfer active, Write transfer active, DAT line active and Command inhibit (DAT) in the Present state register. 1 Stop 0 Transfer

57.3.2.14 Wake up control register (WAKEUPCONTROL)

This register is mandatory for the HC, but wakeup functionality depends on the HC system hardware and software. The HD maintains voltage on the SD bus, by setting SD bus power to 1 in the Power control register, when wakeup event via card interrupt is desired.

Offset: 0x002B Access: Read/Write

	0	1	2	3	4	5	6	7
R	0	0	0	0	0	WAKEUP_EN_CARD_REMOVAL	WAKEUP_EN_CARD_INSERTION	WAKEUP_EN_CARD_INTERRUPT
W								
Reset	0	0	0	0	0	0	0	0

Figure 1844. Wakeup control register (WAKEUPCONTROL)

Table 1825. WAKEUPCONTROL field descriptions

Field	Description
5 WAKEUP_EN_ CARD_REMOVAL	Wakeup event enable on SD card removal. This bit enables wakeup event via Card removal assertion in the Normal interrupt status register. 1 Enable 0 Disable
6 WAKEUP_EN_ CARD_INSERTION	Wakeup event enable on SD card insertion This bit enables wakeup event via Card insertion assertion in the Normal interrupt status register. 1 Enable 0 Disable
7 WAKEUP_EN_ CARD_INTERRUPT	Wakeup event enable on card interrupt This bit enables wakeup event via Card interrupt assertion in the Normal interrupt status register. 1 Enable 0 Disable

57.3.2.15 Clock control register (CLOCKCONTROL)

At the initialization of the HC, the HD set the sdmmcctrl_clk frequency select according to the Capabilities register.

Offset: 0x002C Access: Read/Write

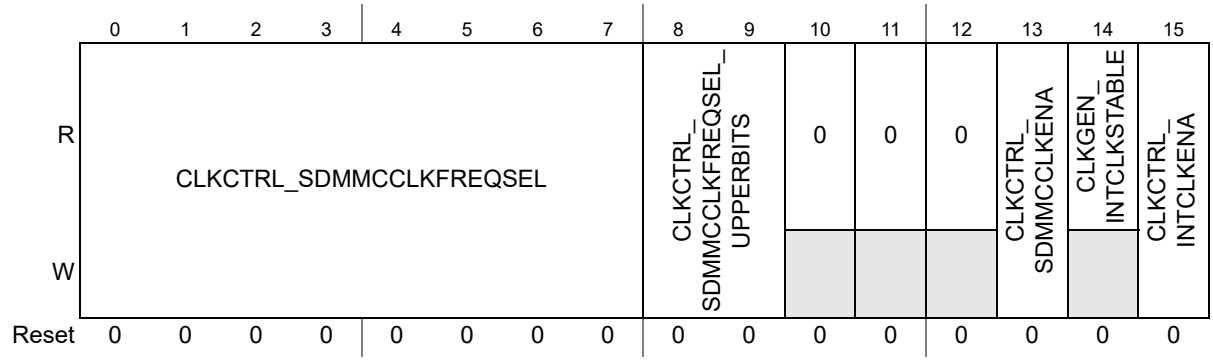

Figure 1845. Clock control register (CLOCKCONTROL)

Table 1826. CLOCKCONTROL field descriptions

Field	Description
0:7 CLKCTRL_ SDMMCCLKFREQSEL	sdmmcctrl_clk frequency select (Lower bits) This register is used to select the frequency of the sdmmccard_clk pin. The frequency is not programmed directly; rather this register holds the divisor of the base clock frequency for SDMMC_CLK clock in the Capabilities register. The length of divider is extended to 10 bits and all divider values are supported. 2 upper bits, [9:8], are programmable in clkctrl_sdmmclkfreqsel_upperbits field. 0x3FF 1/2046 divided clock 0xXXX 1/2N divided clock (Duty 50%) 0x002 1/4 divided clock 0x001 1/2 divided clock 0x000 Base clock (10 MHz-254 MHz) The three default divider values can be calculated by the frequency that is defined by the Base Clock Frequency for SDMMC clock in the Capabilities register. 400 KHz divider value 25 MHz divider value 50 MHz divider value According to the Physical Layer specification, the maximum SDMMC clock frequency is 25 MHz in Normal speed mode and 50 MHz in High speed mode, and never exceeds this limit. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / divisor Thus, choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency. For example, if the base clock frequency for SDMMC clock in the Capabilities register has the value 33 MHz, and the target frequency is 25 MHz, then choosing the divisor value of 01h will yield 16.5 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 KHz, the divisor value of 40h yields the optimal clock value of 258 KHz.
8:9 CLKCTRL_ SDMMCCLKFREQSEL_ UPPERBITS	Upper bits of sdmmcctrl_clk frequency select This bits are assigned to bit [9:8] of clock divider in sdmmcctrl_clk frequency select.
13 CLKCTRL_ SDMMCCLKENA	SDMMC clock enable The HC stops sdmmcctrl_clk when writing this bit to 0. sdmmcctrl_clk frequency select can be changed when this bit is 0. Then, the HC maintains the same clock frequency until sdmmcctrl_clk is stopped. If the HC detects the no card state, this bit is cleared. 1 Enable 0 Disable

Table 1826. CLOCKCONTROL field descriptions (continued)

Field	Description
14 CLKGEN_ INTCLKSTABLE	Internal clock stable This bit is set to 1 when sdmmcctrl_clk clock is stable after writing 1 to Internal clock enable in this register. The SDMMC host driver waits to set sdmmcctrl_clk clock enable until this bit is set to 1. This is useful when using PLL for a clock oscillator that requires setup time. 1 Ready 0 Not ready
15 CLKCTRL_ INTCLKENA	Internal clock enable This bit is set to 0 when the HD is not using the HC or the HC awaits a wakeup event. The HC stops its internal clock to go very low power state. Still, registers may be read and written. Clock starts to oscillate when this bit is set to 1. When clock oscillation is stable, the HC set Internal clock stable in this register to 1. This bit does not affect card detection. 1 Oscillate 0 Stop

57.3.2.16 Timeout control register (TIMEOUTCONTROL)

The following table describes the timeout control register.

At the initialization of the HC, the HD set the data timeout counter value according to the Capabilities register.

Offset: 0x002E Access: Read/Write

	0	1	2	3	4	5	6	7
R	0	0	0	0	TIMEOUT_CTRVALUE			
W								
Reset	0	0	0	0	0	0	0	0

Figure 1846. Timeout control register (TIMEOUTCONTROL)

Table 1827. TIMEOUTCONTROL field descriptions

Field	Description
4:7 TIMEOUT_CTRVALUE	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. Refer to the Data timeout error in the Error interrupt status register for information on factors that dictate timeout generation. Timeout clock frequency will be generated by dividing the TMCLK by this value. When setting this register, prevent inadvertent timeout events by clearing the Data timeout error status enable (in the Error interrupt status enable register) 1111 Reserved 1110 TMCLK * 2^27 ... 0001 TMCLK * 2^14 0000 TMCLK * 2^13 **Note:** TMCLK (Timeout clock) frequency can be either 1 MHz or 1 KHz. Capabilities register, CAPABILITIES31_0, fields CORECFG_TIMEOUTCLKFREQ[5:0] and CORECFG_TIMEOUTCLKUNIT provide the value of TMCLK frequency.

57.3.2.17 Software reset register (SOFTWARERESET)

The following table describes the software reset register.

Note: This register is RW auto clear. The host driver requests a host controller operation by setting the bits. The host controller clears the bits automatically when the operation is completed. Writing a 0 has no effect.

Offset: 0x002F Access: Read/Write

	0	1	2	3	4	5	6	7
R	0	0	0	0	0	0	0	0
W						SWRESET_FOR_DAT	SWRESET_FOR_CMD	SWRESET_FOR_ALL
Reset	0	0	0	0	0	0	0	0

Figure 1847. Software reset register (SOFTWARERESET)

Table 1828. SOFTWARERESET field descriptions

Field	Description
5 SWRESET_FOR_DAT	Software reset for DAT line Only part of data circuit is reset. The following registers and bits are cleared by this bit: Buffer data port register: – Buffer is cleared and initialized. Present state register: – Buffer read enable – Buffer write enable – Read transfer active – Write transfer active – DAT line active – Command inhibit (DAT) Block gap control register: – Continue request – Stop at block gap request Normal interrupt status register: – Buffer read ready – Buffer write ready – Block gap event – Transfer complete 1 Reset 0 Work
6 SWRESET_FOR_CMD	Software reset for CMD line Only part of command circuit is reset. The following registers and bits are cleared by this bit: Present state register: – Command inhibit (CMD) Normal interrupt status register: – Command complete 1 Reset 0 Work
7 SWRESET_FOR_ALL	Software reset for all This reset affects the entire HC except for the card detection circuit. Register bits of type R, RW, RW1C, RWAC are cleared to 0. During its initialization, the HD set this bit to 1 to reset the HC. The HC reset this bit to 0 when Capabilities registers are valid and the HD can read them. Additional use of software reset for all may not affect the value of the Capabilities registers. If this bit is set to 1, the SDMMC card resets itself and must be re initialized by the HD. 1 Reset 0 Work

A reset pulse is generated when writing 1 to each bit of this register. After completing the reset, the HC clears each bit. Because it takes some time to complete software reset, the SDMMC host driver confirms that these bits are 0.

57.3.2.18 Normal interrupt status register (NORMALINTRSTS)

The normal interrupt signal enable affects read of this register, but normal interrupt signal does not affect these reads. An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status bits is set to 1. For all bits except card interrupt and error interrupt, writing 1 to a bit clears it. The card interrupt is cleared when the card stops asserting the interrupt: that is when the card driver services the interrupt condition.

Figure 1848. Normal interrupt status register (NORMALINTRSTS)

Table 1829. NORMALINTRSTS field descriptions

Field	Description
0 REG_ERRORINTRSTS	Error interrupt If any of the bits in the Error interrupt status register are set, then this bit is set. Therefore the HD can test for an error by checking this bit first. 0 No error 1 Error
1 NORMALINTRSTS_BOOTCOMPLETE	Boot terminate interrupt This status is set if the boot operation get terminated. 0 Boot operation is not terminated. 1 Boot operation is terminated. **Note:** SoC does not support Execute In Place from eMMC.
2 NORMALINTRSTS_RCVBOOTACK	Boot ack rcv This status is set if the boot acknowledge is received from device. 0 Boot ack is not received. 1 Boot ack is received. **Note:** SoC does not support Execute In Place from eMMC.
3 NORMALINTRSTS_RETUNINGEVENT	Re-tuning event This status is set if Re-tuning request in the Present state register changes from 0 to 1. Host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-tuning is performed. 0 Re-tuning is not required. **Note:** Re-tuning is not supported.

Table 1829. NORMALINTRSTS field descriptions (continued)

Field	Description
4 NORMALINTRSTS_ INTC	INT_C This status is set if INT_C is enabled and INT_C# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_C interrupt factor. **Note:** INT_C is not supported.
5 NORMALINTRSTS_ INTB	INT_B This status is set if INT_B is enabled and INT_B# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_B interrupt factor. **Note:** INT_B is not supported.
6 NORMALINTRSTS_ INTA	INT_A This status is set if INT_A is enabled and INT_A# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_A interrupt factor. **Note:** INT_A is not supported.
7 NORMALINTRSTS_ CARDINTSTS	Card interrupt Writing this bit to 1 does not clear this bit. 0 No card interrupt 1 Generate card interrupt
8 NORMALINTRSTS_ CARDREMSTS	Card removal This status is set if the card inserted in the Present state register changes from 1 to 0. When the HD writes this bit to 1 to clear this status the status of the card inserted in the Present state register should be confirmed. Because the card detect may possibly be changed when the HD clear this bit an interrupt event may not be generated. 0 Card state stable or debouncing 1 Card removed
9 NORMALINTRSTS_ CARDINSSTS	Card insertion This status is set if the card inserted in the Present state register changes from 0 to 1. When the HD writes this bit to 1 to clear this status, the status of the card inserted in the Present state register should be confirmed. Because the card detect may possibly be changed when the HD clear this bit an interrupt event may not be generated. 0 Card state stable or debouncing 1 Card inserted
10 NORMALINTRSTS_ BUFRDREADY	Buffer read ready This status is set if the Buffer Read Enable changes from 0 to 1. Buffer Read Ready is set to 1 for every CMD19 execution. 0 Not ready to read buffer 1 Ready to read buffer
11 NORMALINTRSTS_ BUFWRREADY	Buffer write ready This status is set if the Buffer Write Enable changes from 0 to 1. 0 Not ready to write buffer 1 Ready to write buffer

Table 1829. NORMALINTRSTS field descriptions (continued)

Field	Description
12 NORMALINTRSTS_ DMAINTERRUPT	DMA interrupt This status is set if the HC detects the host DMA buffer boundary in the Block size register. 0 No DMA interrupt 1 DMA interrupt is generated
13 NORMALINTRSTS_ BLKGAPEVENT	Block gap event If the Stop at block gap request in the Block gap control register is set, this bit is set. Read transaction: This bit is set at the falling edge of the DAT line active status (when the transaction is stopped at SDMMC bus timing. The Read Wait must be supported in order to use this function). Write transaction: This bit is set at the falling edge of write transfer active status (after getting CRC status at SDMMC bus timing). 0 No block gap event 1 Transaction stopped at block gap
14 NORMALINTRSTS_ XFERCOMPLETE	Transfer complete This bit is set when a Read/Write transaction is completed. Read transaction: This bit is set at the falling edge of read transfer active status. There are two cases in which the interrupt is generated. The first is when a data transfer is completed as specified by data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop at block gap request in the Block gap control register (after valid data has been read to the host system). Write transaction: This bit is set at the falling edge of the DAT line active status. There are two cases in which the interrupt is generated. The first is when the last data is written to the card as specified by data length and busy signal is released. The second is when data transfers are stopped at the block gap by setting Stop at block gap request in the Block gap control register and data transfers completed. (after valid data is written to the card and the busy signal is released). **Note:** Transfer complete has higher priority than data timeout error. If both bits are set to 1, the data transfer can be considered complete. 0 No data transfer complete 1 Data transfer complete
15 NORMALINTRSTS_ CMDCOMPLETE	Command complete This bit is set when we get the end bit of the command response (except Auto CMD12 and Auto CMD23). **Note:** Command timeout error has higher priority than command complete. If both are set to 1, it can be considered that the response was not received correctly. 0 No command complete 1 Command complete

Table 1830. Relation between transfer complete and data timeout error

Transfer complete	Data timeout error	Meaning of the status
0	0	Interrupted by another factor
0	1	Timeout occur during transfer
1	Don’t Care	Data transfer complete

Table 1831. Relation between command complete and command timeout error

Command complete	Command timeout error	Meaning of the status
0	0	Interrupted by another factor
Don’t care	1	Response not received within 64 sdmmcctrl_clk cycles
1	0	Response received

57.3.2.19 Error interrupt status register (ERRORINTRSTS)

Status defined in this register can be enabled by the Error interrupt status enable register, but not by the Error interrupt signal enable register. The interrupt is generated when the error interrupt signal enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit and writing to 0 keeps the bit unchanged. More than one status can be cleared at the one register write.

Figure 1849. Error interrupt status register (ERRORINTRSTS)

Table 1832. ERRORINTRSTS field descriptions

Field	Description
3 ERRORINTRSTS_ HOSTERROR	Target response error Occurs when detecting ERROR in m_hresp (DMA transaction). 0 No error 1 Error
6 ERRORINTRSTS_ ADMAERROR	DMA error This bit is set when the host controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error status register. 0 No error 1 Error
7 ERRORINTRSTS_ AUTOCMDERROR	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. 0 No error 1 Error
9 ERRORINTRSTS_ DATAENDBITERROR	Data end bit error Occurs when detecting 0 at the end bit position of read data which uses the DAT line or the end bit position of the CRC status. 0 No error 1 Error
10 ERRORINTRSTS_ DATACRCERROR	Data CRC error Occurs when detecting CRC error when transferring read data which uses the DAT line or when detecting the write CRC status having a value of other than “010”. 0 No error 1 Error
11 ERRORINTRSTS_ DATATIMEOUTERROR	Data timeout error Occurs when detecting one of following timeout conditions: – Busy timeout for R1b, R5b type – Busy timeout after Write CRC status – Write CRC status timeout – Read data timeout 0 No error 1 Timeout
12 ERRORINTRSTS_ CMDINDEXERROR	Command index error Occurs if a command index error occurs in the command response. 0 No error 1 Error
13 ERRORINTRSTS_ CMDENDBITERROR	Command end bit error Occurs when detecting that the end bit of a command response is 0. 0 No error 1 End bit error generated

Table 1832. ERRORINTRSTS field descriptions (continued)

Field	Description
14 ERRORINTRSTS_ CMDCRCERROR	Command CRC error Command CRC error is generated in two cases. – If a response is returned and the command timeout error is set to 0, this bit is set to 1 when detecting a CRT error in the command response – The HC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the HC drives the CMD line to 1 level, but detects 0 level on the CMD line at the next sdmmcctrl_clk edge, then the HC aborts the command (stop driving CMD line) and set this bit to 1. The command timeout error is also set to 1 to distinguish CMD line conflict. 0 No error 1 CRC error generated
15 ERRORINTRSTS_ CMDTIMEOUTERROR	Command timeout error Occurs only if the no response is returned within 64 sdmmcctrl_clk cycles from the end bit of the command. If the HC detects a CMD line conflict, in which case command CRC error is also be set. This bit is set without waiting for 64 sdmmcctrl_clk cycles because the command will be aborted by the HC. 0 No error 1 Timeout

Table 1833. Relation between command CRC error and command timeout error

Command CRC error	Command timeout error	Kinds of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflicts

57.3.2.20 Normal interrupt status enable register (NORMALINTRSTSENA)

The following table describes the normal interrupt status enable register. Setting to 1 enables it.

15 ERRORINTRSIG_ ENABLEREGBIT0	Command timeout error signal enable 0 Masked 1 Enabled

57.3.2.24 Auto CMD error status enable register (AUTOCMDERRSTS)

This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The host driver can determine what kind of Auto CMD12/CMD23 errors occur by this register. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD error is set.

Note: This register is read only and initialized to zero on reset.

Offset: 0x003C Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1854. Auto CMD error status enable register (AUTOCMDERRSTS)

Table 1838. AUTOCMDERRSTS field descriptions

Field	Description
8 AUTOCMDERRSTS_NEXTERROR	Command not issued by Auto CMD12 error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04- D01) in this register. This bit is set to 0 when Auto CMD error is generated by Auto CMD23. 0 No error 1 Not issued
11 AUTOCMDERRSTS_INDEXERROR	Auto CMD index error Occurs if the command index error occurs in response to a command. 0 No error 1 Error
12 AUTOCMDERRSTS_ENDBITERROR	Auto CMD end bit error Occurs when detecting that the end bit of command response is 0. 0 No error 1 End bit error generated
13 AUTOCMDERRSTS_CRCERROR	Auto CMD CRC error Occurs when detecting a CRC error in the command response. 0 No error 1 CRC error generated

Table 1838. AUTOCMDERRSTS field descriptions (continued)

Field	Description
14 AUTOCMDERRSTS_ TIMEOUTERROR	Auto CMD timeout error Occurs if the no response is returned within 64 sdmmcctrl_clk cycles from the end bit of the command. If this bit is set to 1, the other error status bits (D04 - D02) are meaningless. 0 No error 1 Timeout
15 AUTOCMDERRSTS_ NOTEXECERROR	Auto CMD12 not executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the HC cannot issue Auto CMD12 to stop memory multiple block transfer due to some error. If this bit is set to 1, other error status bits (D04 - D01) are meaningless. This bit is set to 0 when Auto CMD error is generated by Auto CMD23. 0 Executed 1 Not executed

Table 1839. Relation between auto CMD12 CRC error and auto CMD12 timeout error

Auto CMD12 CRC error	Auto CMD12 timeout error	Kinds of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

The timing of changing Auto CMD12 error status can be classified in three scenarios:

1. When the HC is going to issue Auto CMD12.
   Set D00 to 1 if Auto CMD12 cannot be issued due to an error in the previous command.
   Set D00 to 0 if Auto CMD12 is issued.
2. At the end bit of Auto CMD12 response.
   Check received responses by checking the error bits D01, D02, D03, D04.
   Set to 1 if error is detected.
   Set to 0 if error is not detected.
3. Before reading the Auto CMD12 error status bit D07.
   Set D07 to 1 if there is a command cannot be issued.
   Set D07 to 0 if there is no command to issue.

Timing of generating the Auto CMD12 error and writing to the Command register are asynchronous. Then D07 is sampled when driver never writing to the Command register. So just before reading the Auto CMD12 Error status register is good timing to set the D07 status bit.

57.3.2.25 Host control 2 register (HOSTCONTROL2)

The following table describes the Host control 2 register.

Offset: 0x003E Access: Read/Write

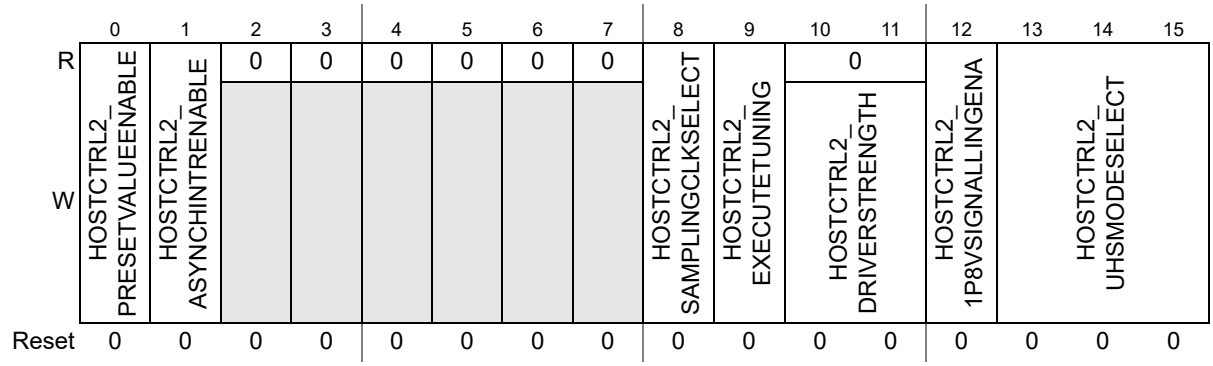

Figure 1855. Host control 2 register (HOSTCONTROL2)

Table 1840. HOSTCONTROL2 field descriptions

Field	Description
0 HOSTCTRL2_ PRESETVALUEENABLE	Preset value enable As the operating sdmmccard_clk frequency and I/O driver strength depend on the host system implementation, it is difficult to determine these parameters in the standard host driver. When preset value enable is set to automatic. This bit enables the functions defined in the Preset value registers. 1 Automatic selection by preset value are enabled 0 sdmmccard_clk and driver strength are controlled by host driver If this bit is set to 0, sdmmccard_clk frequency select and driver strength select in Host control 2 register are set by host driver. If this bit is set to 1, sdmmccard_clk frequency Select and driver strength select in Host control 2 register are set by host controller as specified in the Preset value registers.
1 HOSTCTRL2_ ASYNCHINTRENABLE	Asynchronous interrupt enable 1 Enabled 0 Disabled
8 HOSTCTRL2_ SAMPLINGCLKSELECT	Sampling clock select 1 Tuned clock is used to sample data 0 Fixed clock is used to sample data **Note:** Tunning is not supported. This bit should always set to 0.
9 HOSTCTRL2_ EXECUTETUNING	Execute tuning 1 Execute tuning 0 Not tuned or tuning completed **Note:** Tunning is not supported. This bit should always set to 0.
10:11 HOSTCTRL2_ DRIVERSTRENGTH	Driver strength select In 3.3V signaling, this field is not effective. **Note:** This field is not effective as only 3.3V signaling is supported.

Table 1840. HOSTCONTROL2 field descriptions (continued)

Field	Description
12 HOSTCTRL2_ 1P8VSIGNALLINGENA	1.8V signaling enable This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. **Note:** This field is not effective as only 3.3V signaling is supported.
13:15 HOSTCTRL2_ UHSMODESELECT	This field is used to select DDR mode of eMMC. Set it to 100b to enable High speed DDR mode.

57.3.2.26 Capabilities[31:0] register (CAPABILITIES31_0)

This register provides the HD with information specific to the HC implementation. The HC may implement these values as fixed or loaded from Flash memory during power on initialization.

Offset: 0x0040 Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1856. Capabilities[31:0] register (CAPABILITIES31_0)

Table 1841. CAPABILITIES31_0 field descriptions

Field	Description
0:1 CORECFG_ SLOTTYPE	Slot type support This field indicates usage of a slot by a specific host system. 00 Removable card slot 01 Embedded slot for one device 10 Shared bus slot 11 Reserved
2 CORECFG_ ASYNCHINTRSUPPORT	CORECFG_ASYNCHINTRSUPPORT Enable asynchronous interrupt support 0 Core does not support monitoring of asynchronous interrupt 1 Core supports monitoring of asynchronous interrupt
7 CORECFG_ 3P3VOLTSUPPORT	Voltage support 3.3V This bit indicates whether the HC supports 3.3V. 0 3.3V Not supported 1 3.3V Supported **Note:** 3.3V is supported
8 CORECFG_ SUSPENDRESUME	CORECFG_SUSPENDRESUME SDMMC host controller supports Suspend/Resume functionality. 0 Not supported 1 Supported
9 CORECFG_ SDMASUPPORT	SDMA support This bit indicates whether the HC is capable of using DMA to transfer data between system memory and the HC directly. 0 SDMA Not supported 1 SDMA Supported
10 CORECFG_ HIGHSPEEDSUPPORT	High speed support This bit indicates whether the HC and the host system support High speed mode and they can supply sdmmccard_clk clock frequency from 20 MHz to 50 MHz. 0 High speed not supported 1 High speed supported
12 CORECFG_ ADMA2SUPPORT	ADMA2 support 0 ADMA2 not supported 1 ADMA2 supported **Note:** ADMA2 configuration is selected on programming of CORE_CONFIG.corecfg_adma2support bit.
13 CORECFG_ 8BITSUPPORT	Extended media bus support This bit indicates whether the host controller is capable of using 8-bit bus width mode. 0 Extended media bus not supported 1 Extended media bus supported

Table 1841. CAPABILITIES31_0 field descriptions (continued)

Field	Description
14:15 CORECFG_ MAXBLKLENGTH	Max block length This value indicates the maximum block size that the HD can read and write to the buffer in the HC. The buffer transfers this block size without wait cycles. Three sizes can be defined as indicated below. 00 512 bytes 01 1024 bytes 10 2048 bytes 11 4096 bytes **Note:** max 512 B block size is supported.
16:23 CORECFG_ BASECLKFREQ	Base clock frequency of SDMMC_CLK It's value is 8'b00110010 (50 MHz). 50 MHz is shown as reset value, but sdmmc_clk freq is 100 MHz. 50 MHz clk for SDMMC card and controller should be generated by software by dividing sdmmc_clk from 2. **Note:** Base clock frequency configuration is programmed in CORE_CONFIG.baseclkfreq_sdmmc_clk field.
24 CORECFG_ TIMEOUTCLKUNIT	Timeout clock unit This bit shows the unit of base clock frequency used to detect data timeout error. 0 KHz 1 MHz
26:31 CORECFG_ TIMEOUTCLKFREQ	Timeout clock frequency This bit shows the base clock frequency used to detect data timeout error. It's value is 6'b000001. Because timeout clock unit is 1 MHz, so timeout clock frequency is 1 MHz.

57.3.2.27 Capabilities[63:32] register (CAPABILITIES63_32)

This register provides the HD with information specific to the HC implementation. The HC may implement these values as fixed or loaded from Flash memory during power on initialization.

Offset: 0x0044 Access: Read

Table 1849. HOSTCONTROLLERVER field descriptions

Field	Description
0:7 SDHC_VENVERNUM	Vendor version number The vendor version number is set to 0x10 (1.0)
8:15 SPECIFICATION VERSIONNUMBER	Specification version number The host controller version number is set to 0x02 (Host specification version 3.00).

57.3.2.33 Force event for auto CMD error status register (FORCEEVENTFORAUTOCMDERRSTS)

The Force event register is not a physically implemented register. Rather, it is an address at which the Auto CMD12 Error status register can be written:

- Writing 1: set each bit of the Auto CMD12 Error status register
- Writing 0: no effect

Offset: 0x0050 Access: Write only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0		0	0

Field	Description
8 FORCECMDNOTISSUED BYAUTOCMD12ERR	Force event for command not issued by Auto CMD12 error 1 Interrupt is generated 0 No interrupt
11 FORCEAUTOCMD INDEXERR	Force event for Auto CMD index error 1 Interrupt is generated 0 No interrupt
12 FORCEAUTOCMD ENDBITERR	Force event for Auto CMD index error 1 Interrupt is generated 0 No interrupt
13 FORCEAUTOCMD CRCERR	Force event for Auto CMD CRC error 1 Interrupt is generated 0 No interrupt

Table 1850. FORCEEVENTFORAUTOCMDERRSTS field descriptions (continued)

Field	Description
14 FORCEAUTOCMD TIMEOUTERR	Force event for Auto CMD timeout error 1 Interrupt is generated 0 No interrupt
15 FORCEAUTOCMD NOTEXEC	Force event for Auto CMD12 NOT executed 1 Interrupt is generated 0 No interrupt

57.3.2.34 Force event for error interrupt status register (FORCEEVENTFORERRINTSTS)

The Force event register is not a physically implemented register. Rather, it is an address at which the Error interrupt status register can be written. The effect of a write to this address will be reflected in the Error interrupt status register if the corresponding bit of the Error interrupt status enable register is set:

- Writing 1: set each bit of the Error interrupt status register
- Writing 0: no effect

Offset: 0x0052 Access: Write only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0

15 FORCECMDTIMEOUTERR	Force event for command timeout error 1 Interrupt is generated 0 No interrupt

57.3.2.35 ADMA Error status register (ADMAERRSTS)

When ADMA error interrupt occurs, the ADMA error states field in this register holds the ADMA state and the ADMA System address register holds the address around the error descriptor. The following table describes the ADMA Error interrupt register.

Offset: 0x0054 Access: Read

	0	1	2	3	4	5	6	7
R	0	0	0	0	0	ADMAERRSTS_ADMALENMISMATCHERR	ADMAERRSTS_ADMAERRORSTATE	
W								
Reset	0	0	0	0	0	0	0	0

Figure 1865. ADMA Error status register (ADMAERRSTS)

Table 1852. ADMAERRSTS field descriptions

Field	Description
5 ADMAERRSTS_ ADMALENMISMATCHERR	ADMA length mismatch error This error occurs in the following 2 cases. While block count enable being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. Total data length can not be divided by the block length. 1 Error 0 No error
6:7 ADMAERRSTS_ ADMAERRORSTATE	ADMA error state This field indicates the state of ADMA when error is occurred during ADMA data transfer. This field never indicates “10” because ADMA never stops in this state. D01–D00: ADMA error state when error occurred. Contents of SYS_SDR register: 00 ST_STOP (Stop DMA) points to next of the error descriptor 01 ST_FDS (Fetch Descriptor) points to the error descriptor 10 Never set this state (Not used) 11 ST_TFR (Transfer Data) points to the next of the error descriptor

57.3.2.36 ADMA System address n register (ADMASYSADDRn)

The following table describes the ADMA System address register.

Offset: 0x0058 + n*0x2 (n=0 to 3) Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ADMA_SYSADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1866. ADMA System address n register (ADMASYSADDRn)

Table 1853. ADMASYSADDRn field descriptions

Field	Description
0:15 ADMA_SYSADDRESS	ADMA system address This register holds byte address of executing command of the descriptor table. 32-bit Address descriptor uses lower 32-bit of this register. At the start of ADMA, the host driver set start address of the descriptor table. The ADMA increments this register address, which points to next line, when every fetching a descriptor line. When the ADMA error interrupt is generated, this register holds valid descriptor address depending on the ADMA state. The host driver programs descriptor table on 32-bit boundary and set 32-bit boundary address to this register. ADMA2 ignores lower 2-bit of this register and assumes it to be 00b. 32-bit Address ADMA register value 32-bit system address XXXXXXXX 0x00000000 0x00000000 XXXXXXXX 0x00000004 0x00000004 ... XXXXXXXX 0xFFFFFFFC 0xFFFFFFFC

57.3.2.37 Boot timeout control register (BOOTTIMEOUTCNT)

The following table describes the boot timeout control register.

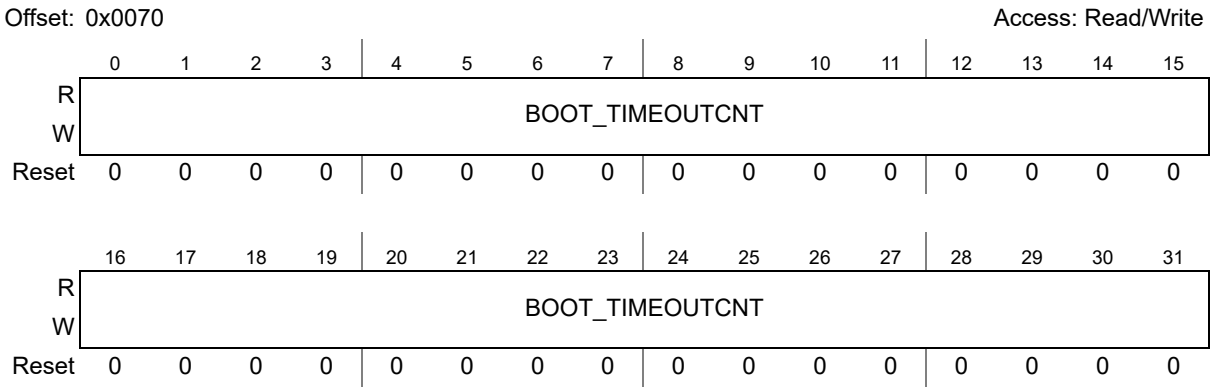

Figure 1867. Boot timeout control register (BOOTTIMEOUTCNT)

Table 1854. BOOTTIMEOUTCNT field descriptions

Field	Description
0:31 BOOT_TIMEOUTCNT	Boot data timeout counter value This value determines the interval by which DAT line timeouts are detected during boot operation for eMMC card. The value is in number of sdmmccard_clk clock. **Note:** SoC does not support Execute In Place from eMMC.

57.3.2.38 Core configuration register (CORE_CONFIG)

The register provides field to configure SDMMC protocol clock frequency (SDMMC_CLK), ADMA2 selection and maximum IO current value.

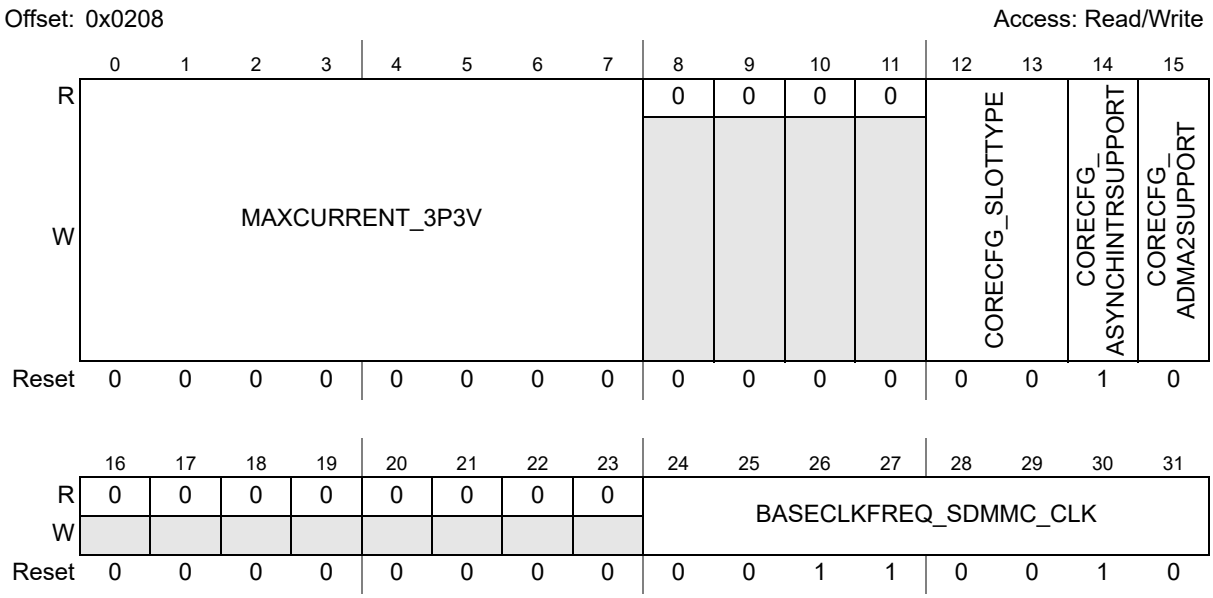

Figure 1868. Core configuration register (CORE_CONFIG)

Table 1855. CORE_CONFIG field descriptions

Field	Description
0:7 MAXCURRENT_3P3V	Maximum current for 3.3V. Value depends on IO drive strength.
12:13 CORECFG_SLOTTYPE	Select slot type 00 Removable card slot 01 Embedded slot for one device 10 Shared bus slot 11 Reserved
14 CORECFG_ ASYNCHINTRSUPPORT	Enable asynchronous interrupt support 0 Core does not support monitoring of asynchronous interrupt 1 Core supports monitoring of asynchronous interrupt
15 CORECFG_ ADMA2SUPPORT	Selection for ADMA2 support
24:31 BASECLKFREQ_ SDMMC_CLK	Base clock frequency for SDMMC clock. This is the frequency of the sdmmc_clk. 8'h32 = 50 MHz

57.3.2.39 Feedback clock selection register (FB_CLK_SEL)

The register is used to program the feedback clock source.

Offset: 0x0210 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

57.4 Driver flow sequence

This section provides the details about various data transfer protocols for 3MCR host controller.

Note: FB_CLK_SEL.feedbackClk_sel[1:0] register field should be programmed for selection of feedback clock. Fore more detail refer to Section 57.2.3: Clocks.

57.4.1 Non-DMA transaction

The sequence for Not Using DMA [non - DMA] is shown in *Figure 1875* and *Table 1862*.

Figure 1875. Data transfer using DAT line sequence (not using DMA)

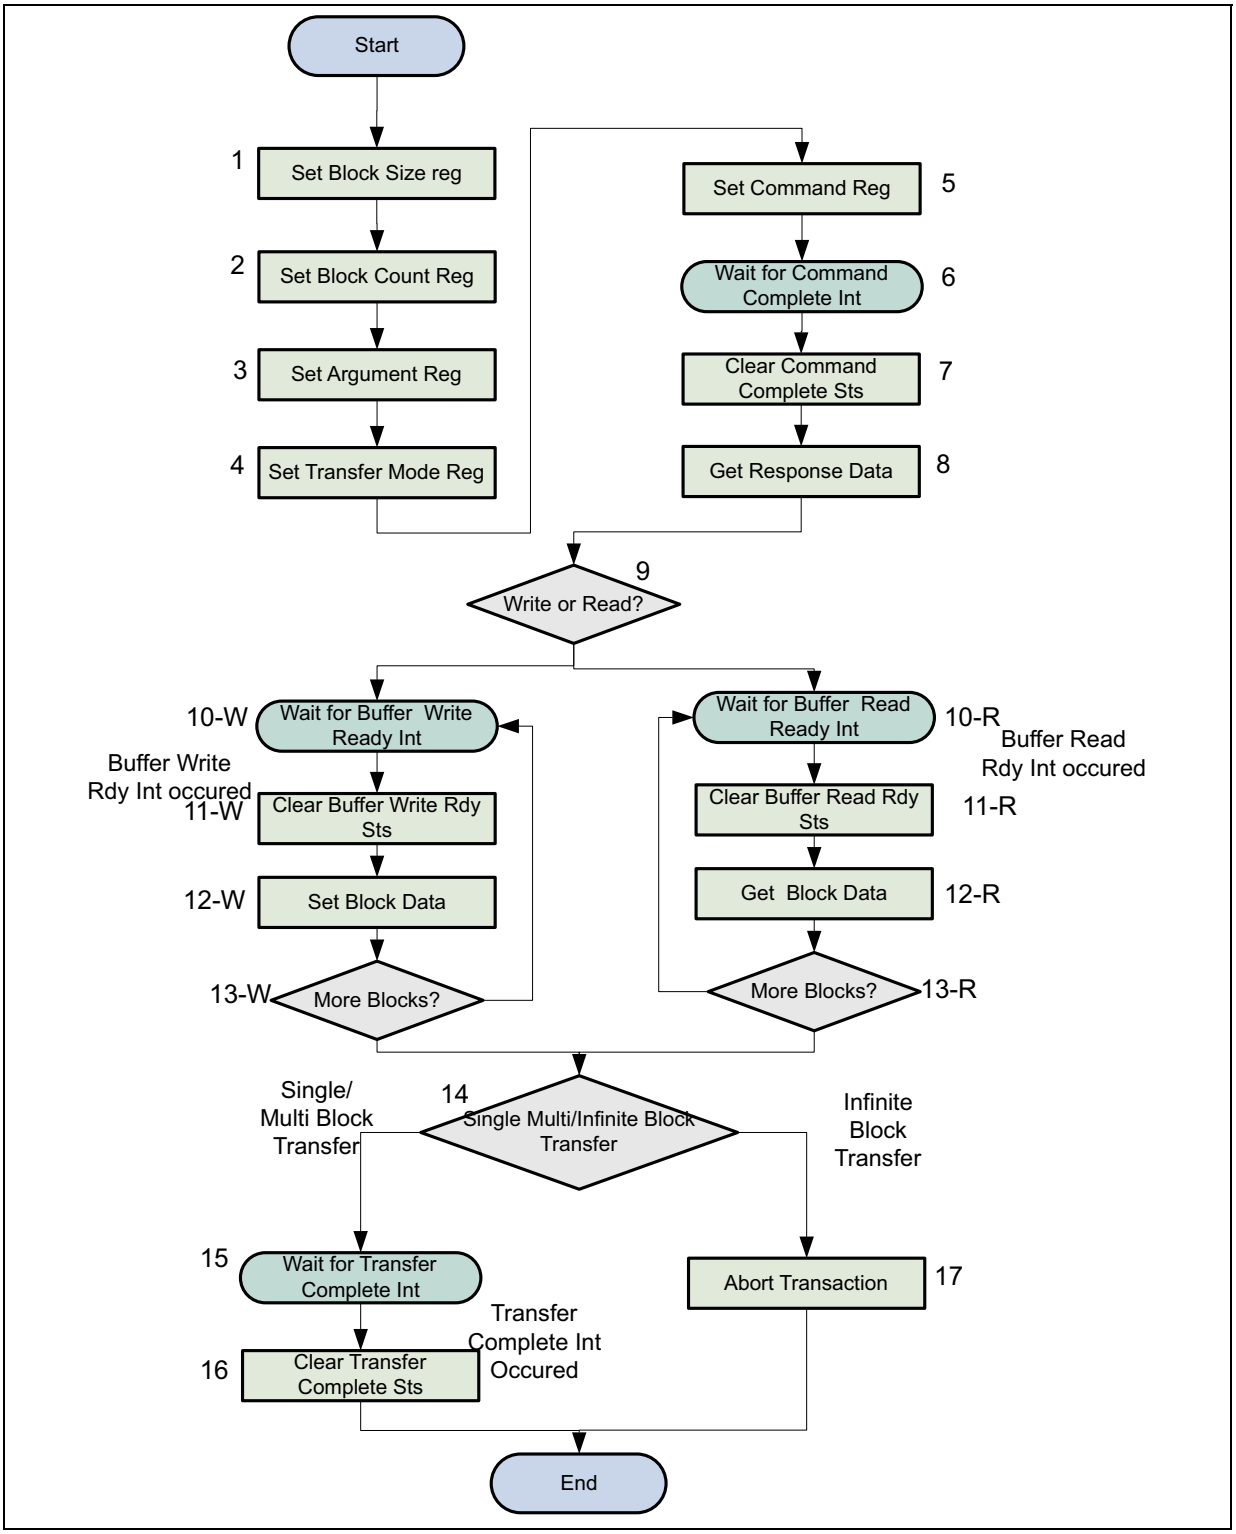

Table 1862. Non-DMA transaction

Step	Description
1	Set the value corresponding to the executed data byte length of one block to Block size register.
2	Set the value corresponding to the executed data block count to Block count register.
3	Set the value corresponding to the issued command to Argument register.
4	Set the value to Multi / Single Block Select and Block Count Enable. Set the value corresponding to the issued command to Data transfer direction, Auto CMD12 Enable and DMA Enable.
5	Set the value to Multi / Single Block Select and Block Count Enable. Set the value corresponding to the issued command to Data transfer direction, Auto CMD12 Enable and DMA Enable.
6	Wait for the Command Complete Interrupt
7	Write 1 to the Command Complete in the Normal interrupt status register for clearing this bit.
8	Read Response register and get necessary information in accordance with the issued command.
9	In the case where this sequence is for write to a card, go to step (10-W). In case of read from a card, go to step (10-R).
10-W	Wait for Buffer Write Ready interrupt. Non DMA Write transfer On receiving the Buffer Write Ready interrupt the system processor will act as a master and start transferring the data via Buffer data port register (FIFO_1). Transmitter starts sending the data in SDMMC bus when a block of data is ready in FIFO_1. While transmitting the data in SDMMC bus the Buffer Write Ready interrupt is sent to the system processor for the second block of data. The system processor will act as a master and start sending the second block of data via Buffer data port register to FIFO_2. Buffer Write Ready interrupt will be asserted only when a FIFO is empty to receive a block of data.
11-W	Write 1 to the Buffer Write Ready in the Normal interrupt status register for clearing this bit.
12-W	Write block data (in according to the number of bytes specified at the step (1)) to Buffer data port register.
13-W	Repeat until all blocks are sent and then go to step (14).
10-R	Non DMA Read transfer Buffer Read Ready interrupt is asserted whenever a block of data is ready in one of the FIFOs. On receiving the Buffer Read Ready interrupt the system processor will act as a master and start reading the data via Buffer data port register (FIFO_1). Receiver start reading the data from SDMMC bus only when a FIFO is empty to receive a block of data. When both the FIFOs are full the host controller will stop the data coming from the card through Read Wait mechanism (if card supports Read Wait) or through clock stopping. Wait for Buffer Read Ready interrupt
11-R	Write 1 to the Buffer Read Ready in the Normal interrupt status register for clearing this bit.
12-R	Read block data (in according to the number of bytes specified at the step (1)) from the Buffer data port register

Table 1862. Non-DMA transaction (continued)

Step	Description
13-R	Repeat until all blocks are received and then go to step (14).
14	If this sequence is for Single or Multiple block transfer, go to step (15). In case of Infinite block transfer, go to step (17).
15	Wait for Transfer Complete Interrupt.
16	Write 1 to the Transfer Complete in the Normal interrupt status register for clearing this bit.
17	Perform the sequence for Abort transaction.

Note: Step (1) and (2) can be executed at the same time. Step (4) and(5) can be executed at the same time.

57.4.2 DMA transaction

The burst types like 8-beat incrementing burst or 4-beat incrementing burst or single transfer is used to transfer or receive the data from the system memory mainly to avoid the hold of the Host/System bus by the master for a longer time.

The sequence for using DMA is shown in *Figure 1876* and *Table 1863*.

Note: For data read/write using SDMA, swapping of bytes is not required. Swapping of bytes should be disabled using EMMC_MSTR_EN_BYTE_SWAP (bit 27) of PCM REG3. This bit should be reset to 0. Reset value of this bit is 1. SDMMC driver should reset it.

