Reference manual

STM32H7A3/7B3 and STM32H7B0 Value line advanced Arm®-based 32-bit MCUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H7A3/7B3 and STM32H7B0 microcontroller memory and peripherals.

The STM32H7A3/7B3 and STM32H7B0 are microcontrollers with different memory sizes, packages and peripherals.

The devices include ST state-of-the-art patented technology.

For ordering information, mechanical and electrical device characteristics please refer to the corresponding datasheets.

For information on the Arm® Cortex®-M7 with FPU cores, please refer to the corresponding Arm *Technical Reference Manuals*.

Contents

1 Documentation conventions 98

1.1 General information 98

1.2 List of abbreviations for registers 98

1.3 Register reset value 99

1.4 Glossary 99

1.5 Availability of peripherals 99

1.6 Availability of security features 99

2 Memory and bus architecture 101

2.1 System architecture 101

2.1.1 Bus matrices 104

2.1.2 TCM buses 104

2.1.3 Bus-to-bus bridges 104

2.1.4 Domain and inter-domain buses 105

2.1.5 CPU buses 105

2.1.6 Bus master peripherals 106

2.1.7 Clocks to functional blocks 107

2.2 AXI interconnect matrix (AXIM) 107

2.2.1 AXI introduction 107

2.2.2 AXI interconnect main features 107

2.2.3 AXI interconnect functional description 108

2.2.4 AXI interconnect registers 110

2.2.5 AXI interconnect register map 119

2.3 Memory organization 130

2.3.1 Introduction 130

2.3.2 Memory map and register boundary addresses 131

2.4 Embedded SRAM 137

2.5 Flash memory overview 138

2.6 Boot configuration 138

3 RAM ECC monitoring (RAMECC) 140

3.1 RAMECC introduction 140

3.2 RAMECC main features 140

3.3 RAMECC functional description 140
3.3.1 RAMECC block diagram 140
3.3.2 RAMECC internal signals 142
3.3.3 RAMECC monitor mapping 142
3.4 RAMECC registers 143
3.4.1 RAMECC interrupt enable register (RAMECC_IER) 143
3.4.2 RAMECC monitor x configuration register (RAMECC_MxCR) 144
3.4.3 RAMECC monitor x status register (RAMECC_MxSR) 144
3.4.4 RAMECC monitor x failing address register (RAMECC_MxFAR) 145
3.4.5 RAMECC monitor x failing data low register (RAMECC_MxFDRL) . . 145
3.4.6 RAMECC monitor x failing data high register (RAMECC_MxFDRH) . 146
3.4.7 RAMECC monitor x failing ECC error code register RAMECC_MxFECR) 146
3.4.8 RAMECC register map 147

4 Embedded flash memory (FLASH) 148
4.1 Introduction 148
4.2 FLASH main features 148
4.3 FLASH functional description 149
4.3.1 FLASH block diagram 149
4.3.2 FLASH internal signals 150
4.3.3 FLASH architecture and integration in the system 150
4.3.4 Flash memory architecture and usage 152
4.3.5 FLASH system performance enhancements 157
4.3.6 FLASH data protection schemes 157
4.3.7 Overview of FLASH operations 158
4.3.8 FLASH read operations 159
4.3.9 FLASH program operations 163
4.3.10 FLASH erase operations 167
4.3.11 FLASH parallel operations 170
4.3.12 Flash memory error protections 170
4.3.13 FLASH one-time programmable area 172
4.3.14 FLASH read-only area 173
4.3.15 Flash bank and register swapping (STM32H7A3/7B3 only) 174
4.3.16 FLASH reset and clocks 178
4.4 FLASH option bytes 178
4.4.1 About option bytes 178

4.4.2 Option byte loading . . . 179
4.4.3 Option byte modification . . . 179
4.4.4 Option bytes overview . . . 181
4.4.5 Description of user and system option bytes . . . 185
4.4.6 Description of data protection option bytes . . . 186
4.4.7 Description of boot address option bytes . . . 187
4.5 FLASH protection mechanisms . . . 187
4.5.1 FLASH configuration protection . . . 187
4.5.2 Write protection . . . 189
4.5.3 Readout protection (RDP) . . . 190
4.5.4 Proprietary code readout protection (PCROP) . . . 194
4.5.5 Secure access mode (STM32H7B0 and STM32H7B3 only) . . . 195
4.6 FLASH low-power modes . . . 197
4.6.1 Introduction . . . 197
4.6.2 Managing the FLASH domain switching to DStop or Standby . . . 197
4.7 FLASH error management . . . 198
4.7.1 Introduction . . . 198
4.7.2 Write protection error (WRPERR) . . . 198
4.7.3 Programming sequence error (PGSERR) . . . 199
4.7.4 Strobe error (STRBERR) . . . 200
4.7.5 Inconsistency error (INCERR) . . . 200
4.7.6 Error correction code error (SNECCERR/DBECCERR) . . . 201
4.7.7 Read protection error (RDPERR) . . . 201
4.7.8 Read secure error (RDSERR) . . . 202
4.7.9 CRC read error (CRCRDERR) . . . 202
4.7.10 Option byte change error (OPTCHANGEERR) . . . 203
4.7.11 Miscellaneous HardFault errors . . . 203
4.8 FLASH interrupts . . . 203
4.9 FLASH registers . . . 206
4.9.1 FLASH access control register (FLASH_ACR) . . . 206
4.9.2 FLASH key register for bank 1 (FLASH_KEYR1) . . . 206
4.9.3 FLASH option key register (FLASH_OPTKEYR) . . . 207
4.9.4 FLASH control register for bank 1 (FLASH_CR1) . . . 207
4.9.5 FLASH status register for bank 1 (FLASH_SR1) . . . 211
4.9.6 FLASH clear control register for bank 1 (FLASH_CCR1) . . . 214
4.9.7 FLASH option control register (FLASH_OPTCR) . . . 215

4.9.8 FLASH option status register (FLASH_OPTSR_CUR) 216
4.9.9 FLASH option status register (FLASH_OPTSR_PRG) 219
4.9.10 FLASH option clear control register (FLASH_OPTCCR) 221
4.9.11 FLASH protection address for bank 1 (FLASH_PRAR_CUR1) 222
4.9.12 FLASH protection address for bank 1 (FLASH_PRAR_PRG1) 222
4.9.13 FLASH secure address for bank 1 (FLASH_SCAR_CUR1) 223
4.9.14 FLASH secure address for bank 1 (FLASH_SCAR_PRG1) 224
4.9.15 FLASH write sector group protection for bank 1 (FLASH_WPSGN_CUR1R) 224
4.9.16 FLASH write sector group protection for bank 1 (FLASH_WPSGN_PRG1R) 225
4.9.17 FLASH register boot address (FLASH_BOOT_CURR) 226
4.9.18 FLASH register boot address FLASH_BOOT_PRGR) 226
4.9.19 FLASH CRC control register for bank 1 (FLASH_CRCCR1) 227
4.9.20 FLASH CRC start address register for bank 1 (FLASH_CRCSADD1R) 228
4.9.21 FLASH CRC end address register for bank 1 (FLASH_CRCEADD1R) 229
4.9.22 FLASH CRC data register (FLASH_CRCDATAR) 229
4.9.23 FLASH ECC fail address for bank 1 (FLASH_ECC_FA1R) 230
4.9.24 FLASH OTP block lock (FLASH_OTPBL_CUR) 230
4.9.25 FLASH OTP block lock (FLASH_OTPBL_PRG) 231
4.9.26 FLASH key register for bank 2 (FLASH_KEYR2) 231
4.9.27 FLASH control register for bank 2 (FLASH_CR2) 232
4.9.28 FLASH status register for bank 2 (FLASH_SR2) 236
4.9.29 FLASH clear control register for bank 2 (FLASH_CCR2) 239
4.9.30 FLASH protection address for bank 2 (FLASH_PRAR_CUR2) 240
4.9.31 FLASH protection address for bank 2 (FLASH_PRAR_PRG2) 240
4.9.32 FLASH secure address for bank 2 (FLASH_SCAR_CUR2) 241
4.9.33 FLASH secure address for bank 2 (FLASH_SCAR_PRG2) 242
4.9.34 FLASH write sector group protection for bank 2 (FLASH_WPSGN_CUR2R) 243
4.9.35 FLASH write sector group protection for bank 2 (FLASH_WPSGN_PRG2R) 243
4.9.36 FLASH CRC control register for bank 2 (FLASH_CRCCR2) 244
4.9.37 FLASH CRC start address register for bank 2 (FLASH_CRCSADD2R) 245
4.9.38 FLASH CRC end address register for bank 2 (FLASH_CRCEADD2R) 246

4.9.39 FLASH ECC fail address for bank 2 (FLASH_ECC_FA2R) 246
4.9.40 FLASH register map and reset values 247

5 Secure memory management (SMM) 253
5.1 SMM introduction 253
5.2 Glossary 253
5.3 Secure access mode 254
5.3.1 Associated features 255
5.3.2 Boot state machine 255
5.3.3 Secure access mode configuration 256
5.4 Root secure services (RSS) 257
5.4.1 Secure area setting service 257
5.4.2 Secure area exiting service 258
5.4.3 OTFDEC encryption service 258
5.5 Secure user software 258
5.5.1 Access rules 258
5.5.2 Setting secure user memory areas 259
5.6 Summary of flash protection mechanisms 260

6 Power control (PWR) 261
6.1 Introduction 261
6.2 PWR main features 261
6.3 PWR block diagram 262
6.4 Power supplies 264
6.4.1 System supply startup 270
6.4.2 Core domain 274
6.4.3 Voltage regulators 274
6.4.4 PWR external supply 276
6.4.5 Backup domain 276
6.4.6 VBAT battery charging 278
6.4.7 Analog supply 278
6.4.8 USB regulator 279
6.5 Power supply supervision 280
6.5.1 Power-on reset (POR)/power-down reset (PDR) 280
6.5.2 Brownout reset (BOR) 281
6.5.3 Programmable voltage detector (PVD) 282

6.5.4 Analog voltage detector (AVD) . . . 283
6.5.5 Battery voltage thresholds . . . 284
6.5.6 Temperature thresholds . . . 285
6.5.7 V_{CORE} maximum voltage level detector . . . 285
6.6 Power management . . . 286
6.6.1 System operating modes . . . 288
6.6.2 Voltage scaling . . . 291
6.6.3 Power control modes . . . 292
6.6.4 Power management examples . . . 294
6.7 Low-power modes . . . 302
6.7.1 Slowing down system clocks . . . 302
6.7.2 Controlling peripheral clocks . . . 302
6.7.3 Entering low-power modes . . . 302
6.7.4 Exiting from low-power modes . . . 303
6.7.5 System Run and CSleep modes . . . 304
6.7.6 System Autonomous mode . . . 304
6.7.7 Stop mode . . . 306
6.7.8 Standby mode . . . 309
6.7.9 Monitoring low-power modes . . . 311
6.8 PWR registers . . . 312
6.8.1 PWR control register 1 (PWR_CR1) . . . 312
6.8.2 PWR control status register 1 (PWR_CSR1) . . . 314
6.8.3 PWR control register 2 (PWR_CR2) . . . 316
6.8.4 PWR control register 3 (PWR_CR3) . . . 317
6.8.5 PWR CPU control register (PWR_CPUCR) . . . 319
6.8.6 PWR SmartRun domain control register (PWR_SRDCR) . . . 320
6.8.7 PWR wake-up clear register (PWR_WKUPCR) . . . 321
6.8.8 PWR wake-up flag register (PWR_WKUPFR) . . . 321
6.8.9 PWR wake-up enable and polarity register (PWR_WKUPEPR) . . . 322
6.8.10 PWR register map . . . 323

7 Low-power SRD domain application example . . . 324
7.1 Introduction . . . 324
7.2 EXTI, RCC and PWR interconnections . . . 324
7.2.1 Interrupts and wake-up . . . 326
7.2.2 Block interactions . . . 326
7.2.3 Role of DMAMUX2 in SRD domain . . . 327

7.3 Low-power application example based on LPUART1 transmission . . . 328
7.3.1 Memory retention . . . 328
7.3.2 Memory-to-peripheral transfer using LPUART1 interface . . . 328
7.3.3 Overall description of the low-power application example based on LPUART1 transmission . . . 333
7.3.4 Alternate implementations . . . 334
7.4 Other low-power applications . . . 335

8 Reset and clock control (RCC) . . . 336
8.1 RCC main features . . . 336
8.2 RCC block diagram . . . 337
8.3 RCC pins and internal signals . . . 337
8.4 RCC reset block functional description . . . 339
8.4.1 Power-on/off reset . . . 339
8.4.2 System reset . . . 340
8.4.3 Local resets . . . 341
8.4.4 Reset source identification . . . 341
8.4.5 Low-power mode security reset (lpwr_rst) . . . 342
8.4.6 Backup domain reset . . . 343
8.4.7 Power-on and wake-up sequences . . . 343
8.5 RCC clock block functional description . . . 346
8.5.1 Clock naming convention . . . 348
8.5.2 Oscillators description . . . 348
8.5.3 Clock security system (CSS) . . . 354
8.5.4 Clock output generation (MCO1/MCO2) . . . 355
8.5.5 PLL description . . . 355
8.5.6 System clock (**sys_ck**) . . . 360
8.5.7 Handling clock generators in Stop and Standby modes . . . 362
8.5.8 Kernel clock selection . . . 363
8.5.9 General clock concept overview . . . 375
8.5.10 Peripheral allocation . . . 379
8.5.11 Peripheral clock gating control . . . 380
8.5.12 CPU and bus matrix clock gating control . . . 385
8.6 RCC interrupts . . . 386
8.7 RCC registers . . . 387
8.7.1 RCC source control register (RCC_CR) . . . 387

8.7.2 RCC HSI calibration register (RCC_HSICFGR) 391
8.7.3 RCC clock recovery RC register (RCC_CRRCR) 391
8.7.4 RCC CSI calibration register (RCC_CSICFGR) 392
8.7.5 RCC clock configuration register (RCC_CFGR) 393
8.7.6 RCC CPU domain clock configuration register 1 (RCC_CDCFGR1) . 395
8.7.7 RCC CPU domain clock configuration register 2 (RCC_CDCFGR2) . 397
8.7.8 RCC SmartRun domain clock configuration register (RCC_SRDCFGR) 397
8.7.9 RCC PLLs clock source selection register (RCC_PLLCKSELR) 398
8.7.10 RCC PLLs configuration register (RCC_PLLCFGR) 400
8.7.11 RCC PLL1 dividers configuration register (RCC_PLL1DIVR) 402
8.7.12 RCC PLL1 fractional divider register (RCC_PLL1FRACR) 404
8.7.13 RCC PLL2 dividers configuration register (RCC_PLL2DIVR) 404
8.7.14 RCC PLL2 fractional divider register (RCC_PLL2FRACR) 406
8.7.15 RCC PLL3 dividers configuration register (RCC_PLL3DIVR) 406
8.7.16 RCC PLL3 fractional divider register (RCC_PLL3FRACR) 408
8.7.17 RCC CPU domain kernel clock configuration register (RCC_CDCCIPR) 408
8.7.18 RCC CPU domain kernel clock configuration register (RCC_CDCCIP1R) 409
8.7.19 RCC CPU domain kernel clock configuration register (RCC_CDCCIP2R) 412
8.7.20 RCC SmartRun domain kernel clock configuration register (RCC_SRDCCIPR) 414
8.7.21 RCC clock source interrupt enable register (RCC_CIER) 416
8.7.22 RCC clock source interrupt flag register (RCC_CIFR) 417
8.7.23 RCC clock source interrupt clear register (RCC_CICR) 419
8.7.24 RCC Backup domain control register (RCC_BDCR) 421
8.7.25 RCC clock control and status register (RCC_CSR) 423
8.7.26 RCC AHB3 reset register (RCC_AHB3RSTR) 423
8.7.27 RCC AHB1 peripheral reset register (RCC_AHB1RSTR) 425
8.7.28 RCC AHB2 peripheral reset register (RCC_AHB2RSTR) 426
8.7.29 RCC AHB4 peripheral reset register (RCC_AHB4RSTR) 427
8.7.30 RCC APB3 peripheral reset register (RCC_APB3RSTR) 429
8.7.31 RCC APB1 peripheral reset register (RCC_APB1LRSTR) 429
8.7.32 RCC APB1 peripheral reset register (RCC_APB1HRSTR) 432
8.7.33 RCC APB2 peripheral reset register (RCC_APB2RSTR) 433
8.7.34 RCC APB4 peripheral reset register (RCC_APB4RSTR) 435

8.7.35 RCC SmartRun domain Autonomous mode register (RCC_SRDAMR) . . . 437
8.7.36 RCC AXI clocks gating enable register (RCC_CKGAENR) . . . 440
8.7.37 RCC reset status register (RCC_RSR) . . . 443
8.7.38 RCC AHB3 clock register (RCC_AHB3ENR) . . . 445
8.7.39 RCC AHB1 clock register (RCC_AHB1ENR) . . . 446
8.7.40 RCC AHB2 clock register (RCC_AHB2ENR) . . . 448
8.7.41 RCC AHB4 Clock Register (RCC_AHB4ENR) . . . 449
8.7.42 RCC APB3 clock register (RCC_APB3ENR) . . . 451
8.7.43 RCC APB1 clock register (RCC_APB1LENR) . . . 452
8.7.44 RCC APB1 clock register (RCC_APB1HENR) . . . 455
8.7.45 RCC APB2 clock register (RCC_APB2ENR) . . . 456
8.7.46 RCC APB4 clock register (RCC_APB4ENR) . . . 458
8.7.47 RCC AHB3 sleep clock register (RCC_AHB3LPENR) . . . 460
8.7.48 RCC AHB1 sleep clock register (RCC_AHB1LPENR) . . . 463
8.7.49 RCC AHB2 sleep clock register (RCC_AHB2LPENR) . . . 464
8.7.50 RCC AHB4 sleep clock register (RCC_AHB4LPENR) . . . 465
8.7.51 RCC APB3 sleep clock register (RCC_APB3LPENR) . . . 467
8.7.52 RCC APB1 low-sleep clock register (RCC_APB1LLPENR) . . . 468
8.7.53 RCC APB1 high-sleep clock register (RCC_APB1HLPENR) . . . 471
8.7.54 RCC APB2 sleep clock register (RCC_APB2LPENR) . . . 472
8.7.55 RCC APB4 sleep clock register (RCC_APB4LPENR) . . . 474
8.8 RCC register map . . . 476

9 Clock recovery system (CRS) . . . 483
9.1 CRS introduction . . . 483
9.2 CRS main features . . . 483
9.3 CRS implementation . . . 483
9.4 CRS functional description . . . 484
9.4.1 CRS block diagram . . . 484
9.4.2 CRS internal signals . . . 484
9.4.3 Synchronization input . . . 485
9.4.4 Frequency error measurement . . . 485
9.4.5 Frequency error evaluation and automatic trimming . . . 486
9.4.6 CRS initialization and configuration . . . 487
9.5 CRS in low-power modes . . . 488
9.6 CRS interrupts . . . 488

9.7 CRS registers 488
9.7.1 CRS control register (CRS_CR) 488
9.7.2 CRS configuration register (CRS_CFGR) 490
9.7.3 CRS interrupt and status register (CRS_ISR) 491
9.7.4 CRS interrupt flag clear register (CRS_ICR) 493
9.7.5 CRS register map 493

10 Hardware semaphore (HSEM) 495
10.1 HSEM introduction 495
10.2 HSEM main features 495
10.3 Functional description 496
10.3.1 HSEM block diagram 496
10.3.2 HSEM internal signals 496
10.3.3 HSEM lock procedures 496
10.3.4 HSEM write/read/read lock register address 498
10.3.5 HSEM unlock procedures 498
10.3.6 HSEM MASTERID semaphore clear 499
10.3.7 HSEM interrupts 499
10.3.8 AHB bus master ID verification 501
10.4 HSEM registers 502
10.4.1 HSEM register semaphore x (HSEM_Rx) 502
10.4.2 HSEM read lock register semaphore x (HSEM_RLRx) 503
10.4.3 HSEM interrupt enable register (HSEM_IER) 504
10.4.4 HSEM interrupt clear register (HSEM_ICR) 504
10.4.5 HSEM interrupt status register (HSEM_ISR) 504
10.4.6 HSEM interrupt status register (HSEM_MISR) 505
10.4.7 HSEM clear register (HSEM_CR) 505
10.4.8 HSEM clear semaphore key register (HSEM_KEYR) 506
10.4.9 HSEM register map 507

11 General-purpose I/Os (GPIO) 508
11.1 Introduction 508
11.2 GPIO main features 508
11.3 GPIO functional description 508
11.3.1 General-purpose I/O (GPIO) 511
11.3.2 I/O pin alternate function multiplexer and mapping 511

11.3.3 I/O port control registers . . . 512
11.3.4 I/O port data registers . . . 512
11.3.5 I/O data bitwise handling . . . 512
11.3.6 GPIO locking mechanism . . . 513
11.3.7 I/O alternate function input/output . . . 513
11.3.8 External interrupt/wake-up lines . . . 513
11.3.9 Input configuration . . . 514
11.3.10 Output configuration . . . 514
11.3.11 I/O compensation cell . . . 515
11.3.12 Alternate function configuration . . . 515
11.3.13 Analog configuration . . . 516
11.3.14 Using the HSE or LSE oscillator pins as GPIOs . . . 517
11.3.15 Using the GPIO pins in the backup supply domain . . . 517
11.4 GPIO registers . . . 518
11.4.1 GPIO port mode register (GPIOx_MODER) (x = A to K) . . . 518
11.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to K) . . . 518
11.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to K) . . . 519
11.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to K) . . . 519
11.4.5 GPIO port input data register (GPIOx_IDR) (x = A to K) . . . 520
11.4.6 GPIO port output data register (GPIOx_ODR) (x = A to K) . . . 520
11.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to K) . . . 521
11.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to K) . . . 521
11.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to K) . . . 522
11.4.10 GPIO alternate function high register (GPIOx_AFRH) (x = A to J) . . . 523
11.4.11 GPIO register map . . . 525

12 System configuration controller (SYSCFG) . . . 527
12.1 Introduction . . . 527
12.2 SYSCFG main features . . . 527
12.3 SYSCFG functional description . . . 527

12.3.1 Analog switch configuration management 527
12.3.2 I2C Fm+ configuration 527
12.3.3 Timer break input lockup management 528
12.3.4 Management of external interrupt line connections to GPIOs 528
12.3.5 I/O speed in low-voltage mode 528
12.3.6 I/O compensation cell management 528
12.4 SYSCFG registers 529
12.4.1 SYSCFG peripheral mode configuration register (SYSCFG_PMCR) . 529
12.4.2 SYSCFG external interrupt configuration register 1 (SYSCFG_EXTICR1) 531
12.4.3 SYSCFG external interrupt configuration register 2 (SYSCFG_EXTICR2) 532
12.4.4 SYSCFG external interrupt configuration register 3 (SYSCFG_EXTICR3) 533
12.4.5 SYSCFG external interrupt configuration register 4 (SYSCFG_EXTICR4) 534
12.4.6 SYSCFG timer break lockup register (SYSCFG_CFGR) 534
12.4.7 SYSCFG compensation cell control/status register (SYSCFG_CCCSR) 536
12.4.8 SYSCFG compensation cell value register (SYSCFG_CCVR) 537
12.4.9 SYSCFG compensation cell code register (SYSCFG_CCCR) 538
12.4.10 SYSCFG register maps 539

13 Block interconnect 540
13.1 Peripheral interconnect 540
13.1.1 Introduction 540
13.1.2 Connection overview 540
13.2 Wakeup from low-power modes 553
13.3 DMA 558
13.3.1 MDMA (CD domain) 559
13.3.2 DMAMUX1, DMA1, DMA2 and BDMA1 (CD domain) 561
13.3.3 DMAMUX2, BDMA2 (SRD domain) 566

14 MDMA controller (MDMA) 569
14.1 MDMA introduction 569
14.2 MDMA main features 569
14.3 MDMA functional description 571

14.3.1 MDMA block diagram . . . 571
14.3.2 MDMA internal signals . . . 571
14.3.3 MDMA overview . . . 571
14.3.4 MDMA channel . . . 573
14.3.5 Source, destination and transfer modes . . . 573
14.3.6 Pointer update . . . 573
14.3.7 MDMA buffer transfer . . . 574
14.3.8 Request arbitration . . . 575
14.3.9 FIFO . . . 575
14.3.10 Block transfer . . . 575
14.3.11 Block repeat mode . . . 576
14.3.12 Linked-list mode . . . 576
14.3.13 MDMA transfer completion . . . 576
14.3.14 MDMA transfer suspension . . . 576
14.3.15 Error management . . . 577
14.4 MDMA interrupts . . . 577
14.5 MDMA registers . . . 578
14.5.1 MDMA global interrupt status register (MDMA_GISR0) . . . 578
14.5.2 MDMA channel x interrupt status register (MDMA_CxISR) . . . 578
14.5.3 MDMA channel x interrupt flag clear register (MDMA_CxIFCR) . . . 580
14.5.4 MDMA channel x error status register (MDMA_CxESR) . . . 580
14.5.5 MDMA channel x control register (MDMA_CxCR) . . . 581
14.5.6 MDMA channel x transfer configuration register (MDMA_CxTCR) . . . 583
14.5.7 MDMA channel x block number of data register (MDMA_CxBNDTR) . 587
14.5.8 MDMA channel x source address register (MDMA_CxSAR) . . . 588
14.5.9 MDMA channel x destination address register (MDMA_CxDAR) . . . 589
14.5.10 MDMA channel x block repeat address update register (MDMA_CxBRUR) . . . 589
14.5.11 MDMA channel x link address register (MDMA_CxLAR) . . . 590
14.5.12 MDMA channel x trigger and bus selection register (MDMA_CxTBR) . . . 591
14.5.13 MDMA channel x mask address register (MDMA_CxMAR) . . . 592
14.5.14 MDMA channel x mask data register (MDMA_CxMDR) . . . 592
14.5.15 MDMA register map . . . 593

15 Direct memory access controller (DMA) . . . 594

15.1 DMA introduction . . . 594

15.2 DMA main features 594
15.3 DMA functional description 596
15.3.1 DMA block diagram 596
15.3.2 DMA internal signals 596
15.3.3 DMA overview 596
15.3.4 DMA transactions 597
15.3.5 DMA request mapping 597
15.3.6 Arbiter 598
15.3.7 DMA streams 598
15.3.8 Source, destination and transfer modes 598
15.3.9 Pointer incrementation 602
15.3.10 Circular mode 603
15.3.11 Double-buffer mode 603
15.3.12 Programmable data width, packing/unpacking, endianness 604
15.3.13 Single and burst transfers 605
15.3.14 FIFO 606
15.3.15 DMA transfer completion 609
15.3.16 DMA transfer suspension 610
15.3.17 Flow controller 611
15.3.18 Summary of the possible DMA configurations 612
15.3.19 Stream configuration procedure 612
15.3.20 Error management 613
15.4 DMA interrupts 614
15.5 DMA registers 615
15.5.1 DMA low interrupt status register (DMA_LISR) 615
15.5.2 DMA high interrupt status register (DMA_HISR) 616
15.5.3 DMA low interrupt flag clear register (DMA_LIFCR) 616
15.5.4 DMA high interrupt flag clear register (DMA_HIFCR) 617
15.5.5 DMA stream x configuration register (DMA_SxCR) 618
15.5.6 DMA stream x number of data register (DMA_SxNDTR) 621
15.5.7 DMA stream x peripheral address register (DMA_SxPAR) 621
15.5.8 DMA stream x memory 0 address register (DMA_SxM0AR) 622
15.5.9 DMA stream x memory 1 address register (DMA_SxM1AR) 622
15.5.10 DMA stream x FIFO control register (DMA_SxFCR) 623
15.5.11 DMA register map 624

16 Basic direct memory access controller (BDMA) 628
16.1 Introduction 628
16.2 BDMA main features 628
16.3 BDMA implementation 629
16.3.1 BDMA1 and BDMA2 629
16.3.2 BDMA request mapping 629
16.4 BDMA functional description 630
16.4.1 BDMA block diagram 630
16.4.2 BDMA pins and internal signals 632
16.4.3 BDMA transfers 632
16.4.4 BDMA arbitration 633
16.4.5 BDMA channels 633
16.4.6 BDMA data width, alignment and endianness 638
16.4.7 BDMA error management 639
16.5 BDMA interrupts 640
16.6 BDMA registers 640
16.6.1 BDMA interrupt status register (BDMA_ISR) 640
16.6.2 BDMA interrupt flag clear register (BDMA_IFCR) 643
16.6.3 BDMA channel x configuration register (BDMA_CCRx) 644
16.6.4 BDMA channel x number of data to transfer register (BDMA_CNDTRx) 648
16.6.5 BDMA channel x peripheral address register (BDMA_CPARx) 648
16.6.6 BDMA channel x memory 0 address register (BDMA_CM0ARx) 649
16.6.7 BDMA channel x memory 1 address register (BDMA_CM1ARx) 650
16.6.8 BDMA register map 650

17 DMA request multiplexer (DMAMUX) 653
17.1 Introduction 653
17.2 DMAMUX main features 654
17.3 DMAMUX implementation 654
17.3.1 DMAMUX1 and DMAMUX2 instantiation 654
17.3.2 DMAMUX1 mapping 654
17.3.3 DMAMUX2 mapping 656
17.4 DMAMUX functional description 659
17.4.1 DMAMUX block diagram 659
17.4.2 DMAMUX signals 660