Figure 1876. Data transfer using DAT line sequence (using DMA)

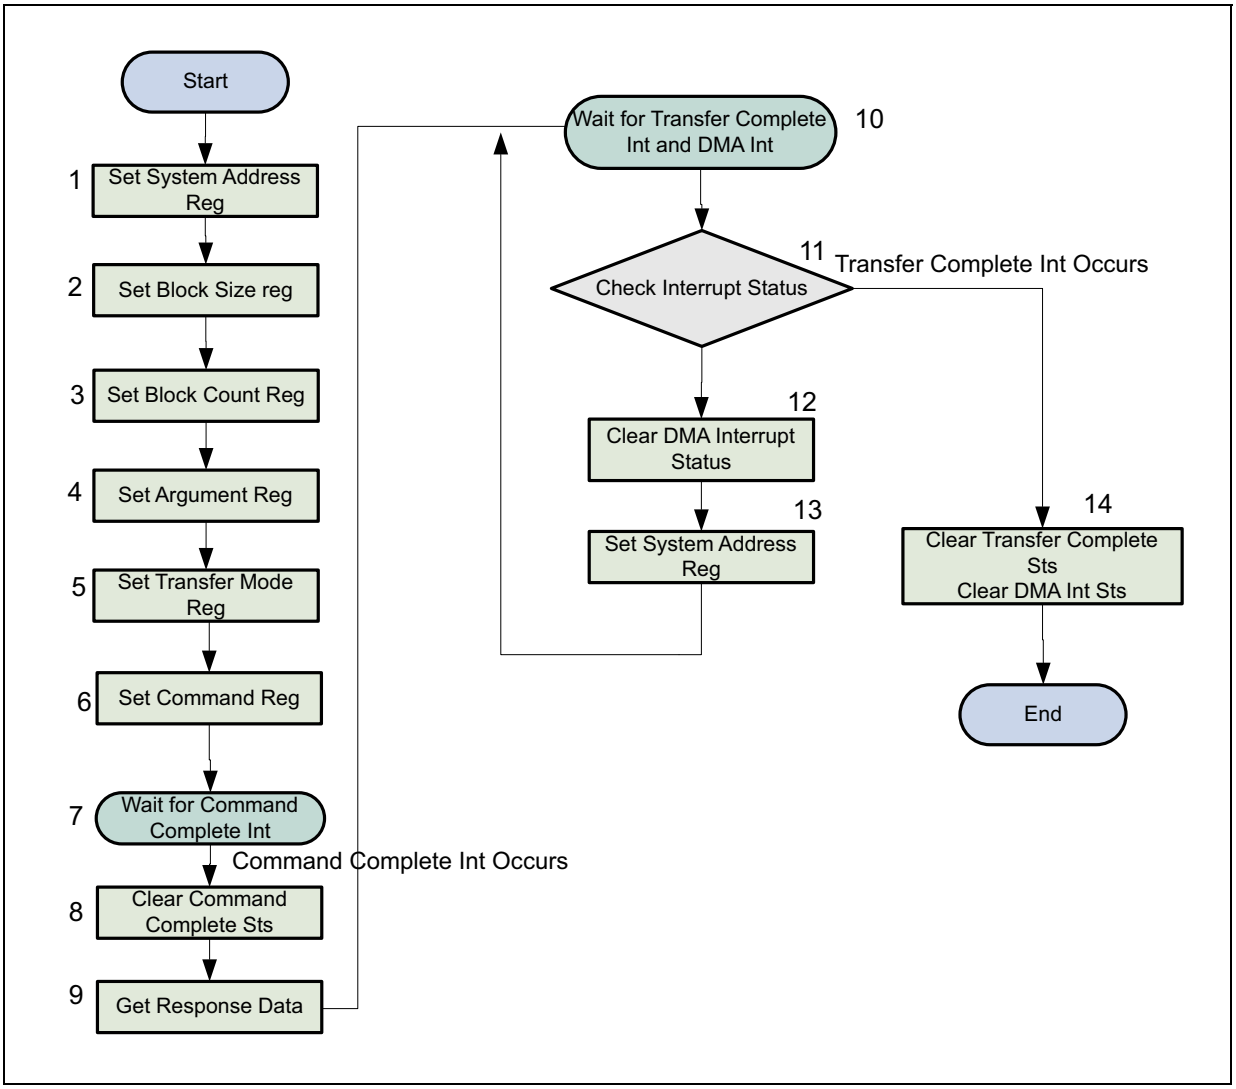

Table 1863. DMA transaction

Step	Description
1	Set the system address for DMA in the System address register.
2	Set the value corresponding to the executed data byte length of one block in the Block size register.
3	Set the value corresponding to the executed data block count in the Block count register.
4	Set the value corresponding to the issued command to Argument register.
5	Set the value to Multi / Single block select and Block count enable. Set the value corresponding to the issued command to Data transfer direction, Auto CMD12 Enable and DMA Enable.
6	Set the value corresponding to the issued command to Command register.
7	Wait for the Command Complete Interrupt.

Table 1863. DMA transaction (continued)

Step	Description
8	Write 1 to the Command Complete in the Normal interrupt status register for clearing this bit.
9	Read Response register and get necessary information in accordance with the issued command. DMA read transfer On receiving the response end bit from the card for the write command (data flowing from host to card) the host controller will act as the master and request the System/Host bus. After receiving the grant the host controller will start reading a block of data from the system memory and fills the first FIFO. Whenever a block of data is ready the transmitter will start sending the data in SDMMC bus. While transmitting the data in SDMMC bus the host controller requests the bus to fill the second block in second FIFO. Ping-pong FIFOs are used to increase the throughput. Similarly the host controller reads a block of data from the system memory whenever a FIFO is empty. This will continue till all the blocks are read from the system memory. Transfer Complete Interrupt will be set only after transferring all the blocks of data to the card. DMA write transfer The block of data received from the card (data flowing from card to host) is stored in first half of the FIFO. Whenever a block of data is ready the host controller will act as the master and request the System/Host bus. After receiving the grant the host controller will start writing a block of data into the system memory from the first FIFO. While transmitting the data into system memory the host controller will receive the second block of data and store in second FIFO. Similarly the host controller write a block of data into the system memory whenever data is ready. This will continue till all the blocks are transferred to the system memory. Transfer Complete Interrupt will be set only after transferring all the blocks of data to the system memory. **Note:** Host controller will receive a block of data from the card only when it has room to store a block of data in FIFO. When both the FIFOs are full the host controller will stop the data coming from the card through Read Wait mechanism (if card supports Read Wait) or through clock stopping.
10	Wait for the Transfer Complete Interrupt and DMA Interrupt.
11	If Transfer Complete is set 1, go to Step(4) else if DMA Interrupt is set to 1, go to Step(12). Transfer Complete is higher priority than DMA Interrupt.
12	Write 1 to the DMA Interrupt in the Normal interrupt status register to clear this bit.
13	Set the next system address of the next data position to the System address register and go to Step (10).
14	Write 1 to the Transfer Complete and DMA Interrupt in the Normal interrupt status register to clear this bit.

Note: Step (2) and Step (3) can be executed at the same time. Step (5) and Step (6) can also be executed at the same time.

For example, if the host wants to transfer 4KB of data to the card. Assume the maximum block size is 512 bytes.

Then the host driver will program the Block size register as 512 and Block count register with the value 8.

The AHB master and transmitter residing inside the 3MCR host controller will get the information (how much data to transfer) from these registers. Using the above information,

the AHB master will act as a master and initiate a data Read transaction to read a block of data (512 bytes) from the system memory. Whenever a block of data is ready in FIFO, the transmitter will start transmitting the block of data (512) on SDMMC bus. After transmitting the entire block of data to the card, the transmitter will wait for a status response from the card. Transmitter will send the next block of data only, when it receives a good status response from the card for the previous block of data otherwise the transaction will be aborted and the host will go for a fresh transaction.

57.4.3 ADMA transactions

Figure 1877 and *Table 1864* describe the ADMA transaction sequence.

Note: For data read/write using ADMA, swapping of bytes is not required. Swapping of bytes should be disabled using EMMC_MSTR_EN_BYTE_SWAP (bit 27) of PCM REG3. This bit should be reset to 0. Reset value of this bit is 1. SDMMC driver should reset it.

SD standard provides TCD value description in little endian format. To provide the correct value of TCD to HC these should be byte swapped in software before programming in SRAM memory.

Figure 1877. ADMA transaction flow

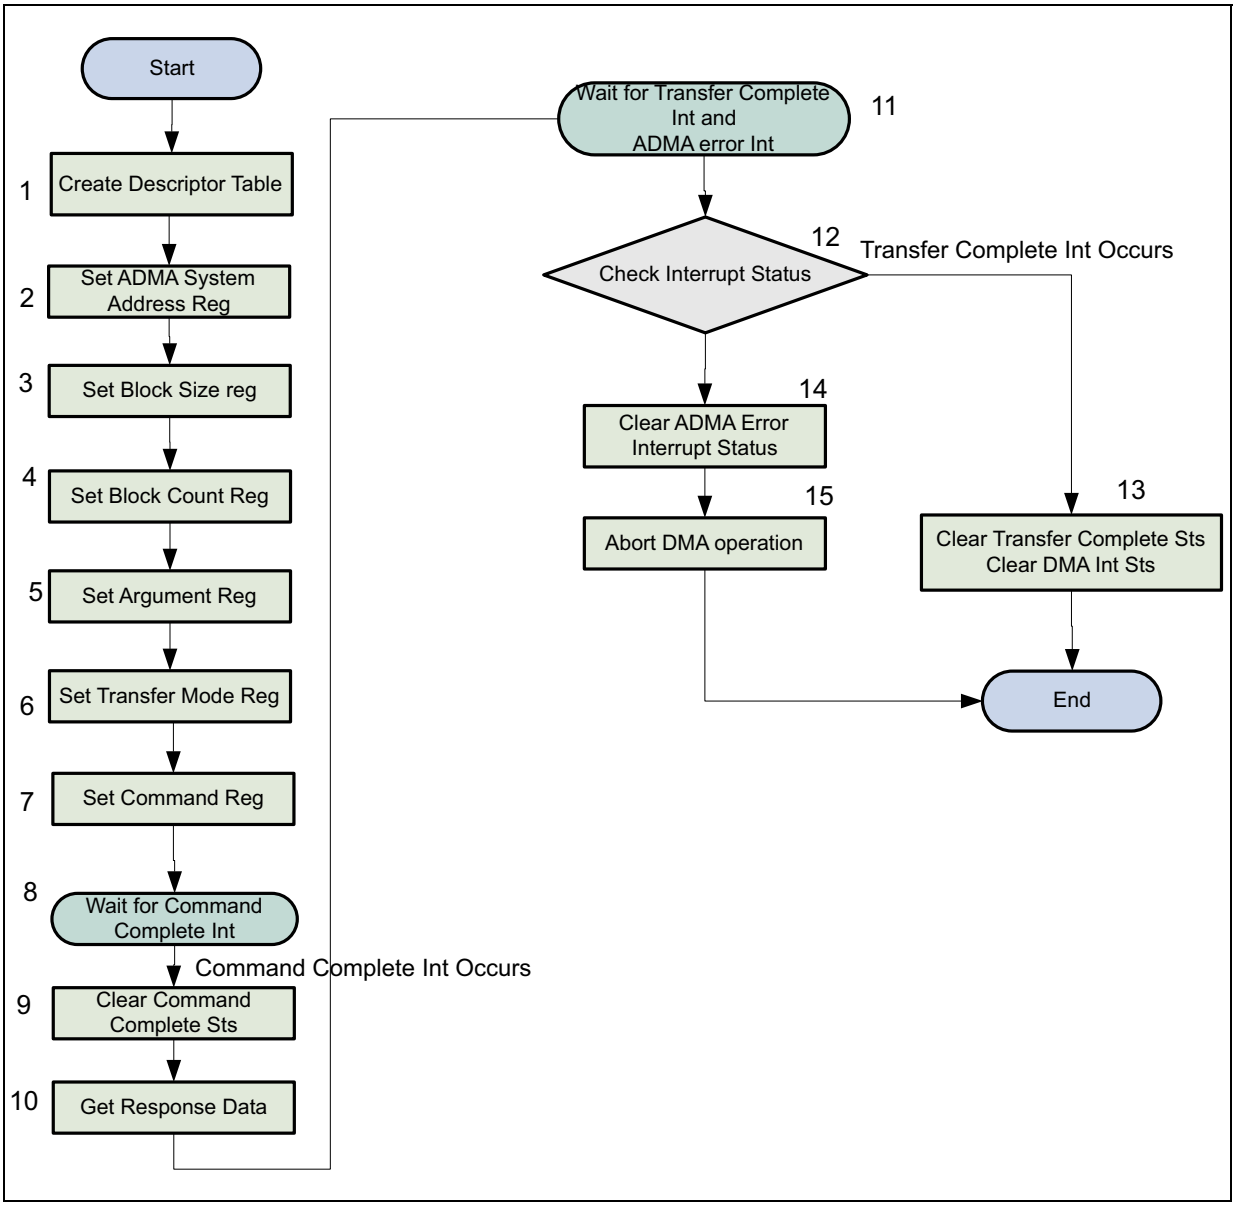

Table 1864. ADMA transaction flow

Step	Description
1	Create descriptor table for ADMA in the system memory.
2	Set the Descriptor address for ADMA in the ADMA System address register.
3	Set the value corresponding to the executed data byte length of one block in the Block size.

Table 1864. ADMA transaction flow (continued)

Step	Description
4	Set the value corresponding to the executed data block count in the Block count register. If the Block Count Enable in the Transfer mode register is set to 1, total data length can be designated by the Block count register and the Descriptor table. These two parameters indicate same data length. However, transfer length is limited by the 16-bit Block count register. If the Block Count Enable in the Transfer mode register is set to 0, total data length is designated by not Block count register but the Descriptor table. In this case, ADMA reads more data than length programmed in descriptor from SDMMC card. Too much read operation is aborted asynchronously and extra read data is discarded when the ADMA is completed
5	Set the argument value to the Argument register.
6	Set the value to the Transfer mode register. The host driver determines Multi / Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable.
7	Set the value to the Command register. When writing to the upper byte [3] of the Command register, the SDMMC command is issued and DMA is started.
8	Wait for the Command Complete Interrupt.
9	Write 1 to the Command Complete in the Normal interrupt status register to clear this bit.
10	Read Response register and get necessary information of the issued command.
11	Wait for the Transfer Complete Interrupt and ADMA Error Interrupt.
12	If Transfer Complete is set 1, go to Step (*13*) else if ADMA Error Interrupt is set to 1, go to Step (14).
13	Write 1 to the Transfer Complete Status in the Normal interrupt status register to clear this bit.
14	Write 1 to the ADMA Error interrupt status in the Error interrupt status register to clear this bit.
15	Abort ADMA operation. SDMMC card operation is stopped by issuing Abort command. If necessary, the host driver checks ADMA Error status register to detect why ADMA error is generated.

Note: Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

57.4.4 Abort transaction (sync and async)

An Abort transaction is performed using CMD12 for a SDMMC memory card.

There are two cases where the HD needs to do an Abort transaction:

1. When the HD stops infinite block transfers.
2. When HD stops transfers while a multiple block transfer is exacting.

There are two ways to issue an Abort command. The first is an asynchronous Abort. The second is an synchronous Abort. In an asynchronous abort sequence, the HD can issue an Abort command at anytime unless command inhibit (CMD) in the Present state register is

set to 1. In a synchronous abort, the HD issues an Abort command after the data transfer stopped by using Stop at block gap request in the Block gap control register.

57.4.4.1 Synchronous abort

The flow for synchronous abort is shown in *Figure 1878* and *Table 1865*.

Figure 1878. Synchronous abort transaction

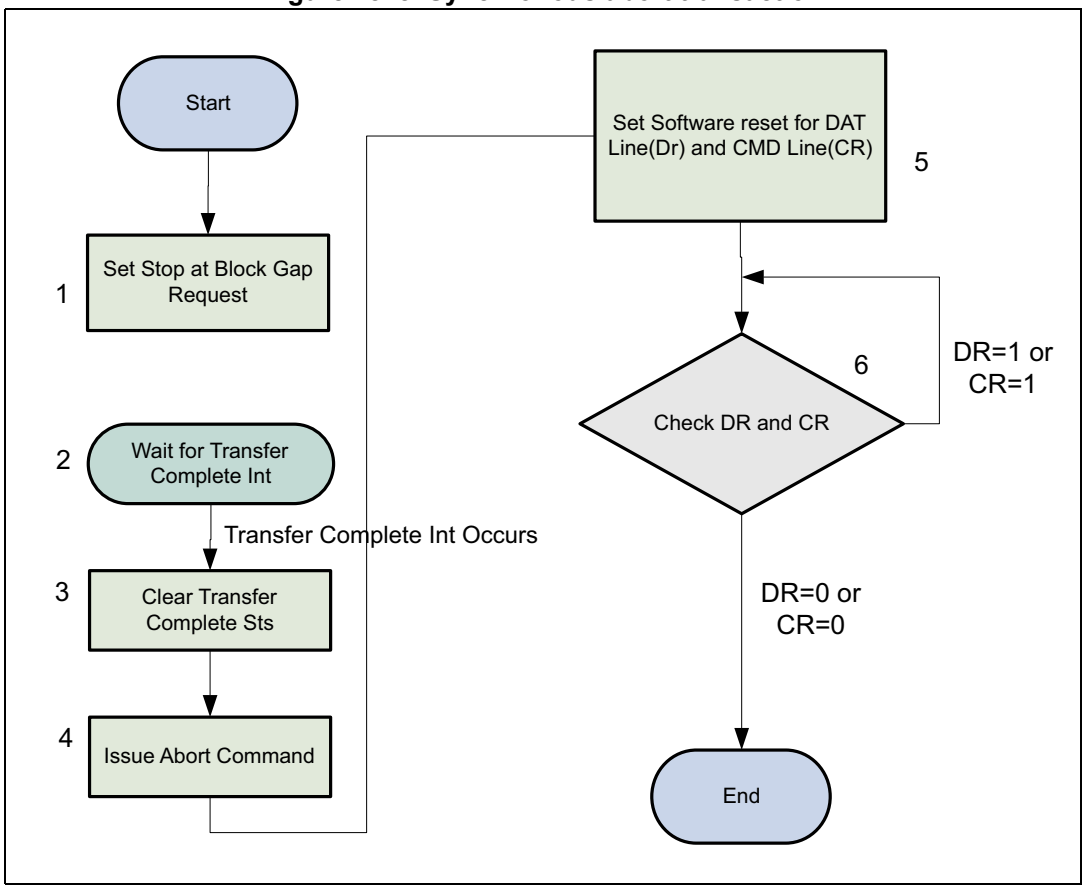

Table 1865. Abort transaction

Step	Description
1	Set the Stop at block gap request in the Block gap control register to 1 to stop SDMMC transactions.
2	Wait for Transfer Complete Interrupt.
3	Set the Transfer Complete to 1 in the Normal interrupt status register to clear this bit.
4	Issue Abort command.
5	Set both Software Reset for DAT Line and Software Reset for CMD Line to 1 in the Software reset register to do software reset.
6	Check Software Reset for DAT Line and Software Reset for CMD Line in the Software reset register. If both Software Reset for DAT Line and Software Reset for CMD Line are 0, go to “END”. If either Software Reset for DAT Line or Software Reset for CMD Line is 1, repeat step(6).

57.4.4.2 Asynchronous abort

The flow for asynchronous abort is shown in *Figure 1879* and *Table 1866*.

Figure 1879. Asynchronous abort

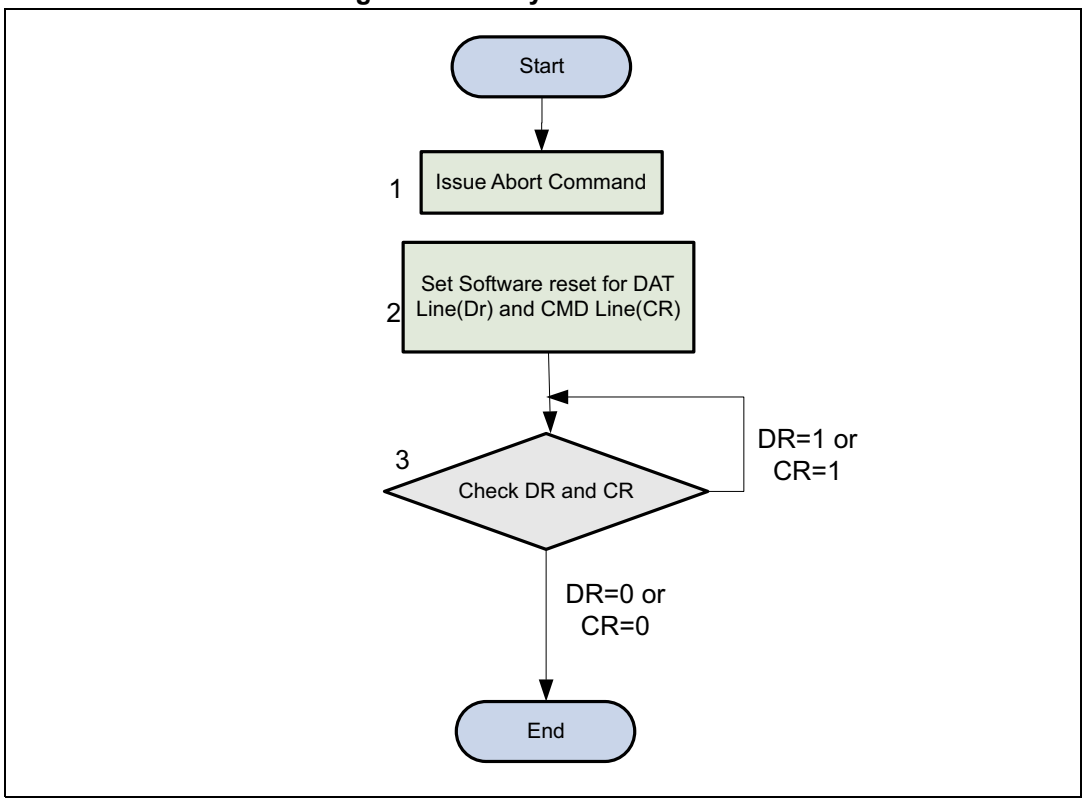

Table 1866. Asynchronous abort

Step	Description
1	Issue Abort command.
2	Set both Software Reset for DAT Line and Software Reset for CMD Line to 1 in the Software reset register to do software reset.
3	Check Software Reset for DAT Line and Software Reset for CMD Line in the Software reset register. If both Software Reset for DAT Line and Software Reset for CMD Line are 0, go to “End”. If either Software Reset for DAT Line or Software Reset for CMD Line is 1, go to step (3).

57.4.5 Boot operation (normal and alternate)

The boot operation is described below.

Note: SoC does not support Execute In Place from eMMC.

57.4.5.1 Normal boot operation

The host driver writes the boot timeout value into Boot timeout control register as per the eMMC4.3+ specification.

When the host driver sets the “boot_en” to 1 in Block gap control register and data_trans_direction bit to “1” in Transfer mode register, the host controller drives the cmd line to “0” for boot operation.

If the host controller is configured to wait for boot ack from the eMMC4.3+ device, the controller receives the boot acknowledgment and asserts the “boot_ack_rcv” interrupt to the driver.

If the host controller does not receive the boot acknowledgment from the device within the timeout value, the host controller will assert the data timeout error interrupt.

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the Boot timeout control register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and host controller sends the same to system whenever a block of data is received from device.

The host controller terminates the boot operation when the programmed number of blocks is transferred to the system. The driver can write “boot_en” as “0” in Block gap control register and then driver waits for boot terminate interrupt. After the boot termination interrupt comes, the host driver issues soft reset for DATA line to the host controller to reset the data state machines to idle state.

The boot operation can also be terminated in between the boot transfer. Program the Stop at block gap request while transfer is going on and then wait for Transfer Complete Interrupt. Once the driver receives the Transfer Complete Interrupt the driver clears the boot enable and then the host driver issues soft reset for DATA line to the host controller to reset the data state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (that is, ignore sending Abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgment to the host, the host controller will assert data_crc_err interrupt on the driver. In this case, the host driver has to stop the boot mode operation by setting boot_en as “0” in Block gap control register and write soft reset for cmd and data line.

If the device sends end bit as “0” in acknowledgment to the host, the host controller will assert data_end_bit_err interrupt on the driver.

The host driver stops the boot mode operation by setting boot_en as “0” in Block gap control register and write soft reset for cmd and data line.

Note: Enable the boot_ack_chk bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot ack first and followed by boot data.

57.4.5.2 Alternate boot operation

The host driver writes the boot timeout value as per the eMMC4.3+ spec into Boot timeout control register.

If the “alt_boot_en” and “boot_en” is set to 1 in Block gap control register and ”data_trans_direction” bit is set to 1 in Transfer mode register, the host controller drives the CMD0 (0xFFFFFFFA) on the CMD line.

The system waits for Command Complete Interrupt before “boot_ack_rcv” interrupt.

If the host controller is configured to wait for boot ack from the eMMC4.3+ device, the controller receives the boot acknowledgment and asserts the “boot_ack_rcv” interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and host controller sends the same to system whenever a block of data is received from device.

The host controller terminates the boot operation when the programmed number of blocks are transferred to the system and the driver programs “boot_en” and alt_boot_en as “0” in Block gap control register and then wait for boot terminate interrupt. Once the driver receives the boot termination interrupt. The driver needs to send CMD0 to inform the device about the boot operation complete. The driver programs Command register with argument “0x00000000” for the cmd0 (CMDTYPE as Abort) and waits for Command Complete. After that the driver need to issues the soft reset for data to host controller to reset the data state machines to idle state.

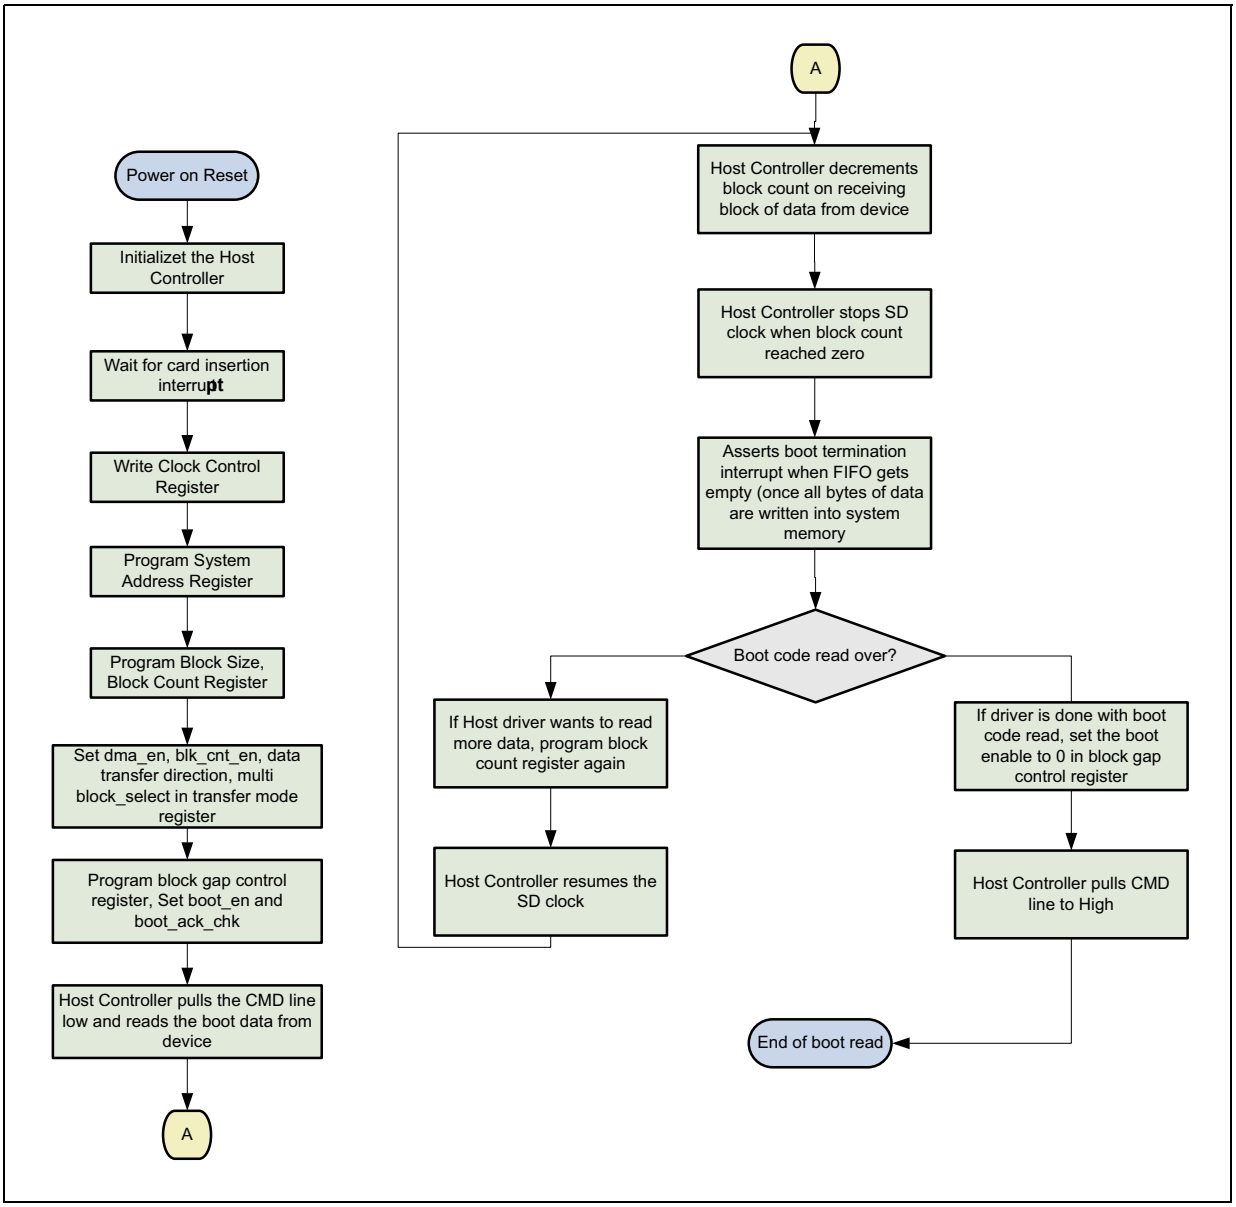
The boot operation can be terminated at any time. Program the Stop at block gap request while transfer is going on and then wait for Transfer Complete Interrupt. Once the driver receives the Transfer Complete Interrupt the driver clears the boot_en and alt_boot_en and then the host driver needs to send CMD0 to inform the device about the boot operation complete. The host driver programs Command register with argument “0x00000000” for the cmd0 (CMDTYPE as Abort) and waits for Command Complete. After that the driver need to issues the soft reset for data to host controller to reset the data state machines to idle state.

If the host controller does not receive the acknowledgment from the device with in timeout value the host controller will assert the data timeout error interrupt.

The driver programs the Boot timeout control register with boot data timeout value.

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above.

If the device sends wrong acknowledgment to the host, then host controller will assert data_crc_err interrupt to the driver. The host driver has to stop the boot mode operation by setting alt_boot_en and boot_en as “0” in Block gap control register and write soft reset for cmd and data line.



If the device sends end bit as “0” in acknowledgment to the host, the host controller asserts data_end_bit_err interrupt on the driver. The host driver stops the boot mode operation by setting alt_boot_en and boot_en as “0” in Block gap control register and write soft reset for cmd and data line.

Note: Enable the boot_ack_chk bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot ack first and followed by boot data.

57.4.5.3 Boot code chunk read operation

The following figure explains the boot code read done as chunks of data (that is the driver can read the boot data as 2 Kbytes, 4 Kbytes, 1 Kbytes and 8 Kbytes instead of 128 Kbytes at a time).

Figure 1880. Boot code access flow diagram

57.5 Timing

This section gives the details about various timing diagrams of MMC. Some text and figures are used from the MMC Specification version 4.51.

57.5.1 Timing diagram

Various timing diagrams are listed below.

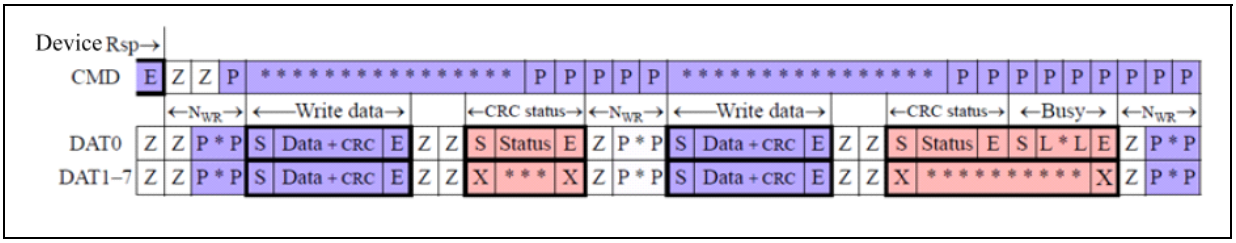

Figure 1882. Multiple block read

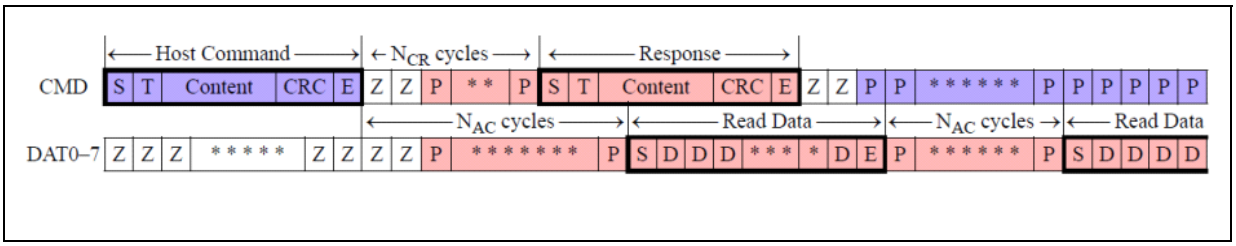

Figure 1883. Boot operation timing with termination between consecutive data blocks

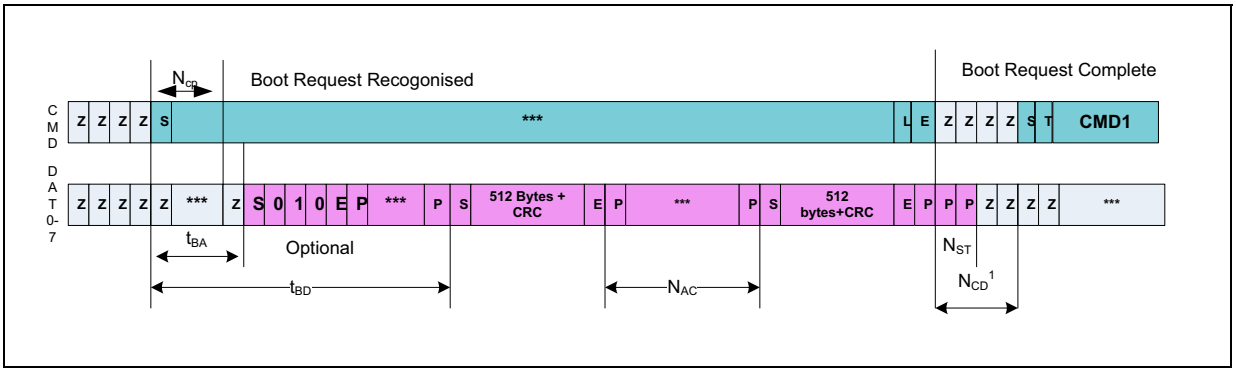

Figure 1884. Boot operation timing with termination during transfer

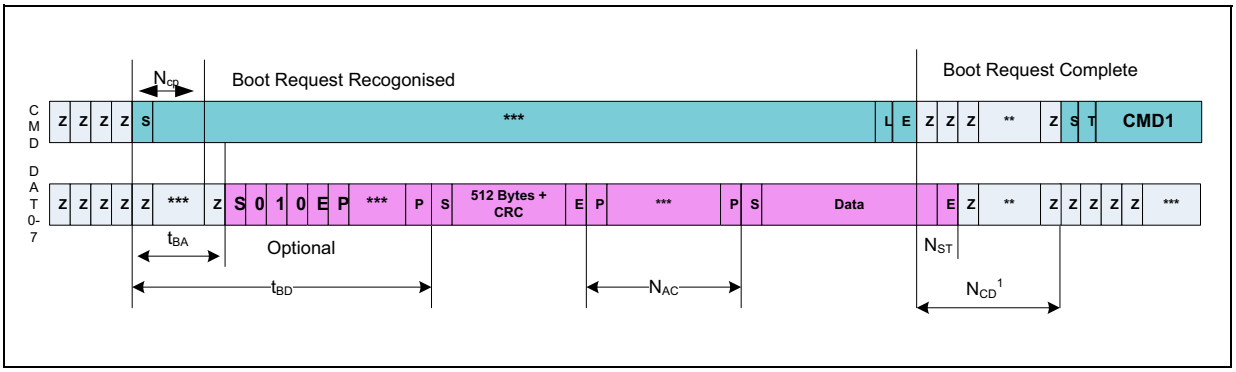

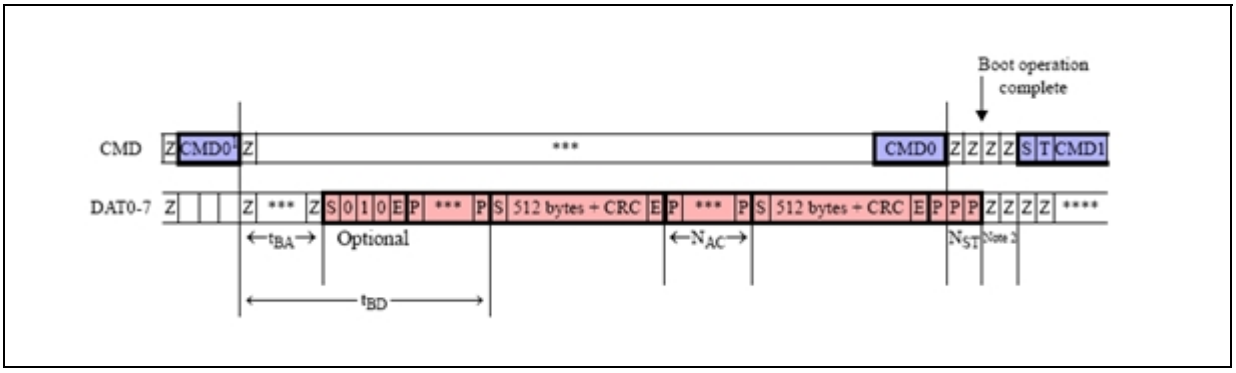

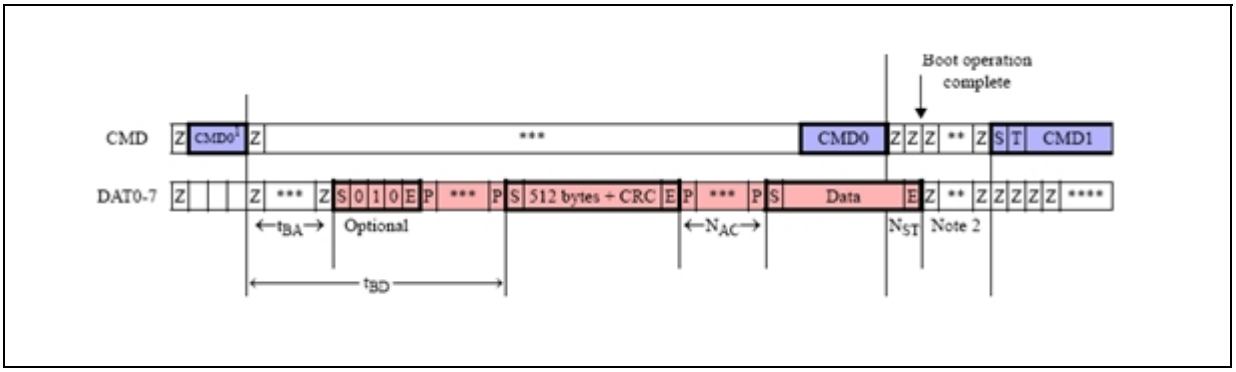

Figure 1885. Alternative boot operation, termination between consecutive data blocks

Note: CMD0 with argument 0xFFFFFFFA

Figure 1886. Alternative boot operation, termination during transfer

Note: CMD0 with argument 0xFFFFFFFA

58 OctoSPI interface (OCTOSPI)

58.1 Introduction

The OCTOSPI is a specialized communication interface targeting single, dual, quad or octal SPI memories. It can operate in any of the three following modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers.
- Status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory supporting both read and write operations.

The OCTOSPI supports two frame formats:

- The classical frame format with the command, address, alternate byte, dummy cycles and data phase
- The HyperBus™ frame format

58.2 OCTOSPI main features

- Three functional modes: indirect, status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- Supports for single, dual, quad and octal communication
- Dual-quad mode, where 8 bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR and DTR support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- HyperBus™ support
- Integrated FIFO for reception and transmission
- 8, 16, and 32-bit data accesses are allowed
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

58.3 OCTOSPI functional description

Figure 1887. OCTOSPI block diagram for octal communication

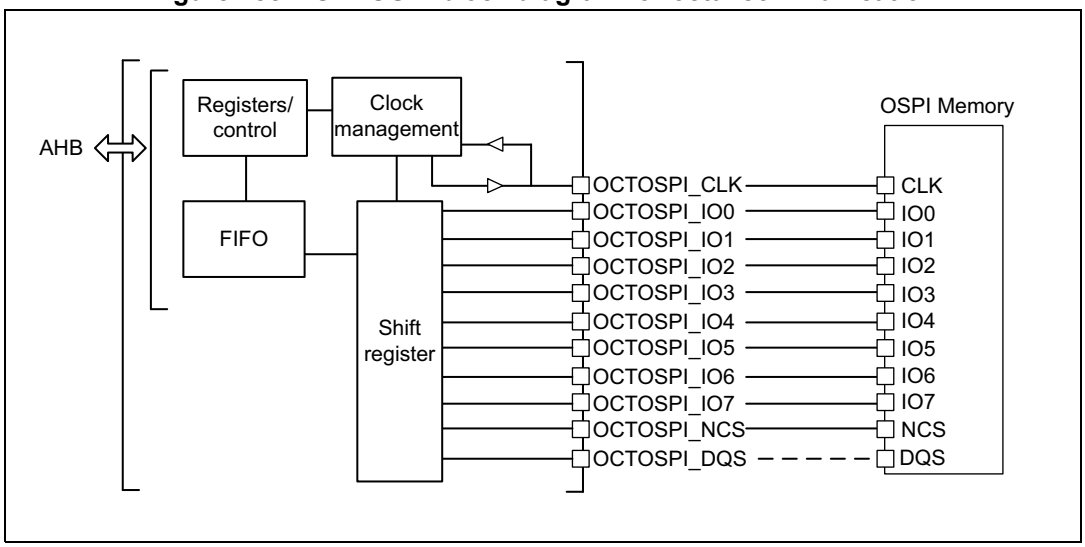

Figure 1888. OCTOSPI block diagram in quad mode

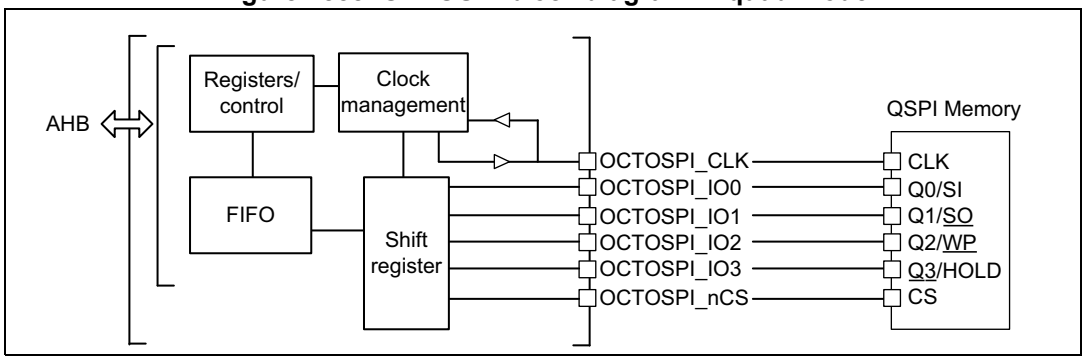

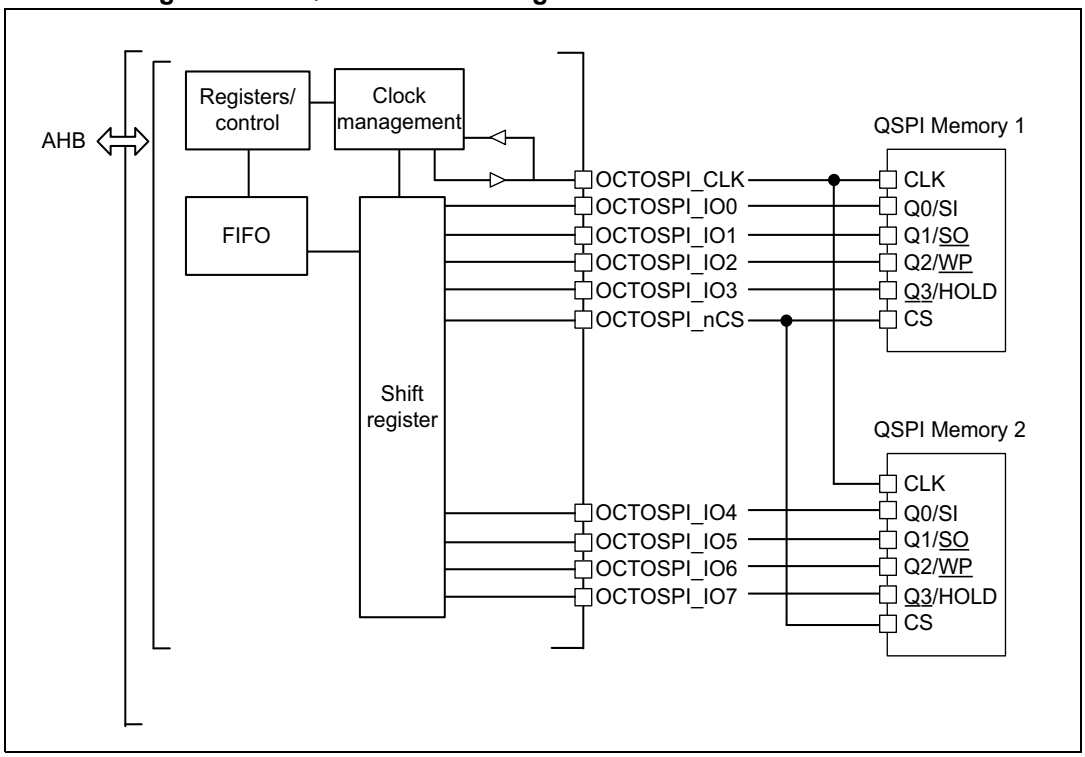

Figure 1889. QuadSPI block diagram when dual-Flash is enabled

The OCTOSPI can operate in two different operating modes:

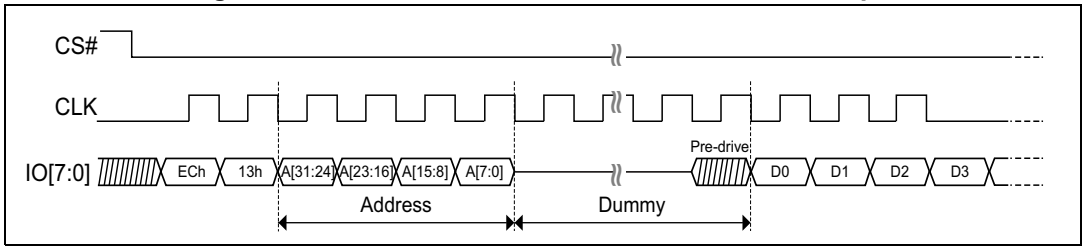
- Regular-command mode
- HyperBus™ mode

In any of these two modes, the OCTOSPI uses from 6 to up to 11 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select used in all modes
- CLK: communication clock used in all modes
- DQS: data strobe used mainly in octal mode
- IO[3:0]: data bus LSB used in all modes
- IO[7:4]: data bus MSB used in dual-quad and octal modes

58.3.1 OCTOSPI regular-command mode

When in regular-command mode, the OCTOSPI communicates with the external device using commands. Each command can include 5 phases:



- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy phase
- Data phase

Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phases must be present.

The nCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported, as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 1890. SDR read command in octal mode example

The specific regular-command mode features are configured through the registers in the 0x0100-0x01FC offset range.

58.3.1.1 Instruction phase

During this phase, a 1 to 4 bytes instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in the ISIZE[1:0] (OCTOSPI_CCR[5:4]) field and the instruction is programmed in the OCTOSPI_IR register's INSTRUCTION[31:0] field.

Though most devices can receive instructions only one bit at a time from the IO0/SO signal (single-SPI mode), the instruction phase can optionally send 2-bits at a time (over IO0/IO1 in dual-SPI mode), 4-bits at a time (over IO0 to IO3 in Quad-SPI mode) or 8-bits at a time (over IO0 to IO7 in octal SPI mode). This can be configured using the IMODE[2:0] (OCTOSPI_CCR[2:0]) field.

The instruction can be sent in DTR (double transfer rate) mode on each rising and falling edge of the clock by setting the IDTR (OCTOSPI_CCR[3]) bit.

When the IMODE=000, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

When in memory-mapped mode, the instruction used for the write operation is specified in the OCTOSPI_WIR register and the instruction format is specified in the OCTOSPI_WCCR register. The instruction used for the read operation and the instruction format are specified in the regular register (OCTOSPI_IR and OCTOSPI_CCR).

58.3.1.2 Address phase

In the address phase, 1 to 4 bytes are sent to the external device to indicate the address of the operation. The number of the address bytes to be sent is configured in the ADSIZE[1:0] (OCTOSPI_CCR[13:12]) field.

In the indirect and automatic-polling modes, the address bytes to be sent are specified in the ADDRESS[31:0] (OCTOSPI_AR) field, while in the memory-mapped mode the address is given directly via the AHB (from the Core or from a DMA).

The address phase can send 1-bit at a time (over SO in single-SPI mode), 2-bits at a time (over IO0/IO1 in dual-SPI mode), 4-bits at a time (over IO0 to IO3 in Quad-SPI mode) or

8-bits at a time (over IO0 to IO7 in octal SPI mode). This can be configured using the ADMODE[2:0] (OCTOSPI_CCR[10:8]) field.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting the ADDTR (OCTOSPI_CCR[11]) bit.

When ADMODE=000, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

When in memory-mapped mode, the address format for the write operation is specified in the OCTOSPI_WCCR register. The address format for the read operation is specified in the regular register (OCTOSPI_CCR).

58.3.1.3 Alternate-bytes phase

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the ABSIZE[1:0] (OCTOSPI_CCR[21:20]) field. The bytes to be sent are specified in the OCTOSPI_ABR register.

The alternate-bytes phase can send 1-bit at a time (over SO in single-SPI mode), 2-bits at a time (over IO0 and IO1 in dual-SPI mode), 4-bits at a time (over IO0 to IO3 in Quad-SPI mode) or 8-bits at a time (over IO0 to IO7 in octal SPI mode). This can be configured using the ABMODE[2:0] (OCTOSPI_CCR[18:16]) field.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting the ABDTR (OCTOSPI_CCR[19]) bit.

When ABMODE=000, the alternate-bytes phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the Quad-SPI mode (ABMODE=011) and send a byte with bits 7 and 3 of ALTERNATE set to ‘1’ (keeping the IO3 line high), and bits 6 and 2 set to ‘0’ (keeping the IO2 line low).

In this case the upper two bits of the nibble to be sent are placed in bits 4:3 of ALTERNATE while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE should be set to 0x8A (1000_1010).

When in memory-mapped mode, the alternate bytes used for the write operation are specified in the OCTOSPI_WABR register and the alternate byte format is specified in the OCTOSPI_WCCR register. The alternate bytes used for read operation and the alternate byte format are specified in the regular register (OCTOSPI_ABR and OCTOSPI_CCR).

58.3.1.4 Dummy-cycles phase

In the dummy-cycles phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in the DCYC[4:0] (OCTOSPI_TCR[4:0]) field. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual, the quad or the octal mode to receive data from the external device.

When in memory-mapped mode, the dummy cycles for the write operations are specified in the OCTOSPI_WTCR register. The dummy cycles for the read operation are specified in the regular register (OCTOSPI_TCR)

58.3.1.5 Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

When in indirect mode, the number of bytes to be sent/received is specified in the OCTOSPI_DLR register.

When in indirect-write mode the data to be sent to the external device must be written to the OCTOSPI_DR register, while in indirect-read mode the data received from the external device is obtained by reading from the OCTOSPI_DR register.

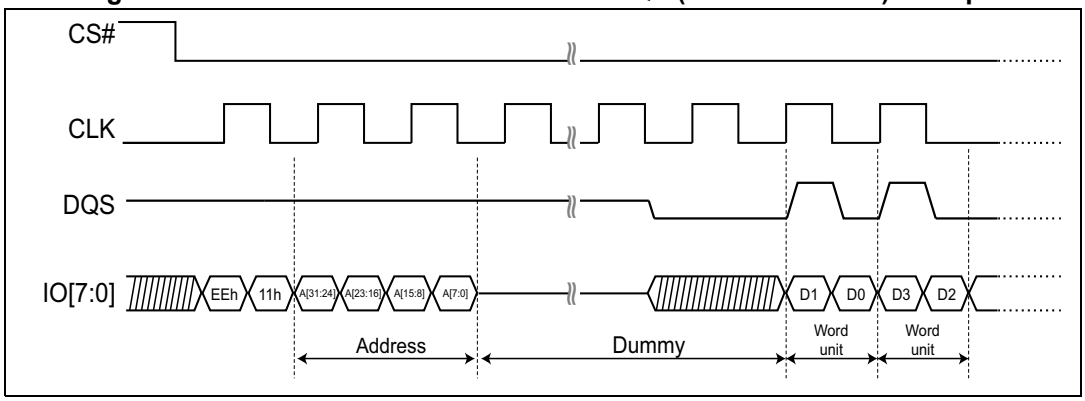
In automatic-polling modes, the number of bytes to be received is specified in the OCTOSPI_DLR register and the data received from the external device can be obtained by reading from the OCTOSPI_DR register.

When in memory-mapped mode, the data which is read or written is sent or received directly over the AHB to the Core or to a DMA.

The data phase can send/receive 1-bit at a time (over SO/SI in single-SPI mode), 2-bits at a time (over IO0/IO1 in dual-SPI mode), 4-bits at a time (over IO0 to IO3 in Quad-SPI mode) or 8-bits at a time (over IO0 to IO7 in octal SPI mode). This can be configured using the DMODE[2:0] (OCTOSPI_CCR[26:24]) field.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting the DDTR (OCTOSPI_CCR[27]) bit.

When DMODE=000, the data phase is skipped, and the command sequence finishes immediately by raising the nCS. This configuration must be used only in indirect-write mode.



When in memory-mapped mode, the data format for the write operation is specified in the OCTOSPI_WCCR register. The data format for the read operation is specified in the regular register (OCTOSPI_CCR).

58.3.1.6 DQS usage

The DQS signal can be used for data strobing during the read transactions when the device is toggling the DQS aligned with the data.

The DQS management can be enabled setting the DQS enable (DQSE) bit of the OCTOSPI communication configuration register (OCTOSPI_CCR).

Figure 1891. DTR read in octal mode with DQS (Macronix mode) example

58.3.2 OCTOSPI regular-command mode signal interface

58.3.2.1 Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/O are shared with IO0). The data received from the external device arrives via SI (whose I/O are shared with IO1).

The different phases can each be configured separately to use this single-bit mode by setting the IMODE/ADMODE/ABMODE/DMODE fields to 001 (in OCTOSPI_CCR and OCTOSPI_WCCR).

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode
- IO1 (SI) is in input mode (high-impedance)
- IO2 is in output mode and forced to ‘0’ (to deactivate the “write protect” function)
- IO3 is in output mode and forced to ‘1’ (to deactivate the “hold” function)
- IO4/IO5/IO6/IO7 are in output mode and forced to ‘0’

This is the case even for the dummy phase if DMODE=001.

58.3.2.2 Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields to 010 (in OCTOSPI_CCR and OCTOSPI_WCCR).

In each phase which is configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases
- IO2 is in output mode and forced to ‘0’
- IO3 is in output mode and forced to ‘1’
- IO4/IO5/IO6/IO7 are in output mode and forced to ‘0’

In the dummy phase when DMODE=01, IO0/IO1 are always high-impedance.

58.3.2.3 Quad-SPI mode

In Quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the Quad-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields to 011 (in OCTOSPI_CCR and OCTOSPI_WCCR).

In each phase which is configured in Quad-SPI mode, IO0/IO1/IO2/IO3 are all are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases. IO4/IO5/IO6/IO7 are in output mode and forced to ‘0’.

In the dummy phase when DMODE=011, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in Quad-SPI mode. If none of the phases are configured to use the Quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the OCTOSPI is active.

58.3.2.4 Octo-SPI mode

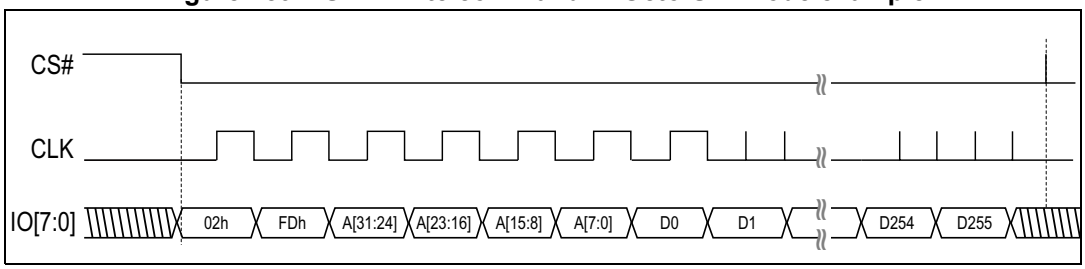
In regular Octo-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the Octo-SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields to 100 (in OCTOSPI_CCR and OCTOSPI_WCCR).

In each phase that is configured in octal mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE=100, IO[0:7] are all high-impedance.

IO[4:7] are used only in Octo-SPI mode. If none of the phases are configured to use Octo-SPI mode, then the pins corresponding to IO[4:7] can be used for other functions even while the OCTOSPI is active.



58.3.2.5 SDR mode

By default, all the phases operate in single data rate (SDR) mode.

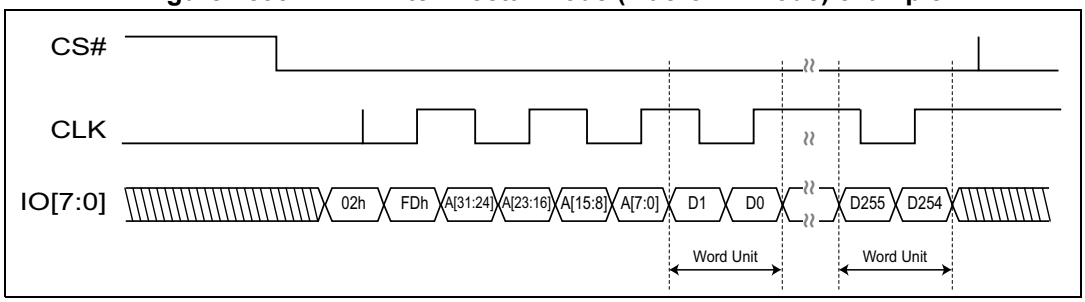
In SDR mode, when the OCTOSPI is driving the IO0/SO, IO1, IO2, IO3, IO4, IO5, IO6 and IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK’s falling edge. By default (when SSHIFT=0), the signals are sampled using the following (rising) edge of CLK:

Figure 1892. SDR write command in Octo-SPI mode example

58.3.2.6 DTR mode

Each of the instruction/address/alternate/data phase can be configured to operate in double transfer rate (DTR) mode setting IDTR/ADDTR/ABDTR/DDTR bit in the OCTOSPI_CCR register.



While in memory-mapped mode, the DTR mode for each phase of the write operations is specified in the OCTOSPI_WCCR register. The DTR mode for each phase of the read operations is specified in the regular register (OCTOSPI_CCR).

In DTR mode, when the OCTOSPI is driving the IO0/SO, IO1, IO2, IO3, IO4, IO5, IO6 and IO7 signals in the instruction/address/alternate-byte/data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external device also send the data using both CLK's rising and falling edges. When DDTR=1, the firmware must clear SSHIFT (OCTOSPI_TCR[30]). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

Note: For operating in DTR mode, the generated serial clock should use prescaler of value 2 of the kernel clock and the OCTOSPI_TCR.DHQC should be set to 1 to delay the SPI output data by quarter cycle of serial clock for best valid data eye position for Flash.

Figure 1893. DTR write in octal mode (Macronix mode) example

58.3.2.7 Dual-quad mode

When the DQM (OCTOSPI_CR[6]) bit is 1, the OCTOSPI is in dual-quad mode, where two external Quad-SPI devices (device A and device B) are used in order to send/receive 8-bits (or 16-bits in DTR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the devices uses the same CLK and nCS signals, but each has a separate IO0, IO1, IO2, and IO3 signals.

The dual-quad mode can be used in conjunction with the single-bit, dual-bit, and quad-bit modes, as well as with either the SDR or the DTR mode.

The device size, as specified in DEVSIZE[4:0] (OCTOSPI_DCR1[20:16]), should reflect the total external device's capacity, which is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte which the OCTOSPI gives for address X+1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the devices' status registers in dual-quad mode, twice as many bytes should be read compared to doing the same read in regular mode. This means that if each device

gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2-bytes (16-bits), and the OCTOSPI will receive one byte from each device.

If each device gives a status of 16-bits, then the OCTOSPI must be configured to read four bytes to get all the status bits of both devices in dual-quad mode. The least-significant byte of the result (in the data register) is the least-significant byte of device A's status register, while the next byte is the least-significant byte of device B's status register. Then, the third byte of the data register is device A's second byte, while the forth byte is device B's second byte (in the case that the devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad mode. For this reason, bit 0 of the data length field (OCTOSPI_DLR[0]) is stuck at 1 when DQM=1.

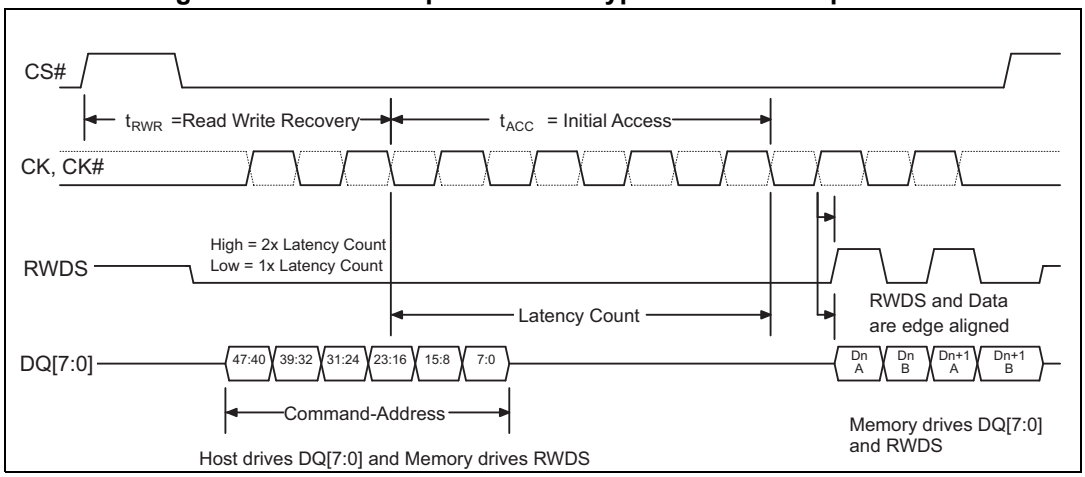
In dual-quad mode, the behavior of device A's interface signals is basically the same as in normal mode. Device B's interface signals have exactly the same waveforms as device A's during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each device always receives the same instruction and the same address. Then, during the data phase, the AIOx and the BIOx buses are both transferring data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

58.3.3 HyperBus™ mode

While in HyperBus™ mode, the OCTOSPI can communicate with the external device using the HyperBus™ protocol.

The HyperBus™ is using 11 pins:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK



The HyperBus™ does not require any command specification nor any alternate bytes, as a consequence, a separated register set is used to define the timing of the transaction.

The HyperBus™ frame is composed of two phases:

- Command/address phase
- Data phase

The nCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 1894. An example of a 1.8v HyperBus™ read operation

The specific HyperBus™ features are configured through the registers in the 0x0200-0x02FC offset range.

58.3.3.1 Command/address phase

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 1867. Command/address phase description

CA bit	Bit Name	Description
47	R/W#	Identify the transaction as a read or a write
46	Address space	Indicates whatever the transaction is accessing the memory or the register space
45	Burst type	Indicates whatever the burst is linear or wrapped
44-16	Row & upper column address	Select the row and the upper column address
15-3	Reserved	-
2-0	Lower column address	Select the starting 16-bit word within the half page

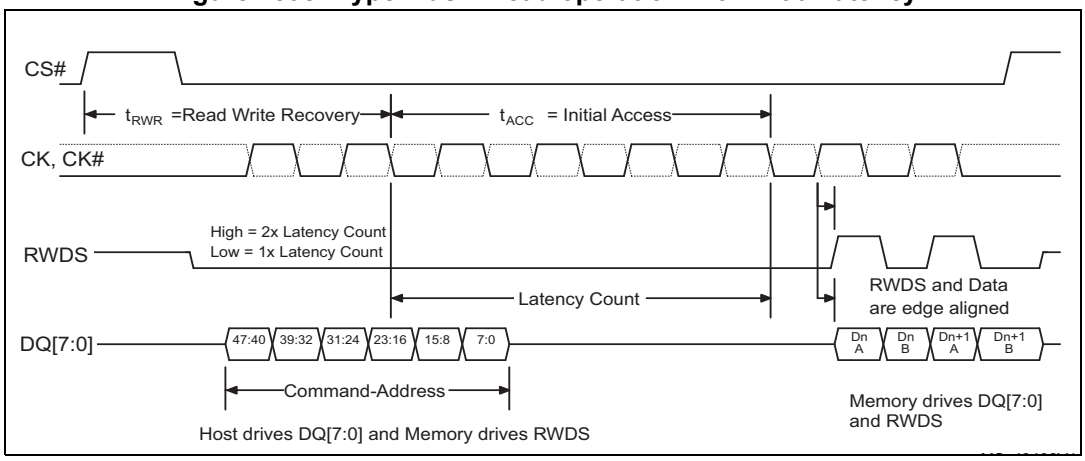
The address space is configured through the memory type (MTYP) field of the OCTOSPI device configuration register (OCTOSPI_DCR1).

The total size of the device is configured in the device size (DEVSIZE) field of the OCTOSPI device configuration register (OCTOSPI_DCR1). In case of MCP, the device size is the sum of all the sizes of all the dies of the MCP.

58.3.3.2 Read and write operation with initial latency

The HyperBus™ read and write operations need to respect two timings:

- T_{RWR} as minimal read/write recovery time for the device
- T_{ACC} as access time for the device



The t_{RWR} is defined in the TRWR field of the OCTOSPI HyperBus™ latency configuration register (OCTOSPI_HLCR).

The t_{ACC} is defined in the TACC field of the OCTOSPI HyperBus™ latency configuration register (OCTOSPI_HLCR).

During the read operation the RWDS is used in two ways:

- By the device, during the command/address phase, to request an additional latency
- By the device, during the data phase, for data strobing

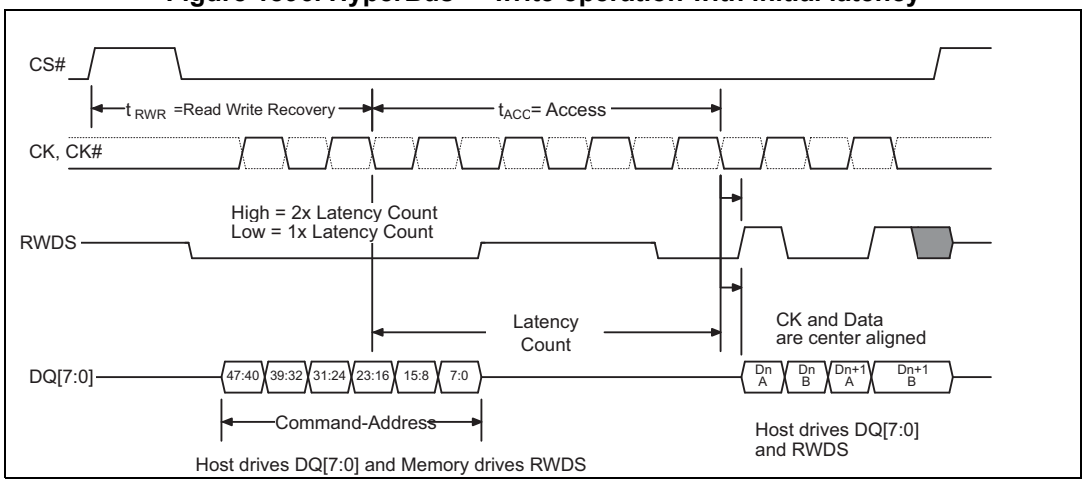


Figure 1895. HyperBus™ read operation with initial latency

During the write operation the RWDS is used:

- By the device, during the command/address phase, to request an additional latency
- By the OCTOSPI IP, during the data phase, for write data masking

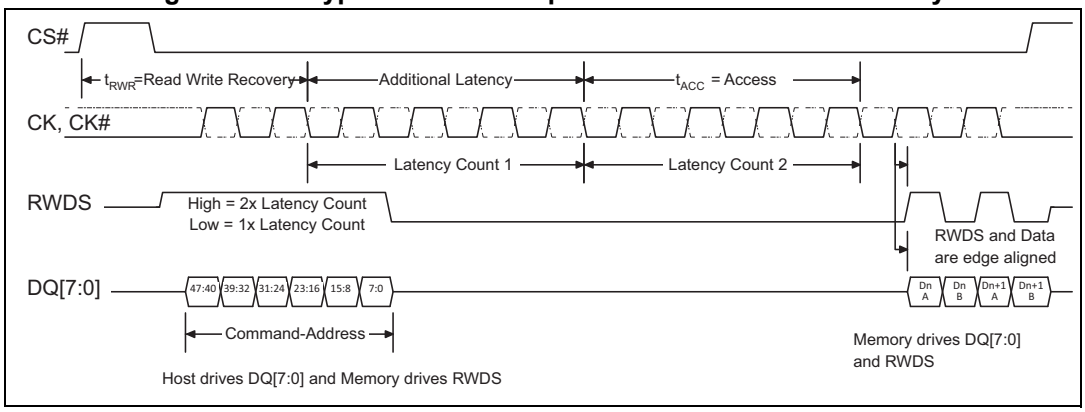
Figure 1896. HyperBus™ write operation with initial latency

58.3.3.3 Read and write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), it must be tied to one of the RWDS signals during the command/address phase.

An additional t_{ACC} duration is added by the OCTOSPI IP to meet the device request.

Figure 1897. HyperBus™ read operation with additional latency



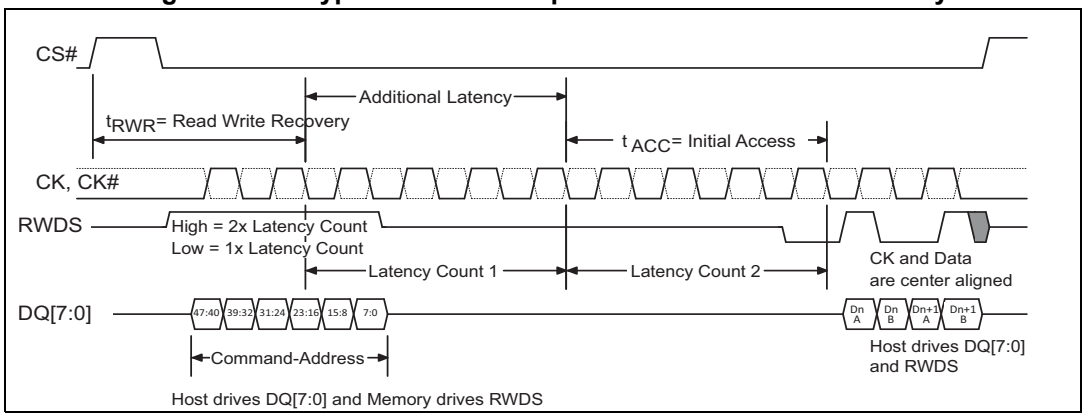


Figure 1898. HyperBus™ write operation with additional latency

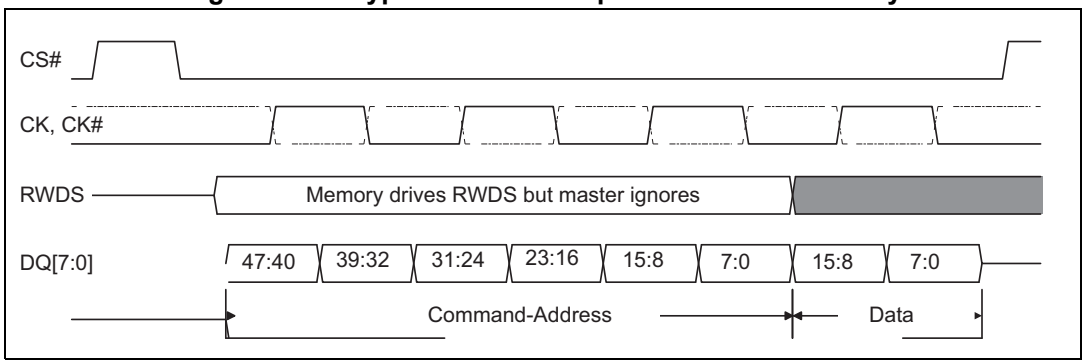
58.3.3.4 Fixed latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

It is possible to force the latency to be fixed to 2 x t_{ACC} by setting the latency mode (LM) bit of the OCTOSPI HyperBus™ latency configuration register (OCTOSPI_HLCR).



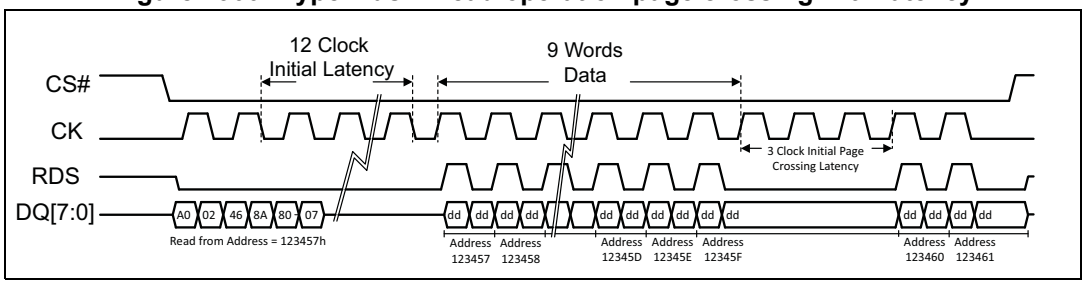
In this fixed latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI IP and an additional latency is always added leading to a fixed 2 x t_{ACC} latency time.

58.3.3.5 Write operation with no latency

Some devices can also require a zero latency for the write operations.

This zero write latency can be forced by setting the write zero latency (WZL) bit of the OCTOSPI HyperBus™ latency configuration register (OCTOSPI_HLCR).

Figure 1899. HyperBus™ write operation with no latency



58.3.3.6 Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 1900. HyperBus™ read operation page crossing with latency

58.3.4 Common functionality between the regular-command mode and HyperBus™

The OCTOSPI supports some specific features common to both the regular-command mode and the HyperBus™ such as:

- Wrap support
- CS boundary and regulation

58.3.4.1 Wrap support

The OCTOSPI supports a hybrid wrap as defined by the HyperBus™ protocol. A hybrid wrap is also supported in the regular-command mode.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size that is supported by the target memory is configured in the wrap size (WRAPSIZE) field of the OCTOSPI device configuration register 2 (OCTOSPI_DCR2).

If the target memory is not supporting the hybrid wrap, the WRAPSIZE field must be set to 0.

58.3.4.2 CS boundary and communication regulation features

Two processes can be activated to regulate the OCTOSPI transactions:

- CS Boundary
- Communication regulation

The CS boundary feature will limit a transaction to a boundary of aligned addresses. The size of the address to be aligned with is configured in the CS boundary (CSBOUND) field of the OCTOSPI device configuration register 3 (OCTOSPI_DCR3) and it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND = 4, the boundary is set to 2^4 = 16 bytes, as a consequence, the nCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND is zero, the feature is disabled.

The CSBOUND feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash.

The communication regulation feature limits the maximum length of a transaction to the value programmed in the maximum transfer (MAXTRAN) field of the OCTOSPI device configuration register 3 (OCTOSPI_DCR3).

Once the number of byte read or write reaches the MAXTRAN+1 value, and if the second OCTOSPI is requesting an access, the nCS is released and a new transaction is issued to address the next data.

If MAXTRAN is zero, no limitation occurs.

The MAXTRAN feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

If both CS boundary and communication regulation are enabled at the same time, the nCS is released on the first condition met.

58.4 OCTOSPI operating modes

The OCTOSPI has three operating modes regardless of the low-level protocol used (it can be either regular or HyperBus)

- Indirect mode (read or write)
- Status polling mode
- Memory-mapped mode

58.4.1 OCTOSPI indirect mode

When in indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE=00 (OCTOSPI_CR[29:28]), the OCTOSPI is in indirect-write mode, where bytes are sent to the external device during the data phase. Data is provided by writing to the data register (OCTOSPI_DR).

When FMODE=01, the OCTOSPI is in indirect-read mode, where bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

The number of bytes to be read/written is specified in the data length register (OCTOSPI_DLR). If OCTOSPI_DLR=0xFFFF_FFFF (all 1's), then the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE (OCTOSPI_CCR[26:24]) should be set to 00.

If OCTOSPI_DLR=0xFFFF_FFFF and DEVSIZE=0x1F (its maximum value indicating at 4 GB device), then in this special case the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF_FFFF), reading continues with address=0x0000_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE=1. In the case of an undefined number of data, the TCF is set when the limit of the external SPI memory is reached according to the device size that is defined in the OCTOSPI_DCR1 register.

58.4.1.1 Triggering the start of a transfer in regular-command mode

Depending on the OCTOSPI's configuration, there are three different ways to trigger the start of a transfer in indirect mode when using regular mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the command, and more specifically, a communication in indirect mode starts at the moment when:

- A write is performed to INSTRUCTION[31:0] (OCTOSPI_IR), if no address is necessary (when ADMODE=000) and if no data needs to be provided by the firmware (when FMODE=01 or DMODE=000)
- A write is performed to ADDRESS[31:0] (OCTOSPI_AR), if an address is necessary (when ADMODE!=000) and if no data needs to be provided by the firmware (when FMODE=01 or DMODE=000)
- A write is performed to DATA[31:0] (OCTOSPI_DR), if an address is necessary (when ADMODE!=000) and if no data needs to be provided by the firmware (when FMODE=00 and DMODE!=000)

A write to the alternate bytes register (OCTOSPI_ABR) never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

58.4.1.2 Triggering the start of a transfer in HyperBus™ mode

Depending on the OCTOSPI's configuration, there are three different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the command, and more specifically, a communication in indirect mode starts at the moment when:

- A write is performed to ADDRESS[31:0] (OCTOSPI_AR) in indirect-read mode (when FMODE=01)
- A write is performed to DATA[31:0] (OCTOSPI_DR) in indirect-write mode (when FMODE=00)

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

58.4.1.3 FIFO and data management

Data in indirect mode passes through a 32-byte FIFO which is internal to the OCTOSPI. FLEVEL[5:0] (OCTOSPI_SR[12:8]) indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE=00), the firmware adds data to the FIFO when it writes in the OCTOSPI_DR. A word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If the firmware adds too many bytes to the FIFO (more than is indicated at DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/halfword accesses to the OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[4:0] is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, the FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. The FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of the FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE=1, there is an interrupt when the FTF is set. If DMAEN=1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by HW as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect-read mode when the FIFO becomes full, the OCTOSPI temporarily stops reading bytes from the external device to avoid an overrun. Note that the reading of the external device does not restart until 4 bytes become vacant in the FIFO (when FLEVEL<=28). Thus, when FTHRES>=29, the application must be sure to read enough bytes to assure that the OCTOSPI starts retrieving data from the external device again. Otherwise, the FTF flag stays at '0' as long as FLEVEL<FTHRES.

58.4.2 OCTOSPI status flag polling mode

In automatic-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The accesses to the device begins in the same manner as in indirect-read mode. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (OCTOSPI_PSMAR) are used to mask the data from the external device in automatic-polling mode. If the MASK[n]=0, then bit n of the result is masked and not considered. If MASK[n]=1, and the content of bit[n] is the same as MATCH[n] (OCTOSPI_PSMAR) then there is a match for bit n.

If the polling-match mode bit (PMM, OCTOSPI_CR[23]) is 0, then “AND” match mode is activated. This means that only when there is a match on all of the unmasked bits, then the status match flag (SMF) is set.

If PMM=1, then “OR” match mode is activated, which means that the SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when the SMF is set if SMIE=1.

If the automatic-polling mode stop (APMS) bit is set, then the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at ‘1’ and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN=0).

The data register (OCTOSPI_DR) contains the latest received status bytes (the FIFO is deactivated). The contents of the data register are not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and the FTF is cleared as soon as the data is read.

58.4.3 OCTOSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory. Note that no more than 256 MB can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE but still within the 256 MB range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Core CPU, a hard fault interrupt is generated
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled

Byte, halfword, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were prefetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the nCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the nCS is held low, the application might want to activate the timeout counter (TCEN=1, OCTOSPI_CR[3]) so that the nCS is released after a period of TIMEOUT[15:0] (OCTOSPI_LPTR), when x cycles have elapsed without an access since the moment that the FIFO becomes full with prefetch data.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

58.5 OCTOSPI configuration

The OCTOSPI configuration is done in three steps:

1. OCTOSPI IP configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

58.5.1 OCTOSPI IP configuration

The OCTOSPI IP is configured using the OCTOSPI_CR. The user must program:

- Functional mode (FMODE field)
- Polling mode behavior as needed (PMM and APMS bits)
- FIFO level for either DMA request generation or interrupt generation (FTHRES field)
- DMA usage (DMAEN bit)
- Timeout counter usage (TCEN bit)
- Dual-quad mode (DQM bit) if needed (only for Quad-SPI configuration)

In case of an interrupt usage, their respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in the OCTOSPI_LPTR register.

The DMA channel must not be enabled during the IP configuration, it must be enabled only once the operation is fully configured to avoid any unexpected request generation.

58.5.2 OCTOSPI device configuration

The parameters related to the external device targeted are configured through the OCTOSPI_DCR1 and the OCTOSPI_DCR2 registers. The user must program:

- Memory type (MTYP field)
- Device size (DEVSIZE field)
- Chip-select minimum high time (CSHT field)
- Number of clock cycles after the nCS rising edge (CKCSHT field)
- Clock mode (FRCK and CKMODE bit)
- Supported wrap size (WRAPSIZE field)
- Device frequency (PRESCALER field)

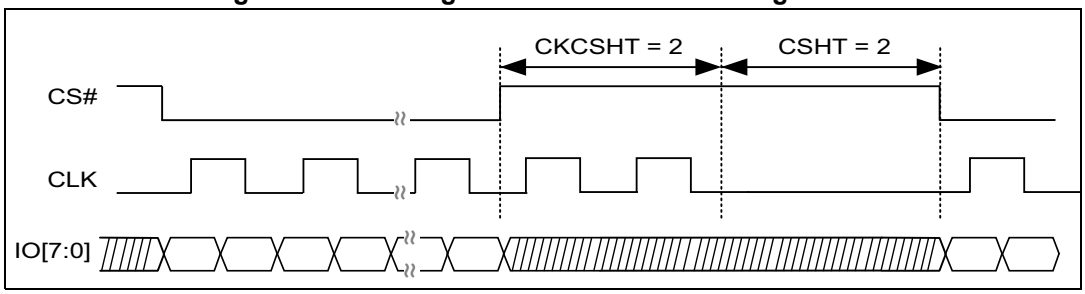
The MTYP[2:0] field defines the type of memory to be used for 8-line modes:

- Micron mode with D0 / D1 ordering in 8-data-bit mode (DMODE = 100)
- Macronix mode with D1 / D0 ordering in 8-data-bit mode (DMODE = 100)
- HyperBus™ memory mode. Protocol follows the Cypress (Spansion) HyperBus™ specification, and an 8-data-bit DDR mode must be selected
- HyperBus™ register mode. Addressing register space, the memory-mapped accesses in this mode must be non-cacheable, or the indirect read/write modes must be used

The DEVSIZE[4:0] field defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

DEVSIZE+1 is effectively the number of address bits required to address the external device. The external device capacity can go up to 4 GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 MB.



If DQM=1, then DEVSIZE indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (nCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time (CSHT) field can be used to specify the minimum number of CLK cycles (up to 8) for which the nCS must remain high.

The clock can be sent after the rising edge of the chip-select signal (nCS). The number of clock cycles to be sent on the CLK/nCLK pins can be programmed up to 7 using the clocked chip-select high time (CKCSHT) field.

Figure 1901. CS high time and clocked CS high timer

The clock mode (CKMODE) bit indicates the level that the CLK takes between commands (when nCS=1).

In HyperBus™ mode, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in the OCTOSPI HyperBus™ latency configuration register (OCTOSPI_HLCR).

58.5.3 OCTOSPI regular-command mode configuration

58.5.3.1 Indirect mode configuration

When FMODE is programmed to 00, the indirect-write mode is selected and the data can be sent to the external device. When FMODE=01, the indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in the OCTOSPI_DLR
2. Specify the frame timing in the OCTOSPI_TCR
3. Specify the frame format in the OCTOSPI_CCR
4. Specify the instruction in the OCTOSPI_IR
5. Specify the optional alternate byte to be sent right after the address phase in the OCTOSPI_ABR
6. Specify the targeted address in the OCTOSPI_AR
7. Unable the DMA channel if needed
8. Read/write the data from/to the FIFO through the OCTOSPI_DR (if no DMA usage)

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as the OCTOSPI_CCR is written. This is the case when both ADMODE and DMODE are 000, or if just ADMODE=000 when in indirect-read mode (FMODE=01).

When an address is required (ADMODE is not 000) and the data register does not need to be written (when FMODE=01 or DMODE=000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE=00 and DMODE!=000), the communication start is triggered by a write in the FIFO through the OCTOSPI_DR.

58.5.3.2 Status flag polling mode configuration

The status flag polling mode is enabled by setting the FMODE field (OCTOSPI_CR[29:28]) to 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in the OCTOSPI_DLR, it will be ignored and only 4 bytes will be read.

The periodicity is specified in the OCTOSPI_PIR register.

Once the status data has been retrieved, it can internally be processed to:

- Set the SMF (status match flag) and generate an interrupt if enabled
- Stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in the OCTOSPI_PSMKR and in ORed or ANDed with the value stored in the OCTOSPI_PSMAR.

In case of a match, the SMF is set and an interrupt is generated if enabled, and, the OCTOSPI can be automatically stopped if the AMPS bit is set. In any case, the latest retrieved value is available in the OCTOSPI_DR.

When the OCTOSPI is used in auto-polling mode, the frames are constructed in the following way:

1. Specify the input mask in the OCTOSPI_PSMKR
2. Specify the comparison value in the OCTOSPI_PSMAR
3. Specify the read period in the OCTOSPI_PIR
4. Specify a number of data bytes to read in the OCTOSPI_DLR
5. Specify the frame timing in the OCTOSPI_TCR
6. Specify the frame format in the OCTOSPI_CCR
7. Specify the instruction in the OCTOSPI_IR
8. Specify the optional alternate byte to be sent right after the address phase in the OCTOSPI_ABR
9. Specify the optional targeted address in the OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as the OCTOSPI_CCR is written. This is the case when ADMODE=000.

When an address is required (ADMODE is not 000), the command sequence starts as soon as the address is updated with a write to the OCTOSPI_AR.

58.5.3.3 Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

Memory-mapped mode is entered by setting the FMODE to 11 in the OCTOSPI_CR register.

The programmed instruction and frame are sent when an AHB master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to the OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

When the OCTOSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in the OCTOSPI_TCR for read operation
2. Specify the frame format in the OCTOSPI_CCR for read operation
3. Specify the instruction in the OCTOSPI_IR
4. Specify the optional alternate byte to be sent right after the address phase in the OCTOSPI_ABR for read operation
5. Specify the frame timing in the OCTOSPI_WTCR for write operation
6. Specify the frame format in the OCTOSPI_WCCR for write operation
7. Specify the instruction in the OCTOSPI_WIR
8. Specify the optional alternate byte to be sent right after the address phase in the OCTOSPI_WABR for read operation

All the configuration operations must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed.

58.5.3.4 OCTOSPI delayed data sampling

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using the SSHIFT (OCTOSPI_TCR[30]) bit, the sampling of the data can be shifted by half of a CLK cycles.

The firmware must clear the SSHIFT when the data phase is configured in DTR mode (DDTR=1).

58.5.3.5 Sending the instruction only once

A Flash memory (like Winbond) might provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using the SIOO bit (OCTOSPI_CCR[31] and OCTOSPI_WCCR[31]).

The SIOO is valid for all functional modes (indirect, automatic polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR (or to OCTOSPI_WCCR for write operations in memory-mapped mode).

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR (or OCTOSPI_WCCR for write operations in memory-mapped mode). The SIOO has no effect when IMODE=00 (no instruction).

58.5.4 OCTOSPI HyperBus™ mode configuration

58.5.4.1 Indirect mode configuration

When the FMODE is programmed to 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE=01, the indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in the OCTOSPI_DLR
2. Specify the targeted address in the OCTOSPI_AR
3. Unable the DMA channel if needed
4. Read/write the data from/to the FIFO through the OCTOSPI_DR (if no DMA usage).

In indirect-read mode (when FMODE=01), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In indirect-write mode (when FMODE=00), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

58.5.4.2 Status flag polling mode configuration

The status flag polling mode is enabled setting the FMODE field (OCTOSPI_CR[29:28]) to 10. In this mode, the programmed frame will be sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in the OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in the OCTOSPI_PIR register.

Once the status data has been retrieved, it can be internally processed to:

- Set the SMF and generate an interrupt if enabled
- Stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in the OCTOSPI_PSMKR and the ORed or ANDed with the value stored in the OCTOSPI_PSMAR.

In case of a match, the SMF is set and an interrupt is generated if enabled, and the OCTOSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in the OCTOSPI_DR.

When the OCTOSPI is used in auto-polling mode, the frames are constructed in the following way:

1. Specify the input mask in the OCTOSPI_PSMKR
2. Specify the comparison value in the OCTOSPI_PSMAR
3. Specify the read period in the OCTOSPI_PIR
4. Specify a number of data bytes to read in the OCTOSPI_DLR
5. Specify the targeted address in the OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

58.5.4.3 Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The memory-mapped mode is entered by setting the FMODE to 11 in the OCTOSPI_CR register. The programmed instruction and frame are sent when an AHB master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to the OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operations must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.

58.5.5 OCTOSPI error management

An error can be generated in the following cases:

- In indirect mode or status flag polling mode when a wrong address has been programmed in the OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0] in the OCTOSPI_DCR1). This sets the TEF and an interrupt is generated if enabled.
- In indirect mode, if the address plus the data length exceed the device size, the TEF is set as soon as the access is triggered.
- In memory-mapped mode when an out of range access is done by an AHB master, it generates an AHB error as a response to the faulty AHB request.
- An access to the memory-mapped area when the memory-mapped mode is disabled, it generates an AHB error as a response to the faulty AHB request.

58.5.6 OCTOSPI busy bit and abort functionality

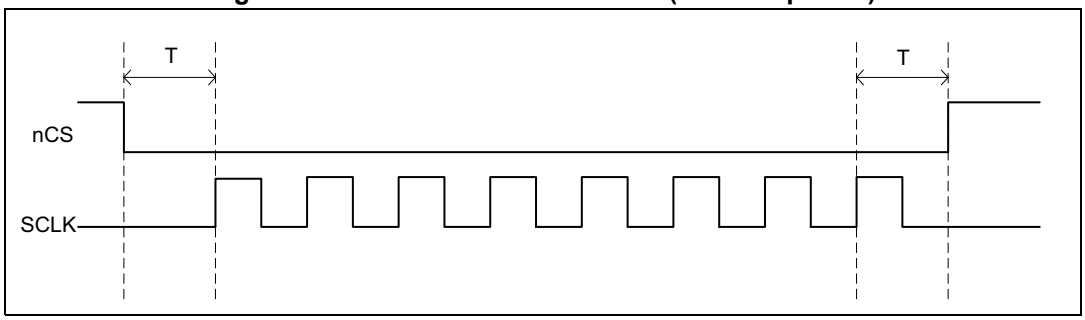
Once the OCTOSPI starts an operation with the external device, the BUSY bit is automatically set in the OCTOSPI_SR.

In indirect mode, the BUSY bit is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In automatic-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS=1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

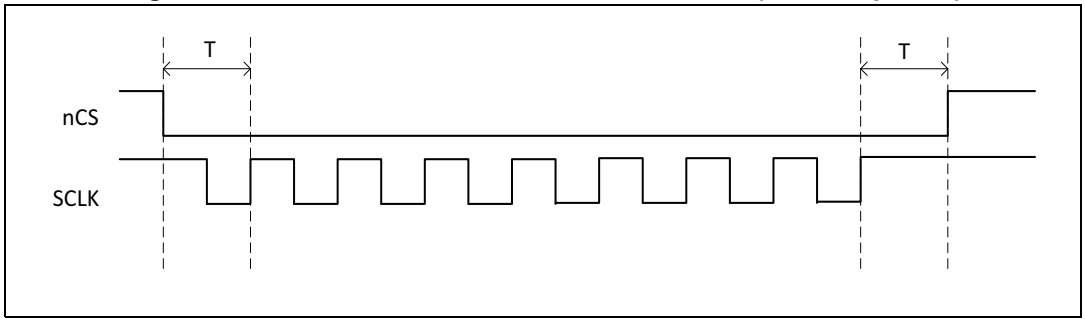
Any operation can be aborted by setting the ABORT bit in the OCTOSPI_CR. Once the abort is completed, the BUSY bit and the ABORT bit are automatically reset, and the FIFO is flushed.



Note that some devices might misbehave if a write operation to a status register is aborted.

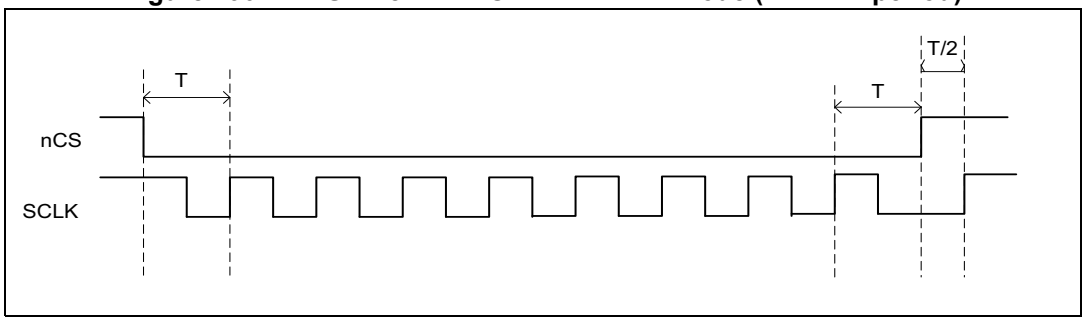
58.5.7 NCS behavior

By default, the nCS is high, deselecting the external device. The nCS falls before an operation begins and rises as soon as it finishes.



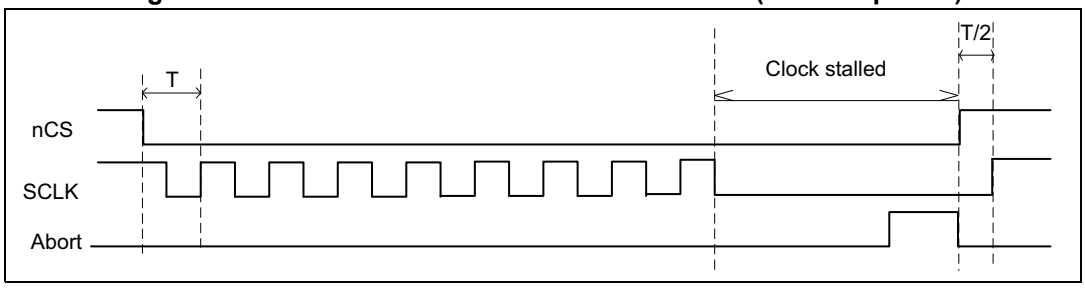
When the CKMODE=0 (“mode0”, where CLK stays low when no operation is in progress), the nCS falls one CLK cycle before an operation’s first rising CLK edge, and the nCS rises one CLK cycle after the operation’s final rising CLK edge, as shown in *Figure 1902*.

Figure 1902. NCS when CKMODE=0 (T = CLK period)



When the CKMODE=1 (“mode3”, where CLK goes high when no operation is in progress) and when in SDR mode, the nCS falls one CLK cycle before an operation’s first rising CLK edge, and the nCS rises one CLK cycle after the operation’s final rising CLK edge, as shown in *Figure 1903*.

Figure 1903. NCS when CKMODE=1 in SDR mode (T = CLK period)



When the CKMODE=1 (“mode3”) and the DDTR=1 (data DTR mode), the nCS falls one CLK cycle before an operation’s first rising CLK edge, and the nCS rises one CLK cycle after the operation’s final active rising CLK edge, as shown in *Figure 1904*. Because the DDR operations must finish with a falling edge, the CLK is low when the nCS rises, and the CLK rises back up one half of a CLK cycle afterwards.

Figure 1904. NCS when CKMODE=1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation or if the FIFO stays empty during a write operation, the operation stalls and the CLK stays low until the firmware services the FIFO. If an abort occurs when an operation is stalled, the nCS rises just after the abort is requested and then the CLK rises one half of a CLK cycle later, as shown in *Figure 1905*.

Figure 1905. NCS when CKMODE=1 with an abort (T = CLK period)

When not in dual-quad mode (DQM=0), only device A is accessed and thus the BnCS stays high. In dual-quad mode, the BnCS behaves exactly the same as the AnCS. Thus, if there is a device B and if the application always stays in dual-quad mode, then the device B may use the AnCS and the pin outputting BnCS can be used for other functions.