17.4.3 DMAMUX channels 660
17.4.4 DMAMUX request line multiplexer 660
17.4.5 DMAMUX request generator 663
17.5 DMAMUX interrupts 664
17.6 DMAMUX registers 665
17.6.1 DMAMUX1 request line multiplexer channel x configuration register (DMAMUX1_CxCR) 665
17.6.2 DMAMUX2 request line multiplexer channel x configuration register (DMAMUX2_CxCR) 666
17.6.3 DMAMUX1 request line multiplexer interrupt channel status register (DMAMUX1_CSR) 667
17.6.4 DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2_CSR) 667
17.6.5 DMAMUX1 request line multiplexer interrupt clear flag register (DMAMUX1_CFR) 668
17.6.6 DMAMUX2 request line multiplexer interrupt clear flag register (DMAMUX2_CFR) 668
17.6.7 DMAMUX1 request generator channel x configuration register (DMAMUX1_RGxCR) 669
17.6.8 DMAMUX2 request generator channel x configuration register (DMAMUX2_RGxCR) 669
17.6.9 DMAMUX1 request generator interrupt status register (DMAMUX1_RGSR) 671
17.6.10 DMAMUX2 request generator interrupt status register (DMAMUX2_RGSR) 671
17.6.11 DMAMUX1 request generator interrupt clear flag register (DMAMUX1_RGCFR) 672
17.6.12 DMAMUX2 request generator interrupt clear flag register (DMAMUX2_RGCFR) 672
17.6.13 DMAMUX register map 673

18 Chrom-ART Accelerator controller (DMA2D) 677
18.1 DMA2D introduction 677
18.2 DMA2D main features 677
18.3 DMA2D functional description 678
18.3.1 General description 678
18.3.2 DMA2D internal signals 679
18.3.3 DMA2D control 679
18.3.4 DMA2D foreground and background FIFOs 680
18.3.5 DMA2D foreground and background PFC 680

18.3.6 DMA2D foreground and background CLUT interface 682
18.3.7 DMA2D blender 683
18.3.8 DMA2D output PFC 683
18.3.9 DMA2D output FIFO 684
18.3.10 DMA2D output FIFO byte reordering 685
18.3.11 DMA2D AXI master port timer 686
18.3.12 DMA2D transactions 686
18.3.13 DMA2D configuration 687
18.3.14 YCbCr support 691
18.3.15 DMA2D transfer control (start, suspend, abort, and completion) 691
18.3.16 Watermark 691
18.3.17 Error management 691
18.3.18 AXI dead time 692
18.4 DMA2D interrupts 692
18.5 DMA2D registers 693
18.5.1 DMA2D control register (DMA2D_CR) 693
18.5.2 DMA2D interrupt status register (DMA2D_ISR) 694
18.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR) 695
18.5.4 DMA2D foreground memory address register (DMA2D_FGMAR) . . . 696
18.5.5 DMA2D foreground offset register (DMA2D_FGOR) 696
18.5.6 DMA2D background memory address register (DMA2D_BGMAR) . . 697
18.5.7 DMA2D background offset register (DMA2D_BGOR) 697
18.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR) 698
18.5.9 DMA2D foreground color register (DMA2D_FGCOLR) 699
18.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR) 700
18.5.11 DMA2D background color register (DMA2D_BGCOLR) 701
18.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR) 702
18.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR) 702
18.5.14 DMA2D output PFC control register (DMA2D_OPFCCR) 703
18.5.15 DMA2D output color register (DMA2D_OCOLR) 704
18.5.16 DMA2D output color register [alternate] (DMA2D_OCOLR) 704
18.5.17 DMA2D output color register [alternate] (DMA2D_OCOLR) 705
18.5.18 DMA2D output color register [alternate] (DMA2D_OCOLR) 705
18.5.19 DMA2D output memory address register (DMA2D_OMAR) 706
18.5.20 DMA2D output offset register (DMA2D_OOR) 706

18.5.21 DMA2D number of line register (DMA2D_NLR) 707
18.5.22 DMA2D line watermark register (DMA2D_LWR) 707
18.5.23 DMA2D AXI master timer configuration register (DMA2D_AMTCR) . . 708
18.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx) 708
18.5.25 DMA2D background CLUT (DMA2D_BGCLUTx) 709
18.5.26 DMA2D register map 709

19 Nested vectored interrupt controller (NVIC) 711

19.1 NVIC features 711
19.1.1 SysTick calibration value register 711
19.1.2 Interrupt and exception vectors 711

20 Extended interrupt and event controller (EXTI) 720

20.1 EXTI main features 720
20.2 EXTI block diagram 721
20.2.1 EXTI connections between peripherals, CPU and SRD domain 721
20.3 EXTI functional description 722
20.3.1 EXTI configurable event input CPU wakeup 723
20.3.2 EXTI configurable event input Any wakeup 724
20.3.3 EXTI direct event input CPU wakeup 726
20.3.4 EXTI direct event input Any wakeup 727
20.3.5 EXTI SRD pending request clear selection 728
20.4 EXTI event input mapping 728
20.5 EXTI functional behavior 731
20.5.1 EXTI CPU interrupt procedure 732
20.5.2 EXTI CPU event procedure 732
20.5.3 EXTI CPU wakeup procedure 733
20.5.4 EXTI SRD domain wakeup for Autonomous run mode procedure . . . 733
20.5.5 EXTI software interrupt/event trigger procedure 733
20.6 EXTI registers 734
20.6.1 EXTI rising trigger selection register (EXTI_RTSR1) 734
20.6.2 EXTI falling trigger selection register (EXTI_FTSR1) 734
20.6.3 EXTI software interrupt event register (EXTI_SWIER1) 735
20.6.4 EXTI SRD pending mask register (EXTI_SRDPMR1) 735
20.6.5 EXTI SRD pending clear selection register low (EXTI_SRDPCR1L) . 736
20.6.6 EXTI SRD pending clear selection register high (EXTI_SRDPCR1H) 737

20.6.7 EXTI rising trigger selection register (EXTI_RTSR2) 737
20.6.8 EXTI falling trigger selection register (EXTI_FTSR2) 738
20.6.9 EXTI software interrupt event register (EXTI_SWIER2) 739
20.6.10 EXTI SRD pending mask register (EXTI_SRDPMR2) 740
20.6.11 EXTI SRD pending clear selection register low (EXTI_SRDPCR2L) . 740
20.6.12 EXTI SRD pending clear selection register high (EXTI_SRDPCR2H) 741
20.6.13 EXTI rising trigger selection register (EXTI_RTSR3) 742
20.6.14 EXTI falling trigger selection register (EXTI_FTSR3) 742
20.6.15 EXTI software interrupt event register (EXTI_SWIER3) 743
20.6.16 EXTI SRD pending mask register (EXTI_SRDPMR3) 744
20.6.17 EXTI SRD pending clear selection register high (EXTI_SRDPCR3H) 744
20.6.18 EXTI interrupt mask register (EXTI_CPUIMR1) 745
20.6.19 EXTI event mask register (EXTI_CPUEMR1) 745
20.6.20 EXTI pending register (EXTI_CPUPR1) 746
20.6.21 EXTI interrupt mask register (EXTI_CPUIMR2) 746
20.6.22 EXTI event mask register (EXTI_CPUEMR2) 747
20.6.23 EXTI pending register (EXTI_CPUPR2) 748
20.6.24 EXTI interrupt mask register (EXTI_CPUIMR3) 748
20.6.25 EXTI event mask register (EXTI_CPUEMR3) 750
20.6.26 EXTI pending register (EXTI_CPUPR3) 751
20.6.27 EXTI register map 751

21 Chrom-GRC (GFXMMU) 754

21.1 Introduction 754
21.2 GFXMMU main features 754
21.3 GFXMMU functional and architectural description 755
21.3.1 Virtual memory 755
21.3.2 MMU architecture 757
21.3.3 Cache and prefetch mechanism 760
21.4 GFXMMU interrupts 763
21.5 GFXMMU registers 764
21.5.1 GFXMMU configuration register (GFXMMU_CR) 764
21.5.2 GFXMMU status register (GFXMMU_SR) 765
21.5.3 GFXMMU flag clear register (GFXMMU_FCR) 766
21.5.4 GFXMMU cache control register (GFXMMU_CCR) 767
21.5.5 GFXMMU default value register (GFXMMU_DVR) 767
21.5.6 GFXMMU buffer 0 configuration register (GFXMMU_B0CR) 768

21.5.7 GFXMMU buffer 1 configuration register (GFXMMU_B1CR) 768
21.5.8 GFXMMU buffer 2 configuration register (GFXMMU_B2CR) 769
21.5.9 GFXMMU buffer 3 configuration register (GFXMMU_B3CR) 769
21.5.10 GFXMMU LUT entry x low (GFXMMU_LUTxL) 770
21.5.11 GFXMMU LUT entry x high (GFXMMU_LUTxH) 770
21.5.12 GFXMMU register map 771

22 Cyclic redundancy check calculation unit (CRC) 772
22.1 CRC introduction 772
22.2 CRC main features 772
22.3 CRC functional description 773
22.3.1 CRC block diagram 773
22.3.2 CRC internal signals 773
22.3.3 CRC operation 773
22.4 CRC registers 775
22.4.1 CRC data register (CRC_DR) 775
22.4.2 CRC independent data register (CRC_IDR) 775
22.4.3 CRC control register (CRC_CR) 776
22.4.4 CRC initial value (CRC_INIT) 777
22.4.5 CRC polynomial (CRC_POL) 777
22.4.6 CRC register map 778

23 Flexible memory controller (FMC) 779
23.1 FMC main features 779
23.2 FMC block diagram 780
23.3 FMC internal signals 782
23.4 AHB interface 782
23.5 AXI interface 782
23.5.1 Supported memories and transactions 783
23.6 External device address mapping 784
23.6.1 NOR/PSRAM address mapping 785
23.6.2 NAND flash memory address mapping 785
23.6.3 SDRAM address mapping 786
23.7 NOR flash/PSRAM controller 790
23.7.1 External memory interface signals 791
23.7.2 Supported memories and transactions 793

23.7.3 General timing rules . . . 794
23.7.4 NOR flash/PSRAM controller asynchronous transactions . . . 795
23.7.5 Synchronous transactions . . . 814
23.7.6 NOR/PSRAM controller registers . . . 820
23.8 NAND flash controller . . . 829
23.8.1 External memory interface signals . . . 829
23.8.2 NAND flash supported memories and transactions . . . 830
23.8.3 Timing diagrams for NAND flash memories . . . 831
23.8.4 NAND flash operations . . . 832
23.8.5 NAND flash prewait feature . . . 833
23.8.6 Computation of the error correction code (ECC) in NAND flash memory . . . 834
23.8.7 NAND flash controller registers . . . 835
23.9 SDRAM controller . . . 841
23.9.1 SDRAM controller main features . . . 841
23.9.2 SDRAM External memory interface signals . . . 841
23.9.3 SDRAM controller functional description . . . 842
23.9.4 Low-power modes . . . 849
23.9.5 SDRAM controller registers . . . 851
23.9.6 FMC register map . . . 858

24 Octo-SPI interface (OCTOSPI) . . . 861
24.1 OCTOSPI introduction . . . 861
24.2 OCTOSPI main features . . . 861
24.3 OCTOSPI implementation . . . 862
24.4 OCTOSPI functional description . . . 863
24.4.1 OCTOSPI block diagram . . . 863
24.4.2 OCTOSPI pins and internal signals . . . 864
24.4.3 OCTOSPI interface to memory modes . . . 865
24.4.4 OCTOSPI regular-command protocol . . . 865
24.4.5 OCTOSPI regular-command protocol signal interface . . . 869
24.4.6 HyperBus protocol . . . 872
24.4.7 Specific features . . . 876
24.4.8 OCTOSPI operating mode introduction . . . 878
24.4.9 OCTOSPI indirect mode . . . 878
24.4.10 OCTOSPI automatic status-polling mode . . . 880
24.4.11 OCTOSPI memory-mapped mode . . . 881

24.4.12 OCTOSPI configuration introduction 882
24.4.13 OCTOSPI system configuration 882
24.4.14 OCTOSPI device configuration 882
24.4.15 OCTOSPI regular-command mode configuration 885
24.4.16 OCTOSPI HyperBus protocol configuration 887
24.4.17 OCTOSPI error management 888
24.4.18 OCTOSPI BUSY and ABORT 889
24.4.19 OCTOSPI reconfiguration or deactivation 889
24.4.20 NCS behavior 889
24.5 Address alignment and data number 891
24.6 OCTOSPI interrupts 892
24.7 OCTOSPI registers 892
24.7.1 OCTOSPI control register (OCTOSPI_CR) 892
24.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1) 895
24.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2) 897
24.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3) 898
24.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4) 898
24.7.6 OCTOSPI status register (OCTOSPI_SR) 899
24.7.7 OCTOSPI flag clear register (OCTOSPI_FCR) 900
24.7.8 OCTOSPI data length register (OCTOSPI_DLR) 900
24.7.9 OCTOSPI address register (OCTOSPI_AR) 901
24.7.10 OCTOSPI data register (OCTOSPI_DR) 901
24.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR) 902
24.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR) 903
24.7.13 OCTOSPI polling interval register (OCTOSPI_PIR) 903
24.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR) . . 903
24.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR) 906
24.7.16 OCTOSPI instruction register (OCTOSPI_IR) 906
24.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR) 907
24.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR) 907
24.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR) 908
24.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR) . . 910
24.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR) 910
24.7.22 OCTOSPI wrap alternate bytes register (OCTOSPI_WPABR) 911
24.7.23 OCTOSPI write communication configuration register (OCTOSPI_WCCR) 911

24.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR) 913
24.7.25 OCTOSPI write instruction register (OCTOSPI_WIR) 914
24.7.26 OCTOSPI write alternate bytes register (OCTOSPI_WABR) 914
24.7.27 OCTOSPI HyperBus latency configuration register (OCTOSPI_HLCR) 915
24.7.28 OCTOSPI register map 915

25 Octo-SPI I/O manager (OCTOSPIM) 919
25.1 Introduction 919
25.2 OCTOSPIM main features 919
25.3 OCTOSPIM implementation 919
25.4 OCTOSPIM functional description 919
25.4.1 OCTOSPIM block diagram 919
25.4.2 OCTOSPIM input/output pins 920
25.4.3 OCTOSPIM matrix 921
25.4.4 OCTOSPIM multiplexed mode 921
25.5 OCTOSPIM registers 923
25.5.1 OCTOSPIM control register (OCTOSPIM_CR) 923
25.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR) 923
25.5.3 OCTOSPIM register map 925

26 Delay block (DLYB) 926
26.1 DLYB introduction 926
26.2 DLYB main features 926
26.3 DLYB functional description 926
26.3.1 DLYB diagram 926
26.3.2 DLYB pins and internal signals 927
26.3.3 General description 927
26.3.4 Delay line length configuration procedure 928
26.3.5 Output clock phase configuration procedure 928
26.4 DLYB registers 929
26.4.1 DLYB control register (DLYB_CR) 929
26.4.2 DLYB configuration register (DLYB_CFGR) 930
26.4.3 DLYB register map 930

27 Analog-to-digital converters (ADC) 931

27.1 ADC introduction . . . 931
27.2 ADC main features . . . 932
27.3 ADC implementation . . . 933
27.4 ADC functional description . . . 934
27.4.1 ADC block diagram . . . 934
27.4.2 ADC pins and internal signals . . . 935
27.4.3 ADC clocks . . . 936
27.4.4 ADC1/2 connectivity . . . 938
27.4.5 Slave AHB interface . . . 940
27.4.6 ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) . . . 940
27.4.7 Single-ended and differential input channels . . . 941
27.4.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT) . . . 941
27.4.9 ADC on-off control (ADEN, ADDIS, ADRDY) . . . 947
27.4.10 Constraints when writing the ADC control bits . . . 948
27.4.11 Channel selection (SQRx, JSQRx) . . . 949
27.4.12 Channel preselection register (ADC_PCSEL) . . . 949
27.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2) . . . 950
27.4.14 Single conversion mode (CONT=0) . . . 951
27.4.15 Continuous conversion mode (CONT=1) . . . 951
27.4.16 Starting conversions (ADSTART, JADSTART) . . . 952
27.4.17 Timing . . . 953
27.4.18 Stopping an ongoing conversion (ADSTP, JADSTP) . . . 953
27.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) . . . 955
27.4.20 Injected channel management . . . 958
27.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) . . . 960
27.4.22 Queue of context for injected conversions . . . 961
27.4.23 Programmable resolution (RES) - fast conversion mode . . . 969
27.4.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP) . . . 969
27.4.25 End of conversion sequence (EOS, JEOS) . . . 969
27.4.26 Timing diagrams example (single/continuous modes, hardware/software triggers) . . . 970
27.4.27 Data management . . . 971
27.4.28 Managing conversions using the DFSDM . . . 979
27.4.29 Dynamic low-power features . . . 979
27.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy) . . . 984

27.4.31 Oversampler 987
27.4.32 Dual ADC modes 993
27.4.33 Temperature sensor 1007
27.4.34 VBAT supply monitoring 1008
27.4.35 Monitoring the internal voltage reference 1009
27.5 ADC interrupts 1011
27.6 ADC registers (for each ADC) 1012
27.6.1 ADC interrupt and status register (ADC_ISR) 1012
27.6.2 ADC interrupt enable register (ADC_IER) 1015
27.6.3 ADC control register (ADC_CR) 1017
27.6.4 ADC configuration register (ADC_CFGR) 1022
27.6.5 ADC configuration register 2 (ADC_CFGR2) 1027
27.6.6 ADC sample time register 1 (ADC_SMPR1) 1029
27.6.7 ADC sample time register 2 (ADC_SMPR2) 1030
27.6.8 ADC channel preselection register (ADC_PCSEL) 1031
27.6.9 ADC watchdog threshold register 1 (ADC_LTR1) 1031
27.6.10 ADC watchdog threshold register 1 (ADC_HTR1) 1032
27.6.11 ADC regular sequence register 1 (ADC_SQR1) 1033
27.6.12 ADC regular sequence register 2 (ADC_SQR2) 1034
27.6.13 ADC regular sequence register 3 (ADC_SQR3) 1035
27.6.14 ADC regular sequence register 4 (ADC_SQR4) 1036
27.6.15 ADC regular Data Register (ADC_DR) 1037
27.6.16 ADC injected sequence register (ADC_JSQR) 1038
27.6.17 ADC injected channel y offset register (ADC_OFRy) 1040
27.6.18 ADC injected channel y data register (ADC_JDRy) 1041
27.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) 1041
27.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) 1042
27.6.21 ADC watchdog lower threshold register 2 (ADC_LTR2) 1042
27.6.22 ADC watchdog higher threshold register 2 (ADC_HTR2) 1043
27.6.23 ADC watchdog lower threshold register 3 (ADC_LTR3) 1043
27.6.24 ADC watchdog higher threshold register 3 (ADC_HTR3) 1044
27.6.25 ADC differential mode selection register (ADC_DIFSEL) 1044
27.6.26 ADC calibration factors register (ADC_CALFACT) 1045
27.6.27 ADC calibration factor register 2 (ADC_CALFACT2) 1045
27.7 ADC common registers 1046

27.7.1 ADC xcommon status register (ADCx_CSR) (x=1/2) 1046
27.7.2 ADC x common control register (ADCx_CCR) (x=1/2) 1048
27.7.3 ADC x common regular data register for dual mode (ADCx_CDR) (x=1/2) 1051
27.7.4 ADC x common regular data register for 32-bit dual mode (ADCx_CDR2) (x=1/2) 1051
27.8 ADC register map 1052

28 Digital temperature sensor (DTS) 1056
28.1 DTS introduction 1056
28.2 DTS main features 1056
28.3 DTS functional description 1057
28.3.1 DTS block diagram 1057
28.3.2 DTS internal signals 1057
28.3.3 DTS block operation 1058
28.3.4 Operating modes 1058
28.3.5 Calibration 1058
28.3.6 Prescaler 1058
28.3.7 Temperature measurement principles 1059
28.3.8 Sampling time 1060
28.3.9 Trigger input 1060
28.3.10 On-off control and ready flag 1061
28.3.11 Temperature measurement sequence 1061
28.4 DTS low-power modes 1062
28.5 DTS interrupts 1063
28.5.1 Temperature window comparator 1063
28.5.2 Synchronous interrupt 1063
28.5.3 Asynchronous wake-up 1063
28.6 DTS registers 1064
28.6.1 Temperature sensor configuration register 1 (DTS_CFGR1) 1064
28.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1) 1065
28.6.3 Temperature sensor ramp value register (DTS_RAMPVALR) 1066
28.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1) 1067
28.6.5 Temperature sensor data register (DTS_DR) 1067
28.6.6 Temperature sensor status register (DTS_SR) 1068
28.6.7 Temperature sensor interrupt enable register (DTS_ITENR) 1069
28.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR) 1070

28.6.9 Temperature sensor option register (DTS_OR) 1071
28.6.10 DTS register map 1072

29 Digital-to-analog converter (DAC) 1074
29.1 DAC introduction 1074
29.2 DAC main features 1074
29.3 DAC implementation 1075
29.4 DAC functional description 1076
29.4.1 DAC block diagram 1076
29.4.2 DAC pins and internal signals 1077
29.4.3 DAC channel enable 1079
29.4.4 DAC data format 1079
29.4.5 DAC conversion 1080
29.4.6 DAC output voltage 1080
29.4.7 DAC trigger selection 1081
29.4.8 DMA requests 1081
29.4.9 Noise generation 1082
29.4.10 Triangle-wave generation 1083
29.4.11 DAC channel modes 1084
29.4.12 DAC channel buffer calibration 1087
29.4.13 DAC channel conversion modes 1088
29.4.14 Dual DAC channel conversion modes (if dual channels are available) 1089
29.5 DAC in low-power modes 1093
29.6 DAC interrupts 1094
29.7 DAC registers 1094
29.7.1 DAC control register (DAC_CR) 1094
29.7.2 DAC software trigger register (DAC_SWTRGR) 1098
29.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) 1098
29.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1) 1099
29.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1) 1099
29.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2) 1100
29.7.7 DAC channel2 12-bit left aligned data holding register (DAC_DHR12L2) 1100

29.7.8 DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2) . . . 1101
29.7.9 Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD) . . . 1101
29.7.10 Dual DAC 12-bit left aligned data holding register (DAC_DHR12LD) . . . 1102
29.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD) . . . 1102
29.7.12 DAC channel1 data output register (DAC_DOR1) . . . 1103
29.7.13 DAC channel2 data output register (DAC_DOR2) . . . 1103
29.7.14 DAC status register (DAC_SR) . . . 1103
29.7.15 DAC calibration control register (DAC_CCR) . . . 1105
29.7.16 DAC mode control register (DAC_MCR) . . . 1105
29.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1) . . . 1107
29.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2) . . . 1107
29.7.19 DAC sample and hold time register (DAC_SHHR) . . . 1107
29.7.20 DAC sample and hold refresh time register (DAC_SHRR) . . . 1108
29.7.21 DAC register map . . . 1109

30 Voltage reference buffer (VREFBUF) . . . 1111
30.1 VREFBUF introduction . . . 1111
30.2 VREFBUF functional description . . . 1111
30.3 VREFBUF registers . . . 1112
30.3.1 VREFBUF control and status register (VREFBUF_CSR) . . . 1112
30.3.2 VREFBUF calibration control register (VREFBUF_CCR) . . . 1113
30.3.3 VREFBUF register map . . . 1113

31 Comparator (COMP) . . . 1114
31.1 Introduction . . . 1114
31.2 COMP main features . . . 1114
31.3 COMP functional description . . . 1115
31.3.1 COMP block diagram . . . 1115
31.3.2 COMP pins and internal signals . . . 1116
31.3.3 COMP reset and clocks . . . 1117
31.3.4 Comparator LOCK mechanism . . . 1117
31.3.5 Window comparator . . . 1118

31.3.6 Hysteresis 1118
31.3.7 Comparator output blanking function 1118
31.3.8 Comparator output on GPIOs 1119
31.3.9 Comparator output redirection 1120
31.3.10 COMP power and speed modes 1121
31.3.11 Scaler function 1122
31.4 COMP low-power modes 1122
31.5 COMP interrupts 1123
31.5.1 Interrupt through EXTI block 1123
31.5.2 Interrupt through NVIC of the CPU 1123
31.6 COMP registers 1124
31.6.1 COMP status register (COMP_SR) 1124
31.6.2 COMP interrupt clear flag register (COMP_ICFR) 1124
31.6.3 COMP option register [alternate] (COMP_OR) 1125
31.6.4 COMP configuration register 1 (COMP_CFGR1) 1126
31.6.5 COMP configuration register 2 (COMP_CFGR2) 1128
31.6.6 COMP register map 1131

32 Operational amplifiers (OPAMP) 1132
32.1 OPAMP introduction 1132
32.2 OPAMP main features 1132
32.3 OPAMP functional description 1132
32.3.1 OPAMP reset and clocks 1132
32.3.2 Initial configuration 1133
32.3.3 Signal routing 1133
32.3.4 OPAMP modes 1134
32.3.5 Calibration 1141
32.4 OPAMP low-power modes 1143
32.5 OPAMP PGA gain 1143
32.6 OPAMP registers 1143
32.6.1 OPAMP1 control/status register (OPAMP1_CSR) 1143
32.6.2 OPAMP1 trimming register in normal mode (OPAMP1_OTR) 1145
32.6.3 OPAMP1 trimming register in high-speed mode (OPAMP1_HSOTR) 1146
32.6.4 OPAMP option register (OPAMP_OR) 1146
32.6.5 OPAMP2 control/status register (OPAMP2_CSR) 1146
32.6.6 OPAMP2 trimming register in normal mode (OPAMP2_OTR) 1148

32.6.7 OPAMP2 trimming register in high-speed mode (OPAMP2_HSOTR) 1149
32.6.8 OPAMP register map 1150

33 Digital filter for sigma delta modulators (DFSDM) 1151

33.1 Introduction 1151
33.2 DFSDM main features 1152
33.3 DFSDM implementation 1153
33.4 DFSDM functional description 1154
33.4.1 DFSDM block diagram 1154
33.4.2 DFSDM pins and internal signals 1155
33.4.3 DFSDM reset and clocks 1157
33.4.4 Serial channel transceivers 1158
33.4.5 Configuring the input serial interface 1168
33.4.6 Parallel data inputs 1168
33.4.7 Channel selection 1171
33.4.8 Digital filter configuration 1171
33.4.9 Integrator unit 1172
33.4.10 Analog watchdog 1173
33.4.11 Short-circuit detector 1175
33.4.12 Extreme detector 1176
33.4.13 Data unit block 1176
33.4.14 Signed data format 1177
33.4.15 Launching conversions 1178
33.4.16 Continuous and fast continuous modes 1178
33.4.17 Request precedence 1179
33.4.18 Power optimization in run mode 1180
33.5 DFSDM interrupts 1180
33.6 DFSDM DMA transfer 1182
33.7 DFSDM channel y registers (y=0..7) 1182
33.7.1 DFSDM channel y configuration register (DFSDM_CHyCFGR1) . . . 1182
33.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2) . . . 1184
33.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM_CHyAWSCDR) 1185
33.7.4 DFSDM channel y watchdog filter data register (DFSDM_CHyWDATR) 1186
33.7.5 DFSDM channel y data input register (DFSDM_CHyDATINR) 1186
33.7.6 DFSDM channel y delay register (DFSDM_CHyDLYR) 1187

33.8 DFSDM filter x module registers (x=0..7) 1188
33.8.1 DFSDM filter x control register 1 (DFSDM_FLTxCR1) 1188
33.8.2 DFSDM filter x control register 2 (DFSDM_FLTxCR2) 1191
33.8.3 DFSDM filter x interrupt and status register (DFSDM_FLTxISR) 1192
33.8.4 DFSDM filter x interrupt flag clear register (DFSDM_FLTxICR) 1194
33.8.5 DFSDM filter x injected channel group selection register (DFSDM_FLTxJCHGR) 1195
33.8.6 DFSDM filter x control register (DFSDM_FLTxFCR) 1195
33.8.7 DFSDM filter x data register for injected group (DFSDM_FLTxJDATAR) 1196
33.8.8 DFSDM filter x data register for the regular channel (DFSDM_FLTxRDATAR) 1197
33.8.9 DFSDM filter x analog watchdog high threshold register (DFSDM_FLTxAWHTR) 1198
33.8.10 DFSDM filter x analog watchdog low threshold register (DFSDM_FLTxAWLTR) 1198
33.8.11 DFSDM filter x analog watchdog status register (DFSDM_FLTxAWSR) 1199
33.8.12 DFSDM filter x analog watchdog clear flag register (DFSDM_FLTxAWCFR) 1200
33.8.13 DFSDM filter x extremes detector maximum register (DFSDM_FLTxEXMAX) 1200
33.8.14 DFSDM filter x extremes detector minimum register (DFSDM_FLTxEXMIN) 1201
33.8.15 DFSDM filter x conversion timer register (DFSDM_FLTxCNVTIMR) . 1201
33.8.16 DFSDM register map 1202

34 Digital camera interface (DCMI) 1217

34.1 DCMI introduction 1217
34.2 DCMI main features 1217
34.3 DCMI functional description 1217
34.3.1 DCMI block diagram 1218
34.3.2 DCMI pins and internal signals 1218
34.3.3 DCMI clocks 1219
34.3.4 DCMI DMA interface 1219
34.3.5 DCMI physical interface 1219
34.3.6 DCMI synchronization 1221
34.3.7 DCMI capture modes 1223
34.3.8 DCMI crop feature 1224

34.3.9 DCMI JPEG format . . . 1225
34.3.10 DCMI FIFO . . . 1225
34.3.11 DCMI data format description . . . 1226
34.4 DCMI interrupts . . . 1228

35.5 PSSI registers . . . 1247
35.5.1 PSSI control register (PSSI_CR) . . . 1247
35.5.2 PSSI status register (PSSI_SR) . . . 1248
35.5.3 PSSI raw interrupt status register (PSSI_RIS) . . . 1249
35.5.4 PSSI interrupt enable register (PSSI_IER) . . . 1250
35.5.5 PSSI masked interrupt status register (PSSI_MIS) . . . 1250
35.5.6 PSSI interrupt clear register (PSSI_ICR) . . . 1251
35.5.7 PSSI data register (PSSI_DR) . . . 1251