58.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 1868. OCTOSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

Table 1870. OCTOSPI_CR field descriptions

Field	Description
2:3 FMODE	Functional mode. This field defines the OCTOSPI's functional mode of operation 00 Indirect-write mode 01 Indirect-read mode 10 Automatic-polling mode 11 Memory-mapped mode If DMAEN=1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE value This field can be written only when BUSY=0
8 PMM	Polling match mode This bit indicates which method should be used to determine a "match" during the automatic-polling mode. 0 AND match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register 1 OR match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register This bit can be modified only when BUSY=0
9 APMS	Automatic poll mode stop This bit determines if the automatic polling is stopped after a match 0 Automatic-polling mode is stopped only by abort or by disabling the OCTOSPI 1 Automatic-polling mode stops as soon as there is a match This bit can be modified only when BUSY=0
11 TOIE	Timeout interrupt enable This bit enables the timeout interrupt 0 Interrupt disable 1 Interrupt enabled
12 SMIE	Status match interrupt enable This bit enables the status match interrupt 0 Interrupt disabled 1 Interrupt enabled
13 FTIE	FIFO threshold interrupt enable This bit enables the FIFO threshold interrupt 0 Interrupt disabled 1 Interrupt enabled
14 TCIE	Transfer complete interrupt enable This bit enables the transfer complete interrupt 0 Interrupt disabled 1 Interrupt enabled
15 TEIE	Transfer error interrupt enable This bit enables the transfer error interrupt 0 Interrupt disabled 1 Interrupt enabled

Table 1870. OCTOSPI_CR field descriptions (continued)

Field	Description
19:23 FTHRES	FIFO threshold level Defines, in indirect mode, the threshold number of bytes in the FIFO which will cause the FIFO threshold flag (FTF, OCTOSPI_SR[2]) to be set In indirect-write mode (FMODE=00): 0 FTF is set if there are 1 or more free bytes available to be written to in the FIFO 1 FTF is set if there are 2 or more free bytes available to be written to in the FIFO ... 0x1F FTF is set if there are 32 free bytes available to be written to in the FIFO In indirect-read mode (FMODE=01): 0 FTF is set if there are 1 or more valid bytes can be read from the FIFO 1 FTF is set if there are 2 or more valid bytes can be read from the FIFO ... 0x1F FTF is set if there are 32 valid bytes can be read from the FIFO If DMAEN=1, then the DMA controller for the corresponding channel must be disabled before changing the FTHRES value
24 FSEL	Flash select This bit selects the Flash memory to be addressed in single/dual/quad mode in single-Flash mode (when DFM = 0) 0 FLASH 1 selected (data exchanged over IO[3:0]) 1 FLASH 2 selected (data exchanged over IO[3:0]) This bit is ignored when DFM = 1 or when octal mode is selected This bit can be modified only when BUSY=0
25 DQM	Dual-quad mode This bit activates the dual-quad mode, where two external devices are used simultaneously to double the throughput and the capacity 0 Dual-quad mode disabled 1 Dual-quad mode enabled This bit can be modified only when BUSY=0.

Table 1870. OCTOSPI_CR field descriptions (continued)

Field	Description
28 TCEN	Timeout counter enable This bit is valid only when the memory-mapped mode (FMODE=11) is selected. Activating this bit causes the chip select (nCS) to be released (and thus reduce the consumption) if there has not been an access after a certain amount of time (this time is defined by TIMEOUT[15:0] (OCTOSPI_LPTR) Enables the timeout counter By default, the OCTOSPI never stops its prefetch operation, keeping the previous read operation active with the nCS maintained low, even if no access to the external device occurs for a long time Since external devices tend to consume more when the nCS is held low, the application might want to activate the timeout counter (TCEN=1, OCTOSPI_CR[3]) so that the nCS is released after a period of TIMEOUT[15:0] (OCTOSPI_LPTR) cycles have elapsed without an access since the moment that the FIFO becomes full with prefetch data 0 Timeout counter is disabled, and thus the chip select (nCS) remains active indefinitely after an access in memory-mapped mode 1 Timeout counter is enabled, and thus the chip select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity This bit can be modified only when BUSY=0
29 DMAEN	DMA enable In indirect mode, DMA can be used to input or output data via the OCTOSPI_DR register DMA transfers are initiated when the FIFO threshold flag (FTF) is set 0 DMA is disabled for indirect mode 1 DMA is enabled for indirect mode **Note:** This field is w1s
30 ABORT	Abort request This bit aborts the on-going command sequence. It is automatically reset once the abort is completed This bit stops the current transfer In polling mode or memory-mapped mode, this bit also resets the APM bit or the DM bit 0 No abort requested 1 Abort requested
31 EN	Enable Enables the OCTOSPI 0 OCTOSPI is disabled 1 OCTOSPI is enabled **Note:** This field is w1s

Field	Description
5:7 MTYP	Memory type These bits indicate the type of memory to be supported 000 Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular SPI protocol in octal/quad/dual/single modes 001 Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular SPI protocol in octal/quad/dual/single modes 010-011 Reserved 010 Reserved 011 Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular SPI protocol in octal/quad/dual/single modes with dedicated address mapping 100 HyperBus™ memory mode, the protocol follows the Cypress (Spansion) HyperBus™ specification. 8-data-bit DDR mode must be selected 101 HyperBus™ register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or indirect read/write modes must be used 110-111 Reserved, must be kept at reset value
11:15 DEVSIZE	Device size This field defines the size of the external device using the following formula: Number of bytes in device = $2^{[DEVSIZE+1]}$ DEVSIZE+1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 GB (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 MB In regular-command mode, if DQM=1, DEVSIZE indicates the total capacity of the two devices together

Table 1871. OCTOSPI_DCR1 field descriptions (continued)

Field	Description
21:23 CSHT	Chip-select high time CSHT+1 defines the minimum number of CLK cycles where the chip select (nCS) must remain high between commands issued to the external device 000 nCS stays high for at least 1 cycle between external device commands 001 nCS stays high for at least 2 cycles between external device commands ... 111 nCS stays high for at least 8 cycles between external device commands
25:27 CKCSHT	Clocked Chip-select high time CKCSHT+1 defines the number of CLK cycles provided on the CLK /nCLK pins when the chip select (nCS) is set to high at the end of a transaction 0 No clock cycles 1 1 clock cycle ... 7 7 clock cycles
30 FRCK	Free running clock This bit configures the free running clock 0 CLK is not free running 1 CLK is free running (always provided)
31 CKMODE	Mode 0 / mode 3 This bit indicates the level that the CLK takes between commands (when nCS=1) 0 CLK must stay low while nCS is high (chip select released). This is referred to as Mode 0 1 CLK must stay high while nCS is high (chip select released). This is referred to as Mode 3

58.7.2.3 Device configuration register 2 (OCTOSPI_DCR2)

Offset: 0x000C Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	WRAPSIZE

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This field should be programmed with a non-zero odd value to get even clock division factor for DTR mode.

Figure 1908. Device configuration register 2 (OCTOSPI_DCR2)

Table 1872. OCTOSPI_DCR2 field descriptions

Field	Description
13:15 WRAPSIZE	Wrap size This field indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this field indicates the wrap-size associated with the command held in the OCTOSPI_WPIR register. 000 Wrapped reads are not supported by the memory 001 Reserved, must be kept at reset value 010 External memory supports wrap size of 16 bytes (important) 011 External memory supports wrap size of 32 bytes (most likely) 100 External memory supports wrap size of 64 bytes (L1 MPU) 101 External memory supports wrap size of 128 bytes 110-111 Reserved, must be kept at reset value
24:31 PRESCALER	Clock prescaler This field defines the scaler factor for generating the CLK based on the kernel clock (value+1) 0x0 $F_{CLK} = F_{KERNEL}$, AHB clock used directly as OCTOSPI's CLK (prescaler bypassed) 0x1 $F_{CLK} = F_{KERNEL}/2$ 0x2 $F_{CLK} = F_{KERNEL}/3$ ... 0xFF $F_{CLK} = F_{KERNEL}/256$ For odd clock division factors, the CLK's duty cycle is not 50%. The clock signal remains high one cycle longer than it stays low This field can be modified only when BUSY=0

Figure 1911. Status register (OCTOSPI_SR)

Table 1875. OCTOSPI_SR field descriptions

Field	Description
18:23 FLEVEL	FIFO level This field gives the number of valid bytes that are being held in the FIFO. FLEVEL=0 when the FIFO is empty, and 32 when it is full In memory-mapped mode and in automatic status polling mode, FLEVEL is zero
26 BUSY	Busy This bit is set when an operation is ongoing This bit clears automatically when the operation with the external device is finished and the FIFO is empty
27 TOF	Timeout flag This bit is set when timeout occurs It is cleared by writing 1 to CTOF
28 SMF	Status match flag This bit is set in automatic-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR) It is cleared by writing 1 to CSMF
29 FTF	FIFO threshold flag In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete It is cleared automatically as soon as the threshold condition is no longer true In automatic-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read

Table 1875. OCTOSPI_SR field descriptions (continued)

Field	Description
30 TCF	Transfer complete flag This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted It is cleared by writing 1 to CTCF
31 TEF	Transfer error flag This bit is set in indirect mode when an invalid address is being accessed in indirect mode It is cleared by writing 1 to CTEF

Figure 1913. Data length register (OCTOSPI_DLR)

Table 1877. OCTOSPI_DLR field descriptions

Field	Description
0:31 DL[31:0]	Data length Number of data to be retrieved (value+1) in indirect and status-polling modes. A value no greater than 3 (indicating 4 bytes) should be used for status-polling mode All 1s in indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE 0x0000_0000 1 byte is to be transferred 0x0000_0001 2 bytes are to be transferred 0x0000_0002 3 bytes are to be transferred 0x0000_0003 4 bytes are to be transferred ... 0xFFFF_FFFD 4,294,967,294 (4G-2) bytes are to be transferred 0xFFFF_FFFE 4,294,967,295 (4G-1) bytes are to be transferred 0xFFFF_FFFF undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE=0x1F DL[0] is stuck at '1' in dual-quad mode (DQM=1) even when '0' is written to this bit, thus assuring that each access transfers an even number of bytes This field has no effect when in memory-mapped mode (FMODE=10) This field can be written only when BUSY=0

58.7.2.9 Address register (OCTOSPI_AR)

Offset: 0x0048 Access: Read/Write

Figure 1915. Data register (OCTOSPI_DR)

Table 1879. OCTOSPI_DR field descriptions

Field	Description
0:31 DATA[31:0]	Data Data to be sent/received to/from the external SPI device In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written In indirect-read mode, reading this register gives (via the FIFO) the data which was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY=1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first In automatic-polling mode, this register contains the last data read from the external device (without masking) Word, halfword, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a halfword write 2, and a word write 4 Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2, and a word read 4. Accesses in indirect mode must be aligned to the bottom of this register: a byte read must read DATA[7:0] and a halfword read must read DATA[15:0]

58.7.2.11 Polling status mask register (OCTOSPI_PSMKR)

Offset: 0x0080 Access: Read/Write

Table 1887. OCTOSPI_LPTR field descriptions

Field	Description
16:31 TIMEOUT[15:0]	Timeout period After each access in memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO This field indicates how many CLK cycles the OCTOSPI waits after the FIFO becomes full and until it raises the nCS, putting the external device in a lower-consumption state This field can be written only when BUSY=0

58.7.2.19 Wrap communication configuration register (OCTOSPI_WPCCR)

Offset: 0x0140 Access: Read/Write

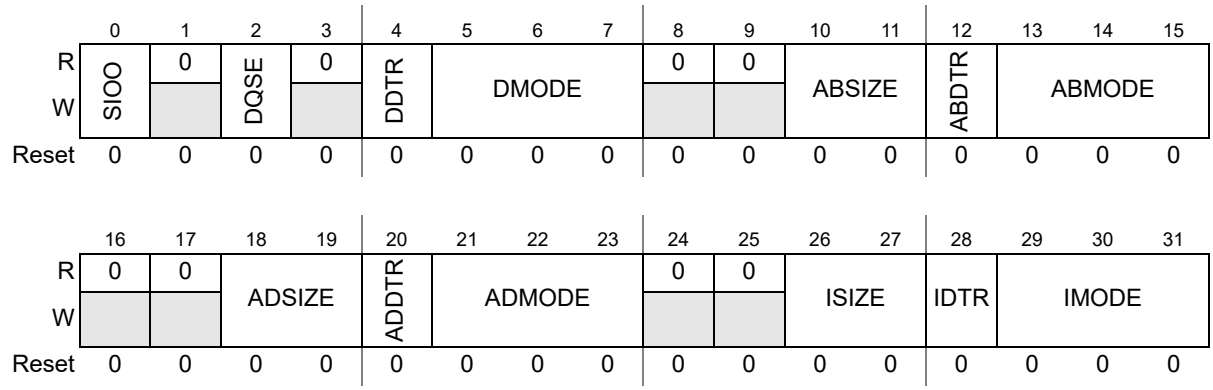

Figure 1924. Wrap communication configuration register (OCTOSPI_WPCCR)

Table 1888. OCTOSPI_WPCCR field descriptions

Field	Description
0 SIOO	Send instruction only once mode refer to *Section 58.5.3.5: Sending the instruction only once*. This bit has no effect when IMODE=00 0 Send instruction on every transaction 1 Send instruction only for the first command This field can be written only when BUSY=0
2 DQSE	DQS enable This bit enables the data strobe management 0 DQS disabled 1 DQS enabled
4 DDTR	Data double transfer rate This bit sets the DTR mode for the data phase: 0 DTR mode disabled for data phase 1 DTR mode enabled for data phase This field can be written only when BUSY=0
5:7 DMODE	Data mode This field defines the data phase's mode of operation: 000 No instruction 001 Data on a single line 010 Data on two lines 011 Data on four lines 100 Data on eight lines 101-111 Reserved, must be kept at reset value This field can be written only when BUSY=0

Table 1888. OCTOSPI_WPCCR field descriptions (continued)

Field	Description
10:11 ABSIZE	Alternate bytes size These bits define alternate bytes size: 00 8-bit alternate bytes 01 16-bit alternate bytes 10 24-bit alternate bytes 11 32-bit alternate bytes This field can be written only when BUSY=0
12 ABDTR	Alternate bytes double transfer rate This bit sets the DTR mode for the alternate bytes phase: 0 DTR mode disabled for alternate bytes phase 1 DTR mode enabled for alternate bytes phase This field can be written only when BUSY=0
13:15 ABMODE	Alternate bytes mode This field defines the alternate byte phase's mode of operation: 000 No instruction 001 Alternate bytes on a single line 010 Alternate bytes on two lines 011 Alternate bytes on four lines 100 Alternate bytes on eight lines 101-111 Reserved, must be kept at reset value This field can be written only when BUSY=0
18:19 ADSIZE	Address size These bits define address size: 00 8-bit address 01 16-bit address 10 24-bit address 11 32-bit address This field can be written only when BUSY=0
20 ADDTR	Address double transfer rate This bit sets the DTR mode for the address phase: 0 DTR mode disabled for address phase 1 DTR mode enabled for address phase This field can be written only when BUSY=0
21:23 ADMODE	Address mode This field defines the address phase's mode of operation: 000 No address 001 Address on a single line 010 Address on two lines 011 Address on four lines 100 Address on eight lines 101-111 Reserved, must be kept at reset value This field can be written only when BUSY=0.

Table 1888. OCTOSPI_WPCCR field descriptions (continued)

Field	Description
26:27 ISIZE	Instruction size This field defines instruction size: 00 8-bit instruction 01 16-bit instruction 10 24-bit instruction 11 32-bit instruction This field can be written only when BUSY=0
28 IDTR	Instruction double transfer rate This bit sets the DTR mode for the instruction phase: 0 DTR mode disabled for instruction phase 1 DTR mode enabled for instruction phase This field can be written only when BUSY=0
29:31 IMODE	Instruction mode This field defines the instruction phase's mode of operation: 000 No instruction 001 Instruction on a single line 010 Instruction on two lines 011 Instruction on four lines 100 Instruction on eight lines 101-111 Reserved, must be kept at reset value This field can be written only when BUSY=0

58.7.2.20 Wrap timing configuration register (OCTOSPI_WPTCR)

58.7.2.33 Delay configuration and status register (OCTOSPI_DELAY_CFG)

Offset: 0x0404 Access: Read/Write

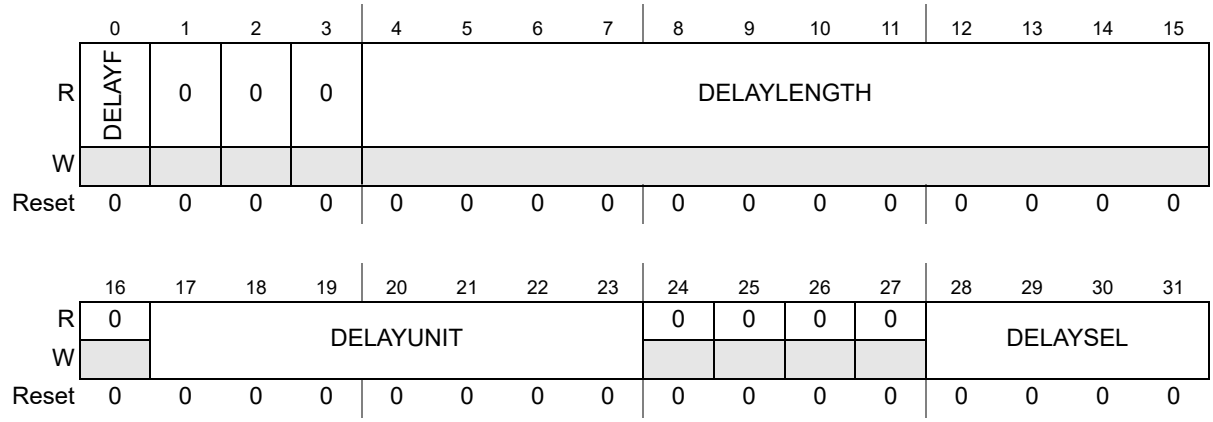

Figure 1938. Delay configuration and status register (OCTOSPI_DELAY_CFG)

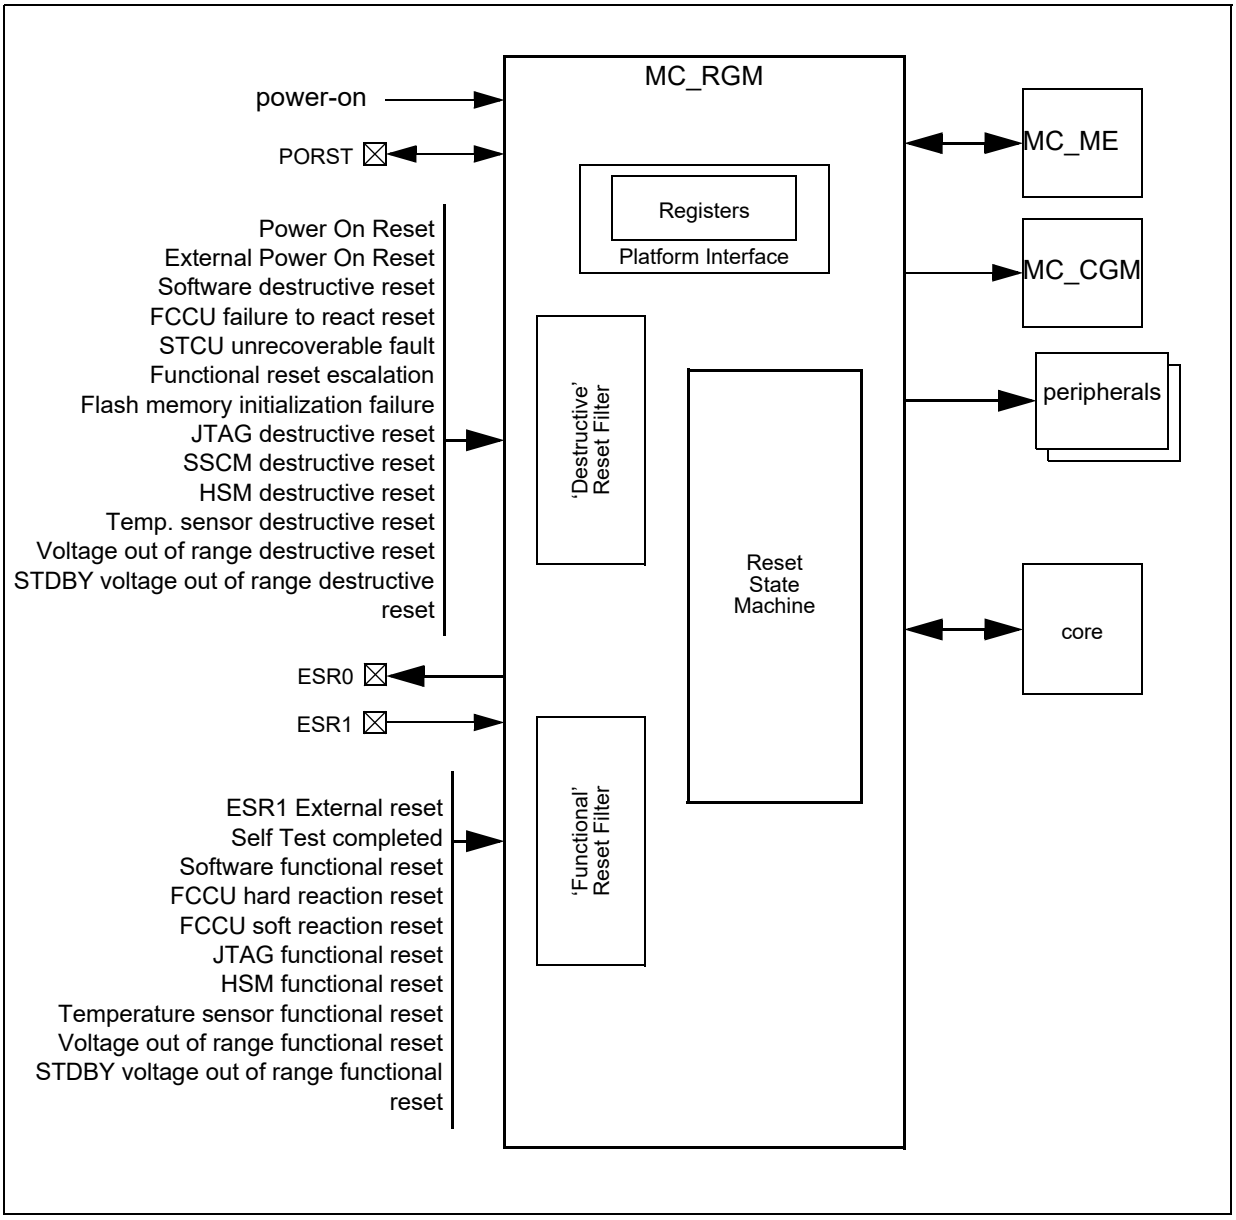
Table 1902. OCTOSPI_DELAY_CFG field descriptions

Field	Description
0 DELAYF	Length valid flag. Indicate when the delay line length value in DELAYLENGTH is valid after a change in DELAYUNIT 0 Length value in DELAYLENGTH is not valid 1 Length value in DELAYLENGTH is valid
4:15 DELAYLENGTH	Delay line length value Reflect the 12 unit delay values sampled at the rising edge of the input clock The value is only valid when DELAYF = 1
17:23 DELAYUNIT	Delay defines the delay of a unit delay cell Can only be written when SE = 1 The unit delay = initial delay + DELAYUNIT x delay step
28:31 DELAYSEL	Select the phase for the output clock Can only be written when SE = 1 Output clock phase = input clock + DELAYSEL x unit delay

59 Reset Generation Module (MC_RGM)

59.1 Introduction



This chapter describes the MC_RGM module.

59.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

Figure 1939 shows the MC_RGM block diagram.

Figure 1939. MC_RGM block diagram

59.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to SAFE mode or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration

59.1.3 Reset sources

The different reset sources are organized into two families: ‘destructive’ and ‘functional’.

- A ‘destructive’ reset source is associated with an event related to a critical (usually hardware) error or dysfunction. When a ‘destructive’ reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software ‘destructive’ reset and external power-on reset cases, which do preserve the system memory content if the chip is not configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Destructive’ resets are:
  - Power On Reset
  - External Power On Reset
  - Software destructive reset
  - FCCU failure to react reset
  - STCU unrecoverable fault
  - Functional reset escalation
  - Flash memory initialization failure
  - JTAG destructive reset
  - SSCM destructive reset
  - HSM destructive reset
  - Temperature sensor destructive reset
  - Voltage out of range destructive reset
  - STDBY voltage out of range destructive reset
- A ‘functional’ reset source is associated with an event related to a less-critical (usually non-hardware) error or dysfunction. When a ‘functional’ reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (for example, debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Functional’ resets are:
  - ESR1 External reset
  - Self Test completed
  - Software functional reset
  - FCCU hard reaction reset
  - FCCU soft reaction reset
  - JTAG functional reset
  - HSM functional reset
  - Temperature sensor functional reset
  - Voltage out of range functional reset
  - STDBY voltage out of range functional reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (that is PHASE*n* states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are

acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (refer to *Section 59.3.1.2: 'Destructive' Event Reset Disable Register (RGM_DERD)* and *Section 59.3.1.3: 'Destructive' Event Alternate Request Register (RGM_DEAR)* for 'destructive' resets and *Section 59.3.1.6: 'Functional' Event Reset Disable Register (RGM_FERD)* and *Section 59.3.1.7: 'Functional' Event Alternate Request Register (RGM_FEAR)* for 'functional' resets).

59.2 External signal description

The MC_RGM interfaces to the output reset pin ESR0.

- *not change register content*
- *cause a transfer error.*

59.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

59.3.1.1 'Destructive' Event Status Register (RGM_DES)

This register contains the status of the 'destructive' reset sources, including those configured not to generate a reset sequence. It can be accessed in read/write on either

supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing ‘1’.

This register is reset only on power-on.

Address: 0x000 Access: User read, Supervisor read/write, Test read/write

Figure 1940. ‘Destructive’ Event Status Register (RGM_DES)

Table 1904. RGM_DES field descriptions

Field	Description
6 F_VOR_STDBY	Flag for voltage out of range from LVDs or HVDs, or both, during standby mode ‘destructive’ reset 0 No voltage out of range ‘destructive’ reset event has occurred since the last clear 1 A voltage out of range ‘destructive’ reset event has occurred **Note:** for LVD100_SB it is not allowed to enable destructive reset, only functional reset is supported.
7 F_VOR_DEST	Flag for voltage out of range ‘destructive’ reset 0 No voltage out of range ‘destructive’ reset event has occurred since the last clear 1 A voltage out of range ‘destructive’ reset event has occurred
8 F_TSR_DEST	Flag for temperature sensor 'destructive' reset 0 No temperature sensor 'destructive' reset event has occurred since the last clear 1 A temperature sensor 'destructive' reset event has occurred
16 F_HSM_DEST	Flag for HSM 'destructive' reset request 0 No HSM 'destructive' reset request event has occurred since the last clear 1 A HSM 'destructive' reset request event has occurred

Table 1904. RGM_DES field descriptions (continued)

Field	Description
17 F_SSCM_DEST	Flag for SSCM 'destructive' reset request 0 No SSCM 'destructive' reset request event has occurred since the last clear 1 A SSCM 'destructive' reset request event has occurred
21 F_JTAG_DEST	Flag for JTAG 'destructive' reset request 0 No JTAG 'destructive' reset request event has occurred since the last clear 1 A JTAG 'destructive' reset request event has occurred
22 F_FIF	Flag for flash memory initialization failure 0 No flash memory initialization failure event has occurred since the last clear 1 A flash memory initialization failure event has occurred
23 F_EDR	Flag for ‘functional’ reset escalation 0 No ‘functional’ reset escalation event has occurred since the last clear 1 A ‘functional’ reset escalation event has occurred
26 F_SUF	Flag for STCU2 unrecoverable fault 0 No STCU2 unrecoverable fault event has occurred since the last clear 1 A STCU2 unrecoverable fault event has occurred
27 F_FFRR	Flag for FCCU failure to react reset 0 No FCCU failure to react reset event has occurred since the last clear 1 A FCCU failure to react reset event has occurred
28 F_SOFT_DEST	Flag for software ‘destructive’ reset 0 No software ‘destructive’ reset event has occurred since the last clear 1 A software ‘destructive’ reset event has occurred
30 F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred **Note:** F_PORST will not be set if an external PORST is asserted during standby mode. Rather MC_RGM.FES.F_JTAG_FUNC will be set.
31 F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

59.3.1.2 ‘Destructive’ Event Reset Disable Register (RGM_DERD)

This register provides dedicated bits to disable particular ‘destructive’ reset sources. When a ‘destructive’ reset source is disabled, the associated ‘destructive’ event will trigger either a SAFE mode request or an interrupt request (refer to *Section 59.3.1.3: ‘Destructive’ Event Alternate Request Register (RGM_DEAR)*). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a ‘destructive’ or power-on reset.

This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x010 Access: User read, Supervisor read/write, Test read/write

Field	Description
28 D_SOFT_DEST	Disable software ‘destructive’ reset 0 A software ‘destructive’ reset triggers a reset sequence
30 D_PORST	Disable external power-on reset 0 An external power-on reset event triggers a reset sequence 1 An external power-on reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR.AR_PORST
31 D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

59.3.1.3 ‘Destructive’ Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a ‘destructive’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0x020 Access: User read, Supervisor read/write, Test read/write

Field	Description
30 AR_PORST	Alternate Request for external power-on reset 0 Generate a SAFE mode request on an external power-on reset event if the reset is disabled 1 Generate an interrupt request on an external power-on reset event if the reset is disabled

59.3.1.4 ‘Destructive’ Reset Enable Register (RGM_DBRE)

This register enables the generation of an external reset on ‘destructive’ reset. It can be accessed in read only in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0x030 Access: User read, Supervisor read, Test read

30 BE_PORST	Reset Enable for external power-on reset 0 ESR0 is asserted on an external power-on reset event if the reset is enabled
31 BE_POR	Reset Enable for power-on reset 0 ESR0 is asserted on a power-on reset event

Note: For more details about ESR0, refer to Section 59.4.3.2: ESR0 Output External reset.

59.3.1.5 ‘Functional’ Event Status Register (RGM_FES)

This register contains the status of the ‘functional’ reset sources, including those configured not to generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on writing ‘1’ if the triggering event has already been cleared at the source.

This register is reset only on power-on.

Note: If a ‘functional’ reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.

59.3.1.6 'Functional' Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources. When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (refer to *Section 59.3.1.7: 'Functional' Event Alternate Request Register (RGM_FEAR)*). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any 'destructive' reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0x310 Access: User read, Supervisor read/write, Test read/write

Figure 1947. 'Functional' Reset Enable Register (RGM_FBRE)

Table 1911. RGM_FBRE field descriptions

Field	Description
6 BE_VOR_FUNC_STDBY	Reset Enable for LVDs or HVDs, or both, voltage out of range during standby 'functional' reset 0 ESR0 is asserted on a voltage out of range 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a voltage out of range 'functional' reset event
7 BE_VOR_FUNC	Reset Enable for voltage out of range 'functional' reset 0 ESR0 is asserted on a voltage out of range 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a voltage out of range 'functional' reset event
8 BE_TSR_FUNC	Reset Enable for temperature sensor 'functional' reset 0 ESR0 is asserted on a temperature sensor 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a temperature sensor 'functional' reset event
16 BE_HSM_FUNC	Reset Enable for HSM 'functional' reset request 0 ESR0 is asserted on a HSM 'functional' reset request event 1 ESR0 is not asserted on a HSM 'functional' reset request event
21 BE_JTAG_FUNC	Reset Enable for JTAG 'functional' reset 0 ESR0 is asserted on a JTAG 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a JTAG 'functional' reset event

Table 1911. RGM_FBRE field descriptions (continued)

Field	Description
25 BE_FCCU_SOFT	Reset Enable for FCCU soft reaction 0 ESR0 is asserted on a FCCU soft reaction event 1 ESR0 is not asserted on a FCCU soft reaction event
26 BE_FCCU_HARD	Reset Enable for a FCCU hard reaction 0 ESR0 is asserted on a FCCU hard reaction reset event 1 ESR0 is not asserted on a FCCU hard reaction reset event
28 BE_SOFT_FUNC	Reset Enable for software 'functional' reset 0 ESR0 is asserted on a software 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a software 'functional' reset event
29 BE_ST_DONE	Reset Enable for self test completed 0 ESR0 is asserted on a self test completed event
30 BE_ESR1	Reset Enable for ESR1 External Reset 0 ESR0 is asserted on an ESR1 external reset event if the reset is enabled 1 ESR0 is not asserted on an ESR1 external reset event

Note: For more details about ESR0, refer to Section 59.4.3.2: ESR0 Output External reset.

59.3.1.9 'Functional' Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

Note: This could be useful for fast reset sequence, for example to skip flash memory reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0x340 Access: User read, Supervisor read/write, Test read/write

16 SS_HSM_FUNC	Short Sequence for HSM 'functional' reset request 1 The reset sequence triggered by a HSM 'functional' reset request event will start from PHASE3

Table 1912. RGM_FESS field descriptions (continued)

Field	Description
21 SS_JTAG_FUNC	Short Sequence for JTAG 'functional' reset 0 The reset sequence triggered by a JTAG 'functional' reset event will start from PHASE1 1 The reset sequence triggered by a JTAG 'functional' reset event will start from PHASE3
25 SS_FCCU_SOFT	Short Sequence for FCCU soft reaction 1 The reset sequence triggered by a FCCU soft reaction event will start from PHASE3
26 SS_FCCU_HARD	Short Sequence for a FCCU hard reaction 0 The reset sequence triggered by a FCCU hard reaction reset event will start from PHASE1
28 SS_SOFT_FUNC	Short Sequence for software 'functional' reset 0 The reset sequence triggered by a software 'functional' reset event will start from PHASE1 1 The reset sequence triggered by a software 'functional' reset event will start from PHASE3
29 SS_ST_DONE	Short Sequence for self test completed 0 The reset sequence triggered by a self test completed event will start from PHASE1
30 SS_ESR1	Short Sequence for ESR1 External Reset 0 The reset sequence triggered by an ESR1 external reset event will start from PHASE1 1 The reset sequence triggered by an ESR1 external reset event if the reset is enabled will start from PHASE3

59.3.1.10 'Functional' Reset Escalation Threshold Register (RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. Refer to *Section 59.4.6: 'Functional' reset escalation* for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Address: 0x604 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7
R	0	0	0	0	FRET

4:7 FRET	‘Functional’ Reset Escalation Threshold 0000 ‘Functional’ reset escalation function disabled 0001 Number of ‘functional’ reset events before escalation to destructive reset … 1111 Number of ‘functional’ reset events before escalation to destructive reset

59.3.1.11 ‘Destructive’ Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for ‘destructive’ reset escalation keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the ‘destructive’ reset software escalation function. Writing any value to this register will reset the ‘destructive’ reset counter. Refer to *Section 59.4.7: ‘Destructive’ reset escalation*, for details on the ‘destructive’ reset escalation function.

This register is reset only on power-on.

Address: 0x608 Access: User read, Supervisor read/write, Test read/write

0 DSPI_8_RST	DSPI_8 reset Writing a ‘1’ to this bit resets the DSPI_8 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_8 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
3 LINFLEXD_0_RST	LINFLEXD_0 reset Writing a ‘1’ to this bit resets the LINFLEXD_0 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 LINFLEXD_2_RST	LINFLEXD_2 reset Writing a ‘1’ to this bit resets the LINFLEXD_2 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1917. RGM_PRST2 register field descriptions (continued)

Field	Description
5 LINFLEXD_4_RST	LINFLEXD_4 reset Writing a ‘1’ to this bit resets the LINFLEXD_4 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 LINFLEXD_6_RST	LINFLEXD_6 reset Writing a ‘1’ to this bit resets the LINFLEXD_6 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_6 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
7 LINFLEXD_8_RST	LINFLEXD_8 reset Writing a ‘1’ to this bit resets the LINFLEXD_8 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_8 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 LINFLEXD_10_RST	LINFLEXD_10 reset Writing a ‘1’ to this bit resets the LINFLEXD_10 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_10 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
9 LINFLEXD_12_RST	LINFLEXD_12 reset Writing a ‘1’ to this bit resets the LINFLEXD_12 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_12 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
10 LINFLEXD_14_RST	LINFLEXD_14 reset Writing a ‘1’ to this bit resets the LINFLEXD_14 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_14 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
11 LINFLEXD_16_RST	LINFLEXD_16 reset Writing a ‘1’ to this bit resets the LINFLEXD_16 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_16 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1917. RGM_PRST2 register field descriptions (continued)

Field	Description
12 LINFLEXD_18_RST	LINFLEXD_18 reset Writing a ‘1’ to this bit resets the LINFLEXD_18 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_18 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 LINFLEXD_20_RST	LINFLEXD_20 reset Writing a ‘1’ to this bit resets the LINFLEXD_20 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_20 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
14 LINFLEXD_22_RST	LINFLEXD_22 reset Writing a ‘1’ to this bit resets the LINFLEXD_22 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_22 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
18 OctalSPI_RST	OctalSPI reset Writing a ‘1’ to this bit resets the OctalSPI peripheral. Writing a ‘0’ to this bit releases the reset to the OctalSPI peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
19 eMMC_RST	SDMMC reset Writing a ‘1’ to this bit resets the SDMMC peripheral. Writing a ‘0’ to this bit releases the reset to the SDMMC peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_0_ CTR_RST	CAN_RAM_SUB_0_CTR reset Writing a ‘1’ to this bit resets the CAN_RAM_SUB_0_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_0_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** RGM is able to reset CAN RAM controller and not CAN RAM content. In other words, it is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_0_CTR_RST bit.

Table 1917. RGM_PRST2 register field descriptions (continued)

Field	Description
22 CAN_RAM_SUB_3_CTR_RST	CAN_RAM_SUB_3_CTR reset Writing a ‘1’ to this bit resets the CAN_RAM_SUB_3_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_3_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** RGM is able to reset CAN RAM controller and not CAN RAM content. In other words, it is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_3_CTR_RST bit.
23 M_CAN_0_SUB_0_RST	M_CAN_0_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_0_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_0_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 M_CAN_1_SUB_0_RST	M_CAN_1_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 M_CAN_2_SUB_0_RST	M_CAN_2_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_2_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 M_CAN_3_SUB_0_RST	M_CAN_3_SUB_0 reset Writing a ‘1’ to this bit resets the M_CAN_3_SUB_0 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_3_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 M_CAN_1_SUB_3_RST	M_CAN_1_SUB_3 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_3 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1917. RGM_PRST2 register field descriptions (continued)

Field	Description
30 M_CAN_2_SUB_3_RST	M_CAN_2_SUB_3 reset Writing a '1' to this bit resets the M_CAN_2_SUB_3 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_2_SUB_3 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 M_CAN_3_SUB_3_RST	M_CAN_3_SUB_3 reset Writing a '1' to this bit resets the M_CAN_3_SUB_3 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_3_SUB_3 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

59.3.1.15 Peripheral Reset Register 3 (RGM_PRST3)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1918* for details.

Address: 0x61C Access: User read, Supervisor read/write, Test read/write

Figure 1954. Peripheral Reset Register 3 (RGM_PRST3)

Table 1918. RGM_PRST3 register field descriptions

Field	Description
0 SAR_ADC_12BIT_0_RST	SAR_ADC_12BIT_0 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_0 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 SAR_ADC_12BIT_2_RST	SAR_ADC_12BIT_2 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_2 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 SAR_ADC_10BIT_ STDBY_RST	SAR_ADC_10BIT_STDBY reset Writing a ‘1’ to this bit resets the SAR_ADC_10BIT_STDBY peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_10BIT_STDBY peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 SAR_ADC_12BIT_B_RST	SAR_ADC_12BIT_B reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_B peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_B peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** In case BCTU_0 is used to trigger SAR_ADC_12BIT_B conversions, force the reset of BCTU_0 before setting SAR_ADC_12BIT_B_RST to 1'b1 by RGM_PRST7[BODY_CTU_0_RST] bit. De-assert BCTU_0 reset (clearing BODY_CTU_0_RST to 1’b0) only after SAR_ADC_12BIT_B is out of reset (clearing SAR_ADC_12BIT_B_RST to 1'b0).
16 PSI5_0_RST	PSI5_0 reset Writing a ‘1’ to this bit resets the PSI5_0 peripheral. Writing a ‘0’ to this bit releases the reset to the PSI5_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
20 FLEXRAY_0_RST	FLEXRAY_0 reset Writing a ‘1’ to this bit resets the FLEXRAY_0 peripheral. Writing a ‘0’ to this bit releases the reset to the FLEXRAY_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1918. RGM_PRST3 register field descriptions (continued)

Field	Description
23 DSPI_LP_RST	DSPI_LP reset Writing a ‘1’ to this bit resets the DSPI_LP peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_LP peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
24 PCM_1_RST	PCM_1 reset Writing a ‘1’ to this bit resets the PCM_1 peripheral. Writing a ‘0’ to this bit releases the reset to the PCM_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 IIC_0_RST	IIC_0 reset Writing a ‘1’ to this bit resets the IIC_0 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 IIC_2_RST	IIC_2 reset Writing a ‘1’ to this bit resets the IIC_2 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_0_RST	DSPI_0 reset Writing a ‘1’ to this bit resets the DSPI_0 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
29 DSPI_2_RST	DSPI_2 reset Writing a ‘1’ to this bit resets the DSPI_2 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1918. RGM_PRST3 register field descriptions (continued)

Field	Description
30 DSPI_4_RST	DSPI_4 reset Writing a ‘1’ to this bit resets the DSPI_4 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 DSPI_6_RST	DSPI_6 reset Writing a ‘1’ to this bit resets the DSPI_6 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_6 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

59.3.1.16 Peripheral Reset Register 4 (RGM_PRST4)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1919* for details.

Address: 0x620 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1955. Peripheral Reset Register 4 (RGM_PRST4)

Table 1919. RGM_PRST4 register field descriptions

Field	Description
1 PIT_1_RST	PIT_1 reset Writing a ‘1’ to this bit resets the PIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the PIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
16 SAR_ADC_12BIT_0_SEQ_RST	SAR_ADC_12BIT_0_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_0_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_0_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
17 SAR_ADC_12BIT_2_SEQ_RST	SAR_ADC_12BIT_2_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_2_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_2_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
18 SAR_ADC_12BIT_1_SEQ_RST	SAR_ADC_12BIT_1_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_1_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_1_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
19 SAR_ADC_12BIT_3_SEQ_RST	SAR_ADC_12BIT_3_SEQ reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_3_SEQ peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_3_SEQ peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1919. RGM_PRST4 register field descriptions (continued)

Field	Description
29 SAR_ADC_10BIT_STDBY_SEQ_RST	SAR_ADC_10BIT_STDBY_SEQ reset Writing a '1' to this bit resets the SAR_ADC_10BIT_STDBY_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_10BIT_STDBY_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 SAR_ADC_12BIT_B_SEQ_RST	SAR_ADC_12BIT_B_SEQ reset Writing a '1' to this bit resets the SAR_ADC_12BIT_B_SEQ peripheral. Writing a '0' to this bit releases the reset to the SAR_ADC_12BIT_B_SEQ peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

59.3.1.17 Peripheral Reset Register 5 (RGM_PRST5)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1920* for details.

Address: 0x624 Access: User read, Supervisor read/write, Test read/write

Figure 1956. Peripheral Reset Register 5 (RGM_PRST5)

Table 1920. RGM_PRST5 register field descriptions

Field	Description
3 M_CAN_1_SUB_2_RST	M_CAN_1_SUB_2 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_2 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 M_CAN_2_SUB_2_RST	M_CAN_2_SUB_2 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_2 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_2_SUB_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
5 M_CAN_3_SUB_2_RST	M_CAN_3_SUB_2 reset Writing a ‘1’ to this bit resets the M_CAN_3_SUB_2 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_3_SUB_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 M_CAN_4_SUB_2_RST	M_CAN_4_SUB_2 reset Writing a ‘1’ to this bit resets the M_CAN_4_SUB_2 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_4_SUB_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
20 GST_RST	GST reset Writing a ‘1’ to this bit resets the GST peripheral. Writing a ‘0’ to this bit releases the reset to the GST peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
22 FCCU_RST	FCCU reset Writing a ‘1’ to this bit resets the FCCU peripheral. Writing a ‘0’ to this bit releases the reset to the FCCU peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
25 CRC_1_RST	CRC_1 reset Writing a ‘1’ to this bit resets the CRC_1 peripheral. Writing a ‘0’ to this bit releases the reset to the CRC_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1920. RGM_PRST5 register field descriptions (continued)

Field	Description
26 CRC_2_RST	CRC_2 reset Writing a ‘1’ to this bit resets the CRC_2 peripheral. Writing a ‘0’ to this bit releases the reset to the CRC_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 DMAMUX_3_1_RST	DMAMUX_3_1 reset Writing a ‘1’ to this bit resets the DMAMUX_3_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DMAMUX_3_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DMAMUX_4_RST	DMAMUX_4 reset Writing a ‘1’ to this bit resets the DMAMUX_4 peripheral. Writing a ‘0’ to this bit releases the reset to the DMAMUX_4 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

59.3.1.18 Peripheral Reset Register 6 (RGM_PRST6)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1921* for details.

Address: 0x628 Access: User read, Supervisor read/write, Test read/write

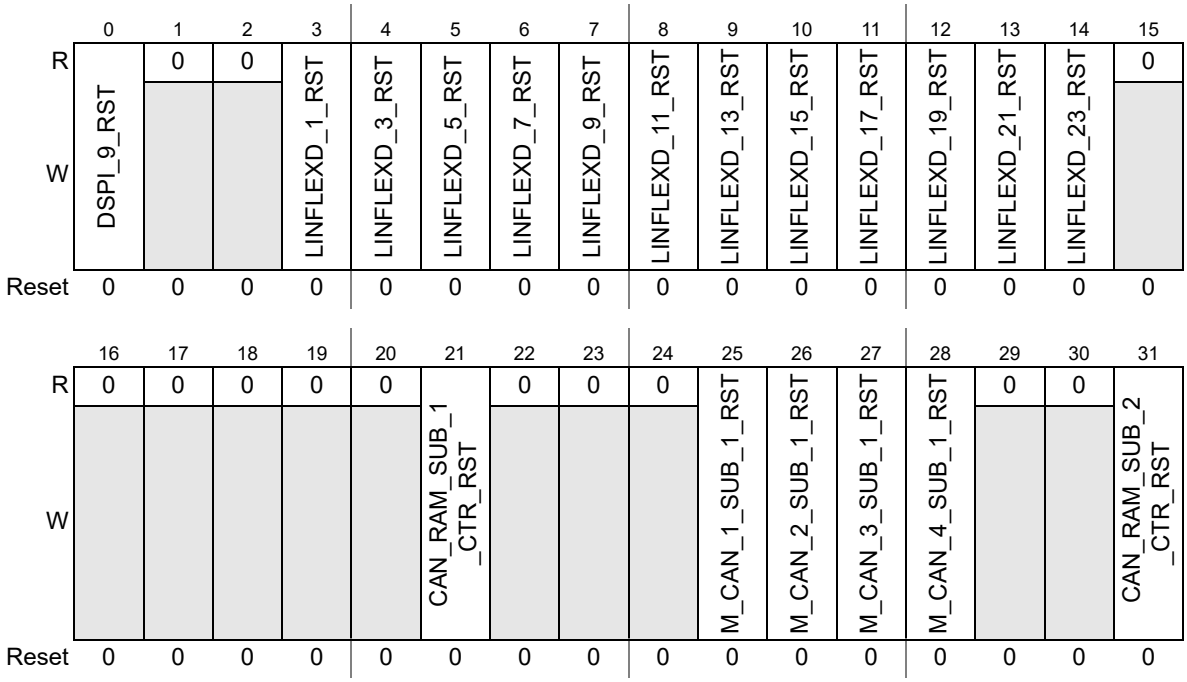

Figure 1957. Peripheral Reset Register 6 (RGM_PRST6)

Table 1921. RGM_PRST6 register field descriptions

Field	Description
0 DSPI_9_RST	DSPI_9 reset Writing a ‘1’ to this bit resets the DSPI_9 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_9 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
3 LINFLEXD_1_RST	LINFLEXD_1 reset Writing a ‘1’ to this bit resets the LINFLEXD_1 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
4 LINFLEXD_3_RST	LINFLEXD_3 reset Writing a ‘1’ to this bit resets the LINFLEXD_3 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1921. RGM_PRST6 register field descriptions (continued)

Field	Description
5 LINFLEXD_5_RST	LINFLEXD_5 reset Writing a ‘1’ to this bit resets the LINFLEXD_5 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
6 LINFLEXD_7_RST	LINFLEXD_7 reset Writing a ‘1’ to this bit resets the LINFLEXD_7 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_7 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
7 LINFLEXD_9_RST	LINFLEXD_9 reset Writing a ‘1’ to this bit resets the LINFLEXD_9 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_9 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
8 LINFLEXD_11_RST	LINFLEXD_11 reset Writing a ‘1’ to this bit resets the LINFLEXD_11 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_11 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
9 LINFLEXD_13_RST	LINFLEXD_13 reset Writing a ‘1’ to this bit resets the LINFLEXD_13 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_13 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
10 LINFLEXD_15_RST	LINFLEXD_15 reset Writing a ‘1’ to this bit resets the LINFLEXD_15 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_15 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
11 LINFLEXD_17_RST	LINFLEXD_17 reset Writing a ‘1’ to this bit resets the LINFLEXD_17 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_17 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1921. RGM_PRST6 register field descriptions (continued)

Field	Description
12 LINFLEXD_19_RST	LINFLEXD_19 reset Writing a ‘1’ to this bit resets the LINFLEXD_19 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_19 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 LINFLEXD_21_RST	LINFLEXD_21 reset Writing a ‘1’ to this bit resets the LINFLEXD_21 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_21 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
14 LINFLEXD_23_RST	LINFLEXD_23 reset Writing a ‘1’ to this bit resets the LINFLEXD_23 peripheral. Writing a ‘0’ to this bit releases the reset to the LINFLEXD_23 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 CAN_RAM_SUB_1_ CTR_RST	CAN_RAM_SUB_1_CTR reset Writing a ‘1’ to this bit resets the CAN_RAM_SUB_1_CTR peripheral. Writing a ‘0’ to this bit releases the reset to the CAN_RAM_SUB_1_CTR peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral **Note:** RGM is able to reset CAN RAM controller and not CAN RAM content. In other words, it is not possible to access CAN RAM content if corresponding CAN RAM controller is kept under reset by CAN_RAM_SUB_0_CTR_RST bit.
25 M_CAN_1_SUB_1_RST	M_CAN_1_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_1_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 M_CAN_2_SUB_1_RST	M_CAN_2_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_2_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_1_SUB_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 M_CAN_3_SUB_1_RST	M_CAN_3_SUB_1 reset Writing a ‘1’ to this bit resets the M_CAN_3_SUB_1 peripheral. Writing a ‘0’ to this bit releases the reset to the M_CAN_3_SUB_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1921. RGM_PRST6 register field descriptions (continued)

Field	Description
28 M_CAN_4_SUB_1_RST	M_CAN_4_SUB_1 reset Writing a '1' to this bit resets the M_CAN_4_SUB_1 peripheral. Writing a '0' to this bit releases the reset to the M_CAN_4_SUB_1 peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 CAN_RAM_SUB_2_CTR_RST	CAN_RAM_SUB_2_CTR reset Writing a '1' to this bit resets the CAN_RAM_SUB_2_CTR peripheral. Writing a '0' to this bit releases the reset to the CAN_RAM_SUB_2_CTR peripheral if the bit's current value is '1', otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

59.3.1.19 Peripheral Reset Register 7 (RGM_PRST7)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Refer to *Table 1922* for details.

Address: 0x62C Access: User read, Supervisor read/write, Test read/write

Figure 1958. Peripheral Reset Register 7 (RGM_PRST7)

Table 1922. RGM_PRST7 register field descriptions

Field	Description
0 SAR_ADC_12BIT_1_RST	SAR_ADC_12BIT_1 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_1 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
1 SAR_ADC_12BIT_3_RST	SAR_ADC_12BIT_3 reset Writing a ‘1’ to this bit resets the SAR_ADC_12BIT_3 peripheral. Writing a ‘0’ to this bit releases the reset to the SAR_ADC_12BIT_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
12 BODY_CTU_0_RST	BODY_CTU_0 reset Writing a ‘1’ to this bit resets the BODY_CTU_0 peripheral. Writing a ‘0’ to this bit releases the reset to the BODY_CTU_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
13 STDBY_CTU_0_RST	STDBY_CTU_0 reset Writing a ‘1’ to this bit resets the STDBY_CTU_0 peripheral. Writing a ‘0’ to this bit releases the reset to the STDBY_CTU_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
14 EMIOS_0_RST	EMIOS_0 reset Writing a ‘1’ to this bit resets the EMIOS_0 peripheral. Writing a ‘0’ to this bit releases the reset to the EMIOS_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
15 EMIOS_1_RST	EMIOS_1 reset Writing a ‘1’ to this bit resets the EMIOS_1 peripheral. Writing a ‘0’ to this bit releases the reset to the EMIOS_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1922. RGM_PRST7 register field descriptions (continued)

Field	Description
16 PSI5_1_RST	PSI5_1 reset Writing a ‘1’ to this bit resets the PSI5_1 peripheral. Writing a ‘0’ to this bit releases the reset to the PSI5_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
17 EMIOS_2_RST	EMIOS_2 reset Writing a ‘1’ to this bit resets the EMIOS_2 peripheral. Writing a ‘0’ to this bit releases the reset to the EMIOS_2 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
21 ETHERNET_0_RST	ETHERNET_0 reset Writing a ‘1’ to this bit resets the ETHERNET_0 peripheral. Writing a ‘0’ to this bit releases the reset to the ETHERNET_0 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
22 ETHERNET_1_RST	ETHERNET_1 reset Writing a ‘1’ to this bit resets the ETHERNET_1 peripheral. Writing a ‘0’ to this bit releases the reset to the ETHERNET_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
26 IIC_1_RST	IIC_1 reset Writing a ‘1’ to this bit resets the IIC_1 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
27 IIC_3_RST	IIC_3 reset Writing a ‘1’ to this bit resets the IIC_3 peripheral. Writing a ‘0’ to this bit releases the reset to the IIC_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
28 DSPI_1_RST	DSPI_1 reset Writing a ‘1’ to this bit resets the DSPI_1 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_1 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Table 1922. RGM_PRST7 register field descriptions (continued)

Field	Description
29 DSPI_3_RST	DSPI_3 reset Writing a ‘1’ to this bit resets the DSPI_3 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_3 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
30 DSPI_5_RST	DSPI_5 reset Writing a ‘1’ to this bit resets the DSPI_5 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_5 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral
31 DSPI_7_RST	DSPI_7 reset Writing a ‘1’ to this bit resets the DSPI_7 peripheral. Writing a ‘0’ to this bit releases the reset to the DSPI_7 peripheral if the bit’s current value is ‘1’, otherwise it has no effect. 0 No forced reset of peripheral 1 Forced reset of peripheral

Caution: Use the RGM_PRST*n* registers with care. Refer to *Section 59.4.8: Individual peripheral resets* for the proper sequence to prevent unexpected chip behavior.

59.3.1.20 Peripheral Reset Status Register 0 (RGM_PSTAT0)

This register provides the current reset status for various peripherals. It can be accessed in read only in all modes. Refer to *Table 1923* for details.

Address: 0x630 Access: User read/write, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

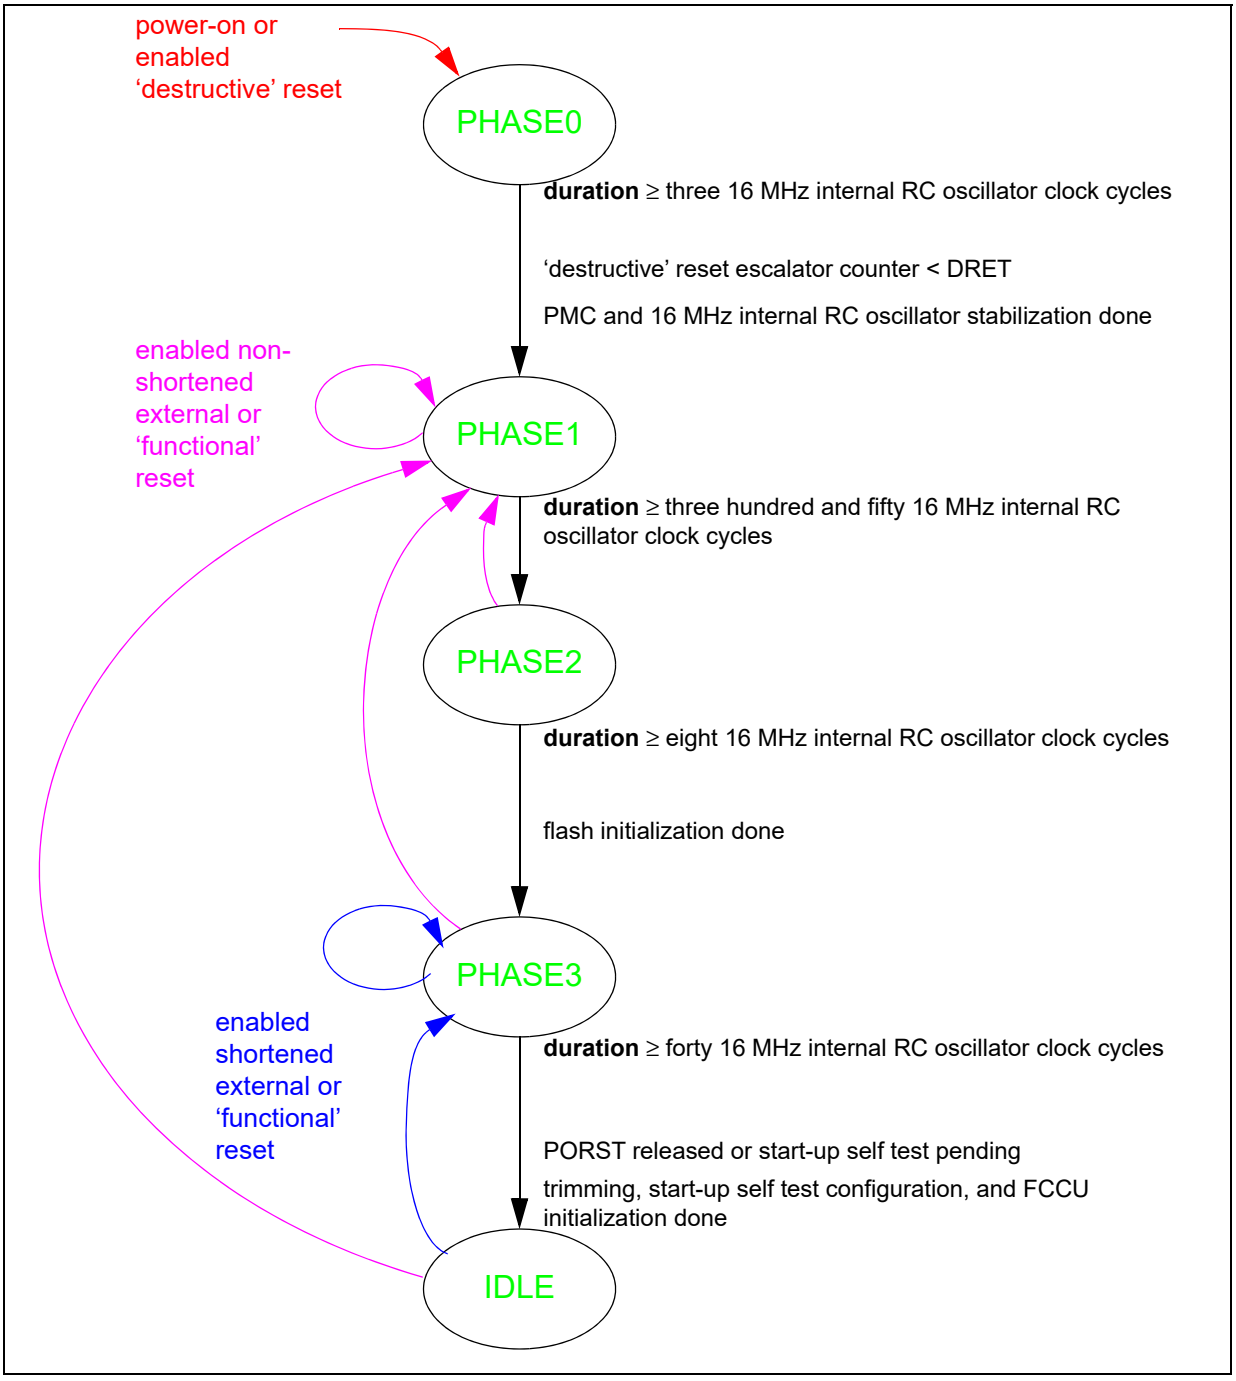
59.4 Functional description

59.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in *Table 1931*.

Table 1931. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion(1)
power-on reset	all executes a start-up self test if enabled	yes
'destructive' resets	all except some clock/reset management executes a start-up self test if enabled	yes
long external reset	all except some clock/reset management and debug executes a start-up self test if enabled	programmable(2)
long external and long 'functional' resets	all except some clock/reset management, STCU, FCCU, and debug	programmable(2)
shortened 'functional' resets(3)	flip-flops except some clock/reset management, STCU, FCCU, and debug	programmable(2)



1. 'external reset assertion' means that the ESR0 pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3.
2. the assertion of the external reset is controlled via the RGM_FBRE register.
3. the short sequence is enabled via the RGM_FESS register.

Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in *Figure 1967*.

Figure 1967. MC_RGM state machine

59.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled ‘destructive’ reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled ‘destructive’ resets have been processed
- all processes that need to be done in PHASE0 are completed
  - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of three 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled ‘destructive’ reset event
- the ‘destructive’ reset escalator counter has not reached the value in the RGM_DRET[DRET] field

59.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or ‘functional’ reset event if it has not been configured to trigger a ‘short’ sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened ‘functional’ resets have been processed
- a minimum of three hundred and fifty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened ‘functional’ reset event

59.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
  - flash initialization
- a minimum of eight 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

59.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened ‘functional’ reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization
- a minimum of forty 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened ‘functional’ reset event
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

59.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

59.4.2 ‘Destructive’ resets

A ‘destructive’ reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exceptions to the latter are the software ‘destructive’ reset and the external power-on reset which do allow the memory content to be preserved if the chip is configured to not execute a self-test on power-on, ‘destructive’, and external resets.

The status flag associated with a given ‘destructive’ reset event (RGM_DES.F_<destructive reset> bit) is set when the ‘destructive’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘destructive’ reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note: The RGM_DERD register can be written only once between two ‘destructive’ reset events.

The chip’s low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD or HVD, or both) is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled ‘destructive’ reset will trigger a reset sequence starting from the beginning of PHASE0.

59.4.2.1 External power-on reset: PORST

The bidirectional external power-on reset pin PORST is a special case ‘destructive’ reset.

The detection of a falling edge on PORST will start the reset sequence.

The chip asserts PORST if the reset sequence was triggered by one of the following:

- a power-on reset
- a ‘destructive’ reset event

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 us after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets, this is the exit of PHASE3 after self test execution has completed.

59.4.3 External reset

59.4.3.1 ESR1 Input External reset

PA[4] can be configured as ESR1 input external reset through WKPU registers (refer to *Figure 24: NMI block diagram SPC58xHx*).

The status flag associated with the external reset falling edge event (RGM_FES.F_ESR1 bit) is set when the external reset is asserted and the power-on reset is not asserted.

Note: The RGM_FERD register can be written only once between two 'destructive' reset events.

Reset Generation Module (MC_RGM): An enabled external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_ESR1 is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the Flash memory.

59.4.3.2 ESR0 Output External reset

PC[1] can be configured as ESR0 output external reset by programming the DCF Record ESR0_CONFIG.

The MC_RGM may assert the external reset ESR0 if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an ESR1 external reset event if configured via the RGM_FBRE register to assert the external reset ESR0
- a 'functional' reset event configured via the RGM_FBRE register to assert the external reset ESR0

In this case, ESR0 is asserted until all conditions for exiting PHASE3 have been met.

59.4.4 ‘Functional’ resets

A ‘functional’ reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content are still intact.

The status flag associated with a given ‘functional’ reset event (RGM_FES.F_<functional reset> bit) is set when the ‘functional’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘functional’ reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note: The RGM_FERD register can be written only once between two power-on reset events.

An enabled ‘functional’ reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a ‘functional’ reset. When RGM_FESS.SS_<functional reset> is set, the associated ‘functional’ reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and

PHASE2. This can be useful especially in case a ‘functional’ reset should not reset the flash memory module.

Refer to *Chapter 64: Mode Entry Module (MC_ME)*, for details on the STANDBY0 and DRUN modes.

59.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_DERD/FERD and RGM_DEAR/FEAR registers as shown in *Table 1932*.

Table 1932. MC_RGM alternate event selection

RGM_DERD/FERD bit value	RGM_DEAR/FEAR bit value	Generated event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (that is at the reset source that caused the alternate request) and also clearing the appropriate RGM_DES/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

If a masked ‘destructive’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

If a masked ‘functional’ reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

59.4.6 ‘Functional’ reset escalation

‘Functional’ reset escalation can be used to generate a ‘destructive’ reset if a number of ‘functional’ or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once ‘functional’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘functional’ or external reset which causes a reset sequence to be initiated (that is entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or ‘destructive’ reset. If the counter reaches the value in the RGM_FRET register’s FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

59.4.7 'Destructive' reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset[z] which causes a reset sequence to be initiated (that is entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (that is entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

59.4.8 Individual peripheral resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRST*n* registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (Refer to the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRST*n* registers.
4. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is set.
5. Clear the bit corresponding to the peripheral in the RGM_PRST*n* registers.
6. Wait until the bit corresponding to the peripheral in the RGM_PSTAT*n* registers is cleared.

The peripheral can be kept in reset indefinitely by not executing steps *5* and *6*. After the completion of step *6*, the peripheral can be enabled again via the MC_ME.

z. Only exception is the external power-on reset pin PORST that does not affect the increase of counter.

60 Boot Assist Flash (BAF)

60.1 Introduction

The BAF code is programmed by ST. The two main tasks of BAF are to provide a serial bootloader feature and to search for the application entry point.
For details regarding how the BAF code is executed, refer to *Chapter 8: Reset and Boot*.

The BAF is executed via the IRCOSC as clock source.

The MCU is booted through a collaboration of several blocks, hardware and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the HW boot core of the device pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. When the Life Cycle is set to FAIL_ANALYSIS, the BAF code shall check the UOPS[BAF_FA] bit inside SSCM as described in *Chapter 61: System Status and Configuration Module (SSCM)*. This bit mirrors the bit 31 of the UTEST_Miscellaneous_2 DCF. It tells whether the BAF shall stay in an endless loop or not when the Life Cycle is set to FAIL_ANALYSIS. In case the DCF is not programmed, the bit shall be 0 (refer to *Figure 1968*). Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module or the M_CAN module. The package pins used by LINFlexDs are the same pins used by the M_CAN modules. Hence, the external PHY can be either LIN or CAN (refer to *Section 60.3.9* for configuration details).

60.2 Memory map

For the BAF location in flash, refer to the Embedded memories chapter. The BAF block base address is 0x0040_4000. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in *Table 1933*.

Note: The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic '0' the BAF Flash block can not be programmed.

Table 1933. BAF memory organization

BAF Component	Address
BAF image header	0x0040_4000
BAF code entry point	0x0040_4100
BAF data area and stack	0x5280_0000–0x5280_0603

60.2.1 BAF image header

BAF image contains a 256-byte header starting from address 0x0040_4000. The BAF header is explained in *Table 1934*.

Table 1934. BAF image header

Address offset	Size (bits)	Field description
0x0000	32	SSCM boot record tag
0x0004	32	BAF start address
0x0008	32	BAF version number
0x000C–0x000F	Reserved	
0x0010	32	Part Clock Jitter Activation Constant
0x0014	32	Clock Jitter Activation Constant
0x0018–0x00FF	Reserved	

60.2.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0x0040_4000. The 32-bit field is explained in *Table 1935*.

Table 1935. BAF image version

Field	Description
0:7	Major Number: This field contains the major version number for the BAF image
8:15	Minor Number: This field contains the minor version number for the BAF image
16:31	Reserved

60.2.1.2 Clock Jitter Activation constant

The Clock Jitter Activation constant is a 32-bit flag, but the smallest element in flash that can be programmed is 64 bits, so the first 32 bits are reserved to allow programming of this constant. This 32-bit flag can be programmed by the customer and is used to activate the Clock Jitter feature that adds clock edge jitter to the baud rate clocks of several communications modules.As part of the BAF startup procedure, BAF copies this constant from flash to the PASS Clock Jitter Enable Register.

Table 1936. BAF Clock Jitter Activation Constant

Field	Description
0:31	Clock Jitter Activation Constant. The initial state of production disable flag is erased - 0xFFFF_FFFF. This equates to NO clock jitter.

60.3 Functional description

A functional description of the BAF modes is contained in the following sections.

60.3.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of these different boot modes.

- Application code execution

  If the internal flash contains application code with a valid boot header, the application is executed.

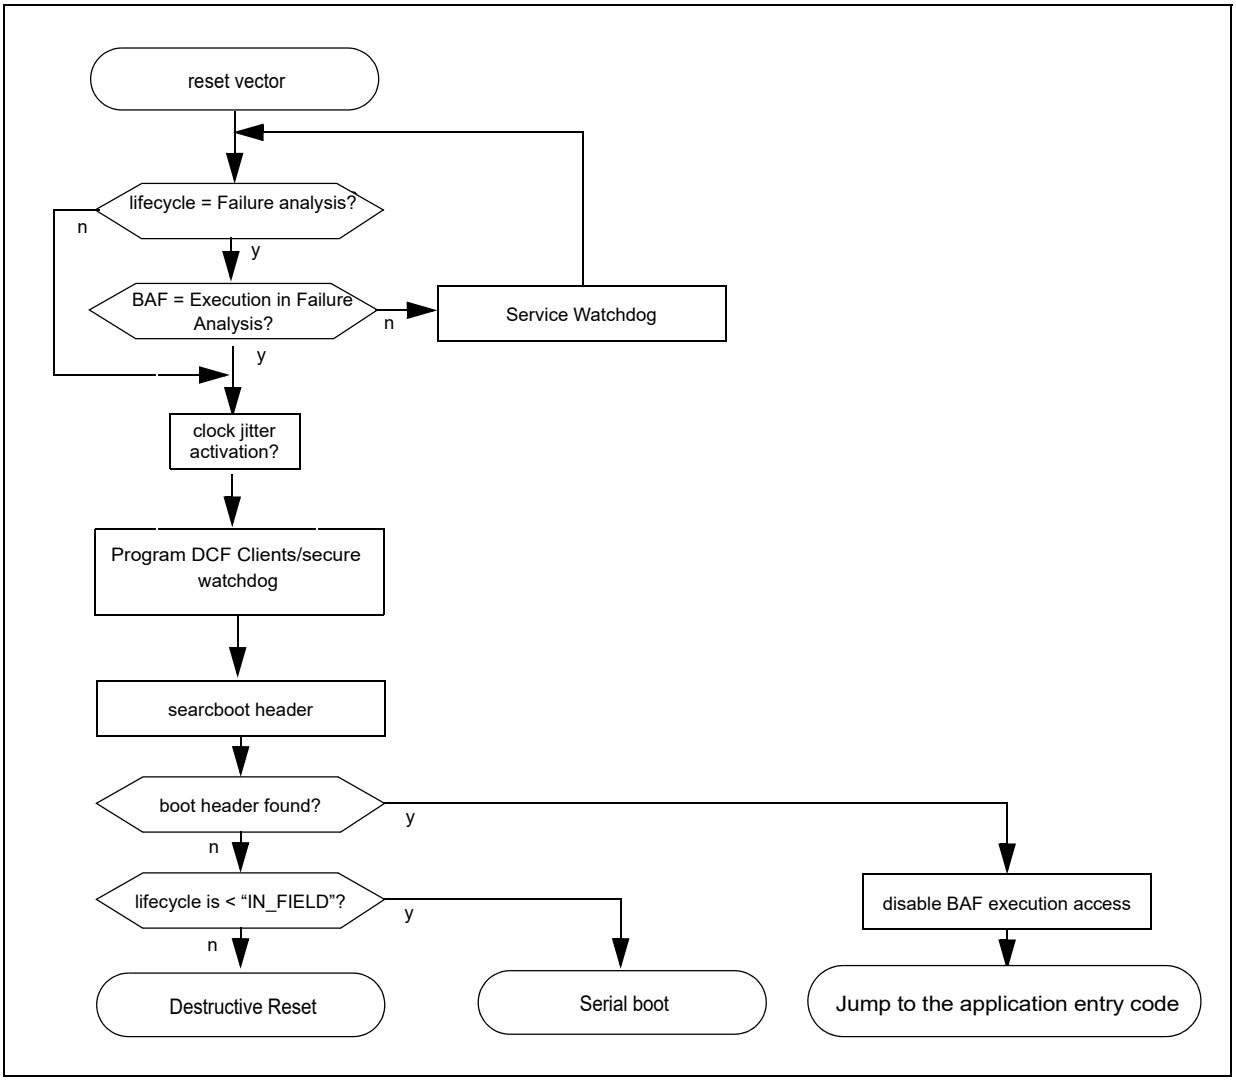
- Serial boot

  If no valid boot header is found and the current life cycle phase of the device is less than Infield, an attempt is made to download the application by a serial protocol using the LINFlexD modules or M_CAN modules. The downloaded code is then executed by the boot CPU.

- Static mode

  The device enters power safe mode and waits for an external reset.

60.3.2 Device initialization



The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the Hardware Security Module (HSM) in the following way:

- HSM: If the HSM is enabled and the “wait for HSM” flag is present, then the boot core waits for the HSM to become ready.
- BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module’s MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
- BAF uses DMEM memory area of the boot CPU as in *Table 1933: BAF memory organization* for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.
- The memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration. At this point the BAF has finished its operation.

60.3.3 Flow of control

Figure 1968 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

Figure 1968. Flow of control

60.3.4 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (SSCM_UOPS[HSB = 1]). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

60.3.5 Initialization of BAF DCF clients

60.3.5.1 ‘Soft’ DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32 bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is 0xFFFF_FFFF). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in *Table 1937*.

The DCF clients which are used for initialization of security watchdog are explained in *Section 60.3.5.2: Security watchdog configuration*.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in *Table 1937* provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside within the BAF or UTEST blocks only. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in *Section 60.3.5.6: SER_BOOT_CBACK – BAF serial boot DCF client*.

Table 1937. BAF DCF client list

Address (hex)	Name	Label	Description
0x0000	Security Watchdog Control Register	SEC_SWT_CR	Data to write to SWT Control Register
0x0001	Security watchdog Time out register	SEC_SWT_TO	Security watchdog counter value
0x0002	Security watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0x0003	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog
0x0004–0x01FF	Reserved		
0x0200	Address	ADDR	The address to which DATAX is written
0x0201	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0x0202	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0x0203	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0x0204–0x020F	Reserved		
0x0210	Callback Address	CALLBACK	The address of a callback function
0x0211	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0x0212–0x0213	Reserved		Reserved for future use.
0x0214	Reserved		Reserved for future use.
0x0215–0x7FFF	Reserved		Reserved for future use.

Note: BAF boots with a watchdog timeout window set to 16ms. Parsing more and more DCF Records may increase boot time. But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

60.3.5.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then program the security watchdog registers. BAF configures only SWT2 as security watchdog for the CPU2 core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

60.3.5.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0000 while parsing, BAF programs the DCF client "Security watchdog control register"

with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

60.3.5.2.2 Security Watchdog TImeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

60.3.5.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in ‘fixed address execution service mode’. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0x0002 while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

Note: To program the core IAC8 special purpose register, the ownership of this register should be with software. If hardware has its ownership software will not be able to write to it using mtspr instruction.

60.3.5.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to BAF which CPU will use the security watchdog. BAF parses the DCF record and if it finds a record with CS14 set and address field set as 0003h, BAF programs this DCF client. This means that BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. *Figure 1969* and *Table 1938* indicate the data layout for this client in the DCF record. This client is written once during reset. Subsequent writes are ignored.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients are not written, data is configured erroneously.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). If the security watchdog is assigned to CPU2 (IOP), first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

DCF Client Address 0x0003

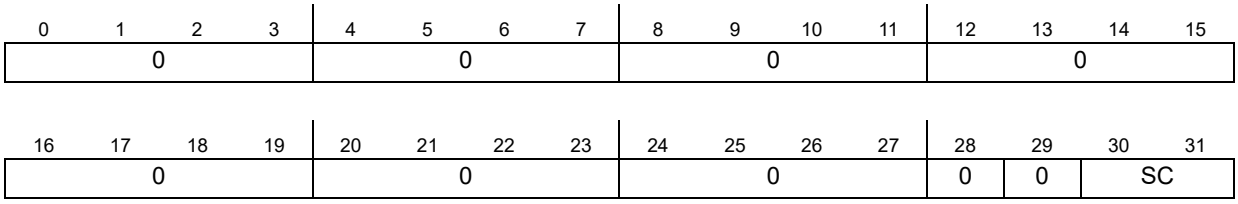


Figure 1969. SEC_SWT_CPU bit configuration

Table 1938. SEC_SWT_CPU field description

Field	Description
30:31 SC	These two bits select the CPU which will use the security watchdog. 00 Reserved 01 Reserved 10 CPU2 (IOP) 11 Reserved

Note: BAF programs FCCU for enabling SWT2 and SWT3 as fault source and makes them hardware recoverable. This is done to ensure that fault latched in FCCU get cleared on reset and on next SWT timeout FCCU can again trigger reset. BAF does not clear the faults latched in FCCU as they can be of interest for application.

60.3.5.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0x0200 while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

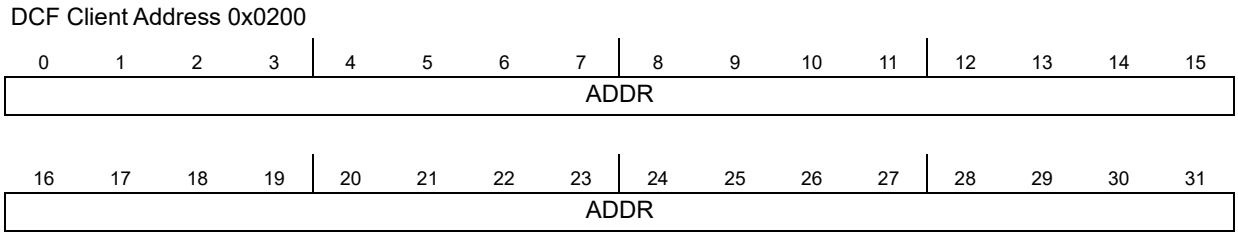

Figure 1970. BAF DCF ADDR client configuration

Table 1939. BAF DCF ADDR client description

Field	Description
0:31 ADDR	32-Bit Address DCF client This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU.

60.3.5.4 BAF DCF client - DATAX

Caution: While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

60.3.5.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0201 while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

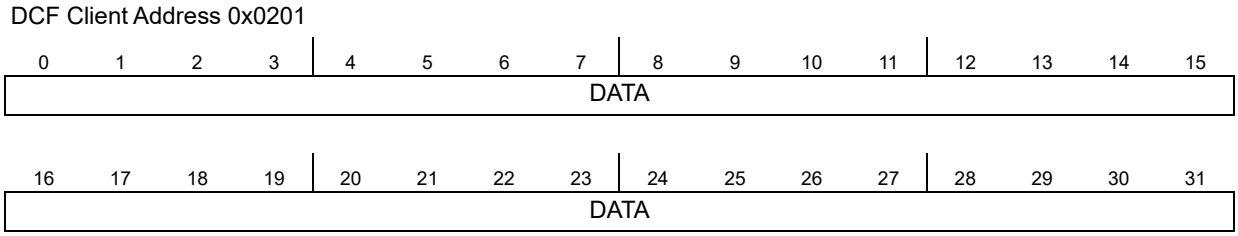

Figure 1971. DATA32 DCF client configuration

Table 1940. DATA32 DCF client configuration

Field	Description
0:31 DATA	32-Bit DCF data

60.3.5.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0202 while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to ‘0’ (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

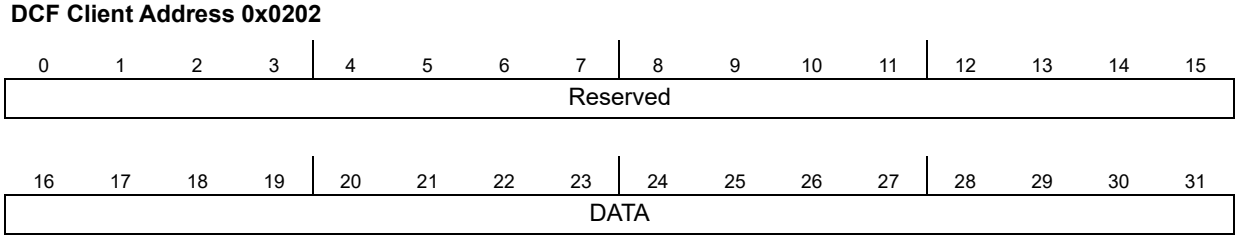

Figure 1972. DATA16 DCF Client Configuration

Table 1941. DATA16 DCF client configuration

Field	Description
16:31 DATA	16-Bit DCF data

60.3.5.4.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0x0203 while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

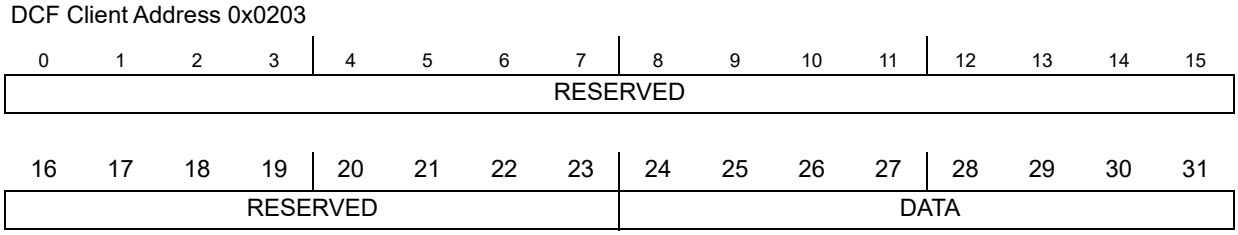

Figure 1973. DATA8 DCF Client Configuration

Table 1942. DATA8 DCF client configuration

Field	Description
24:31 DATA	8-Bit DCF data

60.3.5.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0210 while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in Power Architecture web site and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Caution: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore, several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

60.3.5.6 SER_BOOT_CBACK – BAF serial boot DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0x0211 while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32-bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with Embedded Application Binary Interface (EABI) for PowerPC found in over Architecture web

site and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: No parameters are passed to the function invoked by the BAF.Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed (refer to *Table 1943* for details regarding return value).

Table 1943. Serial boot callback function return value definition

Return values	Description
0x00	Boot from internal flash using standard search for boot record (refer to 'Search boot header and boot options' in *Chapter 7: Device configuration*).
0x01	Serial boot using both M_CAN and LINFlexD (in UART mode) (refer to 'Search boot header and boot options' in *Chapter 7: Device configuration*). **Note:** Serial boot is conditioned by life cycle as described in *Figure 1968*

60.3.6 Production disable activation protocol and implementation

Module failure analysis is a standard requirement. But some OEMs have an additional requirement that upon entering failure analysis mode, the MCU operation is modified in such a way that the MCU can never be used in production ECU. The chosen operational modification for production disable is to apply clock jitters to can modules so that it prevents active communications with another can device on a can network. For detail regarding production disable refer to the PASS chapter.

The BAF maintains a 64-bit flag in BAF code flash region as explained in *Section 60.2.1.2: Clock Jitter Activation constant*. On every POR BAF copies the clock jitter activation constant from this flag to clock jitter enable register in PASS module to enable jitters on can baud clock. Default value of this flag is shown in *Section 60.2.1.2: Clock Jitter Activation constant*. Hence, jitter on the MCAN baud clock is disabled if the default value is used. To enable jitter on can clock the value of this flag should be modified to 0xFFFF_FFFE.

The BAF flash memory is write protected and locked. To enable modification of this flag and activate production disable feature, BAF implements production disable activation protocol as explained in *Table 1945*. BAF implements this protocol in a power.ORG EABI compliant callback routine. This callback routine can be invoked by programming a callback based soft DCF client as explained in *Section 60.3.5.5: CALLBACK – BAF callback DCF client*. The callback function address is shown in *Table 1944*.

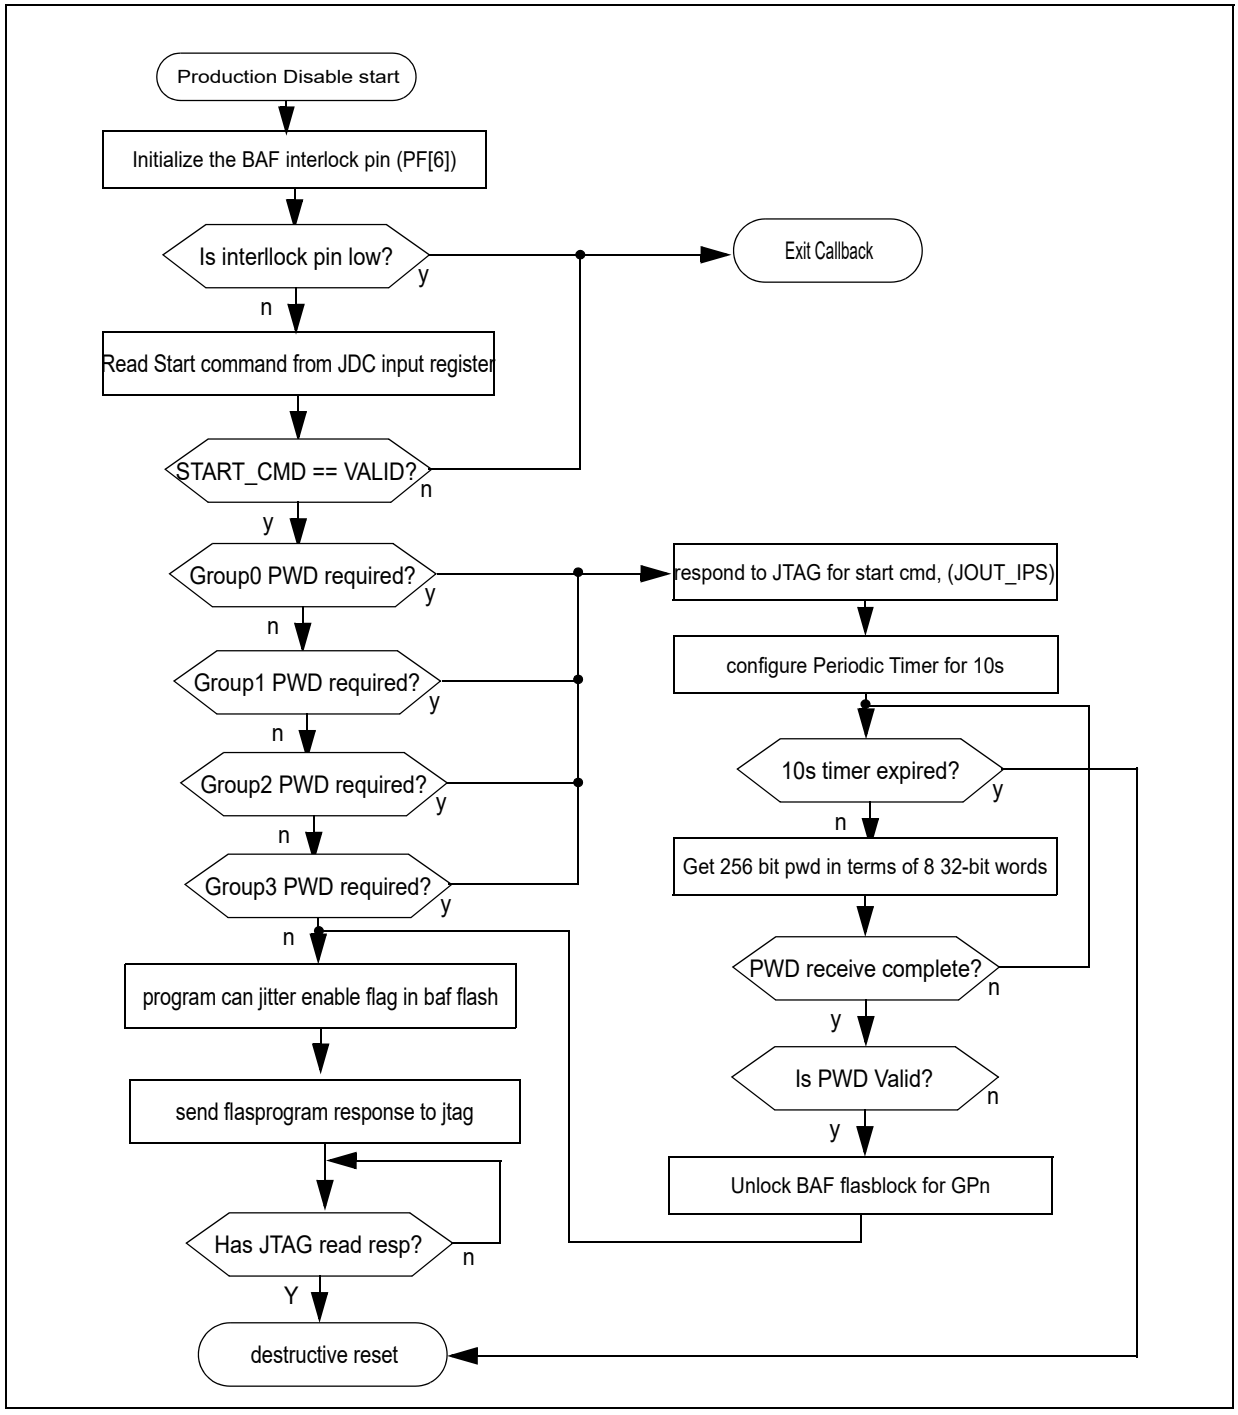

Table 1944. Production Disable Callback routine entry point

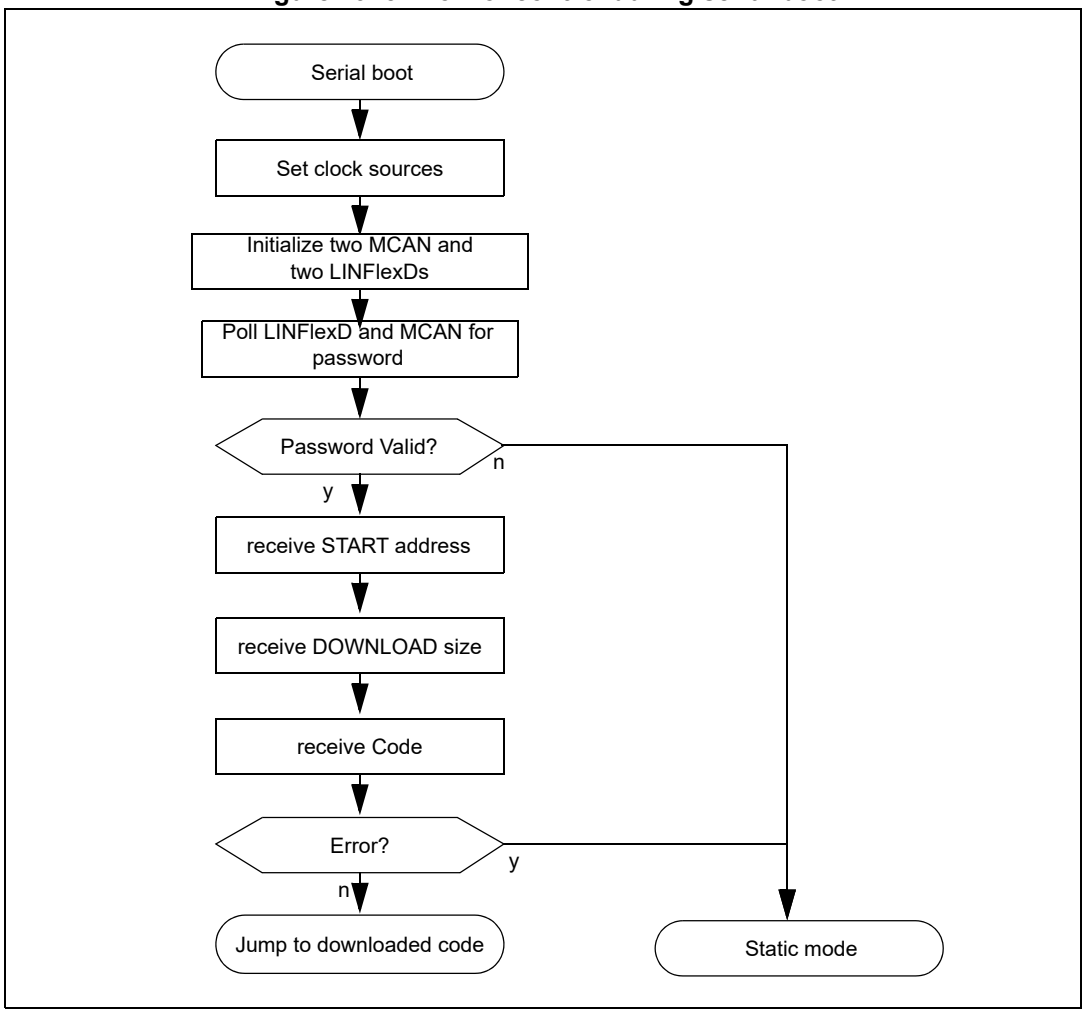
Description	Address
Production disable protocol callback function address	0x0040_40E0

Table 1945. Production Disable protocol description

Step	Description	Tool Action/Response	MCU Action/Response
1	After power-on tool holds the MCU in reset and writes the activation code to JDC via JTAG interface. The tool pulls hardware interlock pin high, then releases reset.	Assert hardware interlock pin Write 0xF5A0_AA55 to JDC	Starts production disable activation
2	The MCU responds by writing to the JDC an acknowledgment code and which of the 4 PASS passwords are required to unlock the BAF flash block		Write 0xFA50_000*n* to JDC if password for pass group n is required to unlock the BAF flash block. (n is either 0,1,2 or 3)
3	The tool reads the acknowledge from JDC module and writes the relevant password to the JDC module. MCU performs password comparison and writes error code to JDC module password provided by tool was incorrect.	Read JDC Write 256 bit password for pass group n to JDC in eight 32-bit words. (n is 0,1,2 or 3)	Write 0xFA50_F00*n* if password does NOT match. Once the status has been read by the tool then cause reset. (n is either 0,1,2 or 3)
4	If more than one password is required to unlock the BAF flash block step 2 and step 3 are repeated until all relevant password has been supplied.		If password matches step 2 and step 3 are repeated for the next pass group until all pass group that lock BAF flash has been processed.
5	The MCU then attempts to program the can jitter activation constant within the BAF flash block. The can jitter activation constant flag is a write once flag. Once written it cannot be re-programed as BAF flash block is OTP. MCU write a code to JDC to signal success or failure of flash programming operation and issue reset.		Program can jitter activation constant in BAF flash block. If successful write 0xFA51_0000 to JDC. If unsuccessful write 0xFA51_F000 to JDC Issue reset.

Figure 1974. Production Disable callback function flow chart

60.3.7 TDM Diary Operation



On every reset, BAF copies the first four bytes of last record of every Tamper Detect Region to corresponding Software Tamper Override Key Region Registers in TDM. BAF reads the base address of TDM Diary from DBA register in TDM. For more details on TDM refer to the corresponding section. This is done as a part of TDM Diary Override enhancement.

60.3.8 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than In Field, it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

If the customer selects serial boot using serial boot using serial boot DCF client, then BAF determines the Life Cycle status of the device. If the Life Cycle is lower than Failure Analysis, it attempts a serial boot.

Figure 1975. Flow of control during serial boot

The clock source in the MC_CGM is configured (with IRCOSC for LINFlexD and with XOSC for CAN) and the PADs are set up for two LINFlexDs and two M_CANs signals, then the code is downloaded using LINFlexD or M_CAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via LINFlexD or M_CAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At start of serial boot sequence the Rx-channels of all two serial interfaces shall be enabled and the BAF code shall take care for polling all two Rx-channels for detecting the valid serial boot message. After a successful detection of the active Rx-channel the corresponding Tx-channel shall be enabled and the inactive Rx-channel shall be disabled.

At the start of the process both LINFlexDs and M_CANs are configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and does not participate further in serial boot.

If a CAN message of 8 bytes with ID 0x11 is received on the M_CAN controller first, the BAF program

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message not containing 8 bytes or NOT with ID 0x11 is received by M_CAN controller or a M_CAN controller generates a CAN error, it is probable that the tool is sending a LINFlexD frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is 0xFE of the password. If not continue polling. The data may be a valid CAN message.
- If it is first byte of the password (0xFE) then disable the M_CAN controller and restore to its reset state.
- Configures the M_CAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

60.3.8.1 Serial boot mode protocol

From a high-level perspective, the download protocol over M_CAN and LIN interfaces follows the steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.

   NO_ECHO bit signifies if actual download data to be echoed or not. If NO_ECHO bit is set, then data will not be echoed otherwise if NO_ECHO bit is clear, then data will be echoed.

Note: Since this device supports only VLE code and no Book E code, the VLE bit is used only for backward compatibility.

3. Host transmits a sequence of data bytes that are to be executed.
4. The boot CPU executes code from start address provided in step 2.

Each step must be completed before the next step starts.

The exact protocol between LINFlexD and M_CAN are slightly different.

60.3.8.2 LINFlexD download protocol

The communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   – If the data is correct, the host can send the next byte of data.
   – If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. *x* bytes of code that is downloaded to SRAM and executed (*x* must match the value specified in step *3.*).

60.3.8.3 M_CAN download protocol

The M_CAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by M_CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 0x11 as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 0x1.
2. A message with 0x12 as the ID and 8-byte length to send the start address, size of the code and VLE mode bit. The MCU transmits back the same data but with an ID of 0x2.
3. A message with 0x13 as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 0x3.