35.5.8 PSSI register map 1252

36 LCD-TFT display controller (LTDC) 1253

36.1 Introduction 1253

36.2 LTDC main features 1253

36.3 LTDC functional description 1254

36.3.1 LTDC block diagram 1254

36.3.2 LTDC pins and internal signals 1254

36.3.3 LTDC reset and clocks 1255

36.4 LTDC programmable parameters 1257

36.4.1 LTDC global configuration parameters 1257

36.4.2 Layer programmable parameters 1259

36.5 LTDC interrupts 1263

36.6 LTDC programming procedure 1264

36.7 LTDC registers 1265

36.7.1 LTDC synchronization size configuration register (LTDC_SSCR) . . . 1265

36.7.2 LTDC back porch configuration register (LTDC_BPCR) 1265

36.7.3 LTDC active width configuration register (LTDC_AWCR) 1266

36.7.4 LTDC total width configuration register (LTDC_TWCR) 1267

36.7.5 LTDC global control register (LTDC_GCR) 1267

36.7.6 LTDC shadow reload configuration register (LTDC_SRCR) 1269

36.7.7 LTDC background color configuration register (LTDC_BCCR) 1269

36.7.8 LTDC interrupt enable register (LTDC_IER) 1270

36.7.9 LTDC interrupt status register (LTDC_ISR) 1271

36.7.10 LTDC interrupt clear register (LTDC_ICR) 1271

36.7.11 LTDC line interrupt position configuration register (LTDC_LIPCR) . . 1272

36.7.12 LTDC current position status register (LTDC_CPSR) 1272

36.7.13 LTDC current display status register (LTDC_CDSR) 1273

36.7.14 LTDC layer x control register (LTDC_LxCR) 1273

36.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR) 1274

36.7.16 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR) 1275

36.7.17 LTDC layer x color keying configuration register (LTDC_LxCKCR) 1276

36.7.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR) 1276

36.7.19 LTDC layer x constant alpha configuration register (LTDC_LxCACR) . . . 1277
36.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR) . . . 1277
36.7.21 LTDC layer x blending factors configuration register (LTDC_LxBFCR) . . . 1278

38.3.6 RNG clocking 1311
38.3.7 Error management 1311
38.3.8 RNG low-power use 1312
38.4 RNG interrupts 1312
38.5 RNG processing time 1313
38.6 RNG entropy source validation 1313
38.6.1 Introduction 1313
38.6.2 Validation conditions 1313
38.6.3 Data collection 1314
38.7 RNG registers 1314
38.7.1 RNG control register (RNG_CR) 1314
38.7.2 RNG status register (RNG_SR) 1316
38.7.3 RNG data register (RNG_DR) 1317
38.7.4 RNG health test control register (RNG_HTCR) 1318
38.7.5 RNG register map 1318

39 Cryptographic processor (CRYP) 1319
39.1 Introduction 1319
39.2 CRYP main features 1319
39.3 CRYP implementation 1320

39.4 CRYP functional description 1321
39.4.1 CRYP block diagram 1321
39.4.2 CRYP internal signals 1322
39.4.3 CRYP DES/TDES cryptographic core 1322
39.4.4 CRYP AES cryptographic core 1323
39.4.5 CRYP procedure to perform a cipher operation 1329
39.4.6 CRYP busy state 1331
39.4.7 Preparing the CRYP AES key for decryption 1332
39.4.8 CRYP stealing and data padding 1332
39.4.9 CRYP suspend/resume operations 1333
39.4.10 CRYP DES/TDES basic chaining modes (ECB, CBC) 1334
39.4.11 CRYP AES basic chaining modes (ECB, CBC) 1339
39.4.12 CRYP AES counter mode (AES-CTR) 1344
39.4.13 CRYP AES Galois/counter mode (GCM) 1348
39.4.14 CRYP AES Galois message authentication code (GMAC) 1353
39.4.15 CRYP AES Counter with CBC-MAC (CCM) 1354
39.4.16 CRYP data registers and data swapping 1359
39.4.17 CRYP key registers 1363
39.4.18 CRYP initialization vector registers 1363
39.4.19 CRYP DMA interface 1364
39.4.20 CRYP error management 1366
39.5 CRYP interrupts 1367
39.6 CRYP processing time 1368
39.7 CRYP registers 1369
39.7.1 CRYP control register (CRYP_CR) 1369
39.7.2 CRYP status register (CRYP_SR) 1371
39.7.3 CRYP data input register (CRYP_DIN) 1372
39.7.4 CRYP data output register (CRYP_DOUT) 1372
39.7.5 CRYP DMA control register (CRYP_DMACR) 1373
39.7.6 CRYP interrupt mask set/clear register (CRYP_IMSCR) 1374
39.7.7 CRYP raw interrupt status register (CRYP_RISR) 1374
39.7.8 CRYP masked interrupt status register (CRYP_MISR) 1375
39.7.9 CRYP key register 0L (CRYP_K0LR) 1376
39.7.10 CRYP key register 0R (CRYP_K0RR) 1376
39.7.11 CRYP key register 1L (CRYP_K1LR) 1377
39.7.12 CRYP key register 1R (CRYP_K1RR) 1377
39.7.13 CRYP key register 2L (CRYP_K2LR) 1378

39.7.14 CRYP key register 2R (CRYP_K2RR) 1378
39.7.15 CRYP key register 3L (CRYP_K3LR) 1379
39.7.16 CRYP key register 3R (CRYP_K3RR) 1379
39.7.17 CRYP initialization vector register 0L (CRYP_IV0LR) 1380
39.7.18 CRYP initialization vector register 0R (CRYP_IV0RR) 1380
39.7.19 CRYP initialization vector register 1L (CRYP_IV1LR) 1381
39.7.20 CRYP initialization vector register 1R (CRYP_IV1RR) 1381
39.7.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR) 1381
39.7.22 CRYP context swap GCM registers (CRYP_CSGCMxR) 1382
39.7.23 CRYP register map 1382

40 Hash processor (HASH) 1385

40.1 Introduction 1385
40.2 HASH main features 1385
40.3 HASH implementation 1386
40.4 HASH functional description 1386
40.4.1 HASH block diagram 1386
40.4.2 HASH internal signals 1387
40.4.3 About secure hash algorithms 1387
40.4.4 Message data feeding 1387
40.4.5 Message digest computing 1389
40.4.6 Message padding 1390
40.4.7 HMAC operation 1392
40.4.8 HASH suspend/resume operations 1394
40.4.9 HASH DMA interface 1396
40.4.10 HASH error management 1396
40.4.11 HASH processing time 1396
40.5 HASH interrupts 1397
40.6 HASH registers 1398
40.6.1 HASH control register (HASH_CR) 1398
40.6.2 HASH data input register (HASH_DIN) 1400
40.6.3 HASH start register (HASH_STR) 1401
40.6.4 HASH digest registers 1402
40.6.5 HASH interrupt enable register (HASH_IMR) 1403
40.6.6 HASH status register (HASH_SR) 1404
40.6.7 HASH context swap registers 1404

40.6.8 HASH register map 1405

41 On-The-Fly decryption engine - AXI (OTFDEC) 1407

41.1 Introduction 1407

41.2 OTFDEC main features 1407

41.3 OTFDEC functional description 1408

41.3.1 OTFDEC block diagram 1408

41.3.2 OTFDEC internal signals 1409

41.3.3 OTFDEC on-the-fly decryption 1409

41.3.4 AES in counter mode decryption 1410

41.3.5 Flow control management 1412

41.3.6 OTFDEC error management 1414

41.4 OTFDEC interrupts 1414

41.5 OTFDEC application information 1415

41.5.1 OTFDEC initialization process 1415

41.5.2 OTFDEC and power management 1416

41.5.3 Encrypting for OTFDEC 1416

41.5.4 OTFDEC Key CRC source code 1417

41.6 OTFDEC registers 1418

41.6.1 OTFDEC region x configuration register (OTFDEC_RxCFGR) 1418

41.6.2 OTFDEC region x start address register (OTFDEC2_RxSTARTADDR) 1419

41.6.3 OTFDEC region x end address register (OTFDEC_RxENDADDR) . 1419

41.6.4 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0) 1420

41.6.5 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1) 1420

41.6.6 OTFDEC region x key register 0 (OTFDEC_RxKEYR0) 1421

41.6.7 OTFDEC region x key register 1 (OTFDEC_RxKEYR1) 1421

41.6.8 OTFDEC region x key register 2 (OTFDEC_RxKEYR2) 1421

41.6.9 OTFDEC region x key register 3 (OTFDEC_RxKEYR3) 1422

41.6.10 OTFDEC interrupt status register (OTFDEC_ISR) 1422

41.6.11 OTFDEC interrupt clear register (OTFDEC_ICR) 1423

41.6.12 OTFDEC interrupt enable register (OTFDEC_IER) 1424

41.6.13 OTFDEC register map 1425

42 Advanced-control timers (TIM1/TIM8) 1429

42.1 TIM1/TIM8 introduction 1429

42.2 TIM1/TIM8 main features 1429

42.3 TIM1/TIM8 functional description 1431
42.3.1 Time-base unit 1431
42.3.2 Counter modes 1433
42.3.3 Repetition counter 1444
42.3.4 External trigger input 1446
42.3.5 Clock selection 1447
42.3.6 Capture/compare channels 1451
42.3.7 Input capture mode 1453
42.3.8 PWM input mode 1454
42.3.9 Forced output mode 1455
42.3.10 Output compare mode 1456
42.3.11 PWM mode 1457
42.3.12 Asymmetric PWM mode 1460
42.3.13 Combined PWM mode 1461
42.3.14 Combined 3-phase PWM mode 1462
42.3.15 Complementary outputs and dead-time insertion 1463
42.3.16 Using the break function 1465
42.3.17 Bidirectional break inputs 1471
42.3.18 Clearing the OCxREF signal on an external event 1472
42.3.19 6-step PWM generation 1474
42.3.20 One-pulse mode 1475
42.3.21 Retriggerable one pulse mode 1476
42.3.22 Encoder interface mode 1477
42.3.23 UIF bit remapping 1479
42.3.24 Timer input XOR function 1480
42.3.25 Interfacing with Hall sensors 1480
42.3.26 Timer synchronization 1483
42.3.27 ADC synchronization 1487
42.3.28 DMA burst mode 1487
42.3.29 Debug mode 1488
42.4 TIM1/TIM8 registers 1489
42.4.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8) 1489
42.4.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8) 1490
42.4.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8) 1493
42.4.4 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 1, 8) 1495

42.4.5 TIMx status register (TIMx_SR)(x = 1, 8) 1497
42.4.6 TIMx event generation register (TIMx_EGR)(x = 1, 8) 1499
42.4.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 1, 8) . . 1500
42.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8) 1501
42.4.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 1, 8) . . 1504
42.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8) 1505
42.4.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8) 1506
42.4.12 TIMx counter (TIMx_CNT)(x = 1, 8) 1510
42.4.13 TIMx prescaler (TIMx_PSC)(x = 1, 8) 1510
42.4.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8) 1510
42.4.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8) 1511
42.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8) 1511
42.4.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8) 1512
42.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 1, 8) 1512
42.4.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 1, 8) 1513
42.4.20 TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) 1513
42.4.21 TIMx DMA control register (TIMx_DCR)(x = 1, 8) 1517
42.4.22 TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8) 1518
42.4.23 TIMx capture/compare mode register 3 (TIMx_CCMR3)(x = 1, 8) 1519
42.4.24 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8) 1520
42.4.25 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8) 1521
42.4.26 TIM1 alternate function option register 1 (TIM1_AF1) 1521
42.4.27 TIM1 Alternate function register 2 (TIM1_AF2) 1523
42.4.28 TIM8 Alternate function option register 1 (TIM8_AF1) 1524
42.4.29 TIM8 Alternate function option register 2 (TIM8_AF2) 1526
42.4.30 TIM1 timer input selection register (TIM1_TISEL) 1528
42.4.31 TIM8 timer input selection register (TIM8_TISEL) 1528
42.4.32 TIM1 register map 1530

42.4.33 TIM8 register map 1532

43 General-purpose timers (TIM2/TIM3/TIM4/TIM5) 1535

43.1 TIM2/TIM3/TIM4/TIM5 introduction 1535

43.2 TIM2/TIM3/TIM4/TIM5 main features 1535

43.3 TIM2/TIM3/TIM4/TIM5 functional description 1537

43.3.1 Time-base unit 1537

43.3.2 Counter modes 1539

43.3.3 Clock selection 1549

43.3.4 Capture/Compare channels 1553

43.3.5 Input capture mode 1554

43.3.6 PWM input mode 1555

43.3.7 Forced output mode 1556

43.3.8 Output compare mode 1557

43.3.9 PWM mode 1558

43.3.10 Asymmetric PWM mode 1561

43.3.11 Combined PWM mode 1562

43.3.12 Clearing the OCxREF signal on an external event 1563

43.3.13 One-pulse mode 1565

43.3.14 Retriggerable one pulse mode 1566

43.3.15 Encoder interface mode 1567

43.3.16 UIF bit remapping 1569

43.3.17 Timer input XOR function 1569

43.3.18 Timers and external trigger synchronization 1570

43.3.19 Timer synchronization 1573

43.3.20 DMA burst mode 1578

43.3.21 Debug mode 1579

43.4 TIM2/TIM3/TIM4/TIM5 registers 1580

43.4.1 TIMx control register 1 (TIMx_CR1)(x = 2 to 5) 1580

43.4.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 5) 1581

43.4.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5) 1583

43.4.4 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 2 to 5) 1586

43.4.5 TIMx status register (TIMx_SR)(x = 2 to 5) 1587

43.4.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5) 1588

43.4.7 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 2 to 5) . 1590

43.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 2 to 5) 1591

43.4.9 TIMx capture/compare mode register 2 (TIMx_CCMR2)(x = 2 to 5) . 1594
43.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2) (x = 2 to 5) 1595
43.4.11 TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5) 1596
43.4.12 TIMx counter (TIMx_CNT)(x = 2 to 5) 1597
43.4.13 TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5) 1598
43.4.14 TIMx prescaler (TIMx_PSC)(x = 2 to 5) 1598
43.4.15 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5) 1599
43.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5) 1599
43.4.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 5) 1599
43.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 5) 1600
43.4.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 2 to 5) 1600
43.4.20 TIMx DMA control register (TIMx_DCR)(x = 2 to 5) 1601
43.4.21 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5) 1602
43.4.22 TIM2 alternate function option register 1 (TIM2_AF1) 1602
43.4.23 TIM3 alternate function option register 1 (TIM3_AF1) 1602
43.4.24 TIM4 alternate function option register 1 (TIM4_AF1) 1603
43.4.25 TIM5 alternate function option register 1 (TIM5_AF1) 1603
43.4.26 TIM2 timer input selection register (TIM2_TISEL) 1604
43.4.27 TIM3 timer input selection register (TIM3_TISEL) 1605
43.4.28 TIM4 timer input selection register (TIM4_TISEL) 1605
43.4.29 TIM5 timer input selection register (TIM5_TISEL) 1606
43.4.30 TIMx register map 1608

44 General-purpose timers (TIM12/TIM13/TIM14) 1611

44.1 TIM12/TIM13/TIM14 introduction 1611
44.2 TIM12/TIM13/TIM14 main features 1611
44.2.1 TIM12 main features 1611
44.2.2 TIM13/TIM14 main features 1612
44.3 TIM12/TIM13/TIM14 functional description 1614
44.3.1 Time-base unit 1614
44.3.2 Counter modes 1616
44.3.3 Clock selection 1619
44.3.4 Capture/compare channels 1621
44.3.5 Input capture mode 1623
44.3.6 PWM input mode (only for TIM12) 1624

44.3.7 Forced output mode . . . 1625
44.3.8 Output compare mode . . . 1626
44.3.9 PWM mode . . . 1627
44.3.10 Combined PWM mode (TIM12 only) . . . 1628
44.3.11 One-pulse mode . . . 1629
44.3.12 Retriggerable one pulse mode (TIM12 only) . . . 1631
44.3.13 UIF bit remapping . . . 1631
44.3.14 Timer input XOR function . . . 1632

44.4.6 TIM12 event generation register (TIM12_EGR) . . . 1641
44.4.7 TIM12 capture/compare mode register 1 (TIM12_CCMR1) . . . 1642
44.4.8 TIM12 capture/compare mode register 1 [alternate] (TIM12_CCMR1) . . . 1643
44.4.9 TIM12 capture/compare enable register (TIM12_CCER) . . . 1646
44.4.10 TIM12 counter (TIM12_CNT) . . . 1647
44.4.11 TIM12 prescaler (TIM12_PSC) . . . 1648
44.4.12 TIM12 auto-reload register (TIM12_ARR) . . . 1648
44.4.13 TIM12 capture/compare register 1 (TIM12_CCR1) . . . 1648
44.4.14 TIM12 capture/compare register 2 (TIM12_CCR2) . . . 1649
44.4.15 TIM12 timer input selection register (TIM12_TISEL) . . . 1649
44.4.16 TIM12 register map . . . 1650
44.5 TIM13/TIM14 registers . . . 1652
44.5.1 TIMx control register 1 (TIMx_CR1)(x = 13 to 14) . . . 1652
44.5.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13 to 14) . . . 1653
44.5.3 TIMx status register (TIMx_SR)(x = 13 to 14) . . . 1653
44.5.4 TIMx event generation register (TIMx_EGR)(x = 13 to 14) . . . 1654

44.5.5 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 13 to 14) . . . 1655
44.5.6 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 13 to 14) . . . 1656
44.5.7 TIMx capture/compare enable register (TIMx_CCER)(x = 13 to 14) . . . 1658
44.5.8 TIMx counter (TIMx_CNT)(x = 13 to 14) . . . 1659
44.5.9 TIMx prescaler (TIMx_PSC)(x = 13 to 14) . . . 1660
44.5.10 TIMx auto-reload register (TIMx_ARR)(x = 13 to 14) . . . 1660
44.5.11 TIMx capture/compare register 1 (TIMx_CCR1)(x = 13 to 14) . . . 1660
44.5.12 TIM13 timer input selection register (TIM13_TISEL) . . . 1661
44.5.13 TIM14 timer input selection register (TIM14_TISEL) . . . 1661
44.5.14 TIM13/TIM14 register map . . . 1662

45 General-purpose timers (TIM15/TIM16/TIM17) . . . 1664

45.1 TIM15/TIM16/TIM17 introduction . . . 1664
45.2 TIM15 main features . . . 1664
45.3 TIM16/TIM17 main features . . . 1665
45.4 TIM15/TIM16/TIM17 functional description . . . 1668
45.4.1 Time-base unit . . . 1668
45.4.2 Counter modes . . . 1670
45.4.3 Repetition counter . . . 1674
45.4.4 Clock selection . . . 1675
45.4.5 Capture/compare channels . . . 1677
45.4.6 Input capture mode . . . 1679
45.4.7 PWM input mode (only for TIM15) . . . 1680
45.4.8 Forced output mode . . . 1681
45.4.9 Output compare mode . . . 1682
45.4.10 PWM mode . . . 1683
45.4.11 Combined PWM mode (TIM15 only) . . . 1684
45.4.12 Complementary outputs and dead-time insertion . . . 1685
45.4.13 Using the break function . . . 1687
45.4.14 Bidirectional break inputs . . . 1692
45.4.15 6-step PWM generation . . . 1693
45.4.16 One-pulse mode . . . 1695
45.4.17 Retriggerable one pulse mode (TIM15 only) . . . 1696
45.4.18 UIF bit remapping . . . 1697
45.4.19 Timer input XOR function (TIM15 only) . . . 1698

45.4.20 External trigger synchronization (TIM15 only) 1699
45.4.21 Slave mode – combined reset + trigger mode 1701
45.4.22 DMA burst mode 1701
45.4.23 Timer synchronization (TIM15) 1703
45.4.24 Using timer output as trigger for other timers (TIM16/TIM17) 1703
45.4.25 Debug mode 1703
45.5 TIM15 registers 1704
45.5.1 TIM15 control register 1 (TIM15_CR1) 1704
45.5.2 TIM15 control register 2 (TIM15_CR2) 1705
45.5.3 TIM15 slave mode control register (TIM15_SMCR) 1707
45.5.4 TIM15 DMA/interrupt enable register (TIM15_DIER) 1708
45.5.5 TIM15 status register (TIM15_SR) 1709
45.5.6 TIM15 event generation register (TIM15_EGR) 1711
45.5.7 TIM15 capture/compare mode register 1 (TIM15_CCMR1) 1712
45.5.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1) 1713
45.5.9 TIM15 capture/compare enable register (TIM15_CCER) 1716
45.5.10 TIM15 counter (TIM15_CNT) 1719
45.5.11 TIM15 prescaler (TIM15_PSC) 1719
45.5.12 TIM15 auto-reload register (TIM15_ARR) 1719
45.5.13 TIM15 repetition counter register (TIM15_RCR) 1720
45.5.14 TIM15 capture/compare register 1 (TIM15_CCR1) 1720
45.5.15 TIM15 capture/compare register 2 (TIM15_CCR2) 1721
45.5.16 TIM15 break and dead-time register (TIM15_BDTR) 1721
45.5.17 TIM15 DMA control register (TIM15_DCR) 1724
45.5.18 TIM15 DMA address for full transfer (TIM15_DMAR) 1724
45.5.19 TIM15 alternate register 1 (TIM15_AF1) 1725
45.5.20 TIM15 input selection register (TIM15_TISEL) 1726
45.5.21 TIM15 register map 1727
45.6 TIM16/TIM17 registers 1730
45.6.1 TIMx control register 1 (TIMx_CR1)(x = 16 to 17) 1730
45.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17) 1731
45.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17) 1732
45.6.4 TIMx status register (TIMx_SR)(x = 16 to 17) 1733
45.6.5 TIMx event generation register (TIMx_EGR)(x = 16 to 17) 1734
45.6.6 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 16 to 17) 1735

45.6.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17) . . . 1736
45.6.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) . 1738
45.6.9 TIMx counter (TIMx_CNT)(x = 16 to 17) . . . 1740
45.6.10 TIMx prescaler (TIMx_PSC)(x = 16 to 17) . . . 1741
45.6.11 TIMx auto-reload register (TIMx_ARR)(x = 16 to 17) . . . 1741
45.6.12 TIMx repetition counter register (TIMx_RCR)(x = 16 to 17) . . . 1742
45.6.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17) . . . 1742
45.6.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) . . . 1743
45.6.15 TIMx DMA control register (TIMx_DCR)(x = 16 to 17) . . . 1746
45.6.16 TIMx DMA address for full transfer (TIMx_DMAR)(x = 16 to 17) . . . 1746
45.6.17 TIM16 alternate function register 1 (TIM16_AF1) . . . 1747
45.6.18 TIM16 input selection register (TIM16_TISEL) . . . 1748
45.6.19 TIM17 alternate function register 1 (TIM17_AF1) . . . 1749
45.6.20 TIM17 input selection register (TIM17_TISEL) . . . 1750
45.6.21 TIM16/TIM17 register map . . . 1751

46 Basic timers (TIM6/TIM7) . . . 1753

46.1 TIM6/TIM7 introduction . . . 1753
46.2 TIM6/TIM7 main features . . . 1753
46.3 TIM6/TIM7 functional description . . . 1754
46.3.1 Time-base unit . . . 1754
46.3.2 Counting mode . . . 1756
46.3.3 UIF bit remapping . . . 1759
46.3.4 Clock source . . . 1759
46.3.5 Debug mode . . . 1760
46.4 TIM6/TIM7 registers . . . 1760
46.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7) . . . 1760
46.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7) . . . 1762
46.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7) . . . 1762
46.4.4 TIMx status register (TIMx_SR)(x = 6 to 7) . . . 1763
46.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7) . . . 1763
46.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7) . . . 1763
46.4.7 TIMx prescaler (TIMx_PSC)(x = 6 to 7) . . . 1764
46.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7) . . . 1764
46.4.9 TIMx register map . . . 1765

47 Low-power timer (LPTIM) 1766
47.1 Introduction 1766
47.2 LPTIM main features 1766
47.3 LPTIM implementation 1767
47.4 LPTIM functional description 1767
47.4.1 LPTIM block diagram 1767
47.4.2 LPTIM pins and internal signals 1768
47.4.3 LPTIM input and trigger mapping 1769
47.4.4 LPTIM reset and clocks 1771
47.4.5 Glitch filter 1771
47.4.6 Prescaler 1772
47.4.7 Trigger multiplexer 1772
47.4.8 Operating mode 1773
47.4.9 Timeout function 1775
47.4.10 Waveform generation 1775
47.4.11 Register update 1776
47.4.12 Counter mode 1777
47.4.13 Timer enable 1777
47.4.14 Timer counter reset 1778
47.4.15 Encoder mode 1778
47.4.16 Debug mode 1780
47.5 LPTIM low-power modes 1780
47.6 LPTIM interrupts 1781
47.7 LPTIM registers 1781
47.7.1 LPTIM interrupt and status register (LPTIM_ISR) 1782
47.7.2 LPTIM interrupt clear register (LPTIM_ICR) 1783
47.7.3 LPTIM interrupt enable register (LPTIM_IER) 1783
47.7.4 LPTIM configuration register (LPTIM_CFGR) 1784
47.7.5 LPTIM control register (LPTIM_CR) 1787
47.7.6 LPTIM compare register (LPTIM_CMP) 1789
47.7.7 LPTIM autoreload register (LPTIM_ARR) 1789
47.7.8 LPTIM counter register (LPTIM_CNT) 1790
47.7.9 LPTIM configuration register 2 (LPTIM_CFGR2) 1790
47.7.10 LPTIM register map 1792

48 System window watchdog (WWDG) 1793

48.1 WWDG introduction 1793
48.2 WWDG main features 1793
48.3 WWDG functional description 1793
48.3.1 WWDG block diagram 1794
48.3.2 WWDG internal signals 1794
48.3.3 Enabling the watchdog 1794
48.3.4 Controlling the down-counter 1794
48.3.5 How to program the watchdog timeout 1795
48.3.6 Debug mode 1796
48.4 WWDG interrupts 1796
48.5 WWDG registers 1796
48.5.1 WWDG control register (WWDG_CR) 1797
48.5.2 WWDG configuration register (WWDG_CFR) 1797
48.5.3 WWDG status register (WWDG_SR) 1798
48.5.4 WWDG register map 1798

49 Independent watchdog (IWDG) 1799
49.1 Introduction 1799
49.2 IWDG main features 1799
49.3 IWDG functional description 1799
49.3.1 IWDG block diagram 1799
49.3.2 IWDG internal signals 1800
49.3.3 Window option 1800
49.3.4 Hardware watchdog 1801
49.3.5 Low-power freeze 1801
49.3.6 Register access protection 1801
49.3.7 Debug mode 1802
49.4 IWDG registers 1803
49.4.1 IWDG key register (IWDG_KR) 1803
49.4.2 IWDG prescaler register (IWDG_PR) 1804
49.4.3 IWDG reload register (IWDG_RLR) 1805
49.4.4 IWDG status register (IWDG_SR) 1806
49.4.5 IWDG window register (IWDG_WINR) 1807
49.4.6 IWDG register map 1808

50 Real-time clock (RTC) 1809

50.1 Introduction . . . 1809
50.2 RTC main features . . . 1809
50.3 RTC functional description . . . 1810
50.3.1 RTC block diagram . . . 1810
50.3.2 RTC pins and internal signals . . . 1811
50.3.3 GPIOs controlled by the RTC and TAMP . . . 1812
50.3.4 Clock and prescalers . . . 1816
50.3.5 Real-time clock and calendar . . . 1817
50.3.6 Programmable alarms . . . 1817
50.3.7 Periodic auto-wake-up . . . 1818
50.3.8 RTC initialization and configuration . . . 1818
50.3.9 Reading the calendar . . . 1820
50.3.10 Resetting the RTC . . . 1821
50.3.11 RTC synchronization . . . 1821
50.3.12 RTC reference clock detection . . . 1822
50.3.13 RTC smooth digital calibration . . . 1823
50.3.14 Timestamp function . . . 1825
50.3.15 Calibration clock output . . . 1825
50.3.16 Tamper and alarm output . . . 1826
50.4 RTC low-power modes . . . 1826
50.5 RTC interrupts . . . 1827
50.6 RTC registers . . . 1827
50.6.1 RTC time register (RTC_TR) . . . 1828
50.6.2 RTC date register (RTC_DR) . . . 1829
50.6.3 RTC sub second register (RTC_SSR) . . . 1830
50.6.4 RTC initialization control and status register (RTC_ICSR) . . . 1830
50.6.5 RTC prescaler register (RTC_PRER) . . . 1832
50.6.6 RTC wake-up timer register (RTC_WUTR) . . . 1832
50.6.7 RTC control register (RTC_CR) . . . 1833
50.6.8 RTC write protection register (RTC_WPR) . . . 1836
50.6.9 RTC calibration register (RTC_CALR) . . . 1837
50.6.10 RTC shift control register (RTC_SHIFTR) . . . 1838
50.6.11 RTC timestamp time register (RTC_TSTR) . . . 1839
50.6.12 RTC timestamp date register (RTC_TSDR) . . . 1839
50.6.13 RTC timestamp sub second register (RTC_TSSSR) . . . 1840
50.6.14 RTC alarm A register (RTC_ALRMAR) . . . 1841

50.6.15 RTC alarm A sub second register (RTC_ALRMASSR) 1842
50.6.16 RTC alarm B register (RTC_ALRMBR) 1843
50.6.17 RTC alarm B sub second register (RTC_ALRMBSSR) 1844
50.6.18 RTC status register (RTC_SR) 1844
50.6.19 RTC masked interrupt status register (RTC_MISR) 1845
50.6.20 RTC status clear register (RTC_SCR) 1846
50.6.21 RTC configuration register (RTC_CFGR) 1847
50.6.22 RTC register map 1848

51 Tamper and backup registers (TAMP) 1850

51.1 Introduction 1850
51.2 TAMP main features 1850
51.3 TAMP functional description 1851
51.3.1 TAMP block diagram 1851
51.3.2 TAMP pins and internal signals 1852
51.3.3 TAMP register write protection 1853
51.3.4 Tamper detection 1853
51.4 TAMP low-power modes 1857
51.5 TAMP interrupts 1857
51.6 TAMP registers 1858
51.6.1 TAMP control register 1 (TAMP_CR1) 1858
51.6.2 TAMP control register 2 (TAMP_CR2) 1859
51.6.3 TAMP filter control register (TAMP_FLTCR) 1861
51.6.4 TAMP active tamper control register 1 (TAMP_ATCR1) 1862
51.6.5 TAMP active tamper seed register (TAMP_ATSEEDR) 1863
51.6.6 TAMP active tamper output register (TAMP_ATOR) 1864
51.6.7 TAMP interrupt enable register (TAMP_IER) 1864
51.6.8 TAMP status register (TAMP_SR) 1866
51.6.9 TAMP masked interrupt status register (TAMP_MISR) 1867
51.6.10 TAMP status clear register (TAMP_SCR) 1868
51.6.11 TAMP monotonic counter register (TAMP_COUNTR) 1869
51.6.12 TAMP configuration register (TAMP_CFGR) 1869
51.6.13 TAMP backup x register (TAMP_BKPxR) 1870
51.6.14 TAMP register map 1871

52 Inter-integrated circuit interface (I2C) 1873

52.1 I2C introduction 1873
52.2 I2C main features 1873
52.3 I2C implementation 1874
52.4 I2C functional description 1874
52.4.1 I2C block diagram 1875
52.4.2 I2C pins and internal signals 1875
52.4.3 I2C clock requirements 1876
52.4.4 I2C mode selection 1876
52.4.5 I2C initialization 1877
52.4.6 I2C reset 1881
52.4.7 I2C data transfer 1882
52.4.8 I2C target mode 1884
52.4.9 I2C controller mode 1893
52.4.10 I2C_TIMINGR register configuration examples 1904
52.4.11 SMBus specific features 1906
52.4.12 SMBus initialization 1909
52.4.13 SMBus I2C_TIMEOUTR register configuration examples 1911
52.4.14 SMBus target mode 1911
52.4.15 SMBus controller mode 1915
52.4.16 Wake-up from Stop mode on address match 1918
52.4.17 Error conditions 1919
52.5 I2C in low-power modes 1921
52.6 I2C interrupts 1921
52.7 I2C DMA requests 1922
52.7.1 Transmission using DMA 1922
52.7.2 Reception using DMA 1923
52.8 I2C debug modes 1923
52.9 I2C registers 1923
52.9.1 I2C control register 1 (I2C_CR1) 1923
52.9.2 I2C control register 2 (I2C_CR2) 1926
52.9.3 I2C own address 1 register (I2C_OAR1) 1928
52.9.4 I2C own address 2 register (I2C_OAR2) 1928
52.9.5 I2C timing register (I2C_TIMINGR) 1929
52.9.6 I2C timeout register (I2C_TIMEOUTR) 1930
52.9.7 I2C interrupt and status register (I2C_ISR) 1931
52.9.8 I2C interrupt clear register (I2C_ICR) 1934

52.9.9 I2C PEC register (I2C_PECR) . . . 1935
52.9.10 I2C receive data register (I2C_RXDR) . . . 1935
52.9.11 I2C transmit data register (I2C_TXDR) . . . 1936
52.9.12 I2C register map . . . 1937

53 Universal synchronous/asynchronous receiver transmitter (USART/UART) . . . 1938

53.1 USART introduction . . . 1938
53.2 USART main features . . . 1939
53.3 USART extended features . . . 1940
53.4 USART implementation . . . 1940
53.5 USART functional description . . . 1941
53.5.1 USART block diagram . . . 1941
53.5.2 USART signals . . . 1942
53.5.3 USART character description . . . 1943
53.5.4 USART FIFOs and thresholds . . . 1945
53.5.5 USART transmitter . . . 1945
53.5.6 USART receiver . . . 1949
53.5.7 USART baud rate generation . . . 1956
53.5.8 Tolerance of the USART receiver to clock deviation . . . 1957
53.5.9 USART auto baud rate detection . . . 1959
53.5.10 USART multiprocessor communication . . . 1961
53.5.11 USART Modbus communication . . . 1963
53.5.12 USART parity control . . . 1964
53.5.13 USART LIN (local interconnection network) mode . . . 1965
53.5.14 USART synchronous mode . . . 1967
53.5.15 USART single-wire half-duplex communication . . . 1971
53.5.16 USART receiver timeout . . . 1971
53.5.17 USART smartcard mode . . . 1972
53.5.18 USART IrDA SIR ENDEC block . . . 1976
53.5.19 Continuous communication using USART and DMA . . . 1979
53.5.20 RS232 hardware flow control and RS485 Driver Enable . . . 1981
53.5.21 USART low-power management . . . 1984
53.6 USART in low-power modes . . . 1987
53.7 USART interrupts . . . 1988
53.8 USART registers . . . 1989

53.8.1 USART control register 1 (USART_CR1) 1989
53.8.2 USART control register 1 [alternate] (USART_CR1) 1992
53.8.3 USART control register 2 (USART_CR2) 1996
53.8.4 USART control register 3 (USART_CR3) 2000
53.8.5 USART baud rate register (USART_BRR) 2004
53.8.6 USART guard time and prescaler register (USART_GTPR) 2004
53.8.7 USART receiver timeout register (USART_RTOR) 2005
53.8.8 USART request register (USART_RQR) 2006
53.8.9 USART interrupt and status register (USART_ISR) 2007
53.8.10 USART interrupt and status register [alternate] (USART_ISR) 2013
53.8.11 USART interrupt flag clear register (USART_ICR) 2018
53.8.12 USART receive data register (USART_RDR) 2020
53.8.13 USART transmit data register (USART_TDR) 2020
53.8.14 USART prescaler register (USART_PRESC) 2021
53.8.15 USART register map 2022

54 Low-power universal asynchronous receiver transmitter (LPUART) 2024

54.1 LPUART introduction 2024
54.2 LPUART main features 2025
54.3 LPUART implementation 2026
54.4 LPUART functional description 2027
54.4.1 LPUART block diagram 2027
54.4.2 LPUART signals 2028
54.4.3 LPUART character description 2029
54.4.4 LPUART FIFOs and thresholds 2030
54.4.5 LPUART transmitter 2031
54.4.6 LPUART receiver 2034
54.4.7 LPUART baud rate generation 2038
54.4.8 Tolerance of the LPUART receiver to clock deviation 2039
54.4.9 LPUART multiprocessor communication 2040
54.4.10 LPUART parity control 2042
54.4.11 LPUART single-wire half-duplex communication 2043
54.4.12 Continuous communication using DMA and LPUART 2043
54.4.13 RS232 hardware flow control and RS485 Driver Enable 2046
54.4.14 LPUART low-power management 2048
54.5 LPUART in low-power modes 2051

54.6 LPUART interrupts 2052
54.7 LPUART registers 2053
54.7.1 LPUART control register 1 (LPUART_CR1) 2053
54.7.2 LPUART control register 1 [alternate] (LPUART_CR1) 2056
54.7.3 LPUART control register 2 (LPUART_CR2) 2059
54.7.4 LPUART control register 3 (LPUART_CR3) 2061
54.7.5 LPUART baud rate register (LPUART_BRR) 2064
54.7.6 LPUART request register (LPUART_RQR) 2064
54.7.7 LPUART interrupt and status register (LPUART_ISR) 2065
54.7.8 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 2070
54.7.9 LPUART interrupt flag clear register (LPUART_ICR) 2073
54.7.10 LPUART receive data register (LPUART_RDR) 2074
54.7.11 LPUART transmit data register (LPUART_TDR) 2074
54.7.12 LPUART prescaler register (LPUART_PRESC) 2075
54.7.13 LPUART register map 2076

55 Serial peripheral interface (SPI) 2078
55.1 Introduction 2078
55.2 SPI main features 2079
55.3 SPI implementation 2079
55.4 SPI functional description 2080
55.4.1 SPI block diagram 2080
55.4.2 SPI signals 2081
55.4.3 SPI communication general aspects 2082
55.4.4 Communications between one master and one slave 2082
55.4.5 Standard multislave communication 2084
55.4.6 Multimaster communication 2087
55.4.7 Slave select (SS) pin management 2087
55.4.8 Communication formats 2091
55.4.9 Configuration of SPI 2093
55.4.10 Procedure for enabling SPI 2094
55.4.11 SPI data transmission and reception procedures 2094
55.4.12 Procedure for disabling the SPI 2099
55.4.13 Data packing 2100
55.4.14 Communication using DMA (direct memory addressing) 2101
55.5 SPI specific modes and control 2103

55.5.1 TI mode . . . 2103
55.5.2 SPI error flags . . . 2103
55.5.3 CRC computation . . . 2107
55.6 Low-power mode management . . . 2108
55.7 SPI wake-up and interrupts . . . 2111
55.8 I2S main features . . . 2112
55.9 I2S functional description . . . 2113
55.9.1 I2S general description . . . 2113
55.9.2 Pin sharing with SPI function . . . 2113
55.9.3 Bitfields usable in I2S/PCM mode . . . 2114
55.9.4 Slave and master modes . . . 2115
55.9.5 Supported audio protocols . . . 2115
55.9.6 Additional Serial Interface Flexibility . . . 2121
55.9.7 Startup sequence . . . 2123
55.9.8 Stop sequence . . . 2125
55.9.9 Clock generator . . . 2125
55.9.10 Internal FIFOs . . . 2128
55.9.11 FIFOs status flags . . . 2129
55.9.12 Handling of underrun situation . . . 2129
55.9.13 Handling of overrun situation . . . 2130
55.9.14 Frame error detection . . . 2131
55.9.15 DMA Interface . . . 2132
55.9.16 Programing examples . . . 2134
55.10 I2S wake-up and interrupts . . . 2136
55.11 SPI/I2S registers . . . 2137
55.11.1 SPI/I2S control register 1 (SPI_CR1) . . . 2137
55.11.2 SPI control register 2 (SPI_CR2) . . . 2139
55.11.3 SPI configuration register 1 (SPI_CFG1) . . . 2139
55.11.4 SPI configuration register 2 (SPI_CFG2) . . . 2142
55.11.5 SPI/I2S interrupt enable register (SPI_IER) . . . 2144
55.11.6 SPI/I2S status register (SPI_SR) . . . 2145
55.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR) . . . 2148
55.11.8 SPI/I2S transmit data register (SPI_TXDR) . . . 2149
55.11.9 SPI/I2S receive data register (SPI_RXDR) . . . 2149
55.11.10 SPI polynomial register (SPI_CRCPOLY) . . . 2150
55.11.11 SPI transmitter CRC register (SPI_TXCRC) . . . 2150

55.11.12 SPI receiver CRC register (SPI_RXCRC) 2151
55.11.13 SPI underrun data register (SPI_UDRDR) 2152
55.11.14 SPI/I2S configuration register (SPI_I2SCFGR) 2152
55.12 SPI register map and reset values 2155

56 Serial audio interface (SAI) 2157
56.1 SAI introduction 2157
56.2 SAI main features 2157
56.3 SAI implementation 2158
56.4 SAI functional description 2159
56.4.1 SAI block diagram 2159
56.4.2 SAI pins and internal signals 2160
56.4.3 Main SAI modes 2161
56.4.4 SAI synchronization mode 2162
56.4.5 Audio data size 2163
56.4.6 Frame synchronization 2163
56.4.7 Slot configuration 2166
56.4.8 SAI clock generator 2168
56.4.9 Internal FIFOs 2171
56.4.10 PDM interface 2173
56.4.11 AC’97 link controller 2181
56.4.12 SPDIF output 2183
56.4.13 Specific features 2186
56.4.14 Error flags 2190
56.4.15 Disabling the SAI 2193
56.4.16 SAI DMA interface 2193
56.5 SAI interrupts 2194
56.6 SAI registers 2196
56.6.1 SAI global configuration register (SAI_GCR) 2196
56.6.2 SAI configuration register 1 (SAI_ACR1) 2196
56.6.3 SAI configuration register 2 (SAI_ACR2) 2199
56.6.4 SAI frame configuration register (SAI_AFRCR) 2201
56.6.5 SAI slot register (SAI_ASLOTR) 2202
56.6.6 SAI interrupt mask register (SAI_AIM) 2203
56.6.7 SAI status register (SAI_ASR) 2205
56.6.8 SAI clear flag register (SAI_ACLRFR) 2207

56.6.9 SAI data register (SAI_ADR) . . . 2208
56.6.10 SAI configuration register 1 (SAI_BCR1) . . . 2208
56.6.11 SAI configuration register 2 (SAI_BCR2) . . . 2211
56.6.12 SAI frame configuration register (SAI_BFRCR) . . . 2213
56.6.13 SAI slot register (SAI_BSLOTR) . . . 2214
56.6.14 SAI interrupt mask register (SAI_BIM) . . . 2215
56.6.15 SAI status register (SAI_BSR) . . . 2216
56.6.16 SAI clear flag register (SAI_BCLRFR) . . . 2218
56.6.17 SAI data register (SAI_BDR) . . . 2219
56.6.18 SAI PDM control register (SAI_PDMCR) . . . 2220
56.6.19 SAI PDM delay register (SAI_PDMDLY) . . . 2221
56.6.20 SAI register map . . . 2223

57 SPDIF receiver interface (SPDIFRX) . . . 2225

57.1 SPDIFRX interface introduction . . . 2225
57.2 SPDIFRX main features . . . 2225
57.3 SPDIFRX functional description . . . 2225
57.3.1 SPDIFRX pins and internal signals . . . 2226
57.3.2 S/PDIF protocol (IEC-60958) . . . 2227
57.3.3 SPDIFRX decoder (SPDIFRX_DC) . . . 2229
57.3.4 SPDIFRX tolerance to clock deviation . . . 2233
57.3.5 SPDIFRX synchronization . . . 2233
57.3.6 SPDIFRX handling . . . 2235
57.3.7 Data reception management . . . 2237
57.3.8 Dedicated control flow . . . 2239
57.3.9 Reception errors . . . 2240
57.3.10 Clocking strategy . . . 2242
57.3.11 Symbol clock generation . . . 2242
57.3.12 DMA interface . . . 2244
57.3.13 Interrupt generation . . . 2245
57.3.14 Register protection . . . 2246
57.4 Programming procedures . . . 2246
57.4.1 Initialization phase . . . 2247
57.4.2 Handling of interrupts coming from SPDIFRX . . . 2248
57.4.3 Handling of interrupts coming from DMA . . . 2248
57.5 SPDIFRX interface registers . . . 2249
57.5.1 SPDIFRX control register (SPDIFRX_CR) . . . 2249

57.5.2 SPDIFRX interrupt mask register (SPDIFRX_IMR) 2251
57.5.3 SPDIFRX status register (SPDIFRX_SR) 2252
57.5.4 SPDIFRX interrupt flag clear register (SPDIFRX_IFCR) 2254
57.5.5 SPDIFRX data input register (SPDIFRX_FMT0_DR) 2255
57.5.6 SPDIFRX data input register (SPDIFRX_FMT1_DR) 2255
57.5.7 SPDIFRX data input register (SPDIFRX_FMT2_DR) 2256
57.5.8 SPDIFRX channel status register (SPDIFRX_CSR) 2257
57.5.9 SPDIFRX debug information register (SPDIFRX_DIR) 2257
57.5.10 SPDIFRX interface register map 2258

58 Single wire protocol master interface (SWPMI) 2259

58.1 Introduction 2259
58.2 SWPMI main features 2260
58.3 SWPMI functional description 2261
58.3.1 SWPMI block diagram 2261
58.3.2 SWPMI pins and internal signals 2261
58.3.3 SWP initialization and activation 2262
58.3.4 SWP bus states 2263
58.3.5 SWPMI_IO (internal transceiver) bypass 2264
58.3.6 SWPMI bit rate 2264
58.3.7 SWPMI frame handling 2265
58.3.8 Transmission procedure 2265
58.3.9 Reception procedure 2270
58.3.10 Error management 2274
58.3.11 Loopback mode 2276
58.4 SWPMI low-power modes 2276
58.5 SWPMI interrupts 2277
58.6 SWPMI registers 2278
58.6.1 SWPMI configuration/control register (SWPMI_CR) 2278
58.6.2 SWPMI Bitrate register (SWPMI_BRR) 2279
58.6.3 SWPMI Interrupt and Status register (SWPMI_ISR) 2280
58.6.4 SWPMI Interrupt Flag Clear register (SWPMI_ICR) 2281
58.6.5 SWPMI Interrupt Enable register (SMPMI_IER) 2282
58.6.6 SWPMI Receive Frame Length register (SWPMI_RFL) 2284
58.6.7 SWPMI Transmit data register (SWPMI_TDR) 2284
58.6.8 SWPMI Receive data register (SWPMI_RDR) 2284

58.6.9 SWPMI Option register (SWPMI_OR) 2285
58.6.10 SWPMI register map and reset value table 2286

59 Management data input/output (MDIOS) 2287
59.1 MDIOS introduction 2287
59.2 MDIOS main features 2287
59.3 MDIOS functional description 2288
59.3.1 MDIOS block diagram 2288
59.3.2 MDIOS pins and internal signals 2288
59.3.3 MDIOS protocol 2288
59.3.4 MDIOS enabling and disabling 2289
59.3.5 MDIOS data 2290
59.3.6 MDIOS APB frequency 2291
59.3.7 Write/read flags and interrupts 2291
59.3.8 MDIOS error management 2292
59.3.9 MDIOS in Stop mode 2293
59.3.10 MDIOS interrupts 2293
59.4 MDIOS registers 2293
59.4.1 MDIOS configuration register (MDIOS_CR) 2293
59.4.2 MDIOS write flag register (MDIOS_WRFR) 2294
59.4.3 MDIOS clear write flag register (MDIOS_CWRFR) 2295
59.4.4 MDIOS read flag register (MDIOS_RDFR) 2295
59.4.5 MDIOS clear read flag register (MDIOS_CRDFR) 2296
59.4.6 MDIOS status register (MDIOS_SR) 2296
59.4.7 MDIOS clear flag register (MDIOS_CLRFR) 2297
59.4.8 MDIOS input data register x (MDIOS_DINRx) 2297
59.4.9 MDIOS output data register x (MDIOS_DOUTRx) 2298
59.4.10 MDIOS register map 2298

60 Secure digital input/output MultiMediaCard interface (SDMMC) . . 2300
60.1 SDMMC main features 2300
60.2 SDMMC implementation 2300
60.3 SDMMC bus topology 2301
60.4 SDMMC operation modes 2303
60.5 SDMMC functional description 2304
60.5.1 SDMMC block diagram 2304

60.5.2 SDMMC pins and internal signals . . . 2304
60.5.3 General description . . . 2305
60.5.4 SDMMC adapter . . . 2307
60.5.5 SDMMC AHB slave interface . . . 2329
60.5.6 SDMMC AHB master interface . . . 2330
60.5.7 MDMA request generation . . . 2331
60.5.8 AHB and SDMMC_CK clock relation . . . 2332
60.6 Card functional description . . . 2333
60.6.1 SD I/O mode . . . 2333
60.6.2 CMD12 send timing . . . 2341
60.6.3 Sleep (CMD5) . . . 2345
60.6.4 Interrupt mode (Wait-IRQ) . . . 2346
60.6.5 Boot operation . . . 2347
60.6.6 Response R1b handling . . . 2350
60.6.7 Reset and card cycle power . . . 2351
60.7 Hardware flow control . . . 2352
60.8 Ultra-high-speed phase I (UHS-I) voltage switch . . . 2352
60.9 SDMMC interrupts . . . 2355
60.10 SDMMC registers . . . 2357
60.10.1 SDMMC power control register (SDMMC_POWER) . . . 2357
60.10.2 SDMMC clock control register (SDMMC_CLKCR) . . . 2358
60.10.3 SDMMC argument register (SDMMC_ARGR) . . . 2360
60.10.4 SDMMC command register (SDMMC_CMDR) . . . 2360
60.10.5 SDMMC command response register (SDMMC_RESPCMDR) . . . 2362
60.10.6 SDMMC response x register (SDMMC_RESPxR) . . . 2363
60.10.7 SDMMC data timer register (SDMMC_DTIMER) . . . 2363
60.10.8 SDMMC data length register (SDMMC_DLENR) . . . 2364
60.10.9 SDMMC data control register (SDMMC_DCTRL) . . . 2365
60.10.10 SDMMC data counter register (SDMMC_DCNTR) . . . 2366
60.10.11 SDMMC status register (SDMMC_STAR) . . . 2367
60.10.12 SDMMC interrupt clear register (SDMMC_ICR) . . . 2370
60.10.13 SDMMC mask register (SDMMC_MASKR) . . . 2372
60.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER) . . . 2375
60.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR) . . . 2375
60.10.16 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER) . . . 2376
60.10.17 SDMMC IDMA buffer 0 base address register (SDMMC_IDMABASE0R) . . . 2377

60.10.18 SDMMC IDMA buffer 1 base address register (SDMMC_IDMABASE1R) . . . 2377
60.10.19 SDMMC data FIFO registers x (SDMMC_FIFORx) . . . 2377
60.10.20 SDMMC register map . . . 2378

61 Controller area network with flexible data rate (FDCAN) . . . 2381

61.1 FDCAN introduction . . . 2381
61.2 FDCAN main features . . . 2384
61.3 FDCAN implementation . . . 2384
61.4 FDCAN functional description . . . 2385
61.4.1 Operating modes . . . 2386
61.4.2 Error management . . . 2395
61.4.3 Message RAM . . . 2395
61.4.4 FIFO acknowledge handling . . . 2407
61.4.5 Bit timing . . . 2408
61.4.6 Clock calibration on CAN . . . 2409
61.4.7 Application . . . 2413
61.4.8 TTCAN operations (FDCAN1 only) . . . 2414
61.4.9 TTCAN configuration . . . 2415
61.4.10 Message scheduling . . . 2417
61.4.11 TTCAN gap control . . . 2424
61.4.12 Stop watch . . . 2425
61.4.13 Local time, cycle time, global time, and external clock synchronization . . . 2425
61.4.14 TTCAN error level . . . 2428
61.4.15 TTCAN message handling . . . 2429
61.4.16 TTCAN interrupt and error handling . . . 2432
61.4.17 Level 0 . . . 2433
61.4.18 Synchronization to external time schedule . . . 2435
61.4.19 FDCAN Rx buffer and FIFO element . . . 2436
61.4.20 FDCAN Tx buffer element . . . 2438
61.4.21 FDCAN Tx event FIFO element . . . 2440
61.4.22 FDCAN standard message ID filter element . . . 2441
61.4.23 FDCAN extended message ID filter element . . . 2443
61.4.24 FDCAN trigger memory element . . . 2444
61.5 FDCAN registers . . . 2446
61.5.1 FDCAN core release register (FDCAN_CREL) . . . 2446

61.5.2 FDCAN Endian register (FDCAN_ENDN) 2446
61.5.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP) 2446
61.5.4 FDCAN test register (FDCAN_TEST) 2447
61.5.5 FDCAN RAM watchdog register (FDCAN_RWD) 2448
61.5.6 FDCAN CC control register (FDCAN_CCCR) 2449
61.5.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) . 2451
61.5.8 FDCAN timestamp counter configuration register (FDCAN_TSCC) . 2452
61.5.9 FDCAN timestamp counter value register (FDCAN_TSCV) 2452
61.5.10 FDCAN timeout counter configuration register (FDCAN_TOCC) . . . 2453
61.5.11 FDCAN timeout counter value register (FDCAN_TOCV) 2454
61.5.12 FDCAN error counter register (FDCAN_ECR) 2454
61.5.13 FDCAN protocol status register (FDCAN_PSR) 2455
61.5.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) . . 2457
61.5.15 FDCAN interrupt register (FDCAN_IR) 2457
61.5.16 FDCAN interrupt enable register (FDCAN_IE) 2460
61.5.17 FDCAN interrupt line select register (FDCAN_ILS) 2462
61.5.18 FDCAN interrupt line enable register (FDCAN_ILE) 2463
61.5.19 FDCAN global filter configuration register (FDCAN_GFC) 2464
61.5.20 FDCAN standard ID filter configuration register (FDCAN_SIDFC) . . 2465
61.5.21 FDCAN extended ID filter configuration register (FDCAN_XIDFC) . . 2465
61.5.22 FDCAN extended ID and mask register (FDCAN_XIDAM) 2466
61.5.23 FDCAN high priority message status register (FDCAN_HPMS) 2467
61.5.24 FDCAN new data 1 register (FDCAN_NDAT1) 2467
61.5.25 FDCAN new data 2 register (FDCAN_NDAT2) 2468
61.5.26 FDCAN Rx FIFO 0 configuration register (FDCAN_RXF0C) 2468
61.5.27 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) 2469
61.5.28 FDCAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) 2470
61.5.29 FDCAN Rx buffer configuration register (FDCAN_RXBC) 2470
61.5.30 FDCAN Rx FIFO 1 configuration register (FDCAN_RXF1C) 2471
61.5.31 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) 2472
61.5.32 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) 2473
61.5.33 FDCAN Rx buffer element size configuration register (FDCAN_RXESC) 2473
61.5.34 FDCAN Tx buffer configuration register (FDCAN_TXBC) 2474
61.5.35 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) 2475
61.5.36 FDCAN Tx buffer element size configuration register (FDCAN_TXESC) 2476
61.5.37 FDCAN Tx buffer request pending register (FDCAN_TXBRP) 2476

61.5.38 FDCAN Tx buffer add request register (FDCAN_TXBAR) 2477
61.5.39 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) . . 2478
61.5.40 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) 2478
61.5.41 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) . . 2479
61.5.42 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) 2479
61.5.43 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) 2480
61.5.44 FDCAN Tx event FIFO configuration register (FDCAN_TXEFC) . . . 2480
61.5.45 FDCAN Tx event FIFO status register (FDCAN_TXEFS) 2481
61.5.46 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) . . . 2482
61.5.47 FDCAN register map 2482
61.6 TTCAN registers 2486
61.6.1 FDCAN TT trigger memory configuration register (FDCAN_TTTMC) 2486
61.6.2 FDCAN TT reference message configuration register (FDCAN_TTRMC) 2486
61.6.3 FDCAN TT operation configuration register (FDCAN_TTOCF) 2487
61.6.4 FDCAN TT matrix limits register (FDCAN_TTMLM) 2489
61.6.5 FDCAN TUR configuration register (FDCAN_TURCF) 2490
61.6.6 FDCAN TT operation control register (FDCAN_TTOCN) 2491
61.6.7 FDCAN TT global time preset register (FDCAN_TTGTP) 2493
61.6.8 FDCAN TT time mark register (FDCAN_TTTMK) 2493
61.6.9 FDCAN TT interrupt register (FDCAN_TTIR) 2494
61.6.10 FDCAN TT interrupt enable register (FDCAN_TTIE) 2496
61.6.11 FDCAN TT interrupt line select register (FDCAN_TTILS) 2498
61.6.12 FDCAN TT operation status register (FDCAN_TTOST) 2499
61.6.13 FDCAN TUR numerator actual register (FDCAN_TURNA) 2501
61.6.14 FDCAN TT local and global time register (FDCAN_TTLGT) 2502
61.6.15 FDCAN TT cycle time and count register (FDCAN_TTCTC) 2502
61.6.16 FDCAN TT capture time register (FDCAN_TTCPT) 2503
61.6.17 FDCAN TT cycle sync mark register (FDCAN_TTCSM) 2503
61.6.18 FDCAN TT trigger select register (FDCAN_TTTS) 2504
61.6.19 FDCAN TT register map 2504
61.7 CCU registers 2506
61.7.1 Clock calibration unit core release register (FDCAN_CCU_CREL) . . 2506
61.7.2 Calibration configuration register (FDCAN_CCU_CCFG) 2506
61.7.3 Calibration status register (FDCAN_CCU_CSTAT) 2508

61.7.4 Calibration watchdog register (FDCAN_CCU_CWD) 2508
61.7.5 Clock calibration unit interrupt register (FDCAN_CCU_IR) 2509
61.7.6 Clock calibration unit interrupt enable register (FDCAN_CCU_IE) . . 2510
61.7.7 CCU register map 2510

62 USB on-the-go high-speed (OTG_HS) 2512

62.1 Introduction 2512
62.2 OTG_HS main features 2513
62.2.1 General features 2513
62.2.2 Host-mode features 2514
62.2.3 Peripheral-mode features 2514
62.3 OTG_HS implementation 2515
62.4 OTG_HS functional description 2515
62.4.1 OTG_HS block diagram 2515
62.4.2 OTG_HS pin and internal signals 2516
62.4.3 OTG_HS core 2516
62.4.4 Embedded full-speed OTG PHY connected to OTG_HS 2517
62.4.5 OTG detections 2517
62.4.6 High-speed OTG PHY connected to OTG_HS 2517
62.5 OTG_HS dual role device (DRD) 2518
62.5.1 ID line detection 2518
62.5.2 HNP dual role device 2518
62.5.3 SRP dual role device 2519
62.6 OTG_HS as a USB peripheral 2519
62.6.1 SRP-capable peripheral 2520
62.6.2 Peripheral states 2520
62.6.3 Peripheral endpoints 2521
62.7 OTG_HS as a USB host 2523
62.7.1 SRP-capable host 2524
62.7.2 USB host states 2524
62.7.3 Host channels 2526
62.7.4 Host scheduler 2527
62.8 OTG_HS SOF trigger 2528
62.8.1 Host SOFs 2528
62.8.2 Peripheral SOFs 2528
62.9 OTG_HS low-power modes 2529