60.3.8.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password 0xFEED_FACE_CAFE_BEEF.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

60.3.8.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit, NO_ECHO bit and 30-bit code length as shown in *Figure 1976* and *Figure 1977*.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

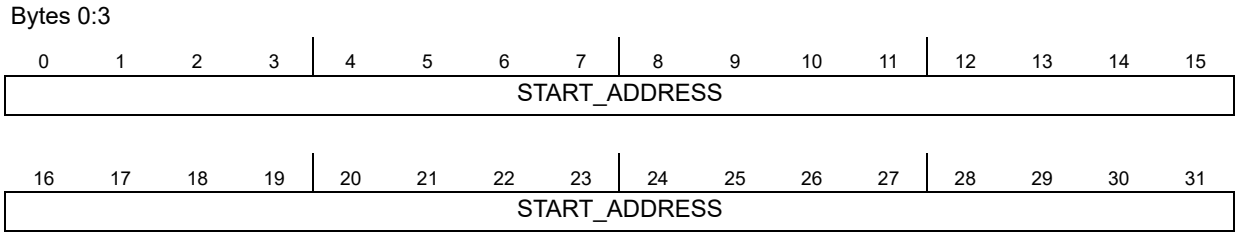


Figure 1976. Start address

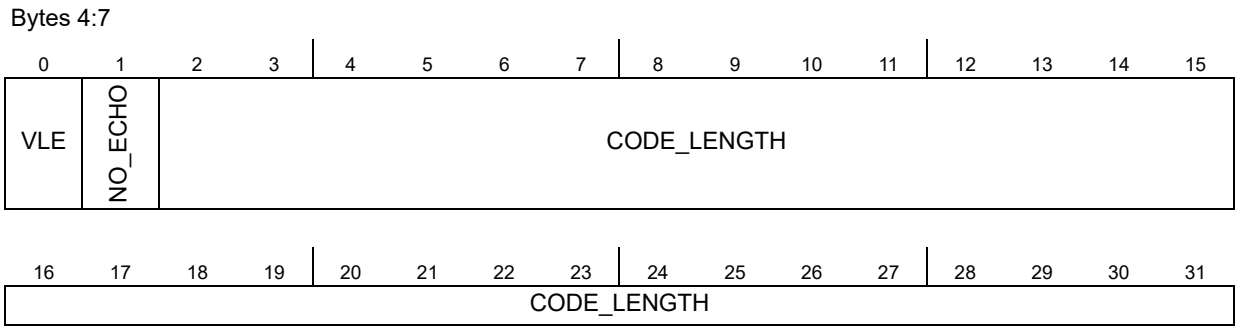

Figure 1977. VLE bit, NO_ECHO bit and code size

60.3.8.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero's and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0x0000_0000_0000_0000) to the next address location. This is written to avoid possible ECC error during core prefetch.

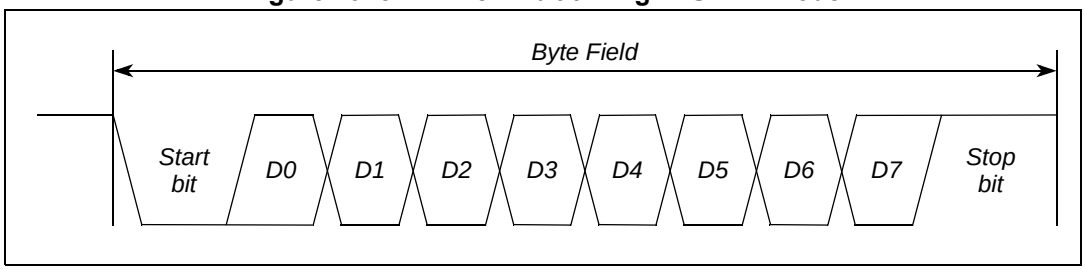
60.3.8.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

60.3.9 Serial boot configuration

60.3.9.1 LINFlexD configuration

Boot using UART protocol is implemented by LINFlexD module.



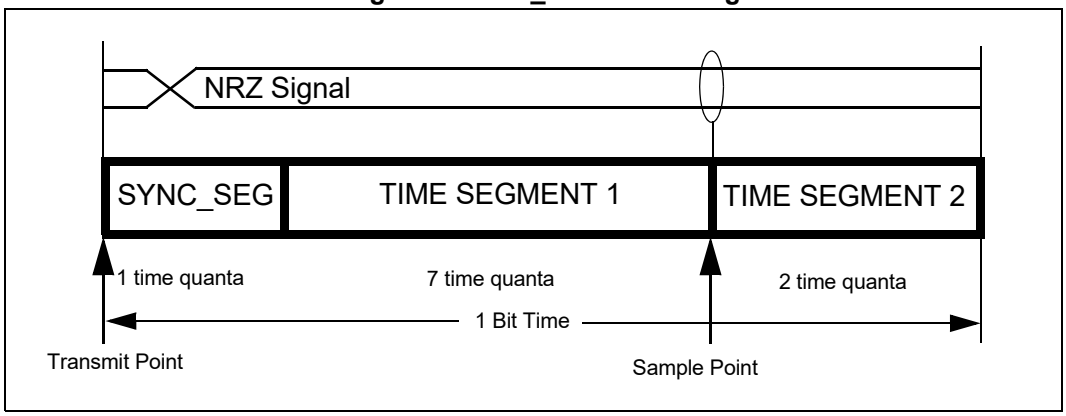
Note: Refer to the pin configuration table in Chapter 7: Device configuration for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx is configured as an input and multiplexed to the LINFlexD module. The LINFlexD_Tx remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data. The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx pin transmission.

The LINFlexD controller is configured to operate with an 8-bit data frame without parity bit and 1 stop bit.

Figure 1978. LINFlexD bit timing in UART mode



60.3.9.2 M_CAN configuration

The M_CAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0A specification (refer to *Table 1946* for baud rates).

The Bit timing is configured as shown in *Figure 1979*

Figure 1979. M_CAN Bit Timing

60.3.9.3 Baud rates

The LINFlexD baud rate is set at 250kbaud. *Table 1946* below shows some possible baud rates.

The M_CAN baud rate is set by the frequency of the external crystal/40.

Table 1946. M_CAN baud rates

Frequency	M_CAN baud rate
8 MHz	200 Kbaud
12 MHz	300 Kbaud
16 MHz	400 Kbaud
20 MHz	500 Kbaud
40 MHz	1000 Kbaud

60.3.9.4 LINFlexD and M_CAN pin configuration

Refer to *Chapter 7: Device configuration* for pin details.

60.3.9.5 Protocol summary

Table 1947 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 1947. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is not echoed, otherwise data is echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	None	None	Branch to downloaded code

Table 1948 shows the M_CAN serial boot protocol.

Table 1948. M_CAN serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	CAN ID 0x011 + 64-bit password	CAN ID 0x001 + 64-bit password	Password checked against fixed password (0xFEED_FACE_CAFE_BEEF). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 0x012 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	CAN ID 0x002 + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 0x013 + 8 to 64-bits of raw binary data	VLE bit + 31 bit number of bytes (MSB first)	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	None	None	Branch to downloaded code

60.4 Resources accessed by BAF code execution

The BAF code execution uses several IPs to achieve the main functions.

- Magic carpet (clocks)

Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).

- LINFlexD and M_CAN

The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.

- PFLASH

PFLASH module is used to disable BAF execution. Remapping of the external overlay memory is configured automatically under certain conditions. The two PFLASH are used.

- Interrupts

No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.

- Security watchdog

When SWT2 is chosen as security watchdog, SWT3 is used for task monitoring purpose.

- FCCU

FCCU is used to configure Fault Reaction of SWT2 and SWT3.

- TDM

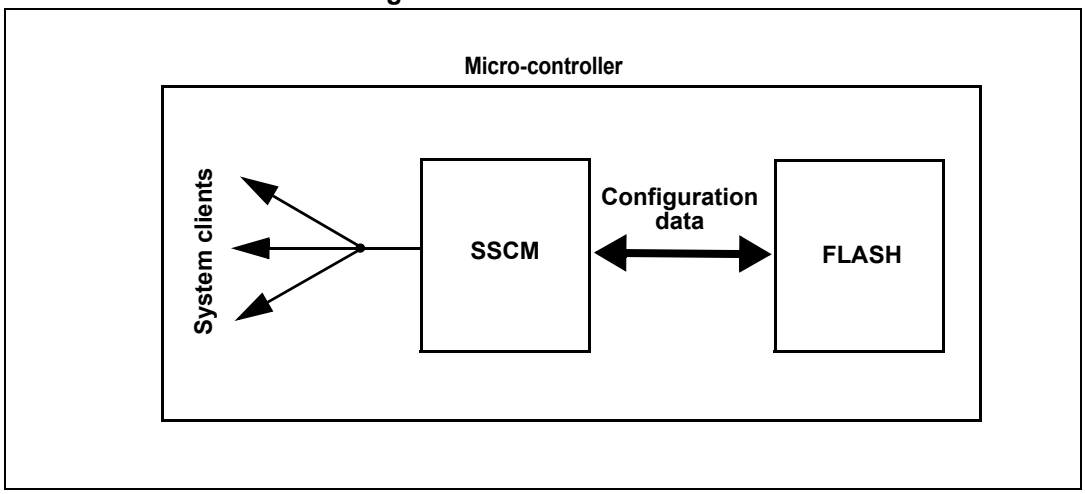
TDM for implementing TDM Diary enhancements.

- SSCM

Used to read some register bits (mirrors of DCF)

- PASS

Used for clock jitter enabling



61 System Status and Configuration Module (SSCM)

61.1 Introduction

61.1.1 Overview

The System Status and Configuration Module (SSCM) is aimed at reading the system configuration from the Flash and distributing to various clients inside the micro-controller, pictured in *Figure 1980*.

Figure 1980. SSCM overview

61.1.2 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Determine HSM boot vector
  - Decodes the Device Life Cycle

61.1.3 Modes of operation

The SSCM operates identically in all system modes.

61.2 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

Table 1949 shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Note: All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit

boundaries. As an example, the STATUS register is accessible by a 16-bit READ/WRITE to address Base + 0x0002, but performing a 16-bit access to Base + 0x0003 is illegal.

Table 1949. SSCM memory map

Address offset	Register	Access	Reset value	Section
0x0000	SSCM System Status (STATUS)	R/W	0xyyy0(1)	*Section 61.2.1.1*
0x0002	SSCM System Memory and ID Register (MEMCONFIG)	R	0xyyyy(1)	*Section 61.2.1.2*
0x0004	Status Register (SR)	R	0xyyyy(1)	*Section 61.2.1.3*
0x0006	SSCM Error Configuration Register (ERROR)	R/W	0x0000	*Section 61.2.1.4*
0x0008–0x0009	Reserved(2)			
0x000A–0x001C	Reserved			
0x0020	SSCM HSM and User Option Status Register (UOPS)	R	0xyyyy_yyyy(1)	*Section 61.2.1.5*
0x0024–0x0027	Reserved			
0x0028	Processor Start Address Register (PSA)	R	0xyyyy_yyyy(1)	*Section 61.2.1.6*
0x002C–0x002F	Reserved			
0x0030	SSCM HSM Start Address Register (HSA)	R	0xyyyy_yyyy(1)	*Section 61.2.1.7*
0x0034	Life Cycle Status Register (LCSTAT)	R	0x0000_0y0y(1)	*Section 61.2.1.8*
0x0038	OTA Signature Address Location register (OSAL)	R	0xyyyy_yyyy(1)	*Section 61.2.1.9*
0x003C–0x0048	Reserved			
0x004C	Non Active Context Logical Address register (NACLA)	R	0xyyyy_yyyy(1)	*Section 61.2.1.10*

1. Refer to register description for reset value details.
2. No register abort on this location.

61.2.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

61.2.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Offset: 0x0000 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CER	0	NXEN1	NXEN	1	0	0	BMODE			VLE	0	0	0	0
W		w1c														
Reset	0	0	0	-(2)	-(2)	1	0	0	-(2)			-(1)	0	0	0	0

1. Reset value depends on the associated option bits in flash memory.
2. Reset value depends on the device status after leaving reset.

Figure 1981. System Status Register (STATUS)

Table 1950. STATUS field descriptions

Field	Description
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error while loading DCF clients (with PARITY Enabled). This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
8:10 BMODE	Device Boot Mode 000 Reserved 001 Reserved 010 Reserved 011 User Code Boot (BAF not executed) 100 Reserved 101 BAF Code Boot (BAF executed) 110 Reserved 111 Reserved This field is only updated during reset. If the device goes into standby mode and wakes up from it again, the bits retain their original value.
11 VLE	Variable Length Instruction Mode When booting in User Code Boot mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0 User Code Boot Location contains standard PPC code 1 User Code Boot Location contains VLE code

61.2.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Offset: 0x0002 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	1	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0

1. Reset value reflects the JTAG ID of the device.

Figure 1982. System memory and ID register (MEMCONFIG)

Table 1951. MEMCONFIG field descriptions

Field	Description
0:9 JPIN	JTAG Part ID Number
11:14 MREV	Minor Mask Revision

61.2.1.3 Status register (SR)

Offset: 0x0004 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	OTA_SIG_BLOCK_DCF	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0/1(1)	0/1(1)

1. Reset value depends on the DCF value.

Figure 1983. Status register (SR)

Table 1952. SR field descriptions

Field	Description
14:15 OTA_SIG_BLOCK_DCF	These 2 bits mirror the OTA signature block 2 bit DCF value. These bits are only meaningful if OTA is enabled. Note the DCF configuration is one time programmable so it is not possible to update it successively.

61.2.1.4 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Offset: 0x0006 Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	OTA_ER	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1984. Error Configuration Register (ERROR)

Table 1953. ERROR field descriptions

Field	Description
13 OTA_ER	This bit captures the error scenario if during the functional reset phase (or when BIST is disabled) the SSCM OTA reading of the signature slot and slot next to signature slot are inconsistent with what is read during the destructive reset phase. This bit is only valid for software when OTA is enabled. This bit is cleared by functional reset.
14 PAE	Peripheral Bus Abort Enable This bit enables bus aborts on: – any access to a peripheral slot that is not used on the device. – illegal accesses to off-platform peripherals. On platform peripherals cannot be controlled by SSCM peripheral abort. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
15 RAE	Register Bus Abort Enable This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception **Note:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the PBRIDGE level). In this case, the PAE and RAE register bits have no effect on the abort.

61.2.1.5 HSM and User Option Status Register (UOPS)

Offset: 0x0020 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	BAF_FA	FL_STDBY	FL_RUN	0	0	0	0	0	0	0	0	0	HSB			HSE
W																
Reset	0/1(1)	0	0	0	0	0	0	0	0	0	0	0	0/1(1)	0/1(1)	0/1(1)	0/1(1)

1. Values are determined by DCF record and life cycle - default is 0.

Figure 1985. HSM and User Option Status Register (UOPS)

Table 1954. UOPS field descriptions

Field	Description
16 BAF_FA	BAF execution mode when bypass mode DCF is zero and lifecycle is FA 0 BAF enters an infinite loop 1 BAF executes as normal **Note:** This bit is mirrored from bit 31 of the UTEST_Miscellaneous_2 DCF client.
17 FL_STDBY	Code flash on after standby mode, despite MC_ME programming 0 Code Flash can be switched off when exiting from STANDBY mode, if programmed in MC_ME.MC_DRUN.CFLAON 1 Code Flash cannot be switched off when exiting from STANDBY mode, even if programmed in MC_ME.MC_DRUN.CFLAON **Note:** This bit is mirrored from bit 30 of UTEST_Miscellaneous_2 DCF client. When this bit is set, writing on MC_ME.MC_DRUN.CFLAON has no effect.
18 FL_RUN	Code flash on during RUNx mode, despite MC_ME programming 0 Code Flash can be switched off in RUNx mode, if programmed in MC_ME.MC_DRUx.CFLAON 1 Code Flash can be switched off in RUNx mode, even if programmed in MC_ME.MC_RUNx.CFLAON **Note:** This bit is mirrored from bit 29 of UTEST_Miscellaneous_2 DCF client. When this bit is set, writing on MC_ME.MC_RUNx.CFLAON has no effect.
28:30 HSB	HSM Boot Configuration 001 When the device is in BAF Code Boot mode, BAF waits for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM waits for HSM ready flag before allowing application code to start. Others: When the device is in BAF Code Boot mode, BAF will not wait for HSM ready flag before allowing application code to start. In User Code Boot mode the SSCM will not wait for HSM ready flag before allowing application code to start. This field can be set via DCF record (refer to the SPC58xHx Microcontroller Security Reference Manual for the HSM details).
31 HSE	HSM Enabled This bit is set to 1 if HSM is enabled via DCF record.

61.2.1.6 Processor Start Address Register (PSA)

Offset 0x0028 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0/1(1)	0/1(1)	0	0	0	0	0	0/1(2)	0/1(2)	0/1(2)

1. Reset value reflects the Test Life Cycle of the device.
2. Reset value is the Life Cycle of the device.

Figure 1988. Life Cycle Status Register (LCSTAT)

Table 1957. LCSTAT field descriptions

Field	Description
29:31 LC	Life Cycle As determined by the SSCM by reading the LC slots. The encoding is: 000 FAIL_ANALYSIS 001 Reserved 010 PROD_OEM 011 CUST_DELIV 100 Reserved 101 Reserved 110 ST_PROD 111 IN_FIELD

61.2.1.9 OTA Signature Address Location register (OSAL)

This register holds the address of the empty slot in OTA signature block.

Note: The content of the OTA_SIG_ADD register has to be manipulated to have the address of the empty slot in one of the four signature blocks. The user can calculate the address of the empty slot of the signature block, Empty_Slot_Of_SignatureBlock using the following formula:

Empty_Slot_Of_SignatureBlock = (OTA_SIG_ADD x 4) + 0X00FC0000

The software should write the new signature in this slot once the OTA flash update is completed. When the OTA block is full the OTA_ISG_ADDR = 0x3FFFFFFF.

These bits are only meaningful if OTA is enabled.

Offset 0x0038 Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OTA_SIG_ADDR															
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)

1. Reset value is device specific.

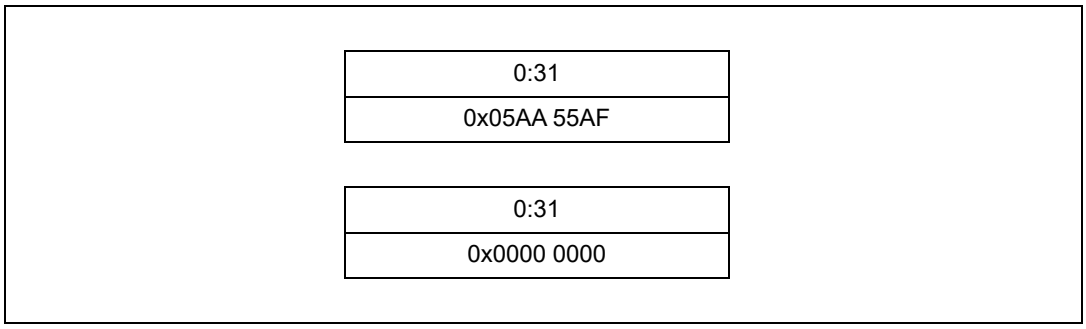
Figure 1990. Non Active Context Logical Address register (NACLA)

Table 1959. NACLA field descriptions

Field	Description
0:31 NON_ACTIVE_ LOGICAL_ADDR	Non active logical address which has to be used for firmware update location.

61.3 Functional description

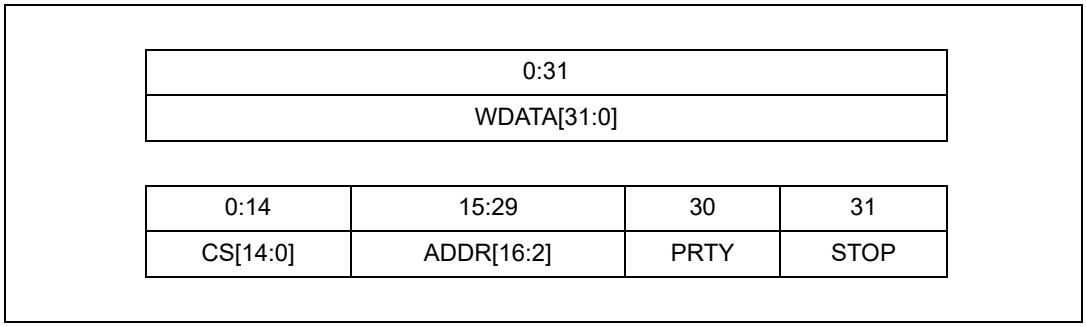
The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.



61.3.1 DCF mechanism

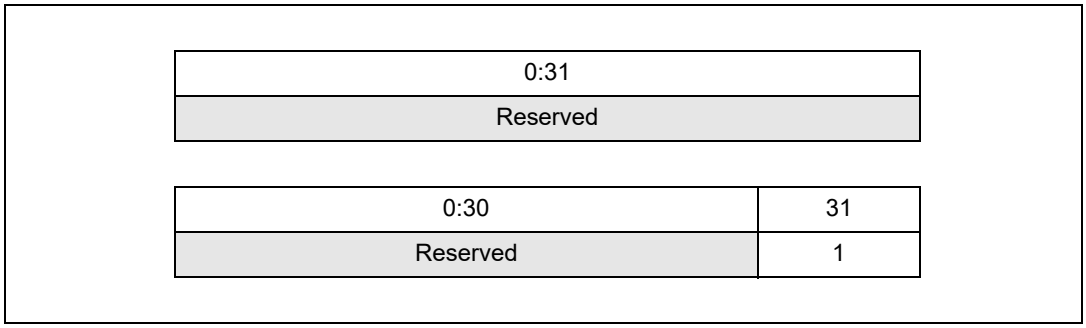
The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.



Each record is 64 bits in length. *Figure 1991* shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Figure 1991. DCF start record

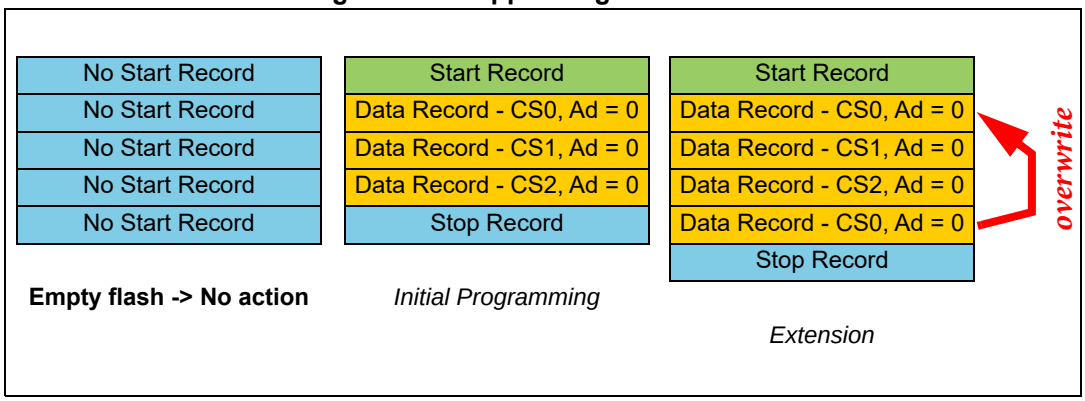


The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - refer to *Figure 1992*. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Figure 1992. Format of a DCF data record

The stop record indicates that processing should stop. The general format of the stop record is shown in *Figure 1993*. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Figure 1993. DCF stop record



If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 1960*.

Table 1960. Series of DCF records in UTEST

ADDR offset	DATA			
0x00	0x05AA_55AF			
0x04	0x0000_0000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8n - 1 + 0x0	Reserved			
8n - 1 + 0x4	Reserved			1
8n + 0x0				
8n + 0x4				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 1994*.

Figure 1994. Appending DCF records

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0x0000_0001 then the PRTY field needs to be set to '1', so that the total number of 1s is even).

61.3.2 ECC error monitoring

During flash memory scanning (such as Life Cycle or DCF records), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs the SSCM will request a destructive reset.

61.3.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

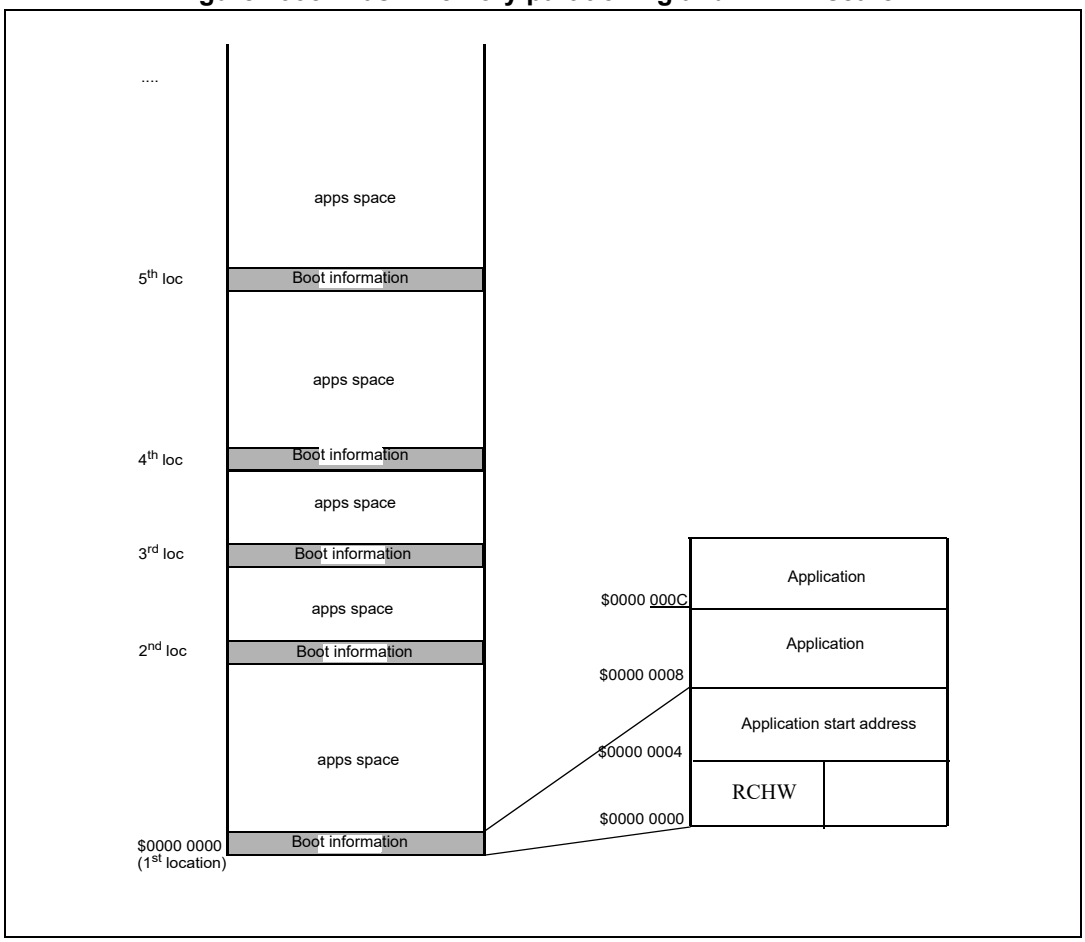
- User Code Boot mode (SSCM): the device will boot from the first bootable section of the flash memory main array (BOOT_ID = 0x5A).
- BAF Code Boot: the device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup (BOOT_ID = 0xA5).
- Standby-Boot : after waking up from Standby Mode, the processor will execute from the Standby RAM. The flash memory will not be accessible in this mode.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location for SSCM and BAF, that is 0x5A and 0xA5 respectively) then the device will enter serial boot mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. Refer to *Section 61.3.6: HSM boot header search* for details.

61.3.4 BAF configuration

In BAF Code Boot mode the boot core will start to execute the BAF code at the location provided in the "Embedded Flash Memory" chapter (TestFlash block memory map). The BMODE field in the SSCM status register will be set to the value 0b101. Details of the BAF operation are described in the BAF chapter.



61.3.5 User code boot sector search

61.3.5.1 Potential boot sectors

As shown in *Figure 1995* in User Code Boot mode, several locations are searched for a valid boot ID. The lowest sector which starts with a valid boot ID will be used to boot the device.

The flash memory locations that are searched for boot information are shown in the “Reset and Boot” chapter (section “HW boot record search (SSCM search)”).

Figure 1995. Flash memory partitioning and RCHW search

61.3.5.2 Reset Configuration Half-Word

For each boot sector in the flash memory, SSCM checks the content of the Reset Configuration Half-Word (RCHW) at offset 0x00. If the RCHW field BOOT_ID holds the value 0x5A then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. (If a device only supports VLE code for future compatibility the flag must always be set to ‘1’.) All other bits are reserved.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	VLE	BOOT_ID							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Reserved

Figure 1996. Reset Configuration Half-Word

Once the device detects that it needs to boot from flash memory, and finds a valid BOOT_ID, it will boot from the application start address at offset 0x04 within the boot sector.

61.3.5.3 Standby Boot mode

In Standby Boot mode, the MCU can be configured to boot from internal flash memory (User Code Boot mode) or from Standby RAM. If the MCU boots from Standby RAM the reset sequence can be abridged - in this case the flash memory will not be available (refer to RGM block guide for mode selection).

The device security status will be stored in the SSCM Standby area, so debugging will be possible if the device is unsecured.

To enter Standby Boot mode (SBM) first the RGM needs to be configured appropriately, then low power standby mode must be entered and subsequently a wakeup interrupt must be received.

The intent of SBM is to allow quick wakeup from low power standby mode. Upon wakeup application code could perform a quick check whether the device is needed, perform a short task, then return to standby again and conserve power.

To further aid this, the device allows to boot without activating the flash memory - which significantly reduces the length of the wakeup sequence (refer to the MC_RGM chapter).

In Standby Boot mode the device will boot from Standby RAM offset 0x00. The application needs to load code to this location before going into low power standby mode. In some cases the entire code will be located here, but it is also possible to merely place a jump command at offset 0x00 and continue execution from another location (for example, the flash memory if it is activated or from the external bus).

If the device boots without enabling the flash memory, it is not possible to determine the security status again. Hence the security status is stored in the SSCM standby area, and the device will therefore have the same access restrictions as were in place before entering low power standby mode. For example, if the device was secure before entering low power standby mode, then debug will not be possible in Standby Boot mode.

Sometimes it is desirable to activate the flash memory even though it was initially bypassed in Standby Boot mode. To do this the application needs to select a run mode which enables the flash memory - the device will transition into that run mode once the flash memory reset sequence is complete.

61.3.6 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (refer to the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.

The HSM Boot Header has the format as described in *Figure 1997*.

Figure 1997. Boot header structure

0x00	Boot Header ID	
0x08	Reserved	Start Address
10x0	Reserved for Configuration Bits	

A valid Boot Header ID has the value 0xFFFF_0000_FFFF_0000.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0x0000_0000_0000_0000. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

61.3.7 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from UTEST flash memory area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- ST Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 256 bits each, at fixed locations in UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- The valid field
- The invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 status:

Table 1961. Life Cycle slots

Use case	Offset	LC slot	Valid field (128 bits)		Invalid field (128 bits)		LC slot status
1	0x00-0x10	1	Erased	Erased	Erased	Erased	Erased
2	0x00-0x10	1	Marked	Erased	Marked	Erased	Inactive
3	0x00-0x10	1	Marked	Erased	Erased	Erased	Active
4	0x00-0x10	1	Any other value				Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 0x55AA_50AF_55AA_50AF, “Erased” is detected by the bit pattern 0xFFFF_FFFF_FFFF_FFFF.

Table 1962 shows how the slots are arranged in memory.

Table 1962. Life Cycle Slots in Memory

Offset	LC Slot word
0x00 - 0x07	Valid[63:0]
0x08 - 0x0F	Don't care

The Life Cycle is determined as shown in *Table 1963*. The priority of the entries is from top to bottom, so the first row which applies determines the resulting Life Cycle.

Table 1963. Resulting Life Cycle

LC Slot 0 ST_PROD(1)	LC Slot 1 CUST_DEL(1)	LC Slot 2 OEM_PROD(1)	LC Slot 3 IN_FIELD(1)	LC Slot 4 FA(1)	Resulting LifeCycle
Active	Erased	Erased	Erased	Erased	ST Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	*Inactive*	**Active**	Erased	Erased	OEM Production
Inactive	*Inactive*	*Inactive*	**Active**	Erased	In Field
Inactive	*Inactive*	*Inactive*	*Inactive*	**Active**	FA
Any other combination				Erased	In Field
Any other combination					System Reset

1. Erased = all slot bits at ‘1’

61.4 Initialization and application information

61.4.1 Reset

The reset state of each individual bit is shown within the Register Description section (refer to *Section 61.2.1: Register descriptions*).

61.5 Additional safety measures

61.5.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the MC_RGM. In case of a spurious reset the SSCM will not interfere with the flash memory bus or overwrite configuration registers. Status internal to the SSCM will be lost, however.

62 Power management controller digital interface (PMC_Dig)

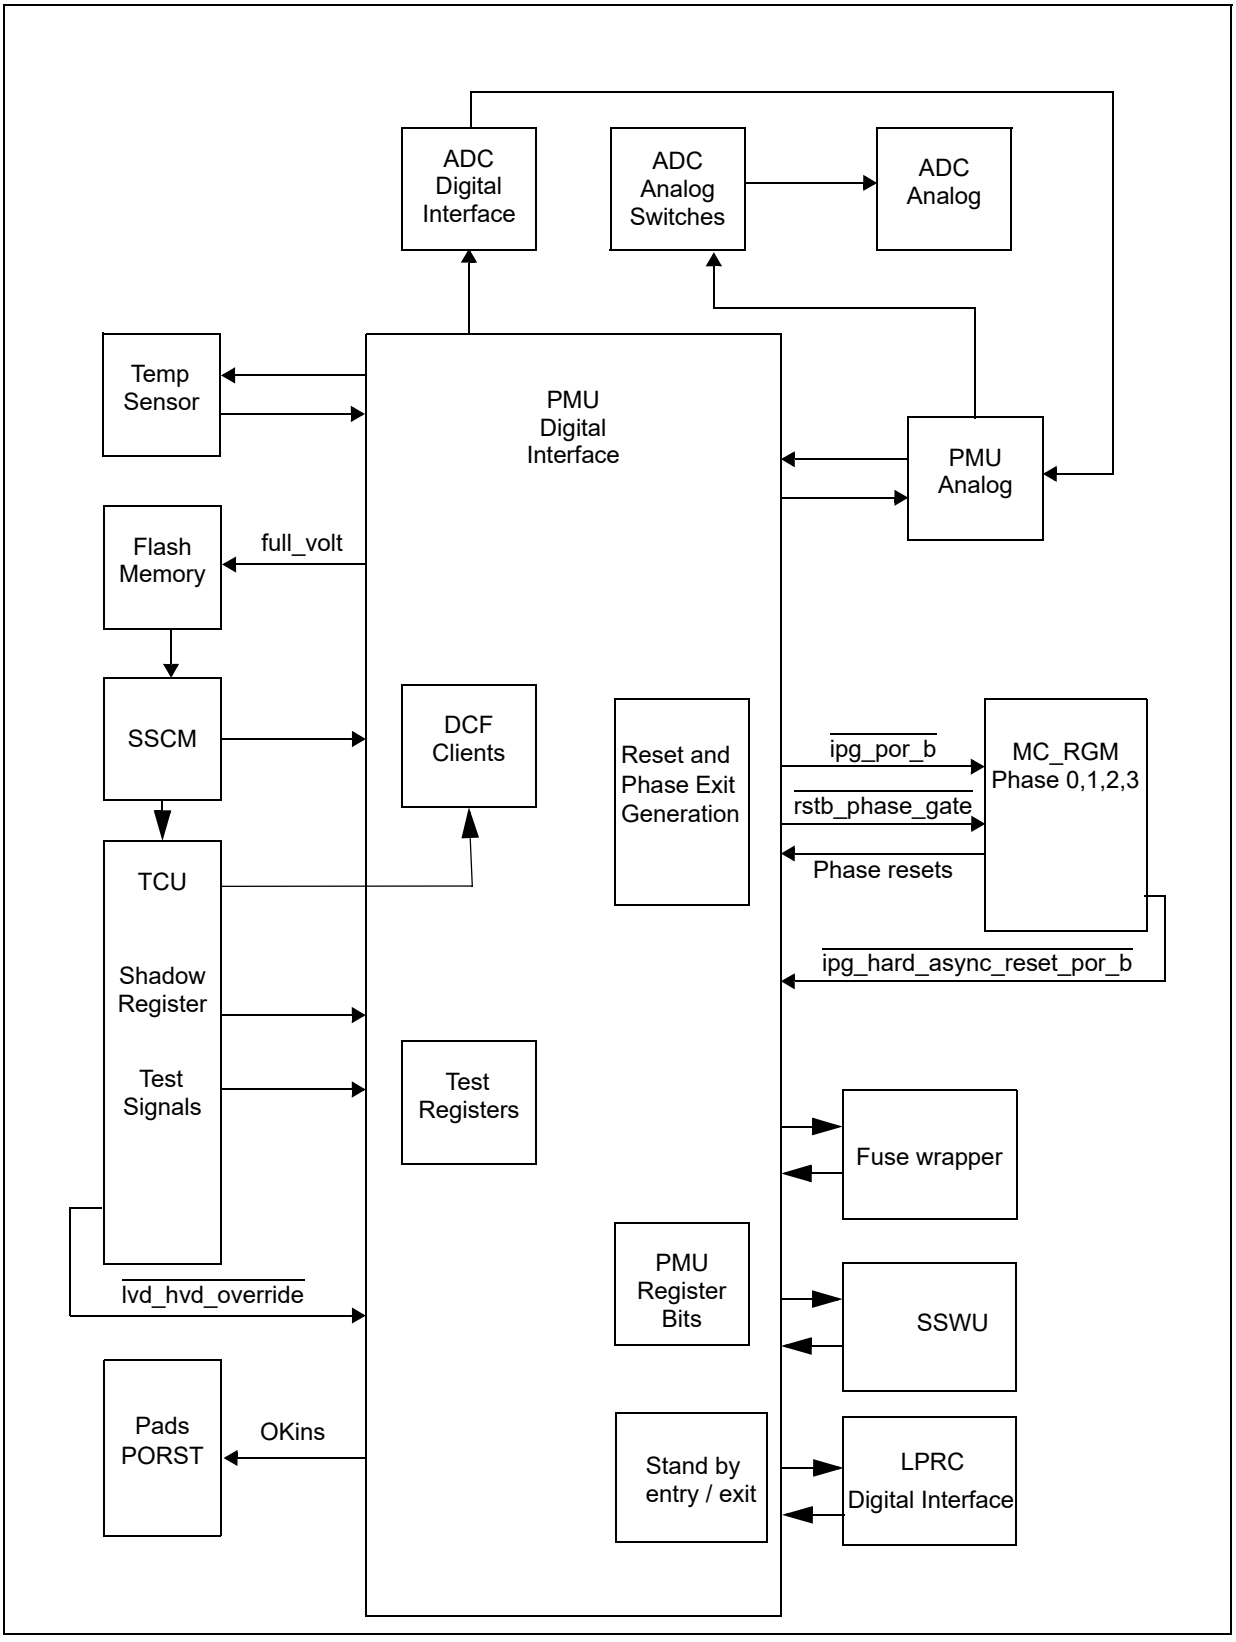
62.1 Introduction

The Control PMU manages the PMU at reset, standby entry, standby exit and during run. It checks the LVD or HVD accuracy.

The PMC analog block interfaces the digital part of the device by the PMC_Dig block.

This chapter describes the digital block of the PMU.

The PMC_Dig contains all of the registers and digital logic to generate all of the enable signals, two stage trim control bits, power on reset (POR) generation, standby entry/exit sequence and test mode logic for the analog block. The PMU digital logic also contains the controls for PMU analog outputs to be sensed with the ADC module.



In addition, the PMU digital logic contains the enable signals, trim bits and other registers for the temperature sensor for SOC and a dedicated temperature sensor for RC regulator.

There are also several custom interfaces to various other blocks: the Reset Generation Module (MC_RGM) block receives the LVD values during POR to use for phase transition conditions and reset generation of fuse_wrapper.

There are two custom interfaces, one to Flash memory via the SSCM (and DCF client blocks) that is used to load the trim values during initial POR. The other to the fuse block via fuse_wrapper that is responsible for first stage trimming, that is to say, bandgap trimming of both regulator and monitor.

The PMU digital block generates a transfer error event to the system if the selected address is out of range of PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed. *Figure 1998* shows the top level block diagram of the digital PMU and its interfaces to the device modules.

Figure 1998. Digital PMU block diagram

62.2 Main features

- PMU management at a main reset
- Resets signal generation

62.2.1 Standard features

- IPS bus interface

62.3 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers
- any other operation (free byte enables or other operations) must be avoided

The PMC_Dig block generates a transfer error in the following cases:

- The PMU digital block generates a transfer error event to the system if the selected address is out of range of PMU digital memory map. A transfer error is not generated if an unused address within the PMU digital memory space is accessed
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register

The registers of the PMC_Dig block are accessible (read/write) in each access mode: user, supervisor or test.

About the Reset used among the registers:

- The POR reset is used on EPR_LVx, EPR_HVx, REE_LVx, REE_HVx, RES_LVx and RES_HVx registers
- The destructive reset is used on REE_TD, RES_TD, FEE_LVx, FEE_HVx and FEE_TD registers
- The functional reset is used on IE_HVx, IE_LVx, IE_G, CTL_TD registers

62.4 Memory map/register definition

Table 1964 shows the PMU memory map. The PMU includes many registers for configuring and monitoring LVD monitors and some other control registers.

1. Refer to *Section 62.5: Registers description*.

Table 1966 shows the correspondence between VD number and VD name, where HV means a 3.3 V/5.0 V supply and LV means a 1.2 V supply.

Table 1966. VD number versus VD name table

VD Number	VD Name	VD Meaning
VD0	POR031_C	LV detector asserts when PMU supply < 0.31 V
VD1	MVD082T_C	LV detector asserts when PMU supply < 0.82 V
VD2	MVD094_C	LV detector asserts when PMU supply < 0.94 V
VD2	MVD094_FA/FB	LV detector asserts when Flash supply < 0.94 V
VD3	LVD100_C	LV detector asserts when PMU supply < 1.0 V
VD3	LVD100_FL	LV detector asserts when Flash supply < 1.0 V
VD3	LVD100_SB	LV detector asserts when standby supply < 1.0 V
VD6	HVD134_C	LV detector asserts when PMU supply > 1.34 V
VD7	UVD140_C	LV detector asserts when PMU supply > 1.40 V
VD7	UVD140_FL	LV detector asserts when Flash supply > 1.40 V
VD8	POR200_C	HV detector asserts when PMU supply < 2.00 V
VD10	MVD270_C	HV detector asserts when PMU supply < 2.70 V
VD10	MVD270_FL	HV detector asserts when Flash supply < 2.70 V
VD10	MVD270_SB	HV detector asserts when standby supply < 2.70 V
VD11	LVD290_EMMC	HV detector asserts when IO SDMMC supply < 2.90 V
VD11	LVD290_AS	HV detector asserts when SAR ADC supply < 2.90 V
VD11	LVD290_C	HV detector asserts when PMU supply < 2.90 V
VD11	LVD290_FL	HV detector asserts when Flash supply < 2.90 V

Table 1966. VD number versus VD name table (continued)

VD Number	VD Name	VD Meaning
VD11	LVD290_ETH0	HV detector asserts when IO ETH0 supply < 2.90 V
VD11	LVD290_ETH1	HV detector asserts when IO ETH1 supply < 2.90 V
VD13	HVD400_C	HV detector asserts when PMU supply > 4.00 V
VD13	HVD400_ETH0	HV detector asserts when IO ETH0 supply > 4.00 V
VD13	HVD400_ETH1	HV detector asserts when IO ETH1 supply > 4.00 V
VD14	LVD400_EMMC	HV detector asserts when IO SDMMC supply < 4.00 V
VD14	LVD400_AS	HV detector asserts when SAR ADC supply < 4.00 V
VD14	LVD400_ETH0	HV detector asserts when IO ETH0 supply < 4.00 V
VD14	LVD400_ETH1	HV detector asserts when IO ETH1 supply < 4.00 V
VD14	LVD400_IM	HV detector asserts when IO MAINS supply < 4.00 V
VD15	UVD600_C	HV detector asserts when PMU supply > 6.00 V
VD15	UVD600_FL	HV detector asserts when Flash supply > 6.00 V
VD15	UVD600_ETH0	HV detector asserts when IO ETH0 supply > 6.00 V
VD15	UVD600_ETH1	HV detector asserts when IO ETH1 supply > 6.00 V

62.5 Registers description

62.5.1 Event Pending Register (EPR_LV0)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 0 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Offset: 0x0000 Access: User read/write, Supervisor read/write, Test read/write

Figure 1999. Event Pending Register (EPR_LV0)

Table 1967. EPR_LV0 field descriptions

Field	Description
3 LVD3_SB	LVD3_SB flag This bit is the low-voltage status flag associated with LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V supply always on IO ring. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a '1' is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 1.00 V point supply
5 LVD3_FL	LVD3_FL flag. This bit is the low-voltage status flag associated with LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a '1' is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 1.00 V point supply
7 LVD3_C	LVD3_C flag This bit is the low-voltage status flag associated with LVD100_C VD, the voltage level detect for the low voltage CORE 1.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 3 threshold, and clears when the supply rises above its corresponding LVD3 threshold and a '1' is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 1.00 V point supply

62.5.2 Reset Event Enable Register (REE_LV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Offset: 0x0004 Access: User read/write, Supervisor read/write, Test read/write

Figure 2000. Reset Event Enable Register (REE_LV0)

Table 1968. REE_LV0 field descriptions

Field	Description
3 REE3_SB	REE3_SB reset enable This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates a system reset. The RES3_SB bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
5 REE3_FL	REE3_FL reset enable This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage of 1.00 V on Flash supply, generates a system reset. The RES3_FL bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE3_C	REE3_C reset enable This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates a system reset. The RES3_C bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

62.5.3 Reset Event Select Register (RES_LV0)

This Reset Event Select Register controls, in LOW VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Offset: 0x0008 Access: User read/write, Supervisor read/write, Test read/write

Figure 2001. Reset Event Select Register (RES_LV0)

Table 1969. RES_LV0 field descriptions

Field	Description
3 RES3_SB	RES3_SB reset event select This bit defines whether LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply of the cold point, generates a destructive reset or a functional reset. The REE3_SB bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset. For LVD100_SB it is not allowed to enable destructive reset, only functional reset is supported.
5 RES3_FL	RES3_FL reset event select This bit defines whether LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES3_C	RES3_C reset event select This bit defines whether LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply of the cold point, generates a destructive reset or a functional reset. The REE3_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

62.5.4 Interrupt Enable (IE_LV0)

This configuration register contains a set of LV0 interrupt Enable bits that correspond to each of the LV0 Event Pending Registers (EPR_LV0). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0x0088. The IE_LV0 bits can be read or written at any time.

Offset: 0x000C Access: User read/write, Supervisor read/write, Test read/write

Figure 2002. Interrupt Enable Register (IE_LV0)

Table 1970. IE_LV0 field descriptions

Field	Description
3 VD3IE_SB	VD3IE_SB Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply event. 0 Interrupt disabled 1 Interrupt enabled Interrupt occurrence in case of LVD happens only in normal mode (interrupt being not powered in standby mode).
5 VD3IE_FL	VD3IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply event. 0 Interrupt disabled 1 Interrupt enabled
7 VD3IE_C	VD3IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply event. 0 Interrupt disabled 1 Interrupt enabled

62.5.5 FCCU Event Enable Register (FEE_LV0)

This FCCU Event Enable Register LV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Offset: 0x0010 Access: User read/write, Supervisor read/write, Test read/write

Figure 2003. FCCU Event Enable Register (FEE_LV0)

Table 1971. FEE_LV0 field descriptions

Field	Description
3 FEE3_SB	FEE3_SB FCCU event enable This bit defines whether a VD assertion of LVD100_SB VD, the voltage level detect for the low voltage of 1.00 V always on IO ring supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the always on IO ring does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the always on IO ring causes an FCCU event. FCCU event in case of LVD happens only in normal mode (FCCU being not powered in standby mode).
5 FEE3_FL	FEE3_FL FCCU event enable This bit defines whether a VD assertion of LVD100_FL VD, the voltage level detect for the low voltage Flash 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Flash causes an FCCU event.
7 FEE3_C	FEE3_C FCCU event enable This bit defines whether a VD assertion of LVD100_C VD, the voltage level detect for the low voltage Core 1.00 V supply, generates an FCCU event. 0 Disabled. A VD assertion of LV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of LV0 on the supply of the Core causes an FCCU event.

62.5.6 Event Pending Register (EPR_LV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in LOW VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0020 Access: User read/write, Supervisor read/write, Test read/write

Figure 2009. Event Pending Register (EPR_HV0)

Table 1977. EPR_HV0 field descriptions

Field	Description
1 LVD11_EMMC	LVD11_EMMC flag This bit is the high-voltage status flag associated with LVD290_EMMC, the voltage level detect for the low voltage IO SDMMC 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply
2 LVD11_AS	LVD11_AS flag This bit is the high-voltage status flag associated with LVD290_AS, the voltage level detect for the low voltage SAR ADC 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply
3 LVD11_ETH0	LVD11_ETH0 flag This bit is the high-voltage status flag associated with LVD290_ETH0, the voltage level detect for the low voltage IO ETH0 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply
4 LVD11_ETH1	LVD11_ETH1 flag This bit is the high-voltage status flag associated with LVD290_ETH1, the voltage level detect for the low voltage IO ETH1 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply
6 LVD11_FL	LVD11_FL flag This bit is the high-voltage status flag associated with LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply
7 LVD11_C	LVD11_C flag This bit is the high-voltage status flag associated with LVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 11 threshold, and clears when the supply rises above its corresponding LVD11 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence 1 VD occurrence detected on the low voltage 2.90 V point supply

62.5.12 Reset Event Enable Register (REE_HV0)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Figure 2010. Reset Event Enable Register (REE_HV0)

Table 1978. REE_HV0 field descriptions

Field	Description
1 REE11_EMMC	LVD11_EMMC reset enable This bit defines whether LVD290_EMMC VD, the voltage level detect for the high voltage assertion on the IO SDMMC 2.90 V supply generates a system reset. The RES11_EMMC bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
2 REE11_AS	LVD11_AS reset enable This bit defines whether LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply generates a system reset. The RES11_AS bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
3 REE11_ETH0	LVD11_ETH0 reset enable This bit defines whether LVD290_ETH0 VD, the voltage level detect for the high voltage assertion on the IO ETH0 2.90 V supply generates a system reset. The RES11_ETH0 bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.