62.10 OTG_HS dynamic update of the OTG_HFIR register 2530
62.11 OTG_HS data FIFOs 2530
62.11.1 Peripheral FIFO architecture 2531
62.11.2 Host FIFO architecture 2532
62.11.3 FIFO RAM allocation 2533
62.12 **OTG_HS** interrupts 2535
62.13 **OTG_HS** control and status registers 2537
62.13.1 CSR memory map 2537
62.14 **OTG_HS** registers 2542
62.14.1 OTG control and status register (OTG_GOTGCTL) 2542
62.14.2 OTG interrupt register (OTG_GOTGINT) 2545
62.14.3 OTG AHB configuration register (OTG_GAHBCFG) 2546
62.14.4 OTG USB configuration register (OTG_GUSBCFG) 2548
62.14.5 OTG reset register (OTG_GRSTCTL) 2550
62.14.6 OTG core interrupt register (OTG_GINTSTS) 2552
62.14.7 OTG interrupt mask register (OTG_GINTMSK) 2557
62.14.8 OTG receive status debug read register (OTG_GRXSTSR) 2559
62.14.9 OTG receive status debug read [alternate] (OTG_GRXSTSR) 2560
62.14.10 OTG status read and pop registers (OTG_GRXSTSP) 2561
62.14.11 OTG status read and pop registers [alternate] (OTG_GRXSTSP) . . 2562
62.14.12 OTG receive FIFO size register (OTG_GRXFSIZ) 2563
62.14.13 OTG host non-periodic transmit FIFO size register (OTG_HNPTXFSIZ)/Endpoint 0 Transmit FIFO size (OTG_DIEPTXF0) 2564
62.14.14 OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS) 2565
62.14.15 OTG general core configuration register (OTG_GCCFG) 2566
62.14.16 OTG core ID register (OTG_CID) 2567
62.14.17 OTG core LPM configuration register (OTG_GLPMCFG) 2568
62.14.18 OTG host periodic transmit FIFO size register (OTG_HPTXFSIZ) 2572
62.14.19 OTG device IN endpoint transmit FIFO x size register (OTG_DIEPTXFx) 2572
62.14.20 Host-mode registers 2573
62.14.21 OTG host configuration register (OTG_HCFG) 2573
62.14.22 OTG host frame interval register (OTG_HFIR) 2574
62.14.23 OTG host frame number/frame time remaining register (OTG_HFNUM) 2575

62.14.24 OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS) . . . 2576
62.14.25 OTG host all channels interrupt register (OTG_HAINT) . . . 2577
62.14.26 OTG host all channels interrupt mask register (OTG_HAINTMSK) . . . 2577
62.14.27 OTG host frame list base address register (OTG_HFLBADDR) . . . 2578
62.14.28 OTG host port control and status register (OTG_HPRT) . . . 2578
62.14.29 OTG host channel x characteristics register (OTG_HCCHARx) . . . 2581
62.14.30 OTG host channel x split control register (OTG_HCSPLTx) . . . 2582
62.14.31 OTG host channel x interrupt register (OTG_HCINTx) . . . 2583
62.14.32 OTG host channel x interrupt mask register (OTG_HCINTMSKx) . . 2584
62.14.33 OTG host channel x transfer size register (OTG_HCTSIZx) . . . 2586
62.14.34 OTG host channel x transfer size register (OTG_HCTSIZSGx) . . . 2587
62.14.35 OTG host channel x DMA address register in buffer DMA [alternate] (OTG_HCDMAx) . . . 2589
62.14.36 OTG host channel x DMA address register in scatter/gather DMA [alternate] (OTG_HCDMASGx) . . . 2589
62.14.37 OTG host channel-n DMA address buffer register (OTG_HCDMABx) . . . 2590
62.14.38 Device-mode registers . . . 2591
62.14.39 OTG device configuration register (OTG_DCFG) . . . 2591
62.14.40 OTG device control register (OTG_DCTL) . . . 2593
62.14.41 OTG device status register (OTG_DSTS) . . . 2595
62.14.42 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK) . . . 2596
62.14.43 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK) . . . 2597
62.14.44 OTG device all endpoints interrupt register (OTG_DAINT) . . . 2598
62.14.45 OTG all endpoints interrupt mask register (OTG_DAINTMSK) . . . 2599
62.14.46 OTG device V_{BUS} discharge time register (OTG_DVBUSDIS) . . . 2600
62.14.47 OTG device V_{BUS} pulsing time register (OTG_DVBUSPULSE) . . . 2600
62.14.48 OTG device threshold control register (OTG_DTHRCTL) . . . 2601
62.14.49 OTG device IN endpoint FIFO empty interrupt mask register (OTG_DIEPEMPMSK) . . . 2602
62.14.50 OTG device each endpoint interrupt register (OTG_DEACHINT) . . . 2602
62.14.51 OTG device each endpoint interrupt mask register (OTG_DEACHINTMSK) . . . 2603

62.14.52 OTG device each IN endpoint-1 interrupt mask register (OTG_HS_DIEPEACHMSK1) . . . 2603
62.14.53 OTG device each OUT endpoint-1 interrupt mask register (OTG_HS_DOEPEACHMSK1) . . . 2604
62.14.54 OTG device IN endpoint x control register (OTG_DIEPCTLx) . . . 2606
62.14.55 OTG device IN endpoint x interrupt register (OTG_DIEPINTx) . . . 2608
62.14.56 OTG device IN endpoint 0 transfer size register (OTG_DIEPTSIZ0) . . . 2610
62.14.57 OTG device IN endpoint x DMA address register (OTG_DIEPDMAx) . . . 2610
62.14.58 OTG device IN endpoint transmit FIFO status register (OTG_DTXFSTSx) . . . 2611
62.14.59 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx) . 2611
62.14.60 OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0) . . . 2612
62.14.61 OTG device OUT endpoint x interrupt register (OTG_DOEPINTx) . . 2614
62.14.62 OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0) . . . 2616
62.14.63 OTG device OUT endpoint x DMA address register (OTG_DOEPDMAx) . . . 2617
62.14.64 OTG device OUT endpoint x control register (OTG_DOEPCTLx) . . . 2617
62.14.65 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx) . . . 2620
62.14.66 OTG power and clock gating control register (OTG_PCGCCTL) . . . 2621
62.14.67 **OTG_HS** register map . . . 2622
62.15 **OTG_HS** programming model . . . 2634
62.15.1 Core initialization . . . 2634
62.15.2 Host initialization . . . 2635

1 Documentation conventions

1.1 General information

The STM32H7A3/7B3 and STM32H7B0 devices embed an Arm®(a) Cortex®-M7 core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **Double word**: data of 64-bit length.
- Flash word: data of 256-bit length
- **IAP (in-application programming)**: IAP is the ability to re-program the flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: device configuration bits stored in the flash memory.
- **AHB**: advanced high-performance bus.
- **AXI**: Advanced extensible interface protocol.
- **PCROP**: proprietary code readout protection.
- **RDP**: readout protection.
- **CD**: CPU power and clock domain.
- **SRD**: Smart Run power and clock domain.

1.5 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

1.6 Availability of security features

For security feature availability refer to the table below:

Table 1. Availability of security features

Security feature	STM32H7B0xB	STM32H7B3xx	STM32H7A3xx
Embedded flash memory (FLASH): – Flash Secure-only area	Available	Available	Not available
Security memory management: – Secure access mode – Root secure services (RSS)			
On-the-fly decryption engine (OTFDEC)			
Cryptographic processor (CRYP)			
Hash processor (HASH)			

2 Memory and bus architecture

2.1 System architecture

An AXI bus matrix, two AHB bus matrices and bus bridges allow interconnecting bus masters with bus slaves, as illustrated in *Table 2* and *Figure 1*.

Table 2. Bus-master-to-bus-slave interconnect

	Bus master / type[1]

SRD SRAM	X	-	-	-	-	X	-	-	-	-	X	X	X	X	X	-	-	X
Backup RAM	X	-	-	-	-	X	-	-	-	-	X	X	X	X	X	-	-	X

1. **Bold** font type denotes 64-bit bus, plain type denotes 32-bit bus.
2. Table cells indicate access and usage, path and type:
   Access possibility and usage:
   “X” = access possible, “-” = access not possible, shading = access useful/usable.
3. Bank 1 is limited to 128 Kbytes on STM32H7B3/B0 devices.
4. OTFDEC2 is available only on STM32H7B0 and STM32H7B3 devices.

Figure 1. System architecture for STM32H7A3/7B3/7B0xx devices

1. Bank 1 is limited to 128 Kbytes on STM32H7B0 devices. STM32H7A3xG and STM32H7A3xI/7B3xx devices feature two banks of 512 Kbytes and 1 Mbyte each, respectively.
2. OTFDEC1 and OTFDEC2 are available only on STM32H7B0 and STM32H7B3 devices.

2.1.1 Bus matrices

AXI bus matrix in CD domain

The CD domain multi AXI bus matrix ensures and arbitrates concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

Refer to *Section 2.2: AXI interconnect matrix (AXIM)* for more information on AXI interconnect.

AHB bus matrices in CD domain

The AHB bus matrices in CD domain ensure and arbitrate concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm.

2.1.2 TCM buses

The DTCM and ITCM (data and instruction tightly coupled RAMs) are connected through dedicated TCM buses directly to the Cortex-M7 core. The MDMA controller can access the DTCM and ITCM through AHBS, a specific CPU slave AHB. The ITCM is accessed by Cortex-M7 at CPU clock speed, with zero wait states.

2.1.3 Bus-to-bus bridges

To allow peripherals with different types of buses to communicate together, there is a number of bus-to-bus bridges in the system.

The AHB/APB bridges allow connecting peripherals on APB1 and APB2 to AHB1. Other bridges in the CD domain and in the SRD domain allow connecting APB3 to AHB3 and APB4 to AHB4, respectively.These AHB/APB bridges provide full synchronous interfacing, which allows the APB peripherals to operate with clocks independent of AHB that they connect to.

The AHB/APB bridges also allow APB1 and APB2 peripherals to connect to DMA1 and DMA2 peripheral buses, respectively, without transiting through AHB1.

The AHB/APB bridges convert 8-bit / 16-bit APB data to 32-bit AHB data, by replicating it to the three upper bytes / the upper half-word of the 32-bit word.

The AXI bus matrix incorporates AHB/AXI bus bridge functionality on its slave bus interfaces. The AXI/AHB bus bridges on its master interfaces marked as 32-bit in *Figure 1* are outside the matrix.

The Cortex-M7 CPU provides AHB/TCM-bus (ITCM and DTCM buses) translation from its AHBS slave AHB, allowing the MDMA controller to access the ITCM and DTCM.

2.1.4 Domain and inter-domain buses

AXI to CD AHB

A 32-bit bus connects the AXI bus matrix to the AHB bus matrix. It allows AXI bus master to access resources (bus slaves) inside the CD domain.

CD AHB to AXI bus

A 32-bit bus connects the AHB bus matrix to the AXI bus matrix. It allows AHB bus masters to access resources (bus slaves) inside the CD domain and indirectly via the CD-to-SRD AHB in the SRD domain.

AXI to SRD AHB

This 32-bit bus connects the CD domain to the SRD domain AHB bus matrix. It allows bus masters in the CD domain to access resources (bus slaves) in the SRD domain.

CD AHB to SRD AHB

This 32-bit bus connects the CD domain to the SRD domain AHB bus matrix. It allows bus masters in the CD domain to access resources (bus slaves) in the SRD domain.

2.1.5 CPU buses

Cortex®-M7 AXIM bus

The Cortex®-M7 CPU uses the 64-bit AXIM bus to access all memories (excluding ITCM, and DTCM) and AHB3, AHB4, APB3 and APB4 peripherals (excluding AHB1, APB1 and APB2 peripherals).

The AXIM bus connects the CPU to the AXI bus matrix in the CD domain.

Cortex®-M7 ITCM bus

The Cortex®-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

Cortex®-M7 DTCM bus

The Cortex®-M7 CPU uses the 2x32-bit DTCM bus for accessing data in the DTCM. The 2x32-bit DTCM bus allows load/load and load/store instruction pairs to be dual-issued on the DTCM memory. It can also fetch instructions.

Cortex®-M7 AHBS bus

The Cortex®-M7 CPU uses the 32-bit AHBS slave bus to allow the MDMA controller to access the ITCM and the DTCM.

Cortex®-M7 AHBP bus

The Cortex®-M7 CPU uses the 32-bit AHBP bus for accessing AHB1, AHB2, APB1 and APB2 peripherals via the AHB bus matrix in the CD domain.

2.1.6 Bus master peripherals

SDMMC1

The SDMMC1 uses a 32-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and flash memories, and external memories through the OCTOSPI1/2 controllers and the FMC.

SDMMC2

The SDMMC2 uses a 32-bit bus, connected to the AHB bus matrix in CD domain. Through the system bus matrices, it can access the internal AXI SRAM1, AXI SRAM2, AXI SRAM3, AHB SRAM1, AHB SRAM2 and flash memories, and external memories through the OCTOSPI1/2 controllers and the FMC.

MDMA controller

The MDMA controller has two bus masters: an AXI 64-bit bus, connected to the AXI bus matrix and an AHB 32-bit bus connected to the Cortex-M7 AHBS slave bus.

The MDMA is optimized for DMA data transfers between memories since it supports linked list transfers that allow performing a chained list of transfers without the need for CPU intervention. Through the system bus matrices and the Cortex-M7 AHBS slave bus, the MDMA can access all internal and external memories through the OCTOSPI1/2 controllers and the FMC.

DMA1 and DMA2 controllers

The DMA1 and DMA2 controllers have two 32-bit buses - memory bus and peripheral bus, connected to the AHB bus matrix in CD domain.

The memory bus allows DMA data transfers between memories. Through the system bus matrices, the memory bus can access external memories through the OCTOSPI1/2 controllers and the FMC and all internal memories except ITCM and DTCM.

The peripheral bus allows DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the system bus matrices, the peripheral bus can access external memories through the OCTOSPI controller and the FMC, all AHB and APB peripherals and all internal memories except ITCM and DTCM. A direct access to APB1 and APB2 is available, without passing through AHB1. Direct path to APB1 and APB2 bridges allows reducing the bandwidth usage on AHB1 bus by improving data treatment efficiency for APB and AHB peripherals.

BDMA1 controller

The BDMA1 controller is connected to the AHB bus matrix in the CD domain. It is dedicated to the DFSDM1 which is connected to the APB2 bus. The BDMA1 allows DMA data transfers between the DFSDM and AHB SRAM or AHB1, APB1 and APB2 peripherals.

BDMA2 controller

The BDMA2 controller uses a 32-bit bus, connected to the AHB bus matrix in SRD domain, for DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. BDMA2 transfers are limited to the SRD domain resources. It can access the internal SRD SRAM, backup SRAM, and AHB4 and APB4 peripherals through the AHB bus matrix in the SRD domain.

Chrom-Art Accelerator (DMA2D)

The DMA2D graphics accelerator uses a 64-bit bus, connected to the AXI bus matrix. Through the system bus matrices, internal AXI SRAM1, AXI SRAM2, AXI SRAM3, AHB SRAM1, AHB SRAM2 and flash memories, and external memories through the OCTOSPI1/2 controllers and the FMC.

LCD-TFT controller (LTDC)

The LCD-TFT display controller, LTDC, uses a 64-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM1, AXI SRAM2, AXI SRAM3 and flash memories, and external memories through the OCTOSPI1/2 controllers and the FMC.

OTG_HS peripheral

The OTG_HS peripheral uses a 32-bit bus, connected to the AHB bus matrix in the CD domain. Through the system bus matrix, it can access all internal memories except ITCM and DTCM, and external memories through the OCTOSPI1/2 controllers and the FMC.

2.1.7 Clocks to functional blocks

Upon reset, clocks to blocks such as peripherals and some memories are disabled (except for the SRAM, DTCM, ITCM and flash memory). To operate a block with no clock upon reset, the software must first enable its clock through RCC_AHBxENR or RCC_APBxENR register, respectively.

2.2 AXI interconnect matrix (AXIM)

2.2.1 AXI introduction

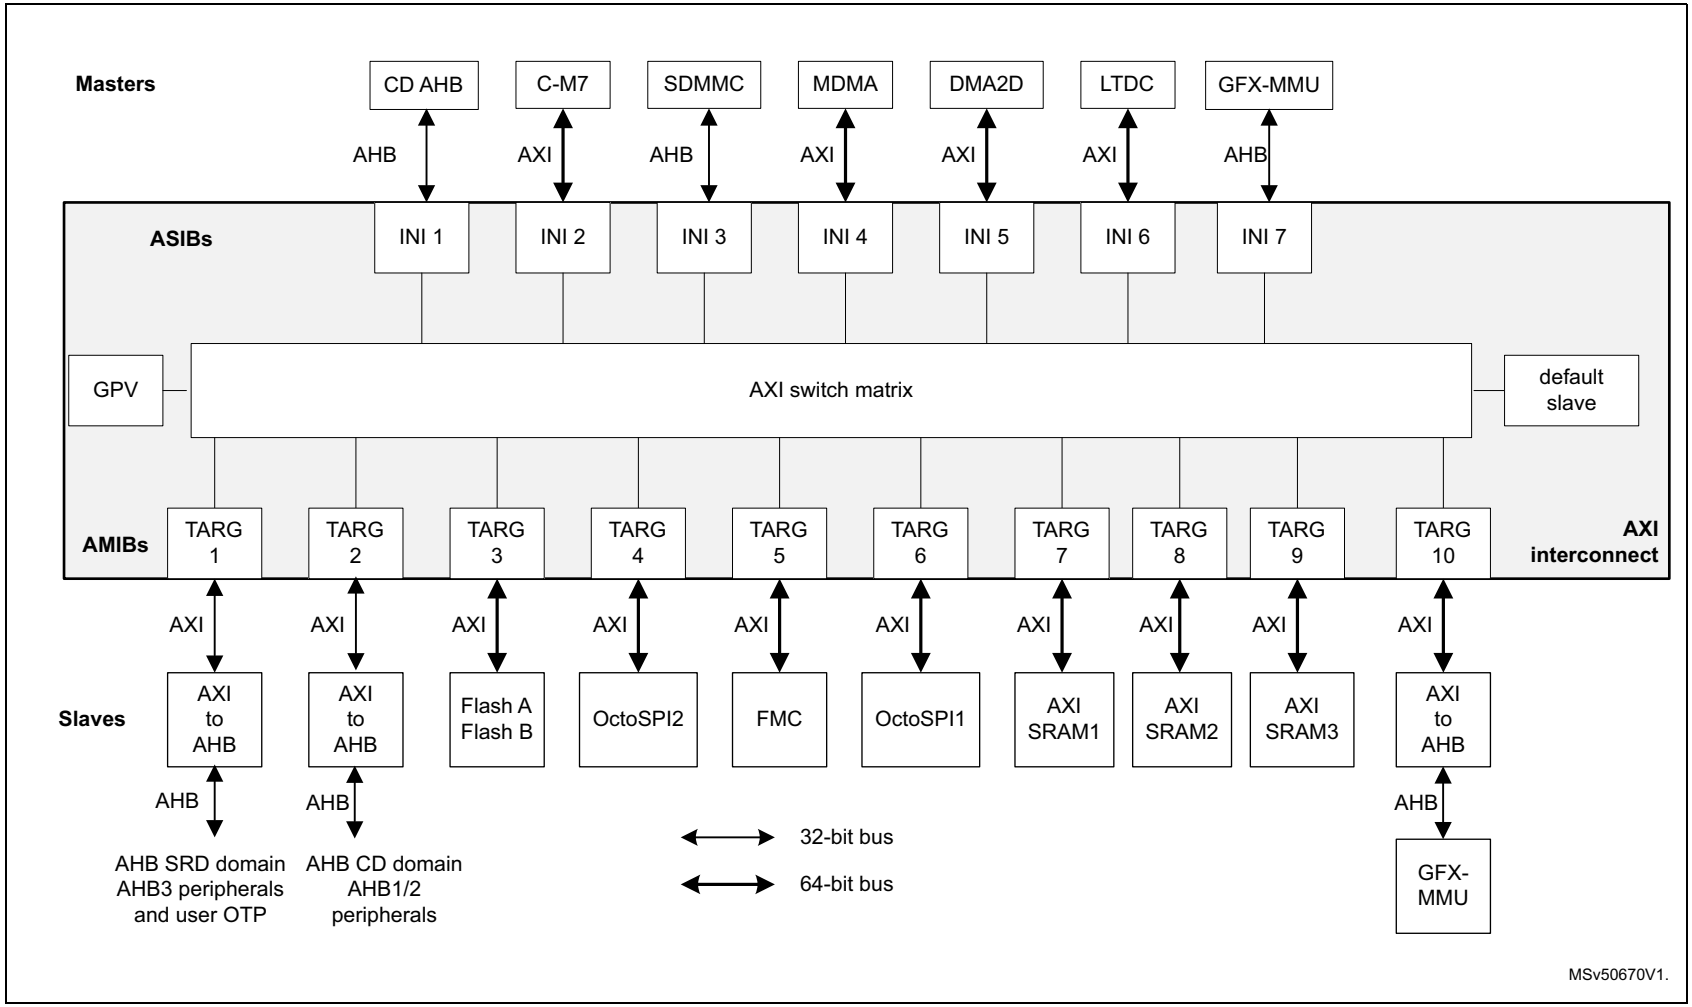
The AXI (advanced extensible interface) interconnect is based on the Arm® CoreLink™ NIC-400 Network Interconnect. The interconnect has seven initiator ports, or ASIBs (AMBA slave interface blocks), and ten target ports, or AMIBs (AMBA master interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a slave on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a master on an AXI or AHB bus. Where an ASIB or AMIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default slave, which generates the return signals. This ensures that such transactions complete and do not block the issuing master and ASIB.

2.2.2 AXI interconnect main features



- 64-bit AXI bus switch matrix with seven ASIBs and ten AMIBs, in CD domain
- AHB/AXI bridge function built into the ASIBs
- concurrent connectivity of multiple ASIBs to multiple AMIBs
- programmable traffic priority management (QoS - quality of service)
- software-configurable via GPV

2.2.3 AXI interconnect functional description

Block diagram

The AXI interconnect is shown in *Figure 2*.

Figure 2. AXI interconnect

ASIB configuration

Table 3 summarizes the characteristics of the ASIBs.

Table 3. ASIB configuration

ASIB	Connected master	Protocol	Bus width	R/W issuing
INI 1	AHB from CD domain	AHB-lite	32	1/4
INI 2	Cortex-M7	AXI4	64	7/32
INI 3	SDMMC1	AHB-lite	32	1/4
INI 4	MDMA	AXI4	64	4/1
INI 5	DMA2D	AXI4	64	2/1
INI 6	LTDC	AXI4	64	2/1
INI 7	GFXMMU	AHB-lite	32	1/1

AMIB configuration

Table 4 summarizes the characteristics of the AMIBs.

Table 4. AMIB configuration

AMIB	Connected slave	Protocol	Bus width	R/W/Total acceptance
TARG 1	Peripheral 3, SRD AHB and user OTP	AXI4(1)	32	1/1/1
TARG 2	CD AHB	AXI4(1)	32	1/1/1
TARG 3	Flash A and Flash B	AXI4	64	3/4/7
TARG 4	OCTOSPI2	AXI4	64	3/2/5
TARG 5	FMC	AXI4	64	3/3/6
TARG 6	OCTOSPI1	AXI4	64	2/1/3
TARG 7	AXI SRAM1	AXI3	64	2/2/4
TARG 8	AXI SRAM2	AXI3	64	2/2/4
TARG 9	AXI SRAM3	AXI3	64	2/2/4
TARG 10	GFXMMU(1)	AXI4	32	2/2/4

1. Conversion to AHB protocol is done via an AXI/AHB bridge sitting between AXI interconnect and the connected slave.

Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the *AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS)*, and the write channel in the *AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS)*. The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus master. This can be useful for real-time-constrained tasks, such as graphics processing (LTDC, DMA2D). Assigning a high priority to masters that can make many and frequent accesses to the same slave (such as the Cortex-M7 CPU) can block access to that slave by other lower-priority masters.

Global programmer view (GPV)

The GPV contains configuration registers for the AXI interconnect (see *Section 2.2.4*). These registers are only accessible by the Cortex-M7 CPU.

2.2.4 AXI interconnect registers

AXI interconnect - peripheral ID4 register (AXI_PERIPH_ID_4)

Address offset: 0x1FD0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS_MERGE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS_MERGE**: Disable packing of beats to match the output data width. Unaligned transactions are not realigned to the input data word boundary.

0: Normal operation

1: Disable packing

AXI interconnect - TARG x long burst functionality modification register (AXI_TARGx_FN_MOD_LB)

Address offset: 0x102C + 0x1000 * x, (x = 1, 2, 10)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FN_MOD_LB
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **FN_MOD_LB**: Controls burst breaking of long bursts

0: Long bursts can not be generated at the output of the ASIB

1: Long bursts can be generated at the output of the ASIB

AXI interconnect - TARG x issuing functionality modification register (AXI_TARGx_FN_MOD)

Address offset: 0x1108 + 0x1000 * x, (x = 1, 2, 7 to 10)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WRITE_ISS_OVERRIDE**: Override AMIB write issuing capability
0: Default issuing capability
1: Force issuing capability to 1 (see *Table 4: AMIB configuration*)

Bit 0 **READ_ISS_OVERRIDE**: Override AMIB read issuing capability
0: Default issuing capability
1: Force issuing capability to 1 (see *Table 4: AMIB configuration*)

AXI interconnect - INI x functionality modification 2 register (AXI_INIx_FN_MOD2)

Address offset: 0x41024 + 0x1000 * x, (x = 1, 3, 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS_MERGE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS_MERGE**: Disables alteration of transactions by the up-sizer unless required by the protocol
0: Normal operation
1: Transactions pass through unaltered where allowed

AXI interconnect - INI x AHB functionality modification register (AXI_INIx_FN_MOD_AHB)

Address offset: 0x41028 + 0x1000 * x, (x = 1, 3, 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WR_INC_OVERRIDE	RD_INC_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WR_INC_OVERRIDE**: Converts all AHB-Lite read transactions to a series of single beat AXI transactions; each AHB-Lite write beat is acknowledged with the AXI buffered write response.
0: Override disabled
1: Override enabled

Bit 0 **RD_INC_OVERRIDE**: Converts all AHB-Lite write transactions to a series of single beat AXI transactions
0: Override disabled
1: Override enabled

AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS)

Address offset: 0x41100 + 0x1000 * x, (x = 1 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AR_QOS[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **AR_QOS[3:0]**: Read channel QoS setting
0x0: Lowest priority
0xF: Highest priority

AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS)

Address offset: 0x41104 + 0x1000 * x, (x = 1 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3 on page 130* for the register boundary addresses.

2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.

2.3.2 Memory map and register boundary addresses

All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following tables.

Table 6. Memory map and default device memory area attributes

Region	Boundary address	Arm® Cortex®-M7	Type	Attributes	Execute never
External devices	0xD000 0000 - 0xDFFF FFFF	FMC SDRAM Bank2 (or reserved in case of FMC remap)	Device	-	Yes
	0xCC00 0000 - 0xCFFF FFFF	FMC SDRAM Bank1 (or remap of FMC NOR/PSRAM/SRAM 4 Bank1)			
	0xC800 0000 - 0xCBFF FFFF	FMC SDRAM Bank1 (or remap of FMC NOR/PSRAM/SRAM 3 Bank1)			
	0xC400 0000 - 0xC7FF FFFF	FMC SDRAM Bank1 (or remap of FMC NOR/PSRAM/SRAM 2 Bank1)			
	0xC000 0000 - 0xC3FF FFFF	FMC SDRAM Bank1 (or remap of FMC NOR/PSRAM/SRAM 1 Bank1)			
	0xA000 0000 - 0xBFFF FFFF	Reserved			
External memories	0x9000 0000 - 0x9FFF FFFF	OCTOSPI1	Normal	Write-through cache attribute	No
	0x8000 0000 - 0x8FFF FFFF	FMC NAND flash memory			
	0x7000 0000 - 0x7FFF FFFF	OCTOSPI2			
	0x6C00 0000 - 0x6FFF FFFF	FMC NOR/PSRAM/SRAM 4 Bank1 (or remap of FMC SDRAM Bank1)		Write-back, write allocate cache attribute	
	0x6800 0000 - 0x6BFF FFFF	FMC NOR/PSRAM/SRAM 3 Bank1 (or remap of FMC SDRAM Bank1)			
	0x6400 0000 - 0x67FF FFFF	FMC NOR/PSRAM/SRAM 2 Bank1 (or remap of FMC SDRAM Bank1)			
	0x6000 0000 - 0x63FF FFFF	FMC NOR/PSRAM/SRAM 1 Bank1 (or remap of FMC SDRAM Bank1)			
Peripherals	0x4000 0000 - 0x5FFF FFFF	Peripherals (refer to *Table 7: Register boundary addresses*)	Device	-	Yes

Table 6. Memory map and default device memory area attributes (continued)

Region	Boundary address	Arm® Cortex®-M7	Type	Attributes	Execute never
RAM	0x3880 1000 - 0x3FFF FFFF	Reserved	Normal	Write-back, write allocate cache attribute	No
	0x3880 0000 - 0x3880 0FFF	Backup SRAM			
	0x3801 0000 - 0x387F FFFF	Reserved			
	0x3800 0000 - 0x3800 7FFF	SDR SRAM			
	0x3002 0000 - 0x37FF 7FFF	Reserved			
	0x3001 0000 - 0x3001 FFFF	AHB SRAM2			
	0x3000 0000 - 0x3000 FFFF	AHB SRAM1			
	0x2600 0000 - 0x2FFF FFFF	Reserved			
	0x2500 0000 - 0x25FF FFFF	GFXMMU			
	0x2410 0000 - 0x24FF FFFF	Reserved			
	0x240A 0000 - 0x240F FFFF	AXI SRAM3			
	0x2404 0000 - 0x2409 FFFF	AXI SRAM2			
	0x2400 0000 - 0x2403 FFFF	AXI SRAM1			
	0x2002 0000 - 0x23FF FFFF	Reserved			
	0x2000 0000 - 0x2001 FFFF	DTCM			
Code	0x1FF2 0000 - 0x1FFF FFFF	Reserved	Normal	Write-through cache attribute	No
	0x1FF0 0000 - 0x1FF1 FFFF	System Memory			
	0x08FF F400 - 0x1FEF FFFF	Reserved			
	0x08FF F000 - 0x08FF F3FF	OTP area	Normal	-	No
	0x0820 0000 - 0x08FF EFFF	Reserved	Normal	Write-through cache attribute	No
	0x0810 0000 - 0x081F FFFF	Flash memory bank 2			
	0x0800 0000 - 0x080F FFFF	Flash memory bank 1			
	0x0001 0000 - 0x07FF FFFF	Reserved			
	0x0000 0000 - 0x0000 FFFF	ITCM RAM

1. Accessing a reserved area results in a bus error. Accessing undefined memory space in a peripheral returns zeros.

2.4 Embedded SRAM

The STM32H7A3/7B3 and STM32H7B0 devices feature:

- Up to 1184 Kbytes of System SRAM
- 128 Kbytes of data TCM RAM
- 64 Kbytes of instruction TCM RAM
- 4 Kbytes of backup SRAM

The embedded system SRAM is divided into up to six blocks:

- CD domain, AXI SRAM:
  - AXI SRAM1 mapped at address 0x2400 0000
  - AXI SRAM2 mapped at address 0x2404 0000
  - AXI SRAM3 mapped at address 0x240A 0000

  All AXI SRAMs can be accessed by all system masters through the AXI bus matrix except BDMA1 and BDMA2.
- CD domain, AHB SRAM:
  - AHB SRAM1 mapped at address 0x3000 0000
  - AHB SRAM2 mapped at address 0x3001 0000

  All the AHB SRAMs can be accessed by all system masters through the CD AHB matrix except for BDMA2.
- SRD domain, SRD SRAM:
  - SRD SRAM is mapped at address 0x3800 0000 and accessible by most of system masters through SRD domain AHB matrix.