Table 1978. REE_HV0 field descriptions (continued)

Field	Description
4 REE11_ETH1	LVD11_ETH1 reset enable This bit defines whether LVD290_ETH1 VD, the voltage level detect for the high voltage assertion on the IO ETH1 2.90 V supply generates a system reset. The RES11_ETH1 bit determines whether a system reset is enabled or not. 0 Disabled. VD assertion on the supply of the cold point does not cause system reset. 1 Enabled. VD assertion on the supply of the cold point causes system reset.
6 REE11_FL	LVD11_FL reset enable This bit defines whether LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply of the cold point generates a system reset. The RES11_FL bit determines whether a system reset is enabled or not. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
7 REE11_C	LVD11_C reset enable This bit defines whether LVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply, of the cold point generates a system reset. The RES11_C bit determines whether a system reset is enabled or not. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

62.5.13 Reset Event Select Register (RES_HV0)

This Reset Event Select Register controls, in HIGH VOLTAGE 0 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Offset: 0x0048 Access: User read/write, Supervisor read/write, Test read/write

Figure 2011. Reset Event Select Register (RES_HV0)

Table 1979. RES_HV0 field descriptions

Field	Description
1 RES11_EMMC	RES11_EMMC reset event select This bit defines whether an LVD assertion on the IO SDMMC 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_ad bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
2 RES11_AS	RES11_AS reset event select This bit defines whether an LVD assertion on the SAR ADC 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_AS bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
3 RES11_ETH0	RES11_ETH0 reset event select This bit defines whether an LVD assertion on the IO ETH0 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_ETH0 bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
4 RES11_ETH1	RES11_ETH1 reset event select This bit defines whether an LVD assertion on the IO ETH1 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_ETH1 bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
6 RES11_FL	RES11_FL reset event select This bit defines whether an LVD assertion on the Flash 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_FL bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
7 RES11_C	RES11_C reset event select This bit defines whether an LVD assertion on the Core 2.90 V supply of the cold point generates a destructive reset or a functional reset. The REE11_C bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

62.5.14 Interrupt Enable (IE_HV0)

This configuration register contains a set of HV0 interrupt Enable bits that correspond to each of the HV0 Event Pending Registers (EPR_HV0). These bits indicate whether an interrupt enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0x0088. The IE_HV0 bits can be read or written at any time.

Offset: 0x004C Access: User read/write, Supervisor read/write, Test read/write

Table 1980. IE_HV0 field descriptions

Field	Description
1 LVD11IE_EMMC	LVD11IE_EMMC Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_EMMC VD, the voltage level detect for the high voltage assertion on the IO SDMMC 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
2 LVD11IE_AS	LVD11IE_AS Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply event occurs. 0Interrupt disabled 1 Interrupt enabled
3 LVD11IE_ETH0	LVD11IE_ETH0 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_ETH0 VD, the voltage level detect for the high voltage assertion on the IO ETH0 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled

Table 1980. IE_HV0 field descriptions (continued)

Field	Description
4 LVD11IE_ETH1	LVD11IE_ETH1 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_ETH1 VD, the voltage level detect for the high voltage assertion on the IO ETH1 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
6 LVD11IE_FL	LVD11IE_FL Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled
7 LVD11IE_C	LVD11IE_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the IVD290_C VD, the voltage level detect for the high voltage Core 2.90 V supply event occurs. 0 Interrupt disabled 1 Interrupt enabled

62.5.15 FCCU Event Enable Register (FEE_HV0)

This FCCU Event Enable Register HV0 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Figure 2013. FCCU Event Enable Register (FEE_HV0)

Table 1981. FEE_HV0 field descriptions

Field	Description
1 FEE11_EMMC	FEE11_EMMC FCCU event enable This bit defines whether a LVD290_EMMC VD, the voltage level detect for the high voltage assertion on the IO SDMMC 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the ADC does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the ADC causes an FCCU event.
2 FEE11_AS	FEE11_AS FCCU event enable This bit defines whether a LVD290_AS VD, the voltage level detect for the high voltage assertion on the SAR ADC 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the ADC does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the ADC causes an FCCU event.
3 FEE11_ETH0	FEE11_ETH0 FCCU event enable This bit defines whether a LVD290_ETH0 VD, the voltage level detect for the high voltage assertion on the IO ETH0 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the IO ETH0 does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the IO ETH0 causes an FCCU event.
4 FEE11_ETH1	FEE11_ETH1 FCCU event enable This bit defines whether a LVD290_ETH1 VD, the voltage level detect for the high voltage assertion on the IO ETH1 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the IO ETH1 does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the IO ETH1 causes an FCCU event.
6 FEE11_FL	FEE11_FL FCCU event enable This bit defines whether a LVD290_FL VD, the voltage level detect for the high voltage assertion on the Flash 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Flash does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Flash causes an FCCU event.
7 FEE11_C	FEE11_C FCCU event enable This bit defines whether a LVD290_C VD, the voltage level detect for the high voltage assertion on the Core 2.90 V supply assertion generates an FCCU event. 0 Disabled. A VD assertion of HV0 on the supply of the Core does not cause an FCCU event. 1 Enabled. A VD assertion of HV0 on the supply of the Core causes an FCCU event.

62.5.16 Event Pending Register (EPR_HV1)

This Event Pending Register indicates the present and past state of the voltage detect signals in HIGH VOLTAGE 1 range. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Table 1982. EPR_HV1 field descriptions

Field	Description
9 LVD14_EMMC	LVD14_EMMC flag This bit is the High voltage status flag associated with LVD400_EMMC VD, the VD for the high voltage IO SDMMC 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_EMMC threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
10 LVD14_AS	LVD14_AS flag This bit is the High voltage status flag associated with LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_AS threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

Table 1982. EPR_HV1 field descriptions (continued)

Field	Description
12 LVD14_ETH0	LVD14_ETH0 flag This bit is the High voltage status flag associated with LVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_ETH0 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
13 LVD14_ETH1	LVD14_ETH1 flag This bit is the High voltage status flag associated with LVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_ETH1 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
14 LVD14_IM	LVD14_IM flag This bit is the High voltage status flag associated with LVD400_IM VD, the VD for the high voltage IO main 4.00 V supply. It is asserted when the supply falls below its corresponding Voltage Detector 14 threshold, and clears when the supply rises under its corresponding LVD14_IM threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
21 HVD13_ETH0	HVD13_ETH0 flag This bit is the High Voltage status flag associated with HVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply falls below its corresponding HVD13_ETH0 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
22 HVD13_ETH1	HVD13_ETH1 flag This bit is the High Voltage status flag associated with HVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply falls below its corresponding HVD13_ETH1 threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.
23 HVD13_C	HVD13_C flag This bit is the High Voltage status flag associated with HVD400_C VD, the VD for the high voltage Core 4.00 V supply. It is asserted when the supply is above its corresponding Voltage Detector 13 threshold, and clears when the supply below its corresponding HVD13_C threshold and a ‘1’ is written to this bit location. 0 Currently no occurrence. 1 VD occurrence detected on the high voltage 4.00 V point supply.

62.5.17 Reset Event Enable Register (REE_HV1)

This Reset Event Enable Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence. If the Flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Table 1983. REE_HV1 field descriptions

Field	Description
9 REE14_EMMC	REE14_EMMC reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_EMMC bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
10 REE14_AS	REE14_AS reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_AS bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

Table 1983. REE_HV1 field descriptions (continued)

Field	Description
12 REE14_ETH0	REE14_ETH0 reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_ETH0 bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
13 REE14_ETH1	REE14_ETH1 reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_ETH1 bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
14 REE14_IM	REE14_IM reset enable This bit defines whether an LVD assertion on the high voltage supply of the cold point generates a system reset. The RES14_IM bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.
21 REE13_ETH0	REE13_ETH0 reset enable This bit defines whether HVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply generates a system reset. The RES13_ETH0 bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.
22 REE13_ETH1	REE13_ETH1 reset enable This bit defines whether HVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply generates a system reset. The RES13_ETH1 bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.
23 REE13_C	REE13_C reset enable This bit defines whether HVD400_C VD, the VD for the high voltage Core 4.00 V supply generates a system reset. The RES13_C bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

62.5.18 Reset Event Select Register (RES_HV1)

This Reset Event Select Register controls, in HIGH VOLTAGE 1 range, whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated

when the selected voltage passes the trigger event. These bits are loaded from the Flash during the boot sequence.

Field	Description
9 RES14_EMMC	RES14_EMMC reset event select This bit defines whether a LVD400_EMMC VD, the VD for the high voltage IO SDMMC 4.00 V supply generates a destructive reset or a functional reset by LVD14_EMMC bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
10 RES14_AS	RES14_AS reset event select This bit defines whether a LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply generates a destructive reset or a functional reset by LVD14_AS bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
12 RES14_ETH0	RES14_ETH0 reset event select This bit defines whether a LVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply generates a destructive reset or a functional reset by LVD14_ETH0 bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

Table 1984. RES_HV1 field descriptions (continued)

Field	Description
13 RES14_ETH1	RES14_ETH1 reset event select This bit defines whether a LVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply generates a destructive reset or a functional reset by LVD14_ETH1 bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
14 RES14_IM	RES14_IM reset event select This bit defines whether a LVD400_IM VD, the VD for the high voltage IO mains 4.00 V supply generates a destructive reset or a functional reset by LVD14_IM bit. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.
21 RES13_ETH0	RES13_ETH0 reset event select This bit defines whether a HVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply generates a destructive reset or a functional reset by HVD13_ETH0 bit. 0 Destructive Reset Generated. HVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the cold point causes a functional system reset.
22 RES13_ETH1	RES13_ETH1 reset event select This bit defines whether a HVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply generates a destructive reset or a functional reset by HVD13_ETH1 bit. 0 Destructive Reset Generated. HVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the cold point causes a functional system reset.
23 RES13_C	RES13_C reset event select This bit defines whether a HVD400_C VD, the VD for the high voltage Core 4.00 V supply generates a destructive reset or a functional reset by HVD13_C bit. 0 Destructive Reset Generated. HVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the cold point causes a functional system reset.

62.5.19 Interrupt Enable Register (IE_HV1)

This configuration register contains a set of HV1 interrupt Enable bits that correspond to each of the HV1 Event Pending Registers (EPR_HV1). These bits indicate whether an interrupt is enabled waiting for a potential voltage event. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are replicated as a read-only monitor in the register (IE_G) at address 0x0088. The IE_HV1 bits can be read or written at any time.

Table 1985. IE_HV1 field descriptions

Field	Description
9 LVDIE14_EMMC	LVDIE14_EMMC Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_EMMC VD, the VD for the high voltage IO SDMMC 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
10 LVDIE14_AS	LVDIE14_AS Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_AS VD, the VD for the high voltage SAR ADC 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
12 LVDIE14_ETH0	LVDIE14_ETH0 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
13 LVDIE14_ETH1	LVDIE14_ETH1 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the LVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

Table 1985. IE_HV1 field descriptions (continued)

Field	Description
14 LVDIE14_IM	LVDIE14_IM Interrupt Enable. This bit determines whether an interrupt is enabled or disabled for the LVD400_IM VD, the VD for the high voltage IO main 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
21 HVDIE13_ETH0	HVDIE13_ETH0 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_ETH0 VD, the VD for the high voltage IO ETH0 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
22 HVDIE13_ETH1	HVDIE13_ETH1 Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_ETH1 VD, the VD for the high voltage IO ETH1 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.
23 HVDIE13_C	HVDIE13_C Interrupt Enable This bit determines whether an interrupt is enabled or disabled for the HVD400_C VD, the VD for the high voltage Core 4.00 V supply event occurs. 0 Interrupt disabled. 1 Interrupt enabled.

62.5.20 FCCU Event Enable Register (FEE_HV1)

This FCCU Event Enable Register HV1 controls whether the voltage detect signal events cause an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Figure 2019. Supply Gauge Status Register (GR_S)

Table 1987. GR_S field descriptions

Field	Description
1 TEMP_2	TEMP_2 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (165 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
2 TEMP_1	TEMP_1 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
3 TEMP_0	TEMP_0 flag This bit is the temperature status flag associated with the temperature for the temperature sensor point (-40 °C). It is asserted when the temperature falls below its corresponding threshold, and clears when the temperature is above its corresponding threshold. 0 Currently no occurrence 1 Temperature occurrence detected
7 VD14_EMMC	VD14_EMMC low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_EMMC for the high voltage 4.00 V IO SDMMC supply. It is asserted when any of the SDMMC supplies falls below the corresponding LVD threshold, and clears when all the SDMMC supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
8 VD14_AS	VD14_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_AS for the high voltage 4.00 V SAR ADC supply. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
9 VD14_ETH0	VD14_ETH0 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_ETH0 for the high voltage 4.00 V IO ETH0 supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies

Table 1987. GR_S field descriptions (continued)

Field	Description
10 VD14_ETH1	VD14_ETH1 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_ETH1 for the high voltage 4.00 V IO ETH1 supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies are above the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
11 VD14_IM	VD14_IM low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD400_ETH1 for the high voltage 4.00 V IO main supply. It is asserted when the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies fall below the corresponding LVD threshold. All the 4.00 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 4.00 V supplies
13 VD13_ETH0	VD13_ETH0 high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_ETH0 for the high voltage 4.00 V IO ETH0 supply. It is asserted when the IO supply rises above its corresponding HVD threshold, and clears when the supply rises above its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply
14 VD13_ETH1	VD13_ETH1 high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_ETH1 for the high voltage 4.00 V IO ETH1 supply. It is asserted when the IO supply rises above its corresponding HVD threshold, and clears when the supply rises above its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply
15 VD13_C	VD13_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD400_C for the high voltage 4.00 V Core supply. It is asserted when the Core supply rises above its corresponding HVD threshold, and clears when the supply falls its corresponding HVD threshold. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 4.00 V supply
20 VD11_EMMC	VD11_EMMC low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_EMMC for the high voltage 2.90 V IO SDMMC supplies. It is asserted when any of the SDMMC supplies falls below the corresponding LVD threshold, and clears when all the SDMMC supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies

Table 1987. GR_S field descriptions (continued)

Field	Description
21 VD11_AS	VD11_AS low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_EMMC for the high voltage 2.90 V SAR ADC supplies. It is asserted when any of the ADC supplies falls below the corresponding LVD threshold, and clears when all the ADC supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
22 VD11_ETH0	VD11_ETH0 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_ETH0 for the high voltage 2.90 V IO ETH0 supplies. It is asserted when any of the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
23 VD11_ETH1	VD11_ETH1 low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_ETH1 for the high voltage 2.90 V IO ETH1 supplies. It is asserted when any of the IO supplies falls below the corresponding LVD threshold, and clears when all the IO supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
24 VD11_FL	VD11_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_FL for the high voltage 2.90 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
25 VD11_C	VD11_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD290_C for the high voltage 2.90 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. All of the 2.90 V LVDs are combined to form this bit. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 2.90 V supplies
27 VD6_C	VD6_C high-voltage detect flag This read-only bit is the high-voltage status flag associated with the voltage level detect HVD134_C for the high voltage 1.34 V Core supplies. It is asserted when any of the Core supplies rises above the corresponding HVD threshold, and clears when all the Core supplies fall below the corresponding HVD threshold. All the 1.34 V HVDs are combined to form this bit. 0 Currently no occurrence 1 HVD occurrence detected on the high voltage 1.34 V supply

Table 1987. GR_S field descriptions (continued)

Field	Description
29 VD3_SB	VD3_SB low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_SB for the low voltage 1.00 V always on supplies. It is asserted when any of the always on ring supplies falls below the corresponding LVD threshold, and clears when the always on supply rises above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.00 V supplies
30 VD3_FL	VD3_FL low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_FL for the high voltage 1.00 V Flash supplies. It is asserted when any of the Flash supplies falls below the corresponding LVD threshold, and clears when all the Flash supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.00 V supplies
31 VD3_C	VD3_C low-voltage detect flag This read-only bit is the low-voltage status flag associated with the voltage level detect LVD100_C for the low voltage 1.00 V Core supplies. It is asserted when any of the Core supplies falls below the corresponding LVD threshold, and clears when all the Core supplies rise above the corresponding LVD threshold. 0 Currently no occurrence 1 LVD occurrence detected on the high voltage 1.00 V supplies

62.5.22 Pending Gauge Status Register (GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

62.5.23 Global Interrupt Enable Register (IE_G)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt is enabled. A ‘0’ indicates that no interrupt is enabled, and a ‘1’ indicates that an interrupt is enabled. These bits are enabled via a write of ‘1’ to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

62.5.29 Event Pending Register (EPR_TD)

This Event Pending Register indicates the present and past state of the temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a ‘1’ must be written to the flag bit that needs to be cleared.

Offset: 0x0300 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2027. Event Pending Register (EPR_TD)

Table 1995. EPR_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (165 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_2 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_2] is also asserted, a system reset is generated, *which clears IETD_2 and negate the interrupt request*. If REE_TD[TEMP_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
30 TEMP_1	TEMP_1 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150 °C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_1 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_1] is also asserted, a system reset is generated, *which clears IETD_1 and negate the interrupt request*. If REE_TD[TEMP_1] is asserted and a destructive reset is selected (via RES_TD[TEMP_1] being 0), then a destructive reset is generated. If RES_TD[TEMP_1] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected
31 TEMP_0	TEMP_0 flag. This bit is the temperature status flag associated with the temperature for the *cold* temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a '1' is written to this bit location. *If the IETD_0 bit is also asserted, an interrupt is sent to the CPU*. If REE_TD[TEMP_0] is also asserted, a system reset is generated, *which clears IETD_0 and negate the interrupt request*. If REE_TD[TEMP_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP_0] is set, then a functional reset is generated. 0 Currently no occurrence 1 Temperature occurrence detected

62.5.30 Reset Event Enable Register (REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Offset: 0x0304 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

R	0	0	0	0	0	0	0	0	0	0	0	0	0	TEMP_2	TEMP_1	TEMP_0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2028. Reset Event Enable Register (REE_TD)

Table 1996. REE_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
30 TEMP_1	TEMP_1 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
31 TEMP_0	TEMP_0 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.

62.5.31 Reset Event Select Register (RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Offset: 0x0308 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2029. Reset Event Select Register (RES_TD)

Table 1997. RES_TD field descriptions

Field	Description
29 TEMP_2	TEMP_2 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_2] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
30 TEMP_1	TEMP_1 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_1] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
31 TEMP_0	TEMP_0 reset event select. This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.

62.5.32 Temperature Sensor Configuration Register (CTL_TD)

The Temperature Sensor Configuration Registers (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to be operable. It also includes two 5-bit signed trim adjustment register fields that are used to modify both TS trim values (one bus for over temperature and one bus for under temperature).

Offset: 0x030C Access: User read/write, Supervisor read/write, Test read/write

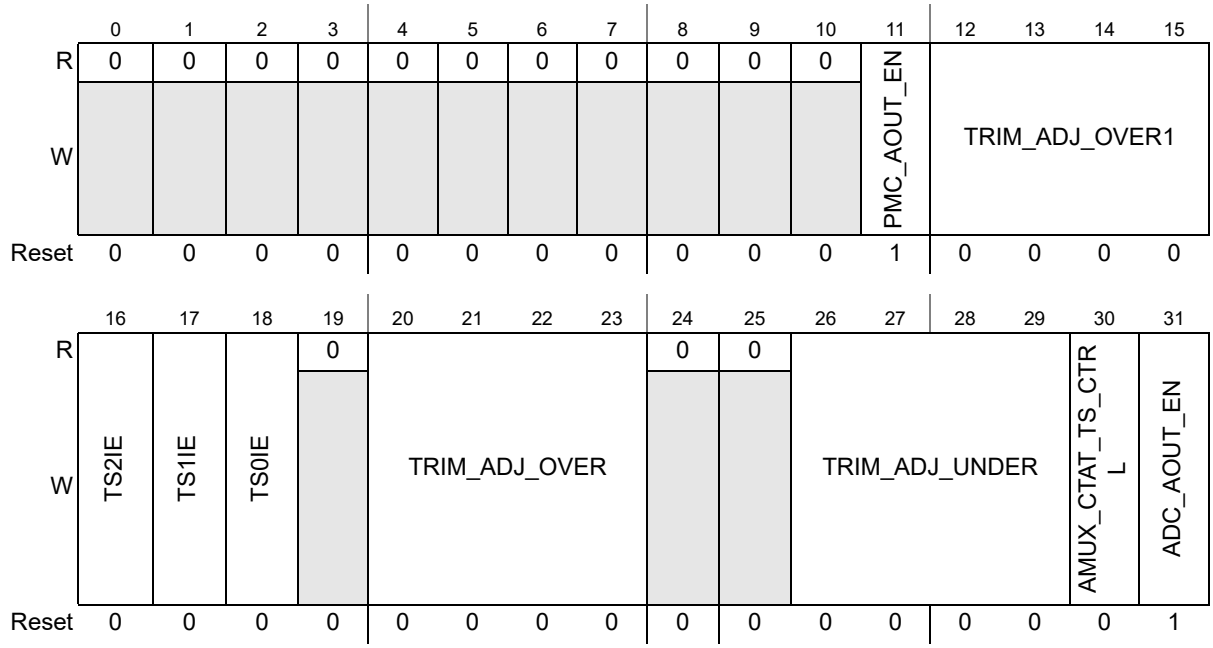

Figure 2030. Temperature Sensor Configuration Register (CTL_TD)

Table 1998. CTL_TD field descriptions

Field	Description
11 PMC_AOUT_EN	PMC_AOUT_EN. Temperature Sensor Enable for PMU. Refer to the Temperature Sensor chapter for details.
12:15 TRIM_ADJ_OVER1	TRIM_ADJ_OVER1[3:0]. Customer adjustable over trim register for PMU. These bits are a signed binary number that is added to the over temperature trim (NT_TD1) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
16 TS2IE	TS2IE Temperature Sensor input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
17 TS1IE	TS1IE Temperature Sensor input 1 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs
18 TS0IE	TS0IE Temperature Sensor input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_G must be set to access this bit. 0 No interrupt occurs 1 An interrupt occurs

Table 1998. CTL_TD field descriptions (continued)

Field	Description
20:23 TRIM_ADJ_OVER	TRIM_ADJ_OVER[3:0]. Customer adjustable over trim register for ADC. These bits are a signed binary number that is added to the over temperature trim (NT_TD2) value. The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
26:29 TRIM_ADJ_UNDER	TRIM_ADJ_UNDER[3:0]. Customer adjustable under trim register. These bits are a signed binary number that is added to the Under temperature trim value (NT_TD0). The TRIM value is protected from overflows and underflows due to this addition. Here MSB bit is sign bit and third bit is tied to zero, the actual trim values are on 2:0 bits. Refer to the Temperature Sensor chapter for details.
30 AMUX_CTAT_TS_CTRL	AMUX_CTAT_TS_CTRL. Analog mux enable. Refer to the Temperature Sensor chapter for details.
31 ADC_AOUT_EN	ADC_AOUT_EN. Temperature Sensor Enable for ADC. Refer to the Temperature Sensor chapter for details.

62.5.33 Temperature Sensor FCCU Event Enable Register (FEE_TD)

This Temperature Sensor FCCU Event Enable Register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

Offset: 0x0318 Access: User read/write, Supervisor read/write, Test read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2036. User BIST Control register (BIST_CTRL)

Table 2004. BIST_CTRL field descriptions

Field	Description
11 IRQST	IRQST is the interrupt request pending status bit to generate a User BIST Interrupt. It is a R/W0 register. That means Set by HW and Cleared by SW. The destructive reset resets this bit. 0 No interrupt occured 1 An interrupt occured
15 IRQEN	IRQEN is the interrupt request enable bit to permit a User BIST Interrupt. It is a R/W register. The destructive reset resets this bit. 0 Interrupt is disabled 1 Interrupt enabled
19 NCFST	NCFST is the Not Critical Fault bit. The assertion of this bit will generate FCCU event once user BIST fails. It is set by HW and Cleared by SW. The destructive reset resets this bit. 0 No User BIST NCF occured 1 A User BIST NCF occured
23 NCFEN	NCFEN is the Not Critical Fault enable bit to permit a User BIST Not Critical Fault and Fault indication is sent to FCCU. It is a R/W register. The destructive reset resets these bits. 0 No User BIST NCF enabled 1 A User BIST NCF enabled

Table 2004. BIST_CTRL field descriptions (continued)

Field	Description
25:27 STATUS	STATUS register consists of 3 read-only bits, that according to the value has its own meaning. 000 BIST_IDLE 001 BIST_RUN 010 BIST_PASSED 011 BIST_FAILED 100 BIST_ABORT 101 Reserved 110 Reserved 111 Reserved
31 START	START User BIST bit. If set by SW a 1 is present in the START bit for a System clock cycle only, then the START bit register is clear by HW. The destructive reset resets this bit. 0 No start pulse. 1 A start pulse occurs of a 1 System clock cycle duration

62.5.39 User BIST Time1 and Time0 register (BIST_TIME10)

The User BIST Time1 and Time0 Register (BIST_TIME10) contains two time numbers Time1 and Time0 giving the System clock cycles number required by the User BIST timer1 and timer0 (refer to *Section 62.10* for more information regarding the User BIST timer registers).

Offset: 0x03D8 Access: User read/write, Supervisor read/write, Test read/write

20:31 TIME_5	TIME_5 is the system clock cycles number required by the TIMER 5 in the User BIST management. The destructive reset resets these bits.

62.5.42 User BIST VD Under Test Monitor register (BIST_DEBUG)

This VD Under Test Monitor register contains a monitor of the Voltage Detector Under Test of the USER BIST sub-block.

Note: The BIST_DEBUG register can only be read while BIST is running. Once BIST is finished the status can be obtained by checking the BIST_FLAGS_PHASE1 and BIST_FLAGS_PHASE2 registers.

Offset: 0x03E4 Access: User read-only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2040. User BIST VD Under Test Monitor register (BIST_DEBUG)

Table 2008. BIST_DEBUG field description

Field	Description
26:31 VD_MON	The six read only bits of field VD_MON give the current VD Under Test of the User BIST unit, among 31 VDs available, according to the following values: 0x1F: LVD100_SB 0x1E: MVD094_C 0x1D: MVD094_FA 0x1C: MVD094_FB 0x1B: LVD100_C 0x1A: LVD100_FL 0x16: MVD270_C_STBY 0x15: MVD270_C 0x14: MVD270_FL 0x13: LVD290_C 0x12: LVD290_FL 0x11: LVD290_EMMC 0x10: LVD290_AS 0x0F: LVD290_ETH1 0x0E: LVD290_ETH0 0x0A: LVD400_EMMC 0x09: LVD400_AS 0x08: LVD400_IM 0x07: LVD400_ETH1 0x06: LVD400_ETH0 0x01: MVD082_B 0x19: HVD134_C 0x18: UVD140_C 0x17: UVD140_FL 0x0D: HVD400_C 0x0C: HVD400_ETH1 0x0B: HVD400_ETH0 0x05: UVD600_C 0x04: UVD600_FL 0x03: UVD600_ETH1 0x02: UVD600_ETH0 0x00: No VD under Test

62.6 Standby entry/exit

Standby entry is an application initiated mode. The standby entry process starts once the application configures [MC_ME_MCTL] register for target mode as standby. For detailed description of entry/exit, refer to MC_PCU.

62.7 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of an analog enable, a set of mode registers, and an overtemp threshold select control.

For more information regarding the Temperature Sensor function, refer to the *Chapter 41: Temperature Sensor*.

62.8 Power On Reset (MC_RGM Phase Gates)

The PMU digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMU and Temperature Sensor Analog blocks.

There are two signals for both the PMU and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMU digital logic also indicates when the RGM allows transition to the next POR phase.

The digital PMU also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMU digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled LVDs and HVDs have become deasserted and the time from the LVD circuits to adjust to new trim values has elapsed, then the signal is sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

62.9 Flash interface (DCF client usage)

The PMU digital is updated during POR from the Flash block via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMU, Temperature Sensor, and ADC Bandgap).

These trim bits that are loaded from the Flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

A DCF client is used to interface to the Flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES bits. Refer to *Section 62.5.30: Reset Event Enable Register (REE_TD)* for more information regarding the REE/RES bits load from Flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (thus to allow the bits to be rewriteable) and same is the reset value of the REE register.

The monitors for which reactions are enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “1” (reset enabled) and in the Reset Event Select (RES_XX) register as “0” (destructive reset selected).

The monitors for which reactions are not enabled will be programmed in the corresponding bit flag of Reset Event Enable (REE_XX) register as “0” (reset disabled) and in the Reset Event Select (RES_XX) register as “1” (functional reset selected).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the POR reset signal.

For more information regarding the DCF records, refer to the DCF Records chapter.

The trim data is read out of the Flash's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the Flash indicates this to the PMU digital via the SSCM module.

Once the PMU trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the Flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD signals must indicate that a valid voltage has been reached before the voltage indication is sent to the Flash.

62.10 Voltage monitor BIST programming

The application has to program the BIST_TIMExx registers according to the following timings, respect to the configured PBRIDGE_CLK:

- BIST_TIME10[Time_0] = 40 µs.
- BIST_TIME10[Time_1] = 50 µs.
- BIST_TIME32[Time_2] = 50 µs.
- BIST_TIME32[Time_3] = 50 µs.
- BIST_TIME65[Time_5] = 200 ns.
- BIST_TIME65[Time_6] = 200 ns.

In case that aforementioned timings are not applied, some voltage monitor BIST could trigger fake faults.

The user can run a BIST mode by setting the BIST_CTRL[START] register bit. The following voltage detectors are then serially tested:

- LVD100_SB
- MVD094_C
- MVD094_FA
- MVD094_FB
- LVD100_C
- LVD100_FL
- MVD270B_SB
- MVD270_C
- MVD270_FL
- LVD290_C
- LVD290_FL
- LVD290_EMMC
- LVD290_AS
- LVD290_ETH1
- LVD290_ETH0
- LVD400_EMMC
- LVD400_AS
- LVD400_IM
- LVD400_ETH1
- LVD400_ETH0
- MVD082_B
- HVD134_C
- UVD140_C
- UVD140_FL
- HVD400_C
- HVD400_ETH1
- HVD400_ETH0
- UVD600_C
- UVD600_FL
- UVD600_ETH1
- UVD600_ETH0

Interrupt can be enabled by programming BIST_CTRL[IRQEN] and interrupt status is checked with BIST_CTRL[IRQST] on completion of BIST sequence.

FCCU event can be enabled by programming BIST_CTRL[NCFEN]. The BIST_CTRL[NCFST] status indicates BIST Fail on completion of BIST sequence.

BIST_DEBUG[VD_MON] register bits allow to know which voltage detector is under test.

The overall status of BIST is provided by the BIST_CTRL[STATUS] register bits.

The status of individual monitors is checked in flag registers BIST_FLAGS_PHASE1 (pass is all zero) and BIST_FLAGS_PHASE2 (pass is all one).

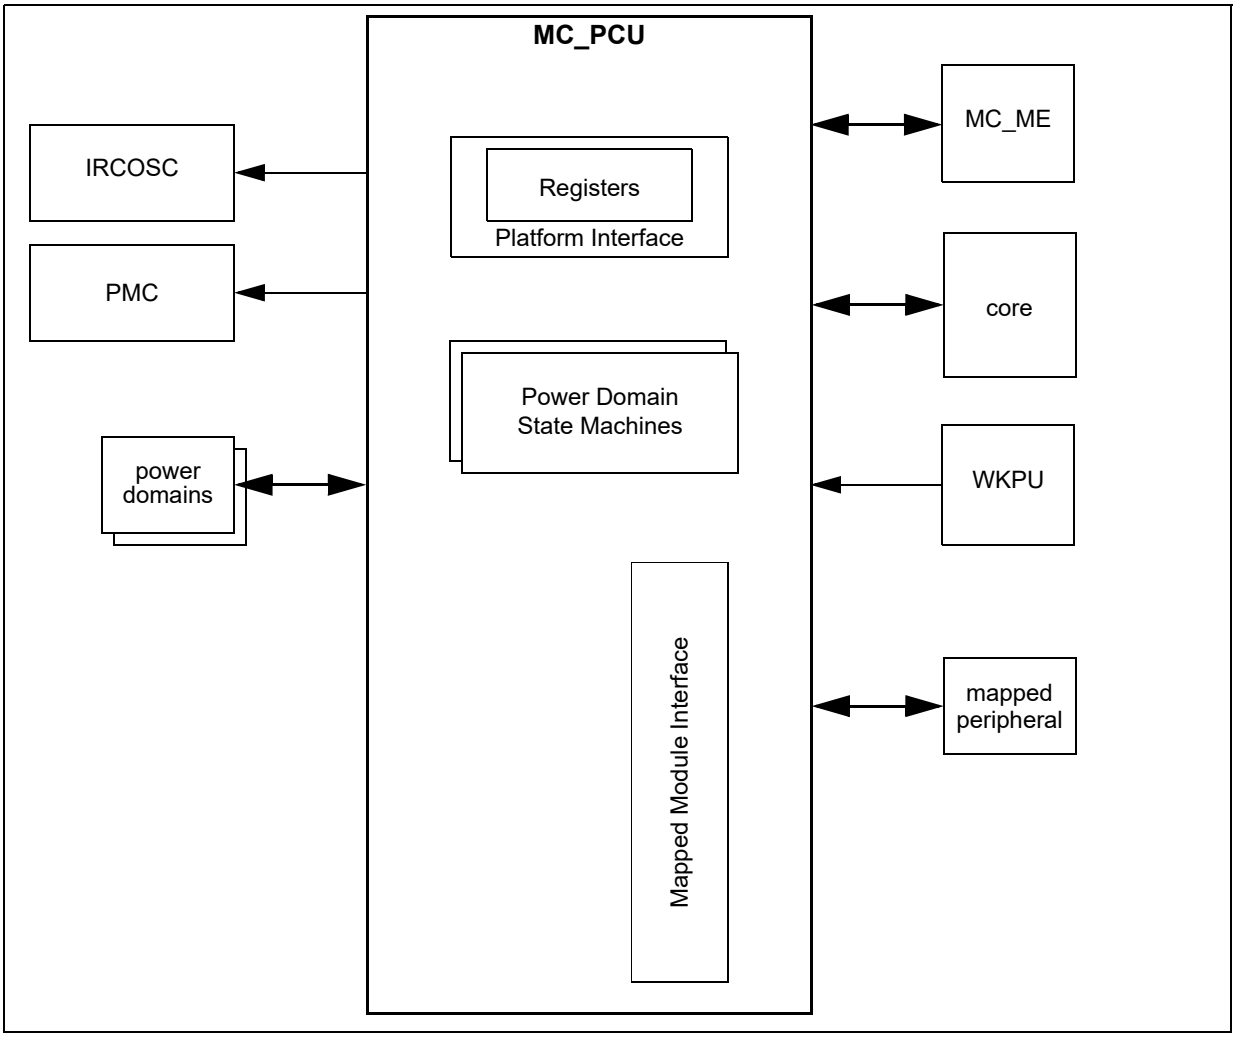
Note: When the SOC supply is 3.3 V, the LVD400_xx monitors are not lifted but when we run BIST all the monitors are masked (during this time the event is seen in PMC_DIG_EPR_HV1 register). When the SOC supply is 5 V, the HVD400_xx monitors are not lifted but when we run BIST, the event is seen in PMC_DIG_EPR_HV1 register.

63 Power Control Unit (MC_PCU)

63.1 Introduction

63.1.1 Overview

The power control unit (MC_PCU) is used to control the overall microcontroller power consumption. There are 4 power domains controlled by the MC_PCU which physically disconnects power to the domains when the specific operating mode allows this.



When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information of such a power domain is lost. When re-connecting a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage.

For each mode, software can configure whether a power domain is connected to the supply voltage (power-up state) or disconnected (power-down state). Maximum power saving is reached by entering the STANDBY mode.

On each mode change request, the MC_PCU evaluates the power domain settings in the power domain configuration registers and initiates a power-down or a power-up sequence for each individual power domain. The power-up/down sequences are handled by finite state machines to ensure a smooth and safe transition from one power state to the other.

Figure 2041 depicts the MC_PCU block diagram.

Figure 2041. MC_PCU block diagram

63.1.2 Features

The MC_PCU includes:

- Support for 4 power domains
- Support for chip modes RESET, DRUN, SAFE, TEST, RUN0…3, HALT, STOP and STANDBY (for further mode details, refer to the MC_ME chapter)
- Power states updating on each mode change and on system wakeup
- A handshake mechanism for power state changes thus guaranteeing operable voltage

63.2 External Signal Description

The MC_PCU has no connections to any external pins.

63.3 Memory Map and Register Definition

63.3.1 Memory Map

Table 2009. MC_PCU Register Description

Address offset	Register name	Location
0x0000	Power Domain #0 Configuration (PCU_PCONF0)	*Section 63.3.2.1*
0x0004	Power Domain #1 Configuration (PCU_PCONF1)	*Section 63.3.2.2*
0x0008	Power Domain #2 Configuration (PCU_PCONF2)	*Section 63.3.2.3*
0x000C	Power Domain #3 Configuration (PCU_PCONF3)	*Section 63.3.2.4*
0x0010–0x003F	Reserved	
0x0040	Power Domain Status Register (PCU_PSTAT)	*Section 63.3.2.5*

Note: Any access to unused registers as well as write accesses to read-only registers will not change register content and will cause a transfer error

63.3.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at address offset 0x0040, as a half-word at address offset 0x0042, or as a byte at address offset 0x0043.

W																
Reset	0	0	0	0	0	1	0	1	1	1	1	1	1	1	1	1

Figure 2043. Power Domain #1 Configuration Register (PCU_PCONF1)

This register defines for power domain #1 whether it is on or off in each chip mode. The bit field description is the same as in *Table 2010*. As the platform, clock generation, and mode control reside in power domain #1, this power domain is only powered down during the STANDBY mode. Therefore, none of the bits are programmable. This register is available for completeness reasons.

The difference between PCU_PCONF0 and PCU_PCONF1 is the reset value of the STBY0 bit: during the STANDBY mode, power domain #1 is disconnected from the power supply, and therefore PCU_PCONF1.STBY0 is always ‘0’. Power domain #0 is always on, and therefore PCU_PCONF0.STBY0 is ‘1’.

For further details about STANDBY mode, refer to *Section 63.4.4.1: STANDBY Mode transition*. NO_FEATURE

63.3.2.3 Power Domain #2 Configuration Register (PCU_PCONF2)

Figure 2046. Power Domain Status Register (PCU_PSTAT)

This register reflects the power status of all available power domains.

Table 2011. PCU_PSTAT field descriptions

Field	Description
28 PD3	Power status for power domain #3 0 Power domain is inoperable. 1 Power domain is operable.
29 PD2	Power status for power domain #2 0 Power domain is inoperable. 1 Power domain is operable.

Table 2011. PCU_PSTAT field descriptions (continued)

Field	Description
30 PD1	Power status for power domain #1 0 Power domain is inoperable. 1 Power domain is operable.
31 PD0	Power status for power domain #0 0 Power domain is inoperable. 1 Power domain is operable.

63.4 Functional description

63.4.1 General

The MC_PCU controls all available power domains on a chip mode basis. The PCU_PCONF*n* registers specify during which system/user modes a power domain is powered up. The power state for each individual power domain is reflected by the bits in the PCU_PSTAT register.

On a mode change, the MC_PCU evaluates which power domain(s) must change power state. The power state is controlled by a state machine (FSM) for each individual power domain which ensures a clean and safe state transition.

63.4.2 Reset / Power-On Reset

After any reset, the chip will transition to the RESET mode during which all power domains are powered up (refer to the MC_ME chapter). Once the reset sequence has been completed, the DRUN mode is entered and software can begin the MC_PCU configuration.

63.4.3 MC_PCU configuration

By default, all power domains are powered in all modes other than STANDBY. Software can change the configuration for each power domain on a mode basis by programming the PCU_PCONF*n* registers.

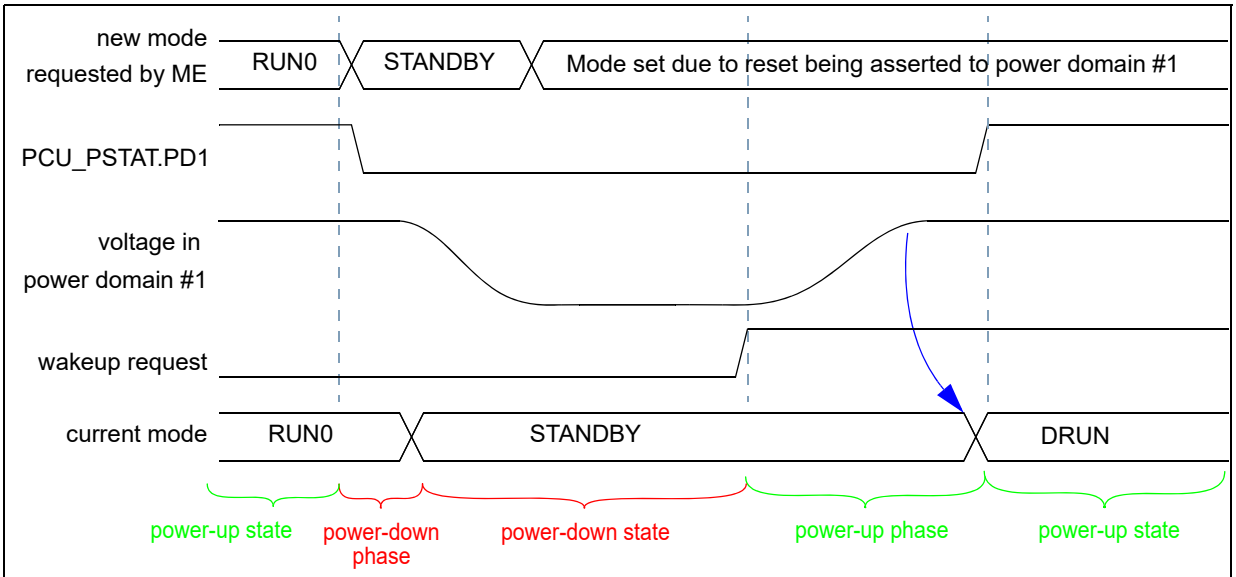
Each power domain which is powered down is held in a reset state. Read/write accesses to peripherals in those power domains will result in a transfer error.

63.4.4 Mode transitions

On a mode change requested by the MC_ME, the MC_PCU evaluates the power configurations for all power domains. It compares the settings in the PCU_PCONF*n* registers for the new mode with the settings for the current mode. If the configuration for a power domain differs between the modes, a power state change request is generated. These requests are handled by a finite state machine to ensure a smooth and safe transition from one power state to another.

63.4.4.1 STANDBY Mode transition

STANDBY offers the maximum power saving. The level of power saving is software-controllable via the settings in the PCU_PCONF*n* registers for power domain #2 onwards. Power domain #0 stays connected to the power supply while power domain #1 is



disconnected from the power supply. Amongst others power domain #1 contains the platform and the MC_ME. Therefore this mode differs from all other user/system modes.

Once STANDBY is entered it can only be left via a system wakeup. On exiting the STANDBY mode, all power domains are powered up according to the settings in the PCU_PCONF*n* registers, and the DRUN mode is entered. In DRUN mode, both domains #0 and #1 are powered.

Figure 2047 shows an example for a mode transition from RUN0 to STANDBY to DRUN. All power domains which have PCU_PCONF*n*.STBY cleared will enter power-down phase. In this example power domain #1 will be disabled during STANDBY mode.

When the MC_PCU receives the mode change request to STANDBY mode it starts the power down phase for power domain #1. During the power down phase, clocks are disabled and reset is asserted resulting in a loss of all information for this power domain. Then the power domain is disconnected from the power supply (power-down state).

Figure 2047. MC_PCU Events During Power Sequences (STANDBY mode)

Notes:

Not drawn to scale; PCONF1.RUN0 = 1; PCONF1.STBY0 = 0

When the MC_PCU receives a system wakeup request, it starts the power-up phase. The power domain is re-connected to the power supply and the voltage in power domain #1 will increase slowly. Once the voltage is in an operable range, clocks are enabled and the reset is be deasserted (power-up state).

Prior to standby entry, PCTL for WKPU should be disabled.

Note: It is possible that due to a wakeup request, power-up is requested before a power domain completed its power-down sequence. In this case, the information in that power domain is lost.

Exiting the STANDBY mode can only be done via a system wakeup event from:

- API/SSWU module (mapped on WKUP0 line),
- RTC timer (mapped on WKUP1 line),
- external wakeup pads (WKUPx line, where x>1).

Refer to the wakeup vector mapping table in the Device Configuration chapter for complete wakeup lines list and to SPC58xHx IO_Definition document for pad/wakeup lines mapping.

63.4.4.2 Power Saving for Memories During STANDBY Mode

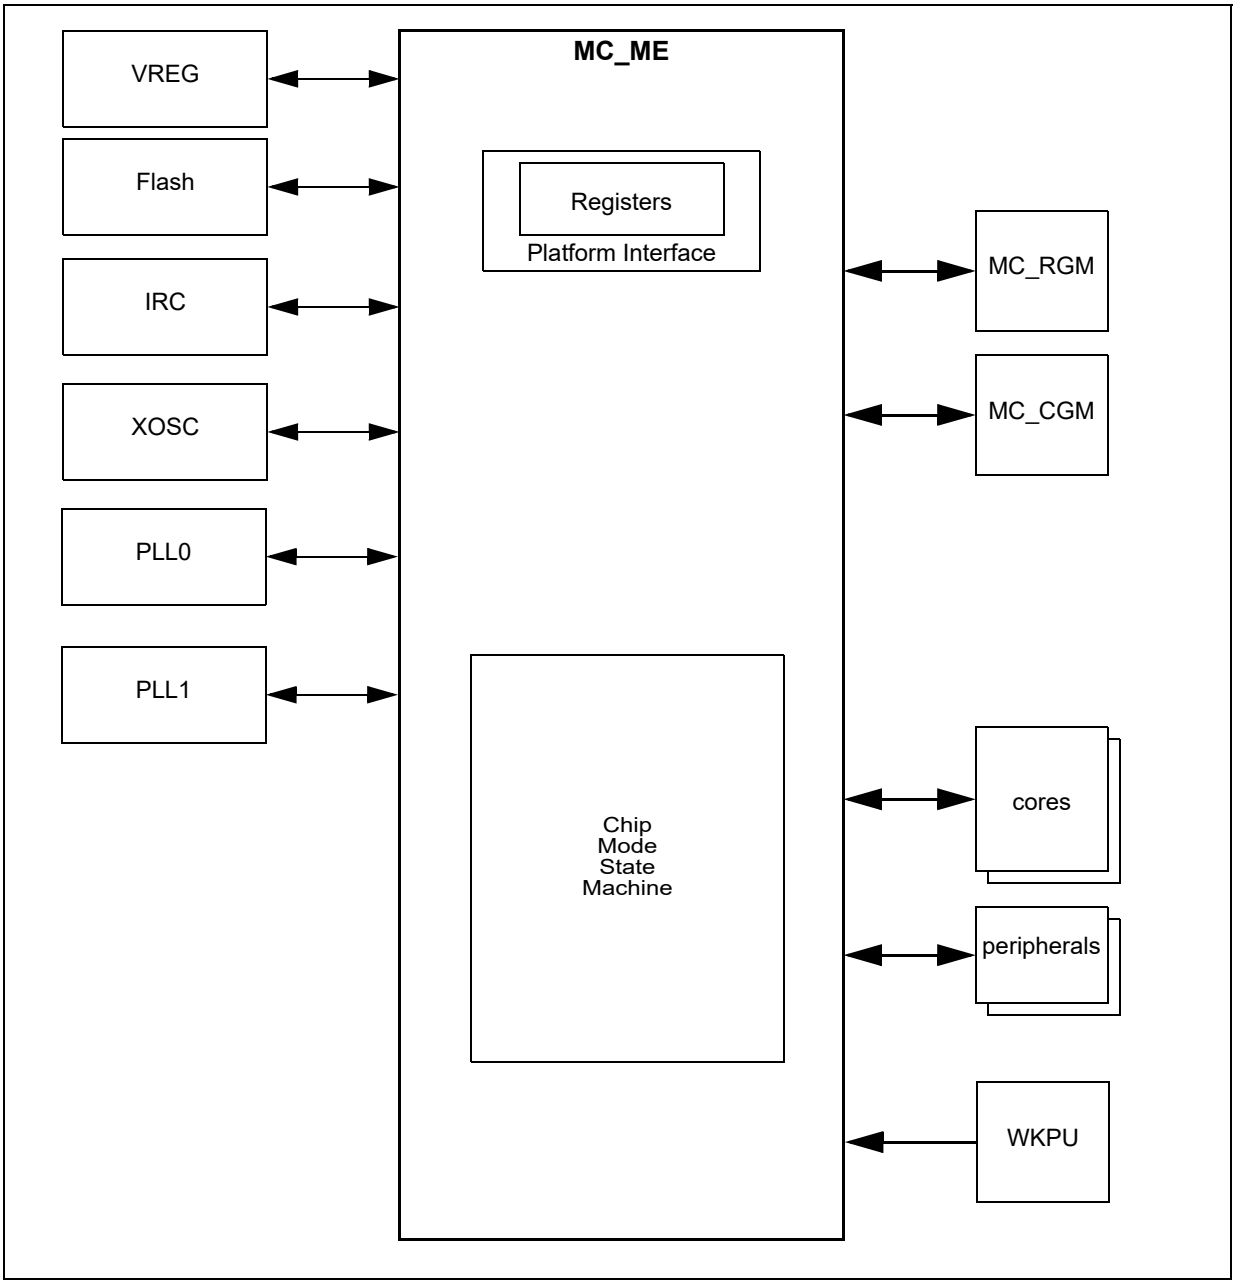
All memories which are not powered down during STANDBY mode automatically enter a power saving state. No software configuration is required to enable this power saving state. While a memory is residing in this state an increased power saving is achieved. Data in the memories is retained.