The system AHB SRAM can be accessed as bytes, half-words (16-bit units) or words (32-bit units), while the system AXI SRAM can be accessed as bytes, half-words, words or double-words (64-bit units). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters can read/write-access an SRAM section concurrently with the OTG_HS peripheral accessing another SRAM section.

The TCM SRAMs are dedicated to the Cortex®-M7:

- DTCM-RAM on TCM interface is mapped at the address 0x2000 0000 and accessible by Cortex®-M7, and by MDMA through AHBS slave bus of the Cortex®-M7 CPU. The DTCM-RAM can be used as read-write segment to host critical real-time data (such as stack and heap) for application running on Cortex®-M7 CPU.
- ITCM-RAM on TCM interface mapped at the address 0x0000 0000 and accessible by Cortex®-M7 and by MDMA through AHBS slave bus of the Cortex®-M7 CPU. The ITCM-RAM can be used to host code for time-critical routines (such as interrupt handlers) that requires deterministic execution.

The backup RAM is mapped at the address 0x3880 0000 and is accessible by most of the system masters through SRD domain AHB matrix. With a battery connected to the V_{BAT} pin, the backup SRAM can be used to retain data during low-power mode (Standby and V_{BAT} mode).

Error code correction (ECC)

ITCM-RAM data are protected by ECC:

- 8 ECC bits are added per 64-bit word for ITCM-RAM.

The ECC mechanism is based on the SECDED algorithm. It supports single- and double-error correction.

2.5 Flash memory overview

The flash memory interface manages CPU AXI accesses to the flash memory. It implements the erase and program flash memory operations and the read and write protection mechanisms.

The flash memory is organized as follows:

- For STM32H7A3/7B3: two main memory block divided into sectors.
- For STM32H7B0: one main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to *Section 4: Embedded flash memory (FLASH)* for more details.

2.6 Boot configuration

In the STM32H7A3/7B3 and STM32H7B0, two different boot areas can be selected through the BOOT pin and the boot base address programmed in the BOOT_ADD0 and BOOT_ADD1 option bytes as shown in the *Table 8*.

Table 8. Boot modes

Boot mode selection		Boot area
BOOT	**Boot address option bytes**	
0	BOOT_ADD0[15:0]	Boot address defined by user option byte BOOT_ADD0[15:0] ST programmed value: Flash memory at 0x0800 0000
1	BOOT_ADD1[15:0]	Boot address defined by user option byte BOOT_ADD1[15:0] ST programmed value: System bootloader at 0x1FF0 0000

The values on the BOOT pin are latched on the 4th rising edge of SYSCLK after reset release. It is up to the user to set the BOOT pin after reset.

The BOOT pin is also re-sampled when the device exits the Standby mode. Consequently, they must be kept in the required Boot mode configuration when the device is in the Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

The BOOT_ADD0 and BOOT_ADD1 address option bytes allows to program any boot memory address from 0x0000 0000 to 0x3FFF 0000 which includes:

- All flash address space
- All RAM address space: ITCM, DTCM RAMs and SRAMs
- The TCM-RAM

The BOOT_ADD0 / BOOT_ADD1 option bytes can be modified after reset in order to boot from any other boot address after next reset.

If the programmed boot memory address is out of the memory mapped area or a reserved area, the default boot fetch address is programmed as follows:

- Boot address 0: FLASH at 0x0800 0000
- Boot address 1: ITCM-RAM at 0x0000 0000

When the flash level 2 protection is enabled, only boot from flash memory is available. If the boot address already programmed in the BOOT_ADD0 / BOOT_ADD1 option bytes is out of the memory range or belongs to the RAM address range, the default fetch will be forced from flash memory at address 0x0800 0000.

Embedded bootloader

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the flash memory using one of the following serial interfaces:

- USART1 on PA9/PA10 pins, USART2 on PA3/PA2 pins, and USART3 on PB10/PB11/PD8/PD9 pins
- I2C1 on PB6/PB9 pins, I2C2 on PF0/PF1 pins, I2C3 on PA8/PC9 pins
- USB OTG FS in Device mode (DFU) on PA11/PA12 pins
- SPI1 on PA7/PA6/PA5/PA4 pins, SPI2 on PI3/PI2/PI1/PI0 pins, SPI3 on PC12/PC11/PC10/PA15 pins, and SPI4 on PE14/PE13/PE12/PE11 pins
- FDCAN1 on PD0/PD1/PH13/PH14

For additional information, refer to the application note AN2606.

3 RAM ECC monitoring (RAMECC)

3.1 RAMECC introduction

The STM32H7A3/7B3 and STM32H7B0 devices feature a RAM ECC monitoring unit (RAMECC). It provides a mean for application software to verify ECC status and execute service routines when an error occurs.

Note: For further information on STM32 RAMECC usage, refer to application note AN5342 "Error correction code (ECC) management for internal memories protection on STM32H7 Series" available from www.st.com.

3.2 RAMECC main features

TCM and Cache SRAMs are protected by ECC. The ECC mechanism is based on the SECDED algorithm. It supports single- and double-error detection, as well as single-error correction:

- 7 ECC bits are added per 32-bit word.
- 8 ECC bits are added per 64-bit word for ITCM-RAM.

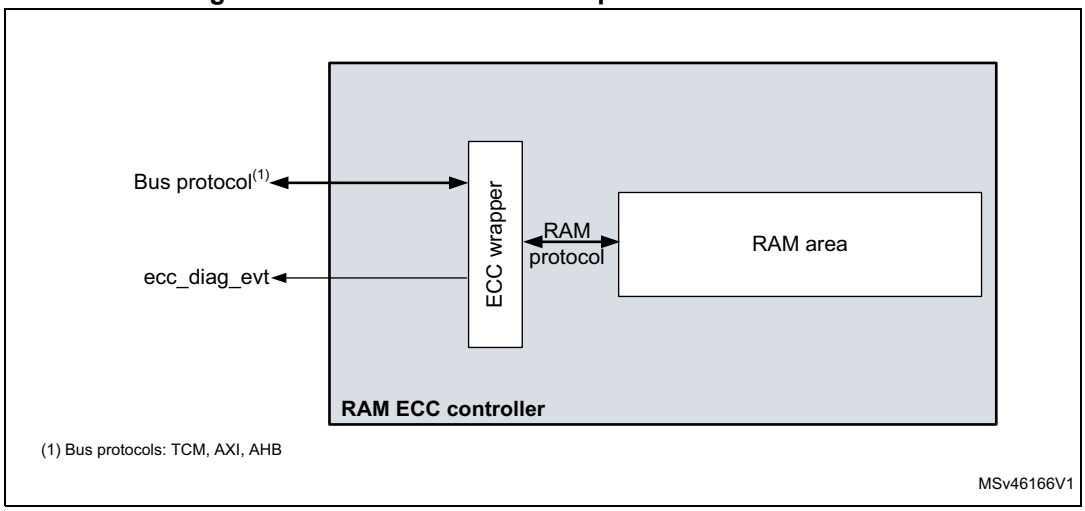
RAM data word integrity is checked at each memory read access, or partial RAM word write operation. Two cycles are required to perform a partial RAM word write (read-modify-write).

The RAMECC monitoring unit includes the following features:

- RAM ECC monitoring per domain
- RAM failing address/data identification

3.3 RAMECC functional description

3.3.1 RAMECC block diagram



An ECC controller is associated to each RAM area. It performs the following functions:

- ECC encoding: ECC code computation and storage.
- ECC decoding: RAM data word loading and ECC code decoding to detect errors
- Error detection: single- and double-error detection
- Error correction: single-error correction.

Note: All the RAM ECC controllers are always enabled.

Figure 3 describes the implementation of RAM ECC controllers.

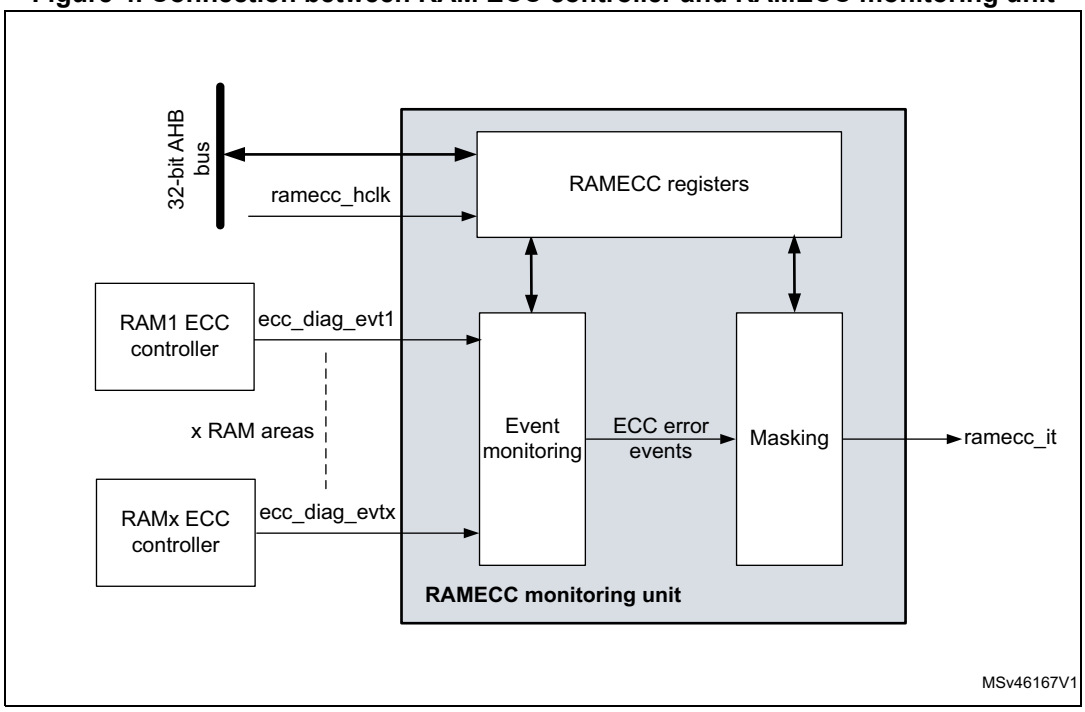


Figure 3. RAM ECC controller implementation schematic

A RAM ECC monitoring area is defined for the CD domain (see *Section 3.3.3: RAMECC monitor mapping*. The RAMECC allows the collection of ECC diagnostic events and provides a mean for the CPU to verify the ECC status.

Figure 4 shows the connection schematic between the RAM ECC controller and the RAMECC monitoring unit.

Figure 4. Connection between RAM ECC controller and RAMECC monitoring unit

3.3.2 RAMECC internal signals

Table 9 gives the list of the internal signals that control the RAMECC unit.

Table 9. RAMECC internal input/output signals

Internal signal name	Signal type	Description
ramecc_hclk	Input	AHB clock
ecc_diag_evtx	Input	ECC diagnostic event generated by RAMx ECC controller x
ramecc_it	Output	Interrupt generated by the RAMECC monitoring unit when an ECC error is detected.

3.3.3 RAMECC monitor mapping

STM32H7A3/7B3 and STM32H7B0 devices features one RAMECC monitoring unit. The inputs from the ECC controllers are mapped as described in *Table 10*. The RAM ECC event monitoring status and configuration registers are described in *Section 3.4: RAMECC registers*.

Table 10. ECC controller mapping

RAMECC unit	Monitor number	SRAM ECC event monitoring status and configuration registers		Size in Kbytes	Address Offset
CD domain RAMECC unit	1	ITCM-RAM ECC monitoring unit		64	0x20
	2	DTCM-RAM ECC monitoring unit	D0TCM	64	0x40
	3		D1TCM	64	0x60

3.4 RAMECC registers

RAMECC registers can be accessed only in 32-bit (word) mode. Byte and half-word formats are not allowed.

3.4.1 RAMECC interrupt enable register (RAMECC_IER)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GECCDEBWIE	GECCDEIE	GECCSEIE	GIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **GECCDEBWIE**: Global ECC double error on byte write (BW) interrupt enable

When GECCDEBWIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a byte write operation to RAM (incomplete word write).

0: no interrupt generated when an ECC double detection error occurs on byte write

1: interrupt generated if an ECC double detection error occurs on byte write

Bit 2 **GECCDEIE**: Global ECC double error interrupt enable

When GECCDEIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from RAM.

0: no interrupt generated when an ECC double detection error occurs

1: interrupt generated if an ECC double detection error occurs

Bit 1 **GECCSEIE**: Global ECC single error interrupt enable

When GECCSEIE bit is set to 1, an interrupt is generated when an ECC single error occurs during a read operation from RAM.

0: no interrupt generated when an ECC single error occurs

1: interrupt generated when an ECC single error occurs

Bit 0 **GIE**: Global interrupt enable

When GIE bit is set to 1, an interrupt is generated when an enabled global ECC error (GECCDEBWIE, GECCDEIE or GECCSEIE) occurs.

0: no interrupt generated when an ECC error occurs

1: interrupt generated when an ECC error occurs

3.4.2 RAMECC monitor x configuration register (RAMECC_MxCR)

Address offset: 0x20 * x

Reset value: 0x0000 0000

x is the ECC monitoring unit number

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCELEN	ECCDEBWIE	ECCDEIE	ECCSEIE	Res.	Res.
										rw	rw	rw	rw		

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **ECCELEN**: ECC error latching enable

When ECCELEN bit is set to 1, if an ECC error occurs (both for single error correction or double detection) during a read operation, the context (address, data and ECC code) that generated the error are latched to their respective registers.

0: no error context preserved when an ECC error occurs

1: error context preserved when an ECC error occurs

Bit 4 **ECCDEBWIE:** ECC double error on byte write (BW) interrupt enable

When ECCDEBWIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a byte write operation to RAM.

0: no interrupt generated when an ECC double detection error occurs on byte write

1: interrupt generated if an ECC double detection error occurs on byte write

Bit 3 **ECCDEIE:** ECC double error interrupt enable

When ECCDEIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a read operation from RAM.

0: no interrupt generated when an ECC double detection error occurs

1: interrupt generated if an ECC double detection error occurs

Bit 2 **ECCSEIE**: ECC single error interrupt enable

When ECCSEIE bit is set to 1, monitor x generates an interrupt when an ECC single error occurs during a read operation from RAM.

0: no interrupt generated when an ECC single error occurs

1: interrupt generated when an ECC single error occurs

Bits 1:0 Reserved, must be kept at reset value.

3.4.3 RAMECC monitor x status register (RAMECC_MxSR)

Address offset: 0x24 + 0x20 * (x - 1), (x= ECC monitoring unit number)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DEBWDF	DEDF	SEDCF
													rc_w0	rc_w0	rc_w0

Bits 31: 3 Reserved, must be kept at reset value.

Bit 2 **DEBWDF:** ECC double error on byte write (BW) detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 1 **DEDF:** ECC double error detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 0 **SEDCF:** ECC single error detected and corrected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected and corrected
1: error detected and corrected

3.4.4 RAMECC monitor x failing address register (RAMECC_MxFAR)

Address offset: 0x28 + 0x20 * (x-1), (x= ECC monitoring unit number)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FADD[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FADD[31:0]:** ECC error failing address
When an ECC error occurs the FADD bitfield contains the address that generated the ECC error.

3.4.5 RAMECC monitor x failing data low register (RAMECC_MxFDRL)

Address offset: 0x2C + 0x20 * (x-1), (x= ECC monitoring unit number)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FDATAL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FDATAL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FDATAL[31:0]:** Failing data low

When an ECC error occurs the FDATAL bitfield contains the LSB part of the data that generated the error. For 32-bit word SRAM, this bitfield contains the full memory word that generated the error.

3.4.6 RAMECC monitor x failing data high register (RAMECC_MxFDRH)

Address offset: 0x30 + 0x20 * (x-1), (x= ECC monitoring unit number)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FDATAH[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FDATAH[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FDATAH[31:0]:** Failing data high (64-bit memory)

When an ECC error occurs the FDATAH bitfield contains the MSB part of the data that generated the error.

Note: This register is reserved in case of 32-bit word SRAM.

3.4.7 RAMECC monitor x failing ECC error code register RAMECC_MxFECR)

Address offset: 0x34 + 0x20 * (x-1), (x= ECC monitoring unit number)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FEC [31:0]:** Failing error code

When an ECC error occurs the FEC bitfield contains the ECC failing code that generated the error.

3.4.8 RAMECC register map

Table 11. RAMECC register map and reset values

Offset	Register name reset value	Register size																														
		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 130* for the register boundary addresses.

4 Embedded flash memory (FLASH)

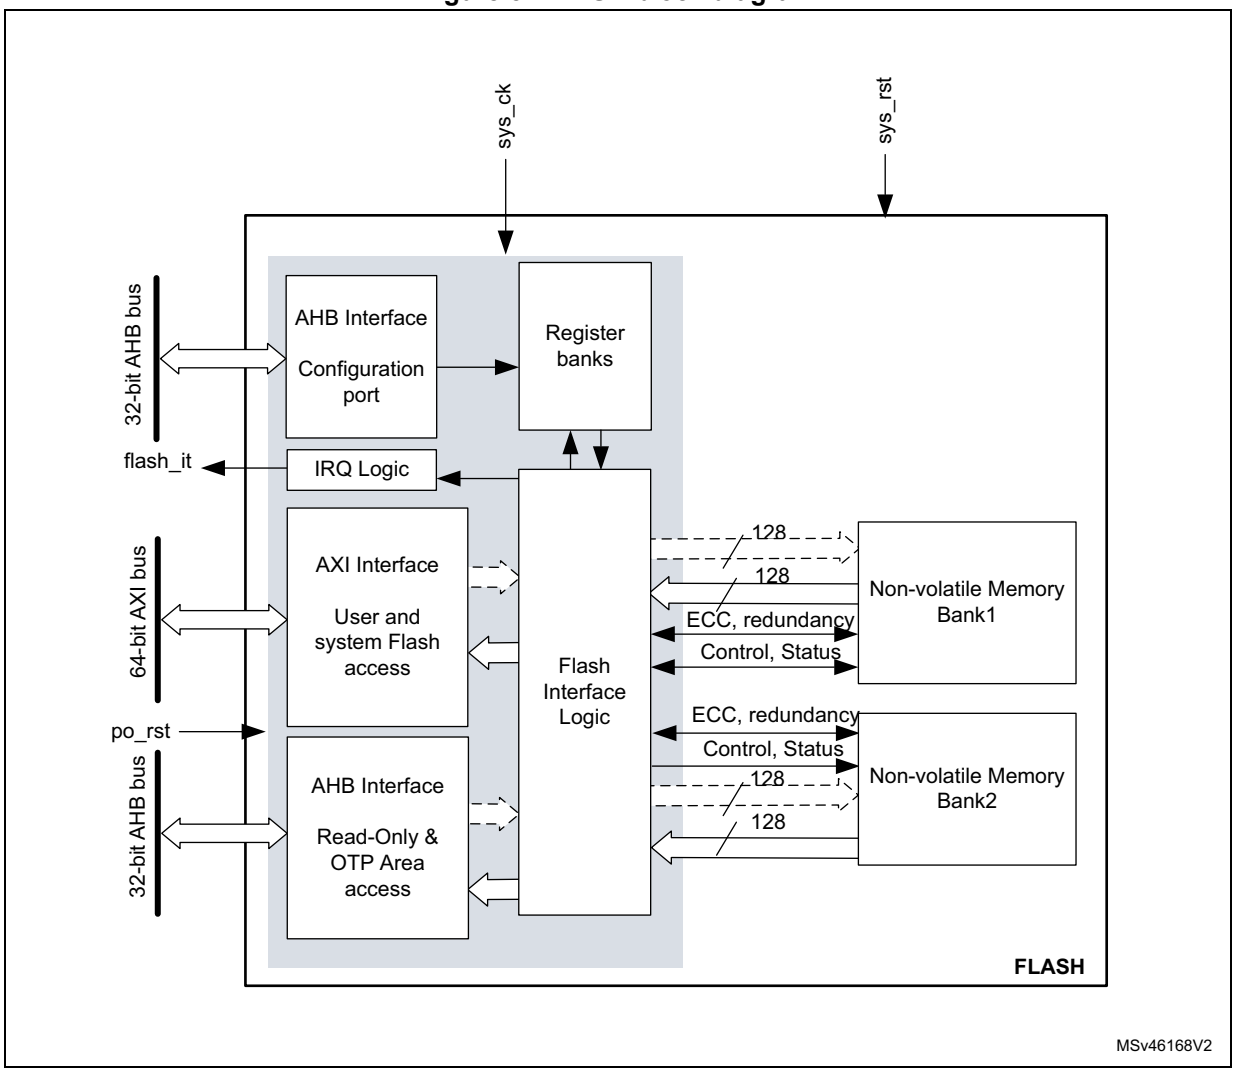
4.1 Introduction

The embedded flash memory (FLASH) manages the accesses of any master to the embedded non-volatile memory, that is up to 2 Mbytes. It implements the read, program and erase operations, error corrections as well as various integrity and confidentiality protection mechanisms.

The embedded flash memory manages the automatic loading of non-volatile user option bytes at power-on reset, and implements the dynamic update of these options.

The embedded flash memory also features a one-time-programmable (OTP) area and a read-only area provisioned by STMicroelectronics during the product manufacturing.

4.2 FLASH main features



- Up to 2 Mbytes of non-volatile memory divided into two banks of up to 1 Mbyte each
- flash memory read operations supporting multiple length (64 bits, 32bits, 16bits or one byte)
- Flash memory programming by 128 bits (user area) and 16 bits (OTP area)
- 8-Kbytes sector erase, bank erase and dual-bank mass erase
- Dual-bank organization supporting (only available on SMT32H7A3/7B3 devices):
  - simultaneous operations: two read/program/erase operations executed in parallel on both banks
  - Bank swapping: the address mapping of the user flash memory of each bank can be swapped, along with the corresponding registers.
- Error Code Correction (ECC): one error detection/correction or two error detections per 128-bit flash word using 9 ECC bits
- Cyclic redundancy check (CRC) hardware module
- User configurable non-volatile option bytes
- Flash memory enhanced protections, activated by option bytes
  - Read protection (RDP), preventing unauthorized flash memory dump to safeguard sensitive application code
  - Sector group write-protection (WRPSG), protecting up to 32 group of 4 sectors (32 Kbytes) per bank
  - Two proprietary code readout protection (PCROP) areas (one per user flash bank). When enabled, this area is execute-only.
  - Two secure-only areas (one per user flash bank). When enabled this area is accessible only if the STM32 microcontroller operates in Secure access mode (only available on STM32H7B0 and STM32H7B3 devices).
- 1-Kbyte one-time programmable (OTP) area
- Read-only area provisioned by STMicroelectronics
- Read command queue to streamline flash operations

4.3 FLASH functional description

4.3.1 FLASH block diagram

Figure 5 shows the embedded flash memory block diagram.

Figure 5. FLASH block diagram

Note: Bank 2 is only available on STM32H7A3/7B3 devices.

4.3.2 FLASH internal signals

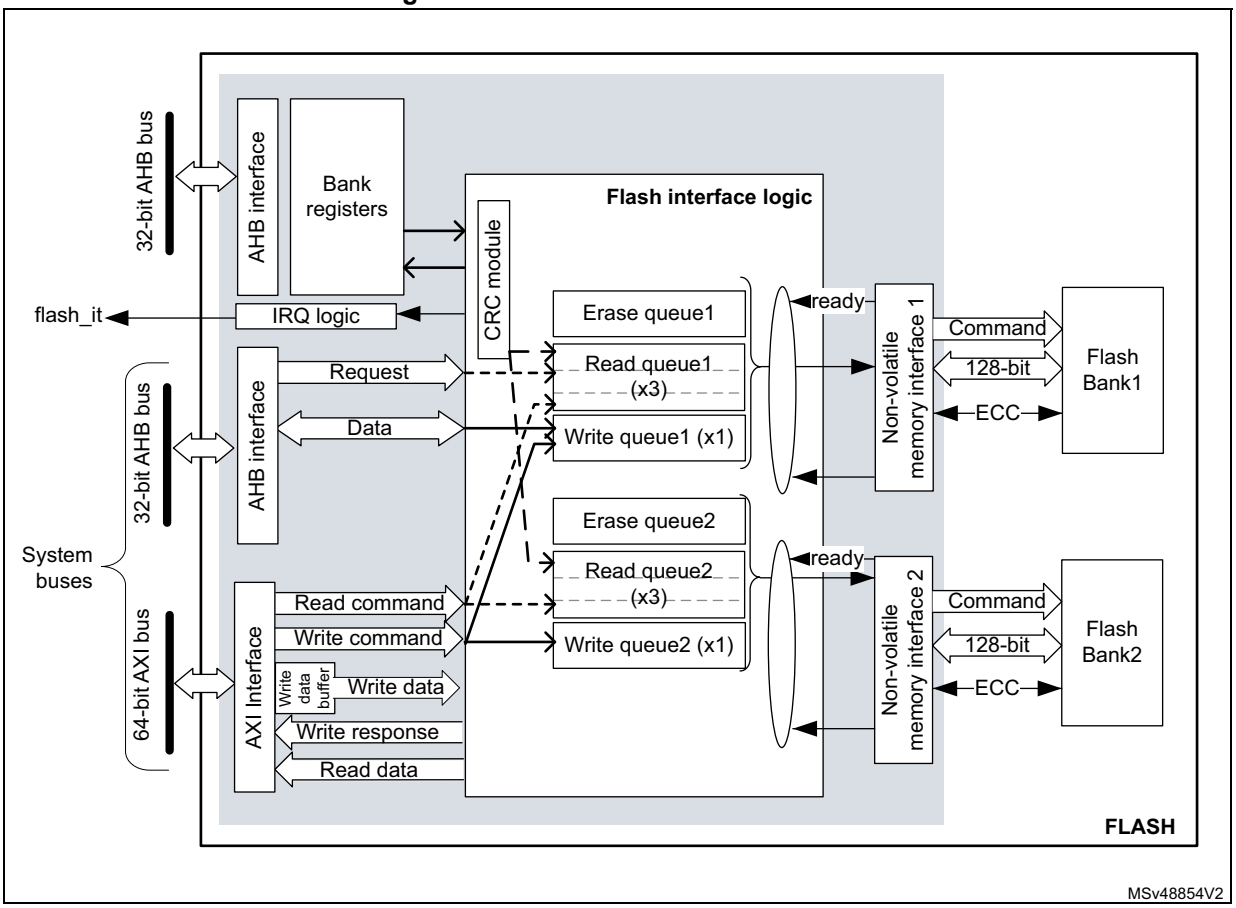
Table 12 describes a list of the useful to know internal signals available at embedded flash memory level. These signals are not available on the microcontroller pads.

Table 12. FLASH internal input/output signals

Signal name	Signal type	Description
sys_ck	Input	CPU domain bus clock (embedded flash memory AXI interface clock)
po_rst	Input	Power on reset
sys_rst	Input	CPU domain system reset
flash_it	Output	Embedded flash memory interrupt request

4.3.3 FLASH architecture and integration in the system

The embedded flash memory is a central resource for the whole microcontroller. It serves as an interface to two non-volatile memory banks, and organizes the memory in a very specific way. The embedded flash memory also proposes a set of security features to protect the assets stored in the non-volatile memory at boot time, at run-time and during firmware and configuration upgrades.



The embedded flash memory offers three different interconnect interfaces:

- An AXI 64-bit slave port to access code/data
- An AHB 32-bit system slave port to access read-only and OTP area
- An AHB 32-bit configuration slave port to access register bank

Note: The application can simultaneously request a read and a write operation through the AXI slave port.

The embedded flash memory microarchitecture is shown in *Figure 6*.

Figure 6. Detailed FLASH architecture

Note: Bank 2 is only available on STM32H7A3/7B3 devices.