63.5 Application information

63.5.1 STANDBY mode considerations

STANDBY offers maximum power saving possibility. But power is only saved during the time a power domain is disconnected from the supply. Increased power is required when a power domain is re-connected to the power supply. Additional power is required during restoring the information (for example in the platform). Care should be taken that the time during which the chip is operating in STANDBY mode is significantly longer than the required time for restoring the information.

64 Mode Entry Module (MC_ME)



64.1 Introduction

64.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

Figure 2048 shows the MC_ME block diagram.

Figure 2048. MC_ME block diagram

64.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTL*n* registers
- additional core clock gating and boot address control based on the ME_CCTL*n* and ME_CADDR*n* registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

64.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as: RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as: RUN0–3, HALT0, STOP0, and STANDBY0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0–3 are the chip software running modes.

Table 2012 describes the MC_ME modes.

Table 2012. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and Flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAF, when present, is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0–3, wakeup request from STANDBY0	system reset assertion, RUN0–3, TEST, STANDBY0 via software, SAFE via software or hardware failure.

Table 2012. MC_ME mode descriptions (continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0–3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0–3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0–3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0–3 modes, HALT0, STOP0, STANDBY0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals such as: clock sources, Flash, main regulator, for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0–3	system reset assertion, SAFE on hardware failure, RUN0–3 on interrupt event or wakeup event
STANDBY0	This is a reduced-leakage low-power mode during which power supply is cut off from most of the chip. Wakeup from this mode takes a relatively long time, and content is lost or must be restored from backup.	software request from RUN0–3, DRUN modes	system reset assertion, DRUN on wakeup event

64.2 External signal description

The MC_ME has no connections to any external pins.

64.3 Memory map and register definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

64.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of ‘1’ or ‘0’ and the corresponding behavior cannot be changed.

64.3.2.1 Global Status Register (ME_GS)

This register contains global mode status.

Offset : 0x000 Access: User read, Supervisor read, Test read

Table 2014. ME_GS field descriptions (continued)

Field	Description
27 S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28:31 S_SYSCLK	System clock switch status These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved ... 1111 system clock is disabled

64.3.2.2 Mode Control Register (ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

Note: Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Offset: 0x004 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2050. Mode Control Register (ME_MCTL)

Table 2015. ME_MCTL field descriptions

Field	Description
0:3 TARGET_MODE	Target chip mode These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0–3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
16:31 KEY	Control key These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101 1010 1111 0000 (0x5AF0) INVERTED KEY: 1010 0101 0000 1111 (0xA50F)

64.3.2.3 Mode Enable Register (ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET, SAFE, DRUN, and RUN0 modes are always enabled.

Offset: 0x008 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2052. Interrupt Status Register (ME_IS)

Table 2017. ME_IS field descriptions

Field	Description
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) This bit is set if a write access to one of the ME_CCTLn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending

Table 2017. ME_IS field descriptions (continued)

Field	Description
28 I_ICONF	Invalid mode configuration interrupt This bit is set whenever a write operation to ME_<*mode*>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, STOP0, or STANDBY0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

64.3.2.5 Interrupt Mask Register (ME_IM)

This register controls whether an event generates an interrupt or not.

Offset: 0x010 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2054. Invalid Mode Transition Status Register (ME_IMTS)

Table 2019. ME_IMTS field descriptions

Field	Description
26 S_MRIG	Mode Request Ignored status This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress, a transition to STOP0 mode is requested while a wakeup or interrupt request is active, a transition to HALT0 mode is requested while an interrupt request is active, or a transition to STANDBY mode is requested while a wakeup request is active. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not ignored 1 Mode transition requested is ignored
27 S_MTI	Mode Transition Illegal status This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is ‘1’). Refer to *Section 64.4.5: Mode Transition Interrupts*, for the exceptions to this behavior. It is cleared by writing a ‘1’ to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a ‘1’ to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a ‘1’ to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

64.3.2.7 Debug Mode Transition Status Register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Field	Description
0:3 PREVIOUS_MODE	Previous chip mode These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 STANDBY0 1110 reserved 1111 reserved
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has responded. 0 Handshake is not busy 1 Handshake is busy

Table 2020. ME_DMTS field descriptions (continued)

Field	Description
11 PMC_PROG	MC_PCU Mode Change in Progress indicator This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
16 CDP_PRPH_0_255	Clock Disable Process Pending status for Peripherals 0–255(1) This bit is set when any peripheral appearing has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table 2020. ME_DMTS field descriptions (continued)

Field	Description
19 IRC_SC	IRC State Change during mode transition indicator This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A secondary clock source is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status 0 No system clock source switching is pending 1 A system clock source switching is pending
23 FLASH_SC	FLASH State Change during mode transition indicator This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224–255(1) This bit is set when any peripheral appearing in ME_PS7 has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
25 CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192–223 This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_160_191	Clock Disable Process Pending status for Peripherals 160–191 This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 2020. ME_DMTS field descriptions (continued)

Field	Description
27 CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128–159 This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96–127 This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64–95 This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32–63 This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0–31 This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTLn register. Refer to *Table 2013* for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

64.3.2.8 RESET Mode Configuration Register (ME_RESET_MC)

This register configures system behavior during RESET mode. Refer to *Table 2021* for details.

Note: The following configuration values are set according to the chip configuration:

XOSCON

Offset: 0x020 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	PDO	0	0	MVRON	0	0	FLAON	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	PLL1ON	PLL0ON	XOSCON	IRCON	SYSCLK			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Figure 2056. RESET Mode Configuration Register (ME_RESET_MC)

64.3.2.9 TEST Mode Configuration Register (ME_TEST_MC)

This register configures system behavior during TEST mode. Refer to *Table 2021* for details.

Note: Byte write accesses are not allowed to this register.

Offset: 0x024 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Figure 2058. SAFE Mode Configuration Register (ME_SAFE_MC)

64.3.2.11 DRUN Mode Configuration Register (ME_DRUN_MC)

This register configures system behavior during DRUN mode. Refer to *Table 2021* for details.

Note: Byte write accesses are not allowed to this register.

The following configuration values are set according to the chip configuration:

XOSCON

Offset: 0x02C Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2063. STANDBY0 Mode Configuration Register (ME_STANDBY0_MC)

This register configures system behavior during STANDBY0 mode. Refer to *Table 2021* for details.

Note: Byte write accesses are not allowed to this register.

Table 2021. ME_<*mode*>_MC Field Descriptions

Field	Description
1:3 PWRLVL	Power level This bit indicates the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled. **Note:** For ME_RESET_MC, ME_HALT0_MC, ME_STOP0_MC and ME_STANDBY0_MC registers this bit field is read-only and always 0.
8 PDO	I/O output power-down control This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional. In STANDBY0 mode, power sequence driver and all pads except those mapped on wakeup lines are not powered and therefore high impedance. Wakeup line configuration remains unchanged
11 MVRON	Main voltage regulator control This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
14:15 FLAON	Flash power-down control This bit specifies the operating mode of the Flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
24 PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on
26 XOSCON	external crystal oscillator control 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on

Table 2021. ME_<*mode*>_MC Field Descriptions (continued)

Field	Description
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28:31 SYSCLK	System clock switch control These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved ... 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

64.3.2.16 Peripheral Status Register 0 (ME_PS0)

This register provides the status of the peripherals. Refer to *Table 2022* for details.

Offset: 0x060 Access: User read, Supervisor read, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

13 S_LINFlexD_20	LINFLEXD_20 status This bit specifies the current status of LINFLEXD_20 which is controlled by the MC_ME. 0 LINFLEXD_20 is frozen 1 LINFLEXD_20 is active
14 S_LINFlexD_22	LINFLEXD_22 status This bit specifies the current status of LINFLEXD_22 which is controlled by the MC_ME. 0 LINFLEXD_22 is frozen 1 LINFLEXD_22 is active

Table 2024. ME_PS2 register field descriptions (continued)

Field	Description
18 S_OctalSPI	OctalSPI status This bit specifies the current status of OctalSPI which is controlled by the MC_ME. 0 OctalSPI is frozen 1 OctalSPI is active
21 S_CANSUBSYS0 _CAN_RAM_CTR	CANSUBSYS0_CAN_RAM_CTR status This bit specifies the current status of CANSUBSYS0_CAN_RAM_CTR which is controlled by the MC_ME. 0 CANSUBSYS0_CAN_RAM_CTR is frozen 1 CANSUBSYS0_CAN_RAM_CTR is active
22 S_CANSUBSYS3 _CAN_RAM_CTR	CANSUBSYS3_CAN_RAM_CTR status This bit specifies the current status of CANSUBSYS3_CAN_RAM_CTR which is controlled by the MC_ME. 0 CANSUBSYS3_CAN_RAM_CTR is frozen 1 CANSUBSYS3_CAN_RAM_CTR is active
23 S_CANSUBSYS0 _MCAN_0	CANSUBSYS0_MCAN_0 status This bit specifies the current status of CANSUBSYS0_MCAN_0 which is controlled by the MC_ME. 0 CANSUBSYS0_MCAN_0 is frozen 1 CANSUBSYS0_MCAN_0 is active
26 S_CANSUBSYS0 _MCAN_1	CANSUBSYS0_MCAN_1 status This bit specifies the current status of CANSUBSYS0_MCAN_1 which is controlled by the MC_ME. 0 CANSUBSYS0_MCAN_1 is frozen 1 CANSUBSYS0_MCAN_1 is active
27 S_CANSUBSYS0 _MCAN_2	CANSUBSYS0_MCAN_2 status This bit specifies the current status of CANSUBSYS0_MCAN_2 which is controlled by the MC_ME. 0 CANSUBSYS0_MCAN_2 is frozen 1 CANSUBSYS0_MCAN_2 is active
28 S_CANSUBSYS0 _MCAN_3	CANSUBSYS0_MCAN_3 status This bit specifies the current status of CANSUBSYS0_MCAN_3 which is controlled by the MC_ME. 0 CANSUBSYS0_MCAN_3 is frozen 1 CANSUBSYS0_MCAN_3 is active
29 S_CANSUBSYS3 _MCAN_1	CANSUBSYS3_MCAN_1 status This bit specifies the current status of CANSUBSYS3_MCAN_1 which is controlled by the MC_ME. 0 CANSUBSYS3_MCAN_1 is frozen 1 CANSUBSYS3_MCAN_1 is active

Table 2024. ME_PS2 register field descriptions (continued)

Field	Description
30 S_CANSUBSYS3_MCAN_2	CANSUBSYS3_MCAN_2 status This bit specifies the current status of CANSUBSYS3_MCAN_2 which is controlled by the MC_ME. 0 CANSUBSYS3_MCAN_2 is frozen 1 CANSUBSYS3_MCAN_2 is active
31 S_CANSUBSYS3_MCAN_3	CANSUBSYS3_MCAN_3 status This bit specifies the current status of CANSUBSYS3_MCAN_3 which is controlled by the MC_ME. 0 CANSUBSYS3_MCAN_3 is frozen 1 CANSUBSYS3_MCAN_3 is active

64.3.2.19 Peripheral Status Register 3 (ME_PS3)

This register provides the status of the peripherals. Refer to *Table 2025* for details.

Offset: 0x06C Access: User read, Supervisor read, Test read

64.3.2.26 Peripheral Control Registers (ME_PCTL*n*)

These registers select the configurations during run and non-run modes for each peripheral. Refer to *Table 2013* for information on which ME_PCTL*n* locations are actually occupied. The unoccupied locations contain a read-only byte value of 0x00.

Note: After modifying any of the ME_RUN_PCn, ME_LP_PCn, and ME_PCTLn registers, software must request a mode change and wait for the mode change to be completed before entering debug mode in order to have consistent behavior between the peripheral clock control process and the clock status reporting in the ME_PS*n registers.*

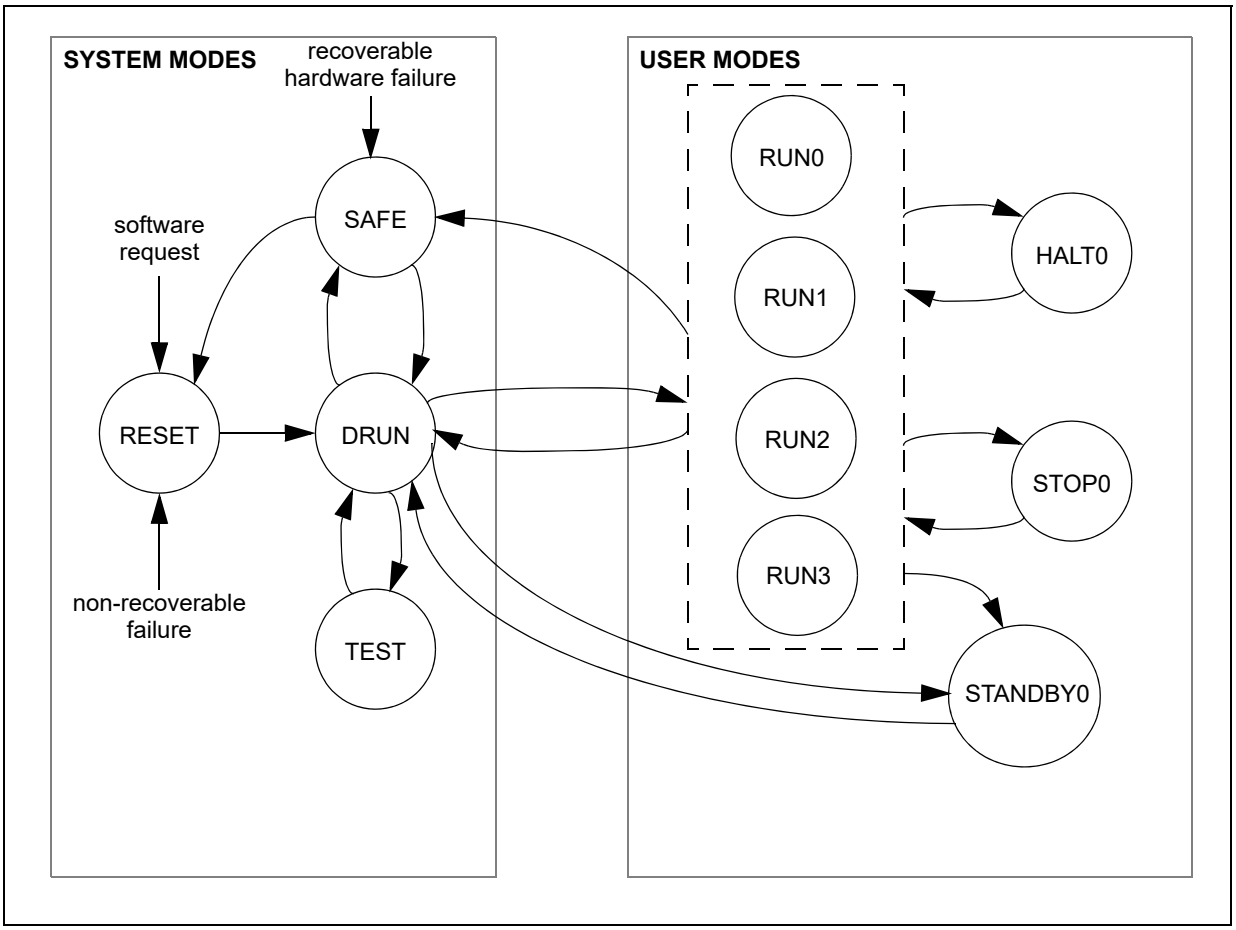
64.4 Functional description

64.4.1 Mode transition request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register. The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, refer to *Section 64.4.5: Mode Transition Interrupts*.



Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means

that transition requests such as: RUN0–3 → RUN0–3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0, STOP0, or STANDBY0 modes.

If CMU reveals a loss of PLL/XOSC clock before a transition request, such transition is not completed. If failure removal and CMU flags are reset, then transition is executed correctly.

Figure 2084. MC_ME Mode Diagram

64.4.2 Modes details

64.4.2.1 RESET mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0–3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either “0000” for a ‘functional’ reset or “1111” for a ‘destructive’ reset.
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (refer to the MC_RGM chapter for details).

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

64.4.2.2 DRUN mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0–3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0011”
- from the STANDBY0 mode after an external wakeup event or internal wakeup alarm

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the Flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in Flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs
- to execute small routines in a ‘ping-pong’ with the STANDBY0 mode

When this mode is entered from STANDBY0 after a wakeup event, the ME_DRUN_MC register content is restored to its pre-STANDBY0 values, and the mode starts in that configuration.

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

64.4.2.3 SAFE mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with “0010”
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (refer to *Chapter 59: Reset Generation Module (MC_RGM)*, for details)

Note: If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by hardware, a SAFE mode interrupt is generated. Refer to *Section 64.4.5.3* for details.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note: If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged.

64.4.2.4 TEST mode

The chip enters this mode on the following event:

- from the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0001"

As soon as the above event has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to "1111", and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

64.4.2.5 RUN0–3 modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0–3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0100–0111"
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0–3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0–3_MC registers. In these modes, the Flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note: Software must ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in the low-power or power-down state in this mode.

64.4.2.6 HALT0 mode

The chip enters this mode on the following event:

- from one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1000”.

As soon as the above event has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The Flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen
- the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (that is within a few system clock cycles of an interrupt event)

The normal exit of the HALT0 mode is from an interrupt event. Wakeup events will not cause HALT0 mode exit.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

64.4.2.7 STOP0 mode

The chip enters this mode on the following event:

- from one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1010”.

As soon as the above event has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the primary PLL
- the secondary PLL

The Flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (for example, allow for system clock source to be re-started)

The normal exit from the STOP0 mode is by an interrupt or a wakeup event. This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0–3 mode configuration has been fully restored before executing critical code.

64.4.2.8 STANDBY0 Mode

The chip enters this mode on the following event:

- from the DRUN or one of the RUN0–3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1101”.

As soon as the above event occurs, a STANDBY0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STANDBY0_MC register. In this mode, the power supply is turned off for most of the chip. The only parts of the chip that are still powered during this mode are pads mapped on wakeup lines and power domain #0 which contains the MC_RGM, MC_PCU, WKPU, PASS, OSC32k, RTC, LPROSC, SSWU, ADC-STDBY, PMC_DIG. The IRC can be optionally switched off. This is the lowest power consumption mode possible on the chip.

This mode is intended as an extreme low-power mode with

- the cores, the Flashes, and almost all peripherals and memories powered down and to be used by software
- to wait until it is required to do something with no need to react quickly (such as, allow for system power-up and system clock source to be re-started)

The exit sequence of this mode is similar to the reset sequence, and the resets to all but power domain #0 are asserted with timing that is the same as reset PHASE1 through PHASE3. Device will boot from the address specified on ME_CADDR0 register. In case that boot from RAM is requested, ME_CADDR0 will address standby RAM (refer to *Table 7: System and stand-by RAM memory map*). In this case, it is also possible to keep Flash in power-down by writing ‘01’ to FLAON field in the ME_DRUN_MC register.

If there is a STANDBY0 mode request while any wakeup event is active, the chip mode does not change.

The IO pins in STANDBY mode can be divided in 2 types:

- Not Low Power pin (NLP)
  They are not active in STANDBY and when STANDBY is entered, both input and output buffers inside the pins are disabled. Thus also internal pull-up/down are disabled.

Floating state will not affect the power consumption because of isolation within the pad is automatically applied.

- Low Power pin (LP)
  The LP pins are active during STANDBY. They are configured in CMOS level logic and this configuration cannot be changed. Moreover, when the device enters the STANDBY mode, the pad-keeper feature is activated for LP pins. It means that:
  – if the pad voltage level is above the pad keeper high threshold (PK_h), a weak pull-up resistor is automatically enabled;
  – if the pad voltage level is below the pad keeper low threshold (PK_l), a weak pull-down resistor is automatically enabled.

For the pad-keeper high/low thresholds refer to the device datasheet. Regarding the pad-keeper weak pull-up/down, these are the same as the ones configurable through SIUL2_MSCR register in running mode, and their values (Rwpu/Rwpd) are showed in the datasheet.

Refer to the SPC58xHx pinout Excel file (package sheets) for the list of LP pins.

64.4.3 Mode transition process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the XOSC is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL's lock status bit.

64.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to *Section 64.4.5*, for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

64.4.3.2 Target mode configuration loading

On completion of the *Target mode request* step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (such as voltage sources, clock sources, Flash, pads) control process.

An overview of resource control possibilities for each mode is shown in *Table 2042*. A 'X' indicates that a given resource is configurable for a given mode.

Table 2042. MC_ME Resource Control Overview

Resource	Mode							
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0	STANDBY0
IRC	on	X on	on	on	on	on	on	X on
XOSC	off	X off	off	X off	X off	X off	X off	off
PLL0	off	X off	off	X off	X off	X off	off	off
PLL1	off	X off	off	X off	X off	X off	off	off
FLASH	normal	X normal	normal	X normal	X normal	X low-power	X power-down	power-down
MVREG	on	on	on	on	on	on	on	off
PDO	off	X off	X on	off	off	off	X off	on

64.4.3.3 Peripheral clocks disable

On completion of the *Target mode request* step and the system clock frequency ramp-down of the *System clock switching* step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0–7 and ME_LP_PC0–7, and the peripheral control registers ME_PCTLn

Note: The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Refer to *Section 64.4.6: Peripheral Clock Gating*, for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

64.4.3.4 Processor low-power mode entry

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the HALT0 mode, the MC_ME requests the processor to enter its halted state. The processor acknowledges its halt state request after completing all outstanding bus transactions.

If, on completion of the *Peripheral clocks disable* step, the mode transition is to the STOP0 or STANDBY0 mode, the MC_ME requests the processor to enter its stopped state. The processor acknowledges its stop state request after completing all outstanding bus transactions.

64.4.3.5 Processor clocks disable

If, on completion of the *Processor low-power mode entry* step, and all processors which are configured in the ME_CCTLn registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

Caution: Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

64.4.3.6 System clock disable

If, on completion of the *Processor clocks disable* step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

64.4.3.7 Clock sources (Main Voltage Regulator Independent) switch-on

On completion of the *Processor low-power mode entry* step, the MC_ME switches on all clock sources, which do not need the main voltage regulator to be on, based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator: in HALT0 mode; in STOP0 mode; in STANDBY0 mode depending on ME_STANDBY0_MC.IRCON bit setting
- the external crystal oscillator: in HALT0 mode and STOP0 mode, depending on ME_HALT0_MC.XOSCON bit and ME_STOP0_MC.XOSCON bit setting correspondingly
- the primary PLL
- the secondary PLL

Note: Clock sources which need the main voltage regulator to be stable are not controlled by this step.

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order not to disturb the system clock which might require one of these clocks before switching to a different target clock.

64.4.3.8 Main Voltage Regulator Switch-On

On completion of the *Target mode request* step, if the main voltage regulator needs to be switched on from its off state based on the MVRON bit of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the MC_PCU to power-up the regulator and waits for the output voltage stable status in order to update the S_MVR bit of the ME_GS register.

This step is required only during the exit of the low-power modes HALT0 and STOP0. In this step, the 16 MHz internal RC oscillator is switched on regardless of the target mode configuration, as the main voltage regulator requires the 16 MHz int. RC osc. during power-up in order to generate the voltage status.

During the STANDBY0 exit sequence, the MC_PCU alone manages the power-up of the main voltage regulator, and the MC_ME is kept in RESET or shut off (depending on the power domain #1 status).

64.4.3.9 Flash memory module switch-on

On completion of the *Main Voltage Regulator Switch-On* step, if the Flash memory needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the Flash memory to exit from its low-power/power-down mode. When the Flash memory is available for access, the S_FLA bit field of the ME_GS register is updated to “11” by hardware.

Caution: It is illegal to switch the FLASH or the DFLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

64.4.3.10 Clock Sources (Main Voltage Regulator Dependent) Switch-On

On completion of the *Clock sources (Main Voltage Regulator Independent) switch-on* and *Main Voltage Regulator Switch-On*, the MC_ME controls all clock sources, which need the main voltage regulator to be on, based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the primary PLL depending on ME_<target mode>_MC.PLL0ON bit
- the secondary PLL depending on ME_<target mode>_MC.PLL1ON bit

64.4.3.11 Pad outputs-on

On completion of the *Main Voltage Regulator Switch-On* step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- slew rate control mechanism is switched on

64.4.3.12 Peripheral clocks enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0–7, ME_LP_PC0–7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. If the value of the PWRLVL field of the ME_<target mode>_MC register is less than that of the ME_<current mode>_MC register's, this step is executed only after the *System clock switching* process is completed.

64.4.3.13 System and processor clocks enable

On completion of the *Flash memory module switch-on* step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTLn registers to be running in the target mode and which have their RMC bits in the ME_CADDRn registers set to '1'. The processor core reset outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the MW_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the *System clock switching* process is completed.

64.4.3.14 Processor low-power mode exit

On completion of the *System and processor clocks enable* step, the MC_ME requests all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode by deasserting the corresponding core_stop bits.

64.4.3.15 System clock switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the external crystal osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (that is the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (that is the external crystal oscillator has stabilized).
- The target clock configuration for the reserved takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (that is the external crystal oscillator has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with “1111”. This is possible only in the TEST mode. In the STANDBY0 mode, the clock configuration is fixed, and the system clock is automatically forced to ‘0’. .

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the *Clock sources (Main Voltage Regulator Independent) switch-on* process has completed if the target system clock source is one of the following:
  - the 16 MHz internal RC oscillator
  - the external crystal oscillator
  - the primary PLL
- the *Peripheral clocks disable* process has completed in order not to change the system clock frequency before peripherals close their internal activities
- the *Peripheral clocks enable* process has completed

An overview of system clock source selection possibilities for each mode is shown in *Table 2043*. A ‘X’ indicates that a given clock source is selectable for a given mode.

Table 2043. MC_ME System Clock Selection Overview

System Clock Source	Mode							
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0	STANDBY0
16 MHz int. RC osc.		X (default)		X (default)	X (default)	X (default)		
external crystal osc.		X		X	X	X		
primary PLL (PHI)		X		X	X	X		

Table 2043. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode							
	RESET	TEST	SAFE	DRUN	RUN0–3	HALT0	STOP0	STANDBY0
secondary PLL		X		X	X	X		
system clock is disabled		X(1)						

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

64.4.3.16 Pad switch-off

If the PDO bit of the ME_<target mode>_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

In STANDBY0 mode, the power sequence driver and all pads except the external reset and those mapped on wakeup or SSWU lines are not powered and therefore high impedance. The wakeup and SSWU line configuration remains unchanged.

This step is executed only after the *Peripheral clocks disable* process has completed.

64.4.3.17 Clock sources switch-off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources switched off at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the *System clock switching* process has completed.

64.4.3.18 Flash memory switch-off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the Flash is to be put in its low-power or power-down mode, the MC_ME requests the Flash to enter the corresponding power mode and waits for the Flash to acknowledge. The exact power mode status of the Flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the *Processor clocks disable* and *System clock disable* processes have completed.

64.4.3.19 Main Voltage Regulator Switch-Off

Based on the MVRON bit of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the main voltage regulator is to be switched off, the MC_ME requests it to power down and clears the availability status bit S_MVR of the ME_GS register.

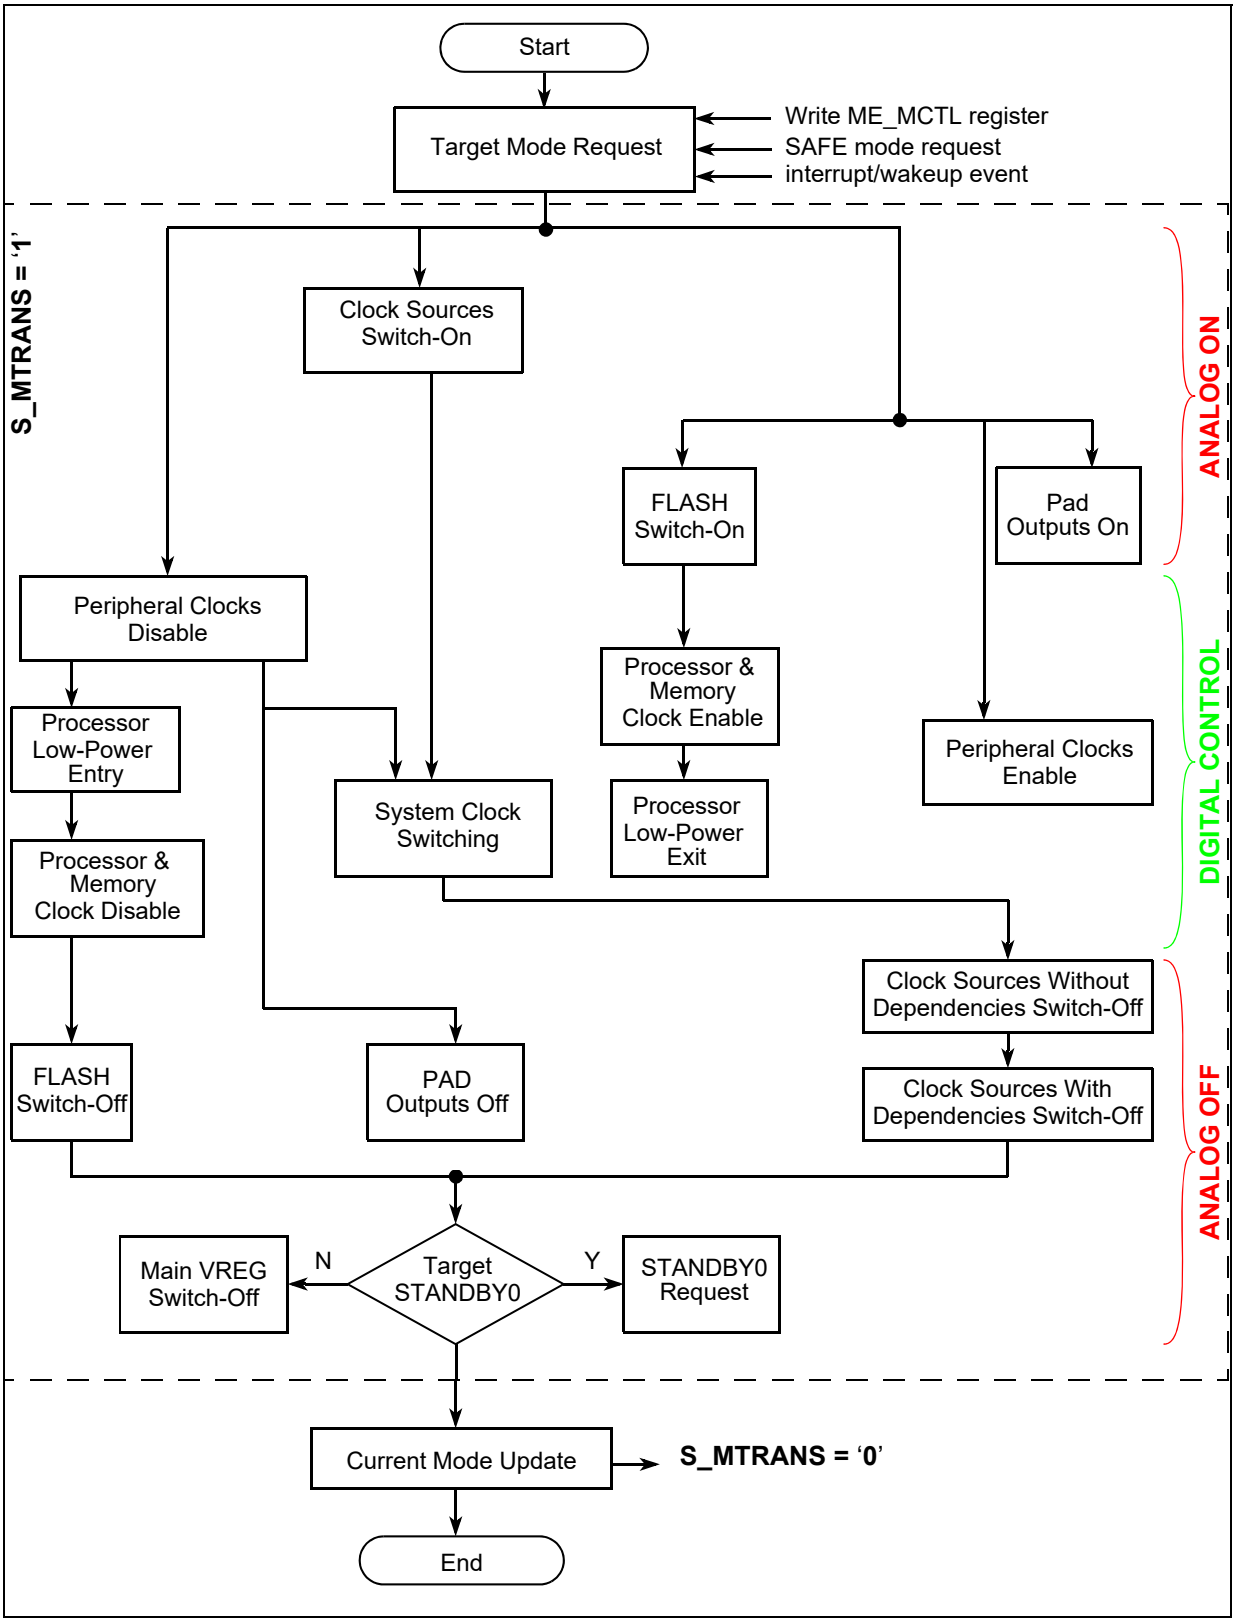
This step is executed only after completing the following processes :

- *Clock sources switch-off*
- *Flash memory switch-off*

If the target mode is STANDBY0, the main voltage regulator is not switched off by the MC_ME and the STANDBY0 request is asserted after the above processes have completed upon which the MC_PCU takes control of the main regulator. As the MC_PCU needs the 16 MHz int. RC osc., the 16 MHz internal RC oscillator remains active until all the STANDBY0 steps are executed by the MC_PCU after which it may be switched off depending on the IRCON bit of the ME_STANDBY0_MC register.

64.4.3.20 Current mode update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :



- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register.
- power sequences are done.
- clock disable/enable process is finished.
- processor low-power mode (stop) entry and exit processes are finished.

Note: SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

Figure 2085. MC_ME Transition Diagram

64.4.4 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz int. RC osc. is selected as the system clock, IRC must be on.
- If the external crystal osc. clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration “00” for the FLAON bit field is reserved.
- System clock configurations marked as ‘reserved’ may not be selected.
- Configuration “1111” for the SYSCLK bit field is allowed for the TEST mode and STANDBY mode, and only in this case may all system clock sources be turned off.

Caution: If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

64.4.5 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

64.4.5.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in *Section 64.4.4: Protection of Mode Configuration Registers*, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is ‘1’.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0–7/ME_LP_PC0–7 and ME_PCTLn registers, the interrupt pending bit I_ICONF_CU of the ME_IS register can be set and an interrupt request can be generated if the mask bit M_ICONF_CU of the ME_IM register is ‘1’.

If an attempt to write to one of the ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is ‘1’. The bit i_iconf_cu is not set if there is at least one peripheral enabled and the related clock source configured to be on.

64.4.5.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new

mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.

- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (that is a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is ‘1’), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a HALT0 mode request occurs while an interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a STOP0 mode request occurs while a wakeup or interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note: As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0–3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined ‘reasonable’ amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

Warning: Depending on the cause of the mode transition not completing, aborting via a request back to the parent mode may not be able to recover. In this case, software should request a change to either SAFE or RESET mode, since the cause of the hang-up is most likely due to a hardware fault.

- Self-transition requests (for example, RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (that is S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0–3 mode properly (that is all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'.

64.4.5.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1' .

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (refer to the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (by programming the ME_MCTL register).

64.4.5.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (that is the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

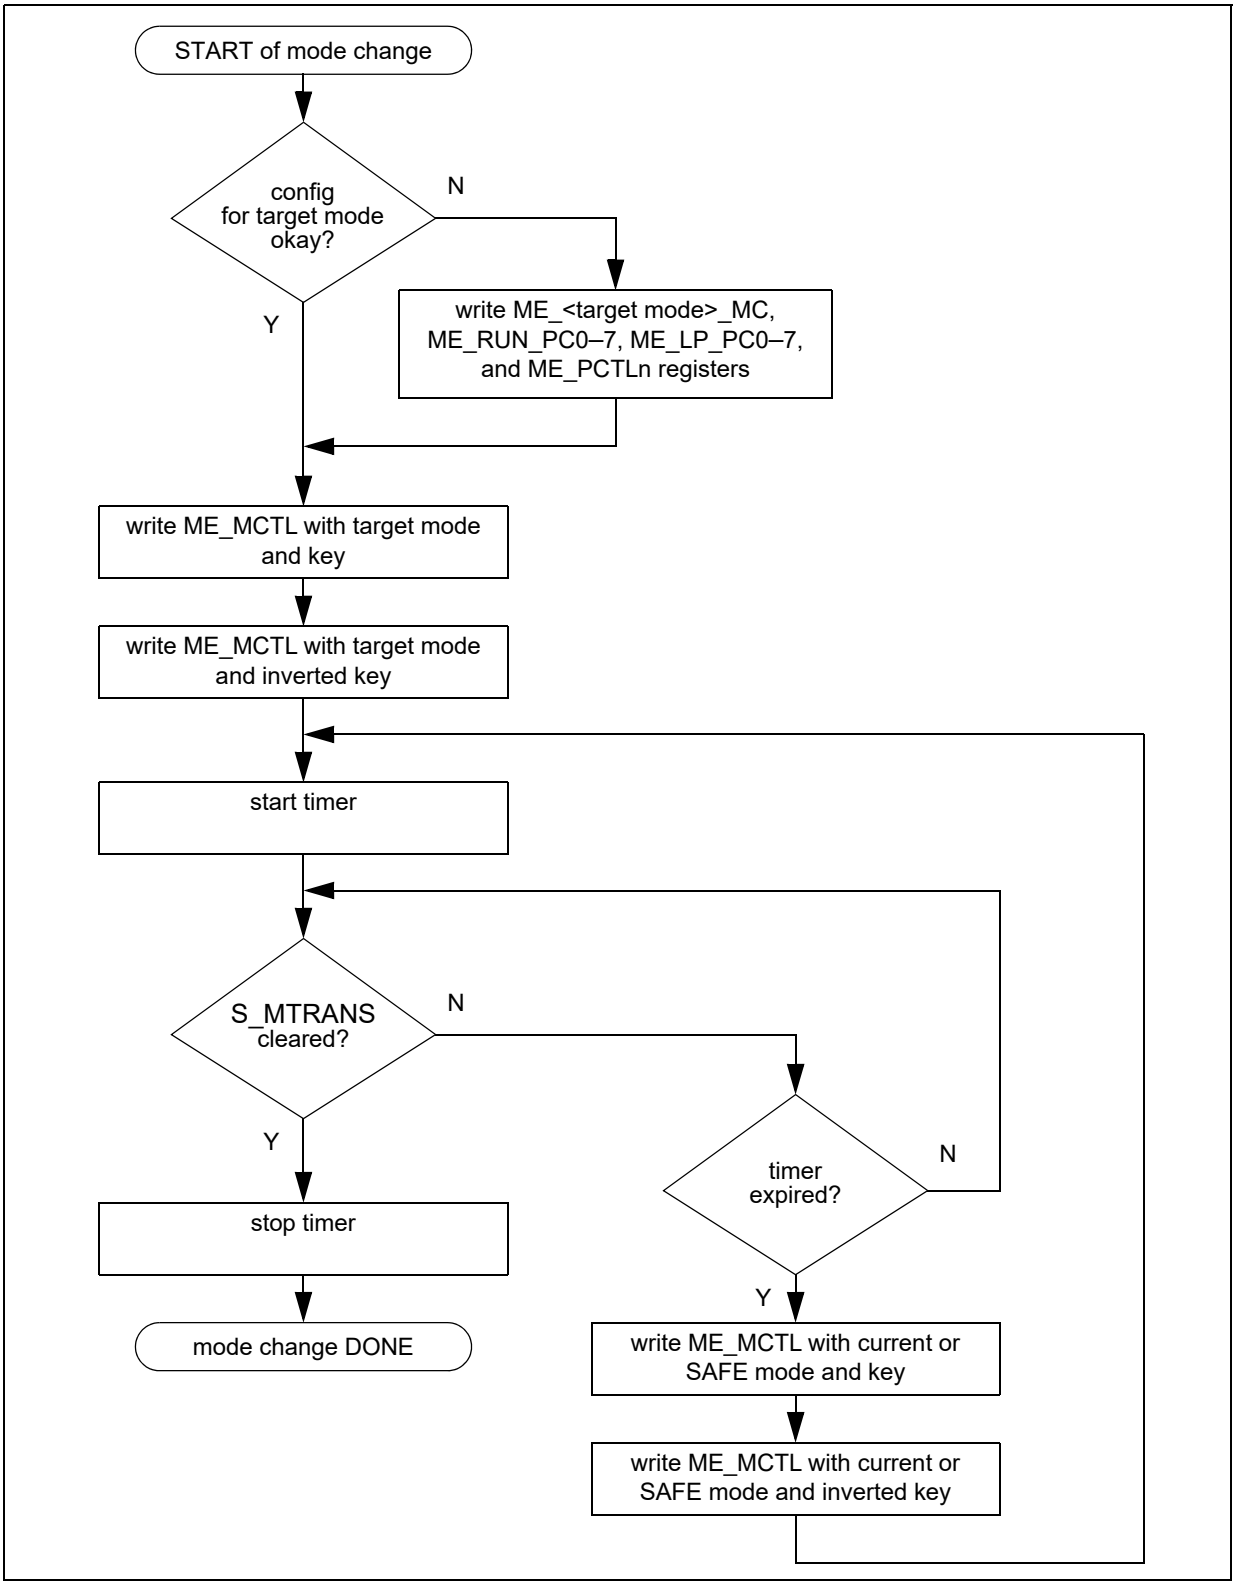
64.4.6 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0–7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0–3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTLn registers.

The low-power peripheral configuration registers ME_LP_PC0–7 are chosen only during the low-power modes HALT0, STOP0, and STANDBY0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTLn registers.

Any modifications to the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.



Whenever the processor enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTLn register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits. Any further modifications of the ME_RUN_PC0–7, ME_LP_PC0–7, and ME_PCTLn registers during a debug session will take effect immediately without requiring any new mode request.

64.4.7 Application Example

Figure 2086 shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

Figure 2086. MC_ME Application Example Flow Diagram

65 e200z4256 Core Debug Support

This chapter describes the debug features of the e200z4256 core.

65.1 Overview

Internal debug support in the e200z4256 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z4256 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z4256 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

65.1.1 Software debug facilities

e200z4256 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

65.1.1.1 *PowerISA 2.06* compatibility

The e200z4256 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

65.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z4256 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger (Refer to *Section 65.1.4, Sharing debug resources by software/hardware*). A data trace port is also provided.

65.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z4256 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (that is the normal setting). Refer to the “Data Trace Control Register (DTC)” section in the Core (e200z420n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

65.1.3 Hardware debug facilities

The e200z4256 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z4256 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

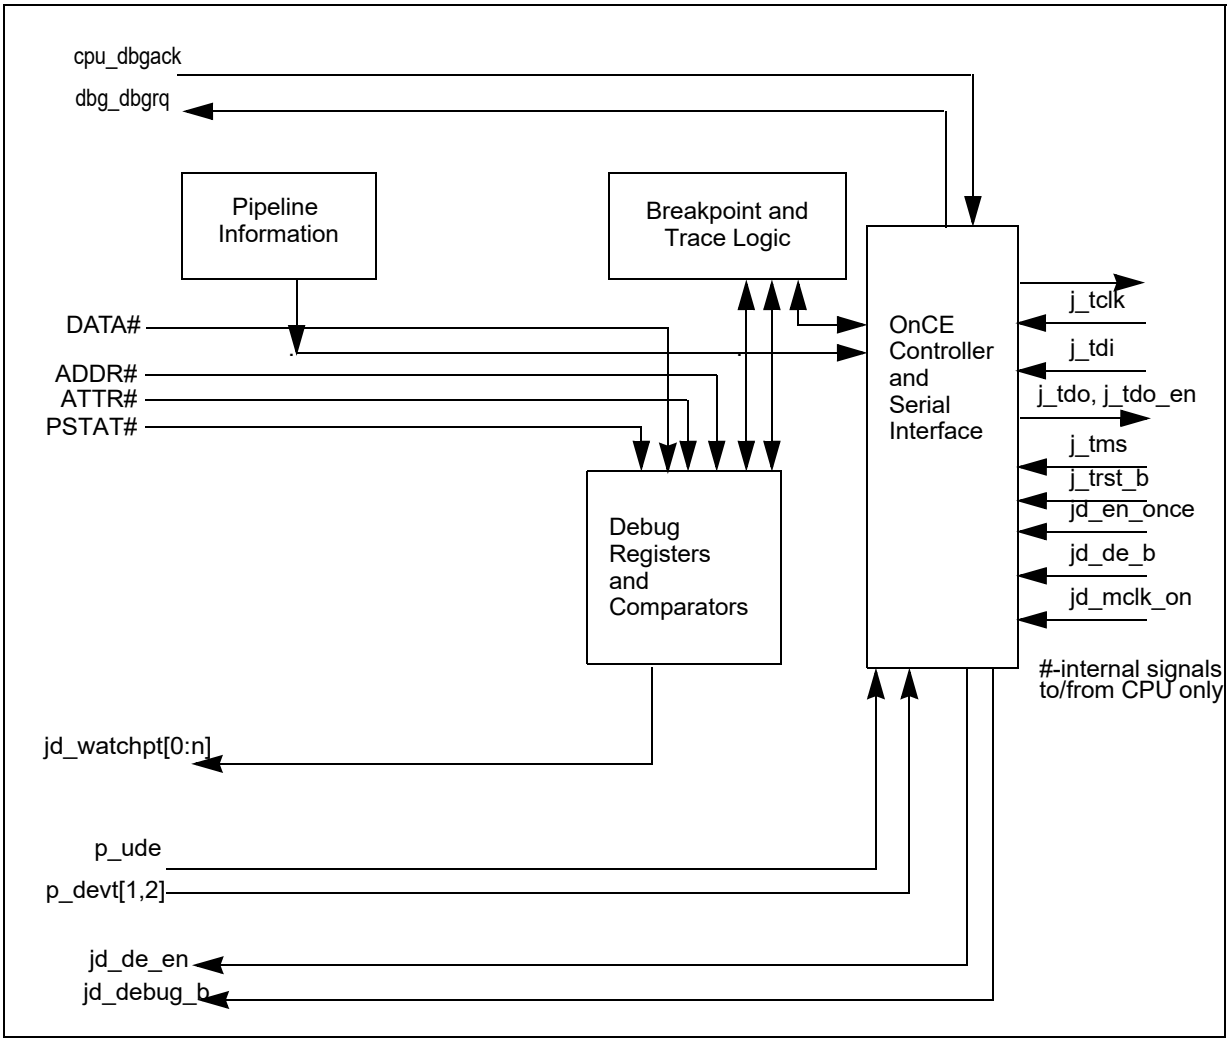
Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in *Section 65.3, Debug registers* are reserved for use by the external debugger. The same events described in *Section 65.2, Software debug events and exceptions* are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via

EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

65.1.4 Sharing debug resources by software/hardware



Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

65.1.4.1 Simultaneous hardware and software debug event handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 2087 shows the e200z4256 debug resources.

Figure 2087. e200z4256 debug resources

65.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z4256 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in *Section 65.2.11, External debug event*.
- The Performance Monitor Interrupt event PMI, which is described in *Section 65.2.13, Performance Monitor Interrupt debug event*.

The e200z4256 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported.

A brief description of each of the event types follows.

65.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

65.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z4256 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, that is no data comparisons are performed since these instructions do not have associated data values.

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.*

65.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 2044 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in *Table 2044*, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 2044. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.

Table 2044. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