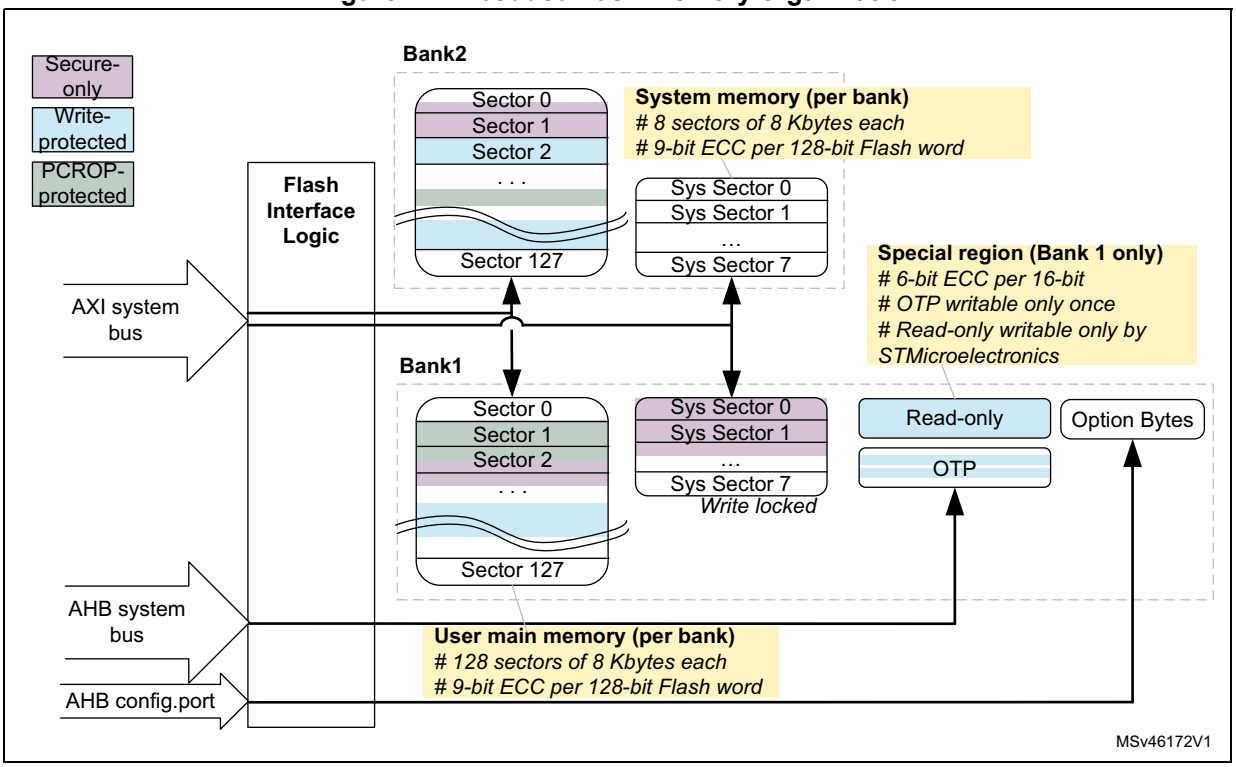
Behind the system interfaces, the embedded flash memory implements various command queues and buffers to perform flash read, write and erase operations with maximum efficiency.

Thanks to the addition of a read and write data buffer, the AXI slave port handles the following access types:

- Multiple length: 64 bits, 32 bits, 16 bits and 8 bits
- Single or burst accesses
- Write wrap burst must not cross 16-byte aligned address boundaries to target exactly one flash word

The AHB system slave port supports only 16-bit or 32-bit word accesses. For 8-bit accesses, an AHB bus error is generated and write accesses are ignored.

The AHB configuration slave port supports 8-bit, 16-bit and 32-bit word accesses.



The embedded flash memory is built in such a way that only one read or write operation can be executed at a time on a given bank.

4.3.4 Flash memory architecture and usage

Flash memory architecture

Figure 7 shows the non-volatile memory organization supported by the embedded flash memory.

Figure 7. Embedded flash memory organization

Note: On STM32H7B0 devices, bank 2 is not available and bank 1 contains 16 sectors of 8 Kbytes each.

The embedded flash non-volatile memory is composed of:

- For STM32H7B3xx and STM32H7A3xI devices: a 2-Mbyte main memory block, organized as two banks of 1 Mbyte each.
- For STM32H7A3xG devices: a 1-Mbyte main memory block, organized as two banks of 512 Kbyte each.
- For STM32H7B0 devices: a 128-Kbyte main memory block, organized in a single bank.
- Each bank is in turn divided in up to 128 sectors of 8 Kbytes each, and features flash-word rows of 128 bits + 9 bits of ECC per word.
- A system memory block of 128 Kbytes, divided into two 64-Kbyte banks. Each bank is in turn divided eight 8-Kbyte sectors. The system flash memory is ECC protected.
- A set of non-volatile option bytes loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.
- A 1 Kbyte one-time-programmable (OTP) area that can be written only once by the application software.
- A 512-byte read-only area that can be written only by STMicroelectronics.

Note: The system flash memory on bank 1 and bank 2 cannot be programmed nor erased by any application.

Since the OTP area has no specific protection, it must not be used to store confidential information.

The overall flash memory architecture and its corresponding access interface is summarized in *Table 13*, *Table 14* and *Table 15*.

Table 13. Flash memory organization (STM32H7A3xI/7B3xI devices)

Flash memory area		Address range	Size (bytes)	Region name	Access interface	SSN1/ 2(1)
User main memory	Bank 1	0x0800 0000-0x0800 1FFF	8 K	Sector 0	AXI port	0x00
		0x0800 2000-0x0800 3FFF	8 K	Sector 1		0x01
		...	...	...		...
		0x080F E000-0x080F FFFF	8 K	Sector 127		0x7F
	Bank 2	0x0810 0000-0x0810 1FFF	8 K	Sector 0		0x00
		0x0810 2000-0x0810 3FFF	8 K	Sector 1		0x01
		...	...	...		...
		0x081F E000-0x081F FFFF	8 K	Sector 127		0x7F
System memory	Bank 1	0x1FF0 0000-0x1FF0 1FFF	8 K	Sys Sector 0 (read-only)	AXI port	N/A(2)
		...	...	...		
		0x1FF0 E000-0x1FF0 FFFF	8 K	Sys Sector 7 (read-only)		
	Bank 2	0x1FF1 0000-0x1FF1 1FFF	8 K	Sys Sector 0 (read-only)		
		...	...	...		...
		0x1FF1 E000-0x1FF1 FFFF	8 K	Sys Sector 7 (read-only)		N/A(2)
Special region	Bank 1	0x08FF F000-0x08FF F3FF	1 K	OTP area	AHB system port	N/A(2)
		0x08FF F800-0x08FF F9FF	512	Read-only area		
Option bytes		N/A	-	User option bytes	Registers only	N/A(2)

1. SSN1/2 contain the target sector number for an erase operation. See *Section 4.3.10* for details.
2. Cannot be erased by application software.

Table 14. Flash memory organization (STM32H7B0 devices)

Flash memory area		Address range	Size (bytes)	Region name	Access interface	SSN1[1]
User main memory	Bank 1	0x0800 0x0000-0x0800 1FFF	8 K	Sector 0	AXI port	0x00
		0x0800 2000-0x0800 3FFF	8 K	Sector 1		0x01
		….	….	…		…
		0x0801 E000-0x0801 FFFF	8 K	Sector 15		0x0F
System memory	Bank 1	0x1FF0 0000-0x1FF0 FFFF	64 K	System flash (read-only)	AXI port	N/A[2]
	Bank 2	0x1FF1 0000-0x1FF1 FFFF	64 K	System flash (read-only)	-	N/A[2]
Special region	Bank 1	0x08FF F000-0x08FF F3FF	1 K	OTP area	AHB system port	N/A[2]
		0x08FF F800-0x08FF F9FF	512	Read-only area		
Option bytes		N/A	-	User option bytes	Registers only[3]	N/A[2]

1. SSN1 contains the target sector number for an erase operation. See *Section 4.3.10* for details.
2. Cannot be erased by application software.
3. On STM32H7B0 devices, only bank 1 option byte registers are applicable. Bank 2 option byte registers must be kept at their reset value.

Table 15. Flash memory organization (STM32H7A3xG devices)

Flash memory area		Address range	Size (bytes)	Region name	Access interface	SSN1/2[1]
User main memory	Bank 1	0x0800 0000-0x0800 1FFF	8 K	Sector 0	AXI port	0x00
		0x0800 2000-0x0800 3FFF	8 K	Sector 1		0x01
		….	….	…		…
		0x0807 E000-0x0807 FFFF	8 K	Sector 63		0x3F

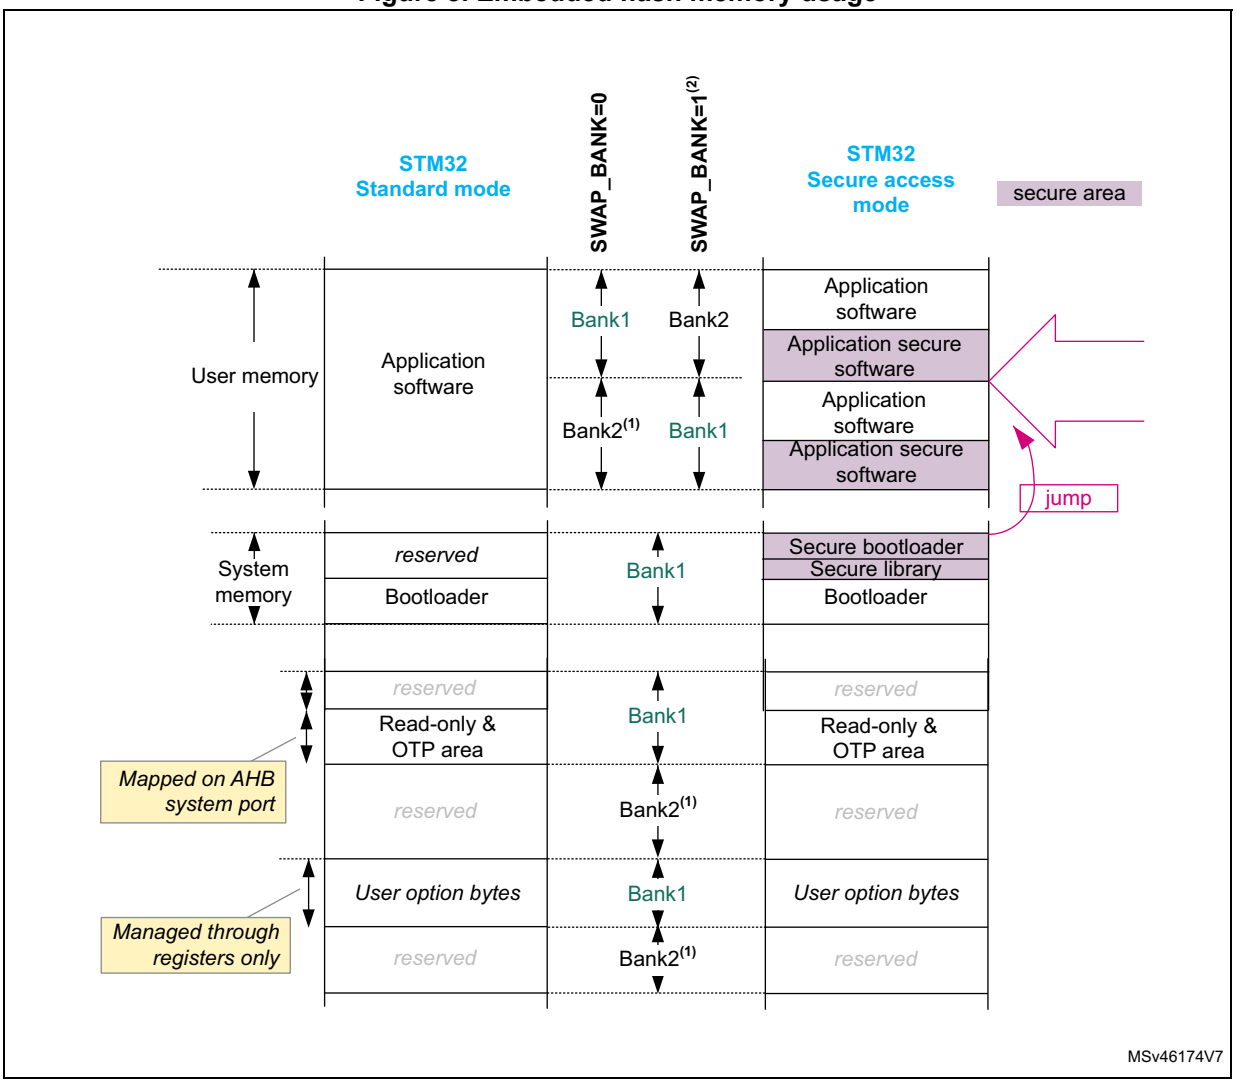
		….	….	…		…
		0x0817 E000-0x0817 FFFF	8 K	Sector 63		0x3F

Table 15. Flash memory organization (STM32H7A3xG devices) (continued)



Flash memory area		Address range	Size (bytes)	Region name	Access interface	SSN1/2(1)
System memory	Bank 1	0x1FF0 0000-0x1FF0 FFFF	64 K	System flash (read-only)	AXI port	N/A(2)
	Bank 2	0x1FF1 0000-0x1FF1 FFFF	64 K	System flash (read-only)		N/A(2)
Special region	Bank 1	0x08FF F000-0x08FF F3FF	1 K	OTP area	AHB system port	N/A(2)
		0x08FF F800-0x08FF F9FF	512	Read-only area		
Option bytes		N/A	-	User option bytes	Registers only	N/A(2)

1. SSN1/2 contain the target sector number for an erase operation. See *Section 4.3.10* for details.
2. Cannot be erased by application software.

Partition usage

Figure 8 shows how the embedded flash memory is used both by STMicroelectronics and the application software.

Figure 8. Embedded flash memory usage

1. Bank 2 is available only on STM32H7A3/7B3 devices.
2. Bank swapping is supported only on STM32H7A3/7B3 devices.

User and system memories are used differently according to whether the microcontroller is configured by the application software in Standard mode or in Secure access mode (STM32H7B0 and STM32H7B3 devices only). This selection is done through the SECURITY option bit (see *Section 4.4.6*):

- In Standard mode, the user memory contains the application code and data, while the system memory is loaded with the STM32 bootloader. When a reset occurs, the core

jumps to the boot address configured through the BOOT pin and the BOOT_ADD0/1 option bytes.

- In Secure access mode, dedicated libraries can be used for secure boot. They are located in user flash and system flash memory:
  - ST libraries in system flash memory assist the application software boot with special features such as secure boot and secure firmware install (SFI).
  - Application secure libraries in user flash memory are used for secure firmware update (SFU).

  In Secure access mode, the microcontroller always boots into the secure bootloader code (unique entry point). Then, if no secure services are required, this code securely jumps to the requested boot address configured through the BOOT pin and the option bytes, as shown in *Figure 8* (see *Section 5: Secure memory management (SMM)* for details).

Note: For more information on option byte setup for boot, refer to Section 4.4.7.

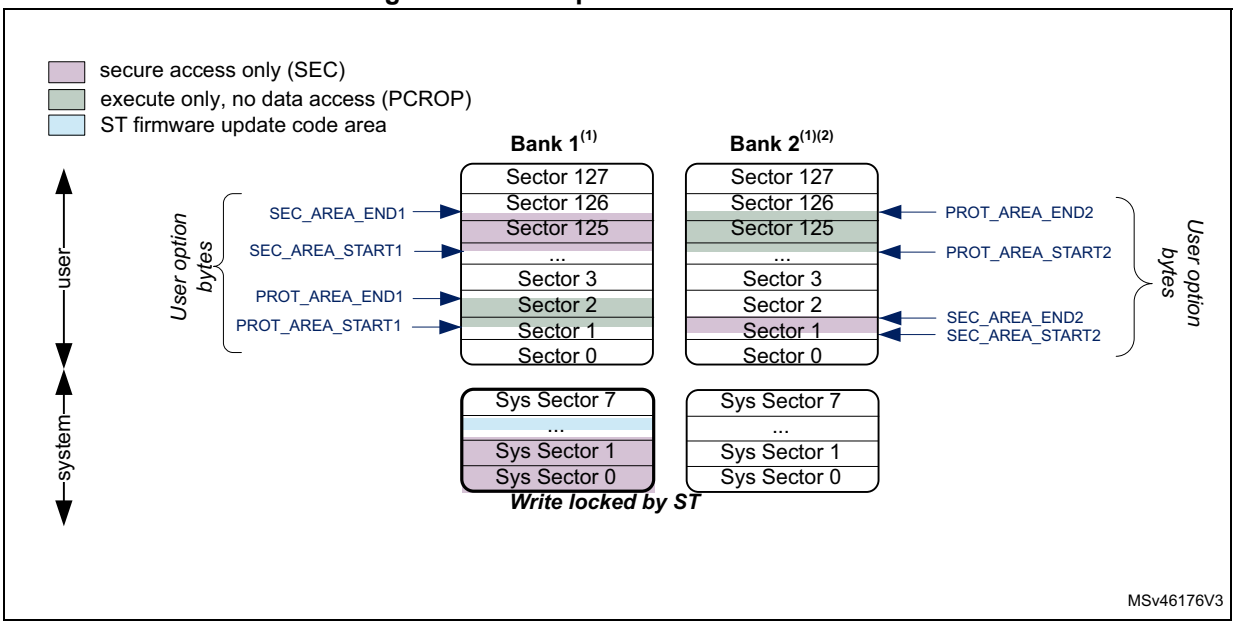
Additional partition usage is the following:

- The option bytes are used by STMicroelectronics and by the application software as non-volatile product options (e.g. boot address, protection configuration and reset behaviors).
- The OTP area is used by the application software. This area is virgin when the device is delivered by STMicroelectronics.
- The read-only area is programmed by STMicroelectronics during manufacturing to contain unique device ID and product information.

Note: For further information on STM32 bootloader flashing by STMicroelectronics, refer to application note AN2606 "STM32 microcontroller system memory boot mode" available from www.st.com.

Bank swapping (STM32H7A3/7B3 only)

As shown in *Figure 8*, the embedded flash memory offers a bank swapping feature that can be configured through the SWAP_BANK bit, always available for the application. For more information please refer to *Section 4.3.15*.



4.3.5 FLASH system performance enhancements

The embedded flash memory does not implement a local cache memory to read or write data. Read command queues (one per bank) are used instead to enhance flash operations.

4.3.6 FLASH data protection schemes

Figure 9 gives an overview of the protection mechanisms supported by the embedded flash memory. A PCROP and a secure-only area can be defined for each bank. The properties of these protected areas are detailed in *Section 4.5*. PCROP is supported by all devices, while the secure-only areas are available only on STM32H7B0/B3.

Figure 9. FLASH protection mechanisms

Note: For STM32H7A3XG devices, bank 1 and bank 2 are limited to 64 sectors.
For STM32H7B0 devices, bank 1 is limited to 16 sectors.
Bank 2 is available only on STM32H7A3/7B3 devices.

4.3.7 Overview of FLASH operations

Read operations

The embedded flash memory can perform read operations on the whole non-volatile memory using various granularities: 64 bits, 32 bits, 16 bits or one byte. User and system flash memories are read through the AXI interface, while the option bytes are read through the register interface. Read-only and OTP special region are read through the system AHB interface.

The embedded flash memory supports read-while-write operations provided the read and write operations target different banks. Similarly read-while-read operations are supported when two read operations target different banks. Read-while-write and read-while-read are supported only on STM32H7A3/7B3 devices.

To increase efficiency, the embedded flash memory implements the buffering of consecutive read requests in the same bank.

For more details on read operations, refer to *Section 4.3.8: FLASH read operations*.

Program/erase operations

The embedded flash memory supports the following program and erase operations:

- Single flash word write (128-bit granularity for user flash memory, 16-bit granularity for OTP area), with the possibility for the application to force-write a user flash word with less than 128 bits in user flash memory
- Single sector erase
- Bank erase (single or dual)
- Option byte update

Thanks to its dual bank architecture, the embedded flash memory can perform any of the above write or erase operation on one bank while a read or another program/erase operation is executed on the other bank.

Dual bank and related operations are supported only on STM32H7A3/7B3 devices.

Note: Program and erase operations are subject to the various protection that could be set on the embedded flash memory, such as write protection and global readout protection (see next sections for details).

For more details refer to *Section 4.3.9: FLASH program operations* and *Section 4.3.10: FLASH erase operations*.

Protection mechanisms

The embedded flash memory supports different protection mechanisms:

- Global readout protection (RDP)
- Proprietary code readout protection (PCROP)
- Write protection
- Secure access only protection

For more details refer to *Section 4.5: FLASH protection mechanisms*.

Option byte loading

Under specific conditions, the embedded flash memory reliably loads the non-volatile option bytes stored in non-volatile memory, thus enforcing boot and security options to the whole system when the embedded flash memory becomes functional again. For more details refer to *Section 4.4: FLASH option bytes*.

Bank/register swapping (STM32H7A3/7B3 only)

The embedded flash memory allows swapping bank 1 and bank 2 memory mapping. This feature can be used after a firmware upgrade to restart the microcontroller on the new firmware after a system reset. For more details on the feature, refer to *Section 4.3.15: Flash bank and register swapping (STM32H7A3/7B3 only)*.

4.3.8 FLASH read operations

Read operation overview

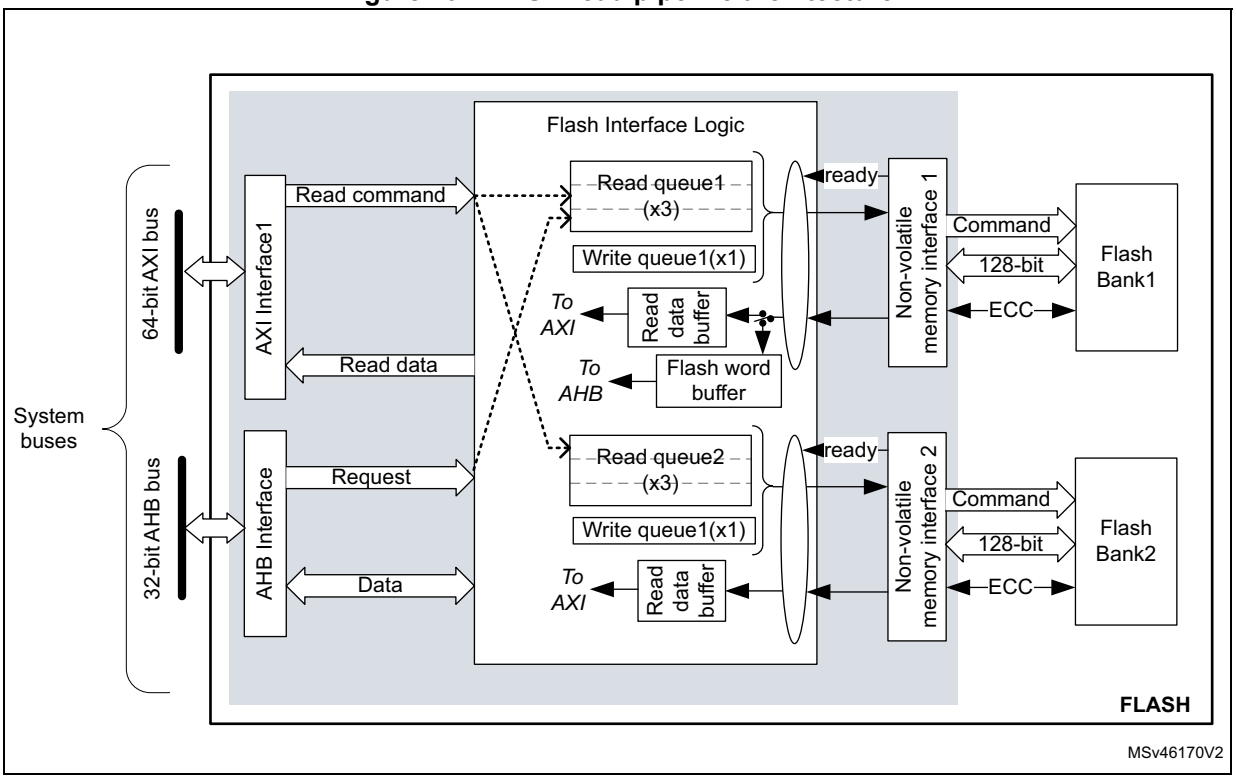
The embedded flash memory supports, for each memory bank, the execution of one read command while two are waiting in the read command queue. Multiple read access types are also supported as defined in *Section 4.3.3: FLASH architecture and integration in the system*.

The read commands to each bank are associated with a 128-bit read data buffer. These commands can be issued either by the AHB (OTP or read-only areas) or by the AXI interface (user flash or system flash memory).

Note: The embedded flash memory can perform single error correction and double error detection while read operations are being executed (see Section 4.3.12: Flash memory error protections).

The AXI interface read channel operates as follows:

- When the read command queue is full, any new AXI read request stalls the bus read channel interface and consequently the master that issued that request.
- If several consecutive read accesses request data that belong to the same flash data word (128 bits), the data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons (e.g. PCROP protected word), the corresponding read error response is issued by the embedded flash memory and no read operation to flash memory is triggered.



The AHB system interface operates a follows:

- If the application reads an OTP data that has not been previously written, a double ECC error is reported and only 1's are returned (see *Section 4.3.13: FLASH one-time programmable area* for details)
- Until the read request has been served, the embedded flash memory stalls the AHB bus and consequently the master that issued that request.

The Read pipeline architecture is summarized in *Figure 10*.

For more information on bus interfaces, refer to *Section 4.3.3: FLASH architecture and integration in the system*.

Figure 10. FLASH read pipeline architecture

Note: Flash bank 2 is available only on STM32H7A3/7B3 devices.

Single read sequence

The recommended simple read sequence is the following:

1. For AXI interface: Freely perform read accesses to any AXI-mapped area. For AHB interface: perform either 16-bit or 32-bit read accesses to the AHB-mapped area (byte accesses generate a bus error).
2. The embedded flash memory effectively executes the read operation from the read command queue buffer as soon as the non-volatile memory is ready and the previously requested operations on this specific bank have been served.

Note: When reading an OTP data that has not been previously written, a double ECC error is reported and only 1's are returned.

Adjusting read timing constraints

The embedded flash memory clock must be enabled and running before reading data from non-volatile memory.

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the flash access control register (FLASH_ACR) according to the embedded flash memory AXI interface clock frequency (sys_ck) and the internal voltage range of the device (V_{core}).

Table 16 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency and its supply voltage ranges.

Table 16. FLASH recommended number of wait states and programming delay

Number of wait states (LATENCY)	Programming delay (WRHIGH FREQ)	AXI Interface clock frequency v.s. V_{CORE} range			
		VOS3 range 0.95 V - 1.05 V	VOS2 range 1.05 V - 1.15 V	VOS1 range 1.15 V - 1.25 V	VOS0 range 1.25 V - 1.35 V
0 WS (1 FLASH clock cycle)	00	22 MHz	34 MHz	38 MHz	42 MHz
1 WS (2 FLASH clock cycles)		44 MHz	68 MHz	76 MHz	84 MHz
2 WS (3 FLASH clock cycles)	01	66 MHz	102 MHz	114 MHz	126 MHz
3 WS (4 FLASH clock cycles)		88 MHz	136 MHz	152 MHz	168 MHz

Table 16. FLASH recommended number of wait states and programming delay (continued)

Number of wait states (LATENCY)	Programming delay (WRHIGH FREQ)	AXI Interface clock frequency v.s. V_{CORE} range			
		VOS3 range 0.95 V - 1.05 V	VOS2 range 1.05 V - 1.15 V	VOS1 range 1.15 V - 1.25 V	VOS0 range 1.25 V - 1.35 V
4 WS (5 FLASH clock cycles)	10	88 MHz	160 MHz	190 MHz	210 MHz
5 WS (6 FLASH clock cycles)		88 MHz	160 MHz	225 MHz	252 MHz
6 WS (7 FLASH clock cycles)	11	88 MHz	160 MHz	225 MHz	280 MHz

Adjusting system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at a voltage scaling value of VOS3. As a result, a conservative 3 wait-state latency is specified in FLASH_ACR register (see *Table 16*).

When changing the AXI bus frequency, the application software must follow the below sequence in order to tune the number of wait states required to access the non-volatile memory.

To increase the embedded flash memory clock source frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 16*.
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AXI bus clock prescaler value are taken in account by reading back the embedded flash memory clock source status and/or the AXI bus prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the embedded flash memory clock source frequency:

1. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded flash

memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).

3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in *Table 16*.
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Error code correction (ECC)

The embedded flash memory embeds an error correction mechanism. Single error correction and double error detection are performed for each read operation. For more details, refer to *Section 4.3.12: Flash memory error protections*.

Read errors

When the ECC mechanism is not able to correct the read operation, the embedded flash memory reports read errors as described in *Section 4.7.6: Error correction code error (SNECCERR/DBECCERR)*.

Read interrupts

See *Section 4.8: FLASH interrupts* for details.

4.3.9 FLASH program operations

Program operation overview

The virgin state of each non-volatile memory bitcell is 1. The embedded flash memory supports programming operations that can change (reset) any memory bitcell to 0. However these operations do not support the return of a bit to its virgin state. In this case an erase operation of the entire sector is required.

Program operation consists in issuing write commands. The embedded flash memory supports the execution of one write command for each memory bank. For write accesses issued by the AXI interface, since a 9-bit ECC code is associated to each 128-bit data flash word, the embedded flash memory must always perform write operations to non-volatile memory with a 128-bit word granularity.

Note: The application can decide to write as little as 8 bits to a 128 flash word. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW1/2 bit of FLASH_CR1/2 register).

System flash memory bank 1 and bank 2 cannot be written by the application software.

It is not recommended to overwrite a flash word that is not virgin. The result may lead to an inconsistent ECC code that will be systematically reported by the embedded flash memory, as described in *Section 4.7.6: Error correction code error (SNECCERR/DBECCERR)*.

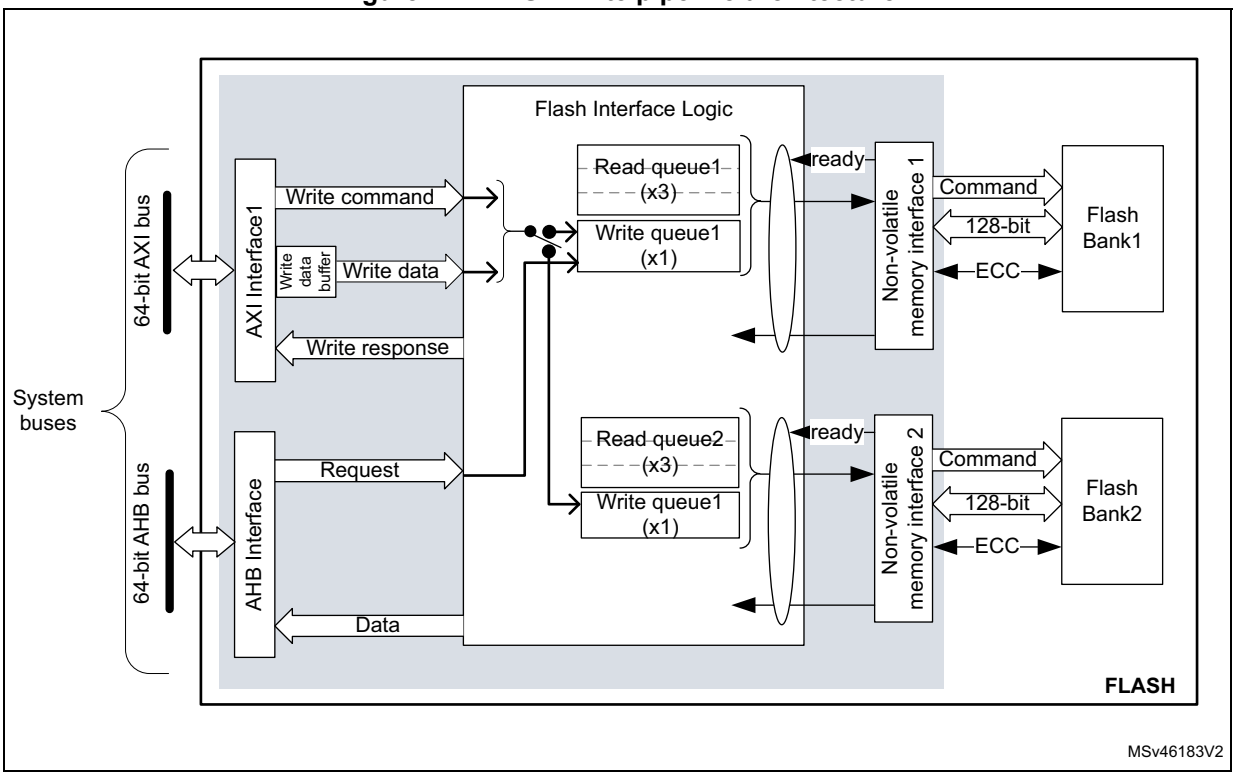
Write access requests issued by the AHB system interface are serialized with AXI commands and can only be used to program the memory OTP area. In this area, since a 6-bit ECC code is associated to each 16-bit data flash word, the embedded flash memory supports 16-bit or 32-bit write operations (8-bit write operations are not supported).

Note: The OTP area is typically write-protected on the final product, as described in Section 4.3.13: FLASH one-time programmable area.

Erase operations to the OTP area are not supported.

The AXI interface write channel operates as follows:

- A 128-bit write data buffer is associated with the AXI interface. It supports multiple write access types (64 bits, 32 bits, 16 bits and 8 bits).
- When the write queue is full, any new AXI write request stalls the bus write channel interface and consequently the master that issued that request.



The AHB system interface operates as follows:

- Write commands issued by the AHB system interface are associated with a 137-bit flash word buffer. Byte accesses are not supported.
- When the write queue is full, any new AHB request stalls the bus interface and consequently the master that issued that request.

The write pipeline architecture is described in *Figure 11*.

For more information on bus interfaces, refer to *Section 4.3.3: FLASH architecture and integration in the system*.

Figure 11. FLASH write pipeline architecture

Note: Flash bank 2 is available only on STM32H7A3/7B3 devices.

Managing write protections

Before programming a user sector, the application software must check the protection of the targeted flash memory area.

The embedded flash memory checks the protection properties of the write transaction target at the output of the write queue buffer, just before the effective write operation to the non-volatile memory:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERR1/2) is raised in FLASH_SR1/2 register.
- If the write operation is valid, the 9-bit ECC code is concatenated to the 128 bits of data and the write to non-volatile memory is effectively executed.

Note: No write protection check is performed when the embedded flash memory accepts AXI write requests.

A similar mechanism exists for OTP areas with the following differences:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERR1/2) is raised in FLASH_SR1/2 register.
- If the write operation is valid, the 6-bit ECC code is concatenated to the 16 bits of data and the write to non-volatile memory is effectively executed.

The write protection flag does not need to be cleared before performing a new programming operation.

Monitoring ongoing write operations

The application software can use three status flags located in FLASH_SR1/2 in order to monitor ongoing write operations. Those status are available for each bank.

- **BSY1/2**: this bit indicates that an effective write, erase or option byte change operation is ongoing to the non-volatile memory.
- **QW1/2**: this bit indicates that a write, erase or option byte change operation is pending in the write queue or command queue buffer. It remains high until the write operation is complete. It supersedes the BSY1/2 status bit.
- **WBNE1/2**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, force-writes the operation using FW1/2 bit in FLASH_CR1/2, or disables all write operations in the corresponding bank.

Enabling write operations

Before programming the user flash memory in bank 1 (respectively bank 2), the application software must make sure that PG1 bit (respectively PG2) is set to 1 in FLASH_CR1 (respectively FLASH_CR2). If it is not the case, an unlock sequence must be used (see *Section 4.5.1: FLASH configuration protection*) and the PG1/2 bit must be set.

When the option bytes need to be modified or a mass erase needs to be started, the application software must make sure that FLASH_OPTCR is unlocked. If it is not the case, an unlock sequence must be used (see *Section 4.5.1: FLASH configuration protection*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register will remain locked until next system reset.

If needed, the application software can update the programming delay as described at the end of this section.

Single write sequence

The recommended single write sequence in bank 1/2 is the following:

1. Unlock the FLASH_CR1/2 register, as described in *Section 4.5.1: FLASH configuration protection* (only if register is not already unlocked).
2. Enable write operations by setting the PG1/2 bit in the FLASH_CR1/2 register.
3. Check the protection of the targeted memory area.
4. Write one flash-word corresponding to 16-byte data starting at 16-byte aligned address.
5. Check that QW1 (respectively QW2) has been raised and wait until it is reset to 0.

If step 4 is executed incrementally (e.g. byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW1/2 bit in FLASH_CR1/2 register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW1/2 bit has no effect.

Note: Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a permanent ECC error.

Any write access requested while the PG1/2 bit is cleared to 0 is rejected. In this case, no error is generated on the bus, but the PGSERR1/2 flag is raised.

Clearing the programming sequence error (PGSERR) and inconsistency error (INCERR) is mandatory before attempting a write operation (see Section 4.7: FLASH error management for details).

Adjusting programming timing constraints

Program operation timing constraints depend of the embedded flash memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the non-volatile memory will not operate correctly, if they are too lax, the programming speed will not be optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to *Table 16* in *Section 4.3.8: FLASH read operations* for the recommended programming delay depending on the embedded flash memory clock frequency.

FLASH_ACR configuration register is common to both banks.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the flash memory might corrupt the flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in *Section 4.7: FLASH error management*.

Programming interrupts

See *Section 4.8: FLASH interrupts* for details.

4.3.10 FLASH erase operations

Erase operation overview

The embedded flash memory can perform erase operations on 8-Kbyte user sectors, on one user flash memory bank or on two user flash memory banks (i.e. mass erase).

Note: System flash memory and read-only/OTP area cannot be erased by the application software.

The erase operation forces all non-volatile bit cells to high state, which corresponds to the virgin state. It clears existing data and corresponding ECC, allowing a new write operation to be performed. If the application software reads back a word that has been erased, all the bits will be read at 1. No ECC error is generated if the word is located in user flash memory, while a double ECC error is raised if the word is located in read-only or OTP area.

Erase operations are similar to read or program operations except that the commands are queued in a special buffer (a one-command deep erase queue).

Erase commands are issued through the AHB configuration interface. If the embedded flash memory receives simultaneously a write and an erase request for the same bank, both operations are accepted but the write operation is executed first.

Note: If data cache is enabled after a flash erase operation, it is recommended to invalidate the cache by software to avoid reading old data.

Erase and security

A user sector can be erased only if it does not contain PCROP, secure-only or write-protected data (see *Section 4.5: FLASH protection mechanisms* for details). In other words, if the application software attempts to erase a user sector with at least one flash word that is protected, the sector erase operation is aborted and the WRPERR1/2 flag is raised in the FLASH_SR1/2 register, as described in *Section 4.7.2: Write protection error (WRPERR)*.

The embedded flash memory allows the application software to perform an erase followed by an automatic protection removal (PCROP, secure-only area and write protection), as described hereafter.

Enabling erase operations

Before erasing a sector in bank 1 (respectively bank 2), the application software must make sure that FLASH_CR1 (respectively FLASH_CR2) is unlocked. If it is not the case, an unlock sequence must be used (see *Section 4.5.1: FLASH configuration protection*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register will remain locked until next system reset.

Similar constraints apply to bank erase requests.

Flash sector erase sequence

To erase a 8-Kbyte user sector, proceed as follows:

1. Check and clear all the error flags due to previous programming/erase operation. Refer to *Section 4.7: FLASH error management* for details.
2. Unlock the FLASH_CR1/2 register, as described in *Section 4.5.1: FLASH configuration protection* (only if register is not already unlocked).
3. Set the SER1/2 bit and SNB1/2 bitfield in the corresponding FLASH_CR1/2 register. SER1/2 indicates a sector erase operation, while SNB1/2 contains the target sector number.
4. Set the START1/2 bit in the FLASH_CR1/2 register.
5. Wait for the QW1/2 bit to be cleared in the corresponding FLASH_SR1/2 register.

Note: If a bank erase is requested simultaneously to the sector erase (BER1/2 bit set), the bank erase operation supersedes the sector erase operation.

Standard flash bank erase sequence

To erase all bank sectors except for those containing secure-only and protected data, proceed as follows:

1. Check and clear all the error flags due to previous programming/erase operation. Refer to *Section 4.7: FLASH error management* for details.
2. Unlock the FLASH_CR1/2 register, as described in *Section 4.5.1: FLASH configuration protection* (only if register is not already unlocked).
3. Set the BER1/2 bit in the FLASH_CR1/2 register corresponding to the targeted bank.
4. Set the START1/2 bit in the FLASH_CR1/2 register to start the bank erase operation. Then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register.

Note: BER1/2 and START1/2 bits can be set together, so above steps 3 and 4 can be merged.

If a sector erase is requested simultaneously to the bank erase (SER1/2 bit set), the bank erase operation supersedes the sector erase operation.

Flash bank erase with automatic protection-removal sequence

To erase all bank sectors including those containing secure-only and protected data without performing an RDP regression (see *Section 4.5.3*), proceed as follows:

1. Check and clear all the error flags due to previous programming/erase operation. Refer to *Section 4.7: FLASH error management* for details.
2. Unlock FLASH_OPTCR register, as described in *Section 4.5.1: FLASH configuration protection* (only if register is not already unlocked).
3. If a PCROP-protected area exists set DMEP1/2 bit in FLASH_PRAR_PRG1/2 register. In addition, program the PCROP area end and start addresses so that the difference is negative, i.e. PROT_AREA_END1/2 < PROT_AREA_START1/2.
4. If a secure-only area exists set DMES1/2 bit in FLASH_SCAR_PRG1/2 register. In addition, program the secure-only area end and start addresses so that the difference is negative, i.e. SEC_AREA_END1/2 < SEC_AREA_START1/2.
5. Set all WRPSGn1/2 bits in FLASH_WPSGN_PRG1/2R to 1 to disable all sector write protection.
6. Unlock FLASH_CR1/2 register, only if register is not already unlocked.
7. Set the BER1/2 bit in the FLASH_CR1/2 register corresponding to the target bank.
8. Set the START1/2 bit in the FLASH_CR1/2 register to start the bank erase with protection removal operation. Then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register. At that point a bank erase operation has erased the whole bank including the sectors containing PCROP-protected and/or secure-only data, and an option byte change has been automatically performed so that all the protections are disabled.

Note: BER1/2 and START1/2 bits can be set together, so above steps 8 and 9 can be merged.

Be aware of the following warnings regarding to above sequence:

- It is not possible to perform the above sequence on one bank while modifying the protection parameters of the other bank.
- No other option bytes than the one indicated above must be changed, and no protection change must be performed in the bank that is not targeted by the bank erase with protection removal request.
- When one or both of the events above occurs, a simple bank erase occurs, no option byte change is performed and no option change error is set.

Flash mass erase sequence

To erase all sectors of both banks simultaneously, excepted for those containing secure-only and protected data, the application software can set the MER bit to 1 in FLASH_OPTCR register, as described below:

1. Check and clear all the error flags due to previous programming/erase operation. Refer to *Section 4.7: FLASH error management* for details.
2. Unlock the two FLASH_CR1/2 registers and FLASH_OPTCR register, as described in *Section 4.5.1: FLASH configuration protection* (only if the registers are not already unlocked).
3. Set the MER bit to 1 in FLASH_OPTCR register. It automatically sets BER1, BER2, START1 and START2 to 1, thus launching a bank erase operation on both banks. Then wait until both QW1 and QW2 bits are cleared in the corresponding FLASH_SR1/2 register.

Flash mass erase with automatic protection-removal sequence

To erase all sectors of both banks simultaneously, including those containing secure-only and protected data, and without performing an RDP regression, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation.
2. Unlock the two FLASH_CR1/2 registers and FLASH_OPTCR register (only if the registers are not already unlocked).
3. If a PCROP-protected area exists, set DMEP1/2 bit in FLASH_PRAR_PRG1/2 register. In addition, program the PCROP area end and start addresses so that the difference is negative. This operation must be performed for both banks.
4. If a secure-only area exists, set DMES1/2 bit in FLASH_SCAR_PRG1/2 register. In addition, program the secure-only area end and start addresses so that the difference is negative. This operation must be performed for both banks.
5. Set all WRPSGn1/2 bits in FLASH_WPSGN_PRG1/2R to 1 to disable all sector write protections. This operation must be performed for both banks.
6. Set the MER bit to 1 in FLASH_OPTCR register, then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register. At that point, a flash bank erase with automatic protection removal is executed on both banks. The sectors containing PCROP-protected and/or secure-only data become unprotected since an option byte change is automatically performed after the mass erase so that all the protections are disabled.

Caution: No other option bytes than the ones mentioned in the above sequence must be changed, otherwise a simple mass erase is executed, no option byte change is performed and no option change error is raised.

4.3.11 FLASH parallel operations

As the non-volatile memory is divided into two independent banks, the embedded flash memory interface can drive different operations at the same time on each bank. For example a read, write or erase operation can be executed on bank 1 while another read, write or erase operation is executed on bank 2.

In all cases, the sequences described in *Section 4.3.8: FLASH read operations*, *Section 4.3.9: FLASH program operations* and *Section 4.3.10: FLASH erase operations* apply.

4.3.12 Flash memory error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detects double errors.

This mechanism uses 9 ECC bits per 128-bit flash word, and applies to user and system memory. For read-only and OTP areas, a stronger 6 ECC bits per 16-bit word is used.

Note: A double ECC error is generated for an OTP virgin word (i.e. a word with 22 bits at 1). When this OTP word is no more virgin, the ECC error disappears.

More specifically, during each read operation from a 128-bit flash word, the embedded flash memory retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the reference value. If they do not match, the corresponding ECC

error is raised as described in *Section 4.7.6: Error correction code error (SNECCERR/DBECCERR)*.

During each program operation, a 9-bit ECC code is associated to each 128-bit data flash word, and the resulting 137-bit flash word information is written in non-volatile memory.

A similar mechanism applies to read-only and OTP areas.

Cyclic redundancy codes (CRC)

The embedded flash memory implements a cyclic redundancy check (CRC) hardware module. This module checks the integrity of a given user flash memory area content (see *Figure 6: Detailed FLASH architecture*).

The area processed by the CRC module can be defined either by sectors or by start/end addresses. It can also be defined as the whole bank (user flash memory area only).

Note: Only one CRC check operation on bank 1 or 2 can be launched at a time. To avoid corruption, do not configure the CRC calculation on the one bank, while calculating the CRC on the other bank.

When enabled, the CRC hardware module performs multiple reads by chunks of 4, 16, 64 or 256 consecutive flash-word (i.e. chunks of 64, 256, 1024 or 4096 bytes). These consecutive read operations are pushed by the CRC module into the required read command queue together with other AXI read requests, thus avoiding to deny AXI read commands.

CRC computation uses CRC-32 (Ethernet) polynomial 0x4C11DB7:

$$X^{32}+ X^{26}+ X^{23}+ X^{22}+ X^{16}+ X^{12}+ X^{11}+ X^{10}+ X^{8}+ X^{7}+ X^{5}+ X^{4}+ X^{2}+ X + 1$$

The CRC operation is concurrent with option byte change as the same hardware is used for both operations. To avoid the CRC computation from being corrupted, the application shall complete the option byte change (by reading the result of the change) before running a CRC operation, and vice-versa.

The sequence recommended to configure a CRC operation in the bank 1/2 is the following:

1. Unlock FLASH_CR1/2 register, if not already unlocked.
2. Enable the CRC feature by setting the CRC_EN bit in FLASH_CR1/2.
3. Program the desired data size in the CRC_BURST field of FLASH_CRCCR1/2.
4. Define the user flash memory area on which the CRC has to be computed.Two solutions are possible:
   - Define the area start and end addresses by programing FLASH_CRCSADD1/2R and FLASH_CRCEADD1/2R, respectively,
   - or select the targeted sectors by setting the CRC_BY_SECT bit in FLASH_CRCCR1/2 and by programming consecutively the target sector numbers in the CRC_SECT field of the FLASH_CRCCR1/2 register. Set ADD_SECT bit after each CRC_SECT programming.
5. Start the CRC operation by setting the START_CRC bit.
6. Wait until the CRC_BUSY1/2 flag is reset in FLASH_SR1/2 register.
7. Retrieve the CRC result in the FLASH_CRCDATAR register.

The CRC can be computed for a whole bank by setting the ALL_BANK bit in the FLASH_CRCCR1/2 register.

Note: The application should avoid running a CRC on PCROP- or secure-only user flash memory area since it may alter the expected CRC value. A special error flag defined in Section 4.7.9: CRC read error (CRCRDERR) can be used to detect such a case.

CRC computation does not raise standard read error flags such as RDSERR1/2, RDPERR1/2 and DBECCERR1/2. Only CRCRDERR1/2 is raised.

4.3.13 FLASH one-time programmable area

The embedded flash memory offers a 1024-byte memory area dedicated to application non-confidential one-time programmable data (OTP). This area is composed of 512 words of 16 bits (plus 6 bits of ECC). It cannot be erased and can be written only once. The OTP area can be accessed through the AHB interface from address 0x08FF F000 to 0x08FF F3FC.

OTP data can be programmed by the application software by chunks of 16 bits. Overwriting a 16-bit half-word which has already been programmed leads to ECC errors and is therefore not supported.

Note: The OTP area is virgin when the device is delivered by STMicroelectronics.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports read errors as described in *Section 4.7.6: Error correction code error (SNECCERR/DBECCERR)*.

When reading OTP data that has not been written by the application software (i.e. virgin OTP), the ECC correction reports a double error detection (DBECCERR), and all 1’s are returned. It is therefore recommended that the application always writes the OTP data before trying to read it.

Note: No special read protection mechanism is implemented on the OTP area.

OTP write protection

OTP data are organized as 16 blocks of 32 OTP words, as shown in *Table 17*. An entire OTP block can be protected (locked) from write accesses by setting the LOCKBi bit corresponding to each OTP block (i = 0 to 15) in the FLASH_OTPBL option byte register. A block can be write-protected whether or not it has been programmed (even partially).

The OTP block locking operation is **irreversible** and independent from the readout protection level described in *Section 4.5.3: Readout protection (RDP)*. It is not possible to lock a block in RDP level 2.

Note: The OTP area can only be accessed in read mode.

Table 17. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF F000	OTP001	OTP000	LOCKB0
	0x08FF F004	OTP003	OTP002	
	...			
	0x08FF F03C	OTP031	OTP030	

Table 17. Flash memory OTP organization (continued)

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 1	0x08FF F040	OTP033	OTP032	LOCKB1
	0x08FF F044	OTP035	OTP034	
	...			
	0x08FF F07C	OTP063	OTP062	
Block 2	0x08FF F080	OTP065	OTP064	LOCKB2
	0x08FF F084	OTP067	OTP066	
	...			
	0x08FF F0BC	OTP127	OTP126	
...				
Block 15	0x08FF F3C0	OTP481	OTP480	LOCKB15
	0x08FF F3C4	OTP483	OTP482	
	...			
	0x08FF F3FC	OTP511	OTP510	

OTP write sequence

Follow the sequence below to write an OTP word:

1. Unlock FLASH_OPTCR and set PG_OTP bit in the FLASH_OPTCR register.
2. Check the protection status of the target OTP word (see *Table 17*). The corresponding LOCKBi bit must be cleared to 0.
3. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 17*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one.
4. Check that QW1 bit in FLASH_SR1 has been raised and wait until it is reset to 0.
5. Optionally, lock the OTP block using LOCKBi to prevent illegal data changes.

Note: Do not write twice an OTP 16-bit word, otherwise an ECC error might be generated.

Writing OTP data at byte level is not supported and generates a bus error.

FLASH_OPTCR and FLASH_SR1 are always used when programming OTP data, regardless of the bank swapping option (enabled or not).

To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting an option change.

4.3.14 FLASH read-only area

The embedded flash memory offers a 512-byte memory area to store read-only data. This area is mapped as described in *Section 4.3.4: Flash memory architecture and usage*. It can be accessed through the AHB system port. This read-only area is protected by a robust ECC scheme, as explained in *Section 4.3.12: Flash memory error protections*.

The read-only information that can be used by the application software are described in *Table 18*. This information is programmed by STMicroelectronics.

Table 18. Read-only public data organization

Read-only data name	Address	Comment
Unique device ID	0x08FF F800	U_ID[31:0]

4.3.15 Flash bank and register swapping (STM32H7A3/7B3 only)

Flash bank swapping

The embedded flash memory bank 1 and bank 2 can be swapped in the memory map accessible through AXI interface. This feature can be used after a firmware upgrade to restart the device on the new firmware. Bank swapping is controlled by the SWAP_BANK bit of the FLASH_OPTCR register.

Table 19 shows the memory map that can be accessed from the embedded flash memory AXI slave interface, depending on the SWAP_BANK bit configuration.

Table 19. FLASH AXI interface memory map and the swapping option

Flash memory area	Flash memory corresponding bank		Start address	End address	Size (bytes)	Region Name
	SWAP_ BANK=0	SWAP_ BANK=1 (1)				
User main memory	Bank 1	Bank 2	0x0800 0000	0x0800 1FFF	8 K	Sector 0
			0x0800 2000	0x0800 3FFF	8 K	Sector 1
			...	...	...	...
			0x0807 E000	0x0807 FFFF	8 K	Sector 63(2)
			...	...	...	...
			0x080F E000	0x080F FFFF	8 K	Sector 127
	Bank 2	Bank 1	0x0810 0000	0x0810 1FFF	8 K	Sector 0
			0x0810 2000	0x0810 3FFF	8 K	Sector 1
			...	...	...	...
			0x0817 E000	0x0817 FFFF	8 K	Sector 63(2)
			...	...	...	...
			0x081F E000	0x081F FFFF	8 K	Sector 127

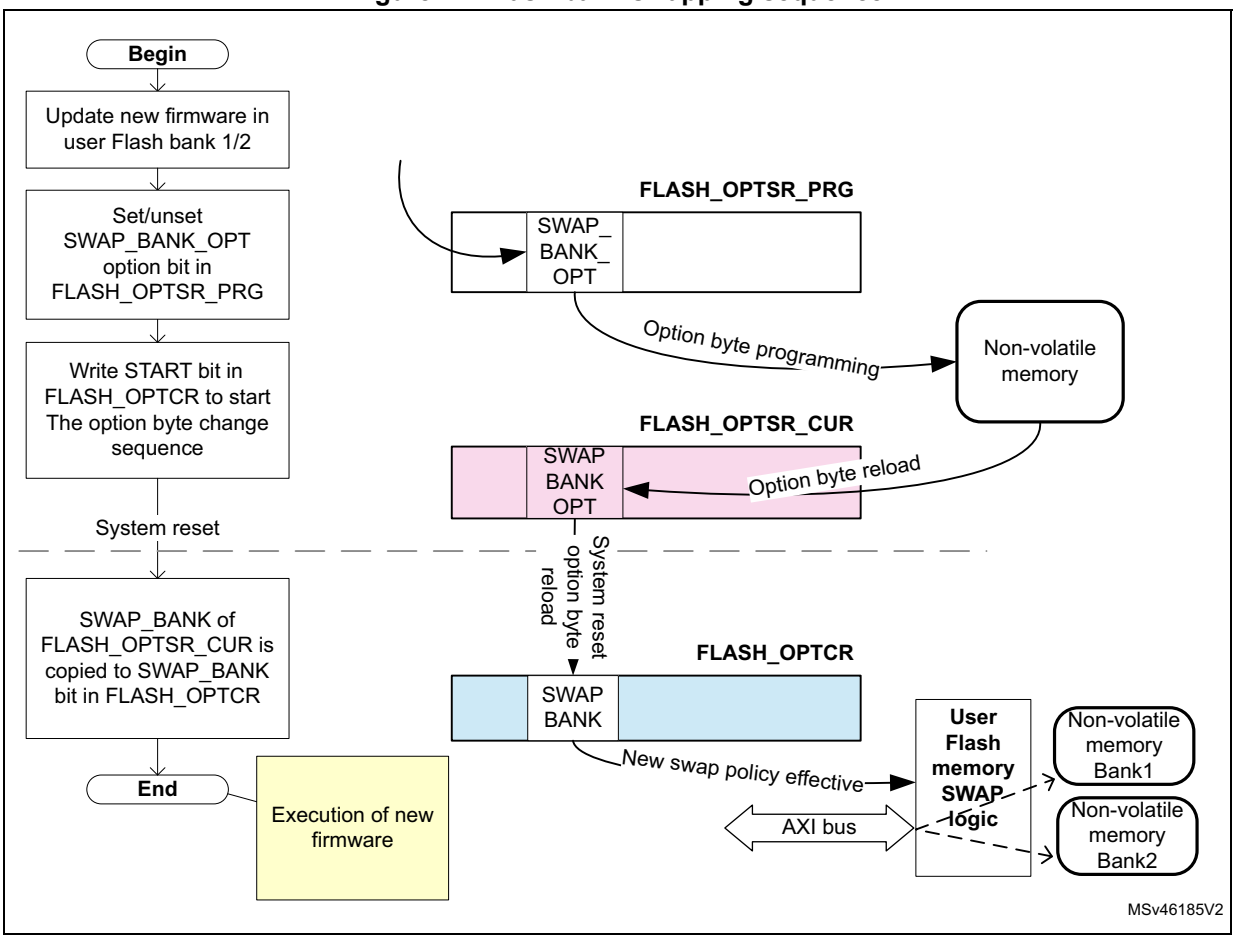
Table 19. FLASH AXI interface memory map and the swapping option (continued)

Flash memory area	Flash memory corresponding bank		Start address	End address	Size (bytes)	Region Name
	SWAP_ BANK=0	SWAP_ BANK=1 (1)				
System memory	Bank 1		0x1FF0 0000	0x1FF0 1FFF	8 K	System 1 Sector 0
			0x1FF0 2000	0x1FF0 3FFF	8 K	System 1 Sector 1
			...	...	...	...
			0x1FF0 E000	0x1FF0 FFFF	8 K	System 1 Sector 7
	Bank 2		0x1FF1 0000	0x1FF1 1FFF	8 K	System 2 Sector 0
			0x1FF1 2000	0x1FF1 3FFF	8 K	System 2 Sector 1
			...	...	...	...
			0x1FF1 E000	0x1FF1 FFFF	8 K	System 2 Sector 7

1. User memory bank 2 and bank swapping are supported only on STM32H7A3/7B3 devices.
2. Bank1 and bank 2 are limited to 64 sectors on STM32H7AxG devices.

The SWAP_BANK bit in FLASH_OPTCR register is loaded from the SWAP_BANK_OPT option bit **only after system reset or POR**.

To change the SWAP_BANK bit (for example to apply a new firmware update), respect the sequence below:



1. Unlock OPTLOCK bit, if not already unlocked.
2. Set the new desired SWAP_BANK_OPT value in the FLASH_OPTSR_PRG register.
3. Start the option byte change sequence by setting the OPTSTART bit in the FLASH_OPTCR register.
4. Once the option byte change has completed, FLASH_OPTSR_CUR contains the expected SWAP_BANK_OPT value, but SWAP_BANK bit in FLASH_OPTCR has not yet been modified and the bank swapping is not yet effective.
5. Force a system reset or a POR. When the reset rises up, the bank swapping is effective (SWAP_BANK value updated in FLASH_OPTCR) and the new firmware shall be executed.

Note: The SWAP_BANK bit in FLASH_OPTCR is read-only and cannot be modified by the application software.

The SWAP_BANK_OPT option bit in FLASH_OPTSR_PRG can be modified whatever the RDP level (i.e. even in level 2), thus allowing advanced firmware upgrade in any level of readout protection.

Figure 12 gives an overview of the bank swapping sequence.

Figure 12. Flash bank swapping sequence

Configuration and option byte register swapping

The embedded flash memory bank swapping option controlled by the SWAP_BANK bit also swaps the two sets of configuration and option byte registers, as shown in *Table 20*. One set of registers is related to bank 1 while the other is related to bank 2. Since some registers are not specific to any particular bank, they are mapped onto two different addresses so that the swapping does not affect the access to these registers.

Table 20. Flash register map vs swapping option

Address offset (1)		Register name		Register targeting bank (1)			
				SWAP_BANK=0		SWAP_BANK=1 (2)	
0x000 or 0x100		FLASH_ACR		N/A		N/A	
0x004	0x104	FLASH_KEYR1	FLASH_KEYR2	Bank 1	Bank 2	Bank 2	Bank 1
0x008 or 0x108		FLASH_OPTKEYR		N/A		N/A	
0x00C	0x10C	FLASH_CR1	FLASH_CR2	Bank 1	Bank 2	Bank 2	Bank 1

0x01C or 0x11C		FLASH_OPTSR_CUR		N/A		N/A	
0x020 or 0x120		FLASH_OPTSR_PRG		N/A		N/A	
0x024 or 0x124		FLASH_OPTCCR		N/A		N/A	
0x028	0x128	FLASH_PRAR_CUR1	FLASH_PRAR_CUR2	Bank 1	Bank 2	Bank 2	Bank 1
0x02C	0x12C	FLASH_PRAR_PRG1	FLASH_PRAR_PRG2	Bank 1	Bank 2	Bank 2	Bank 1
0x030	0x130	FLASH_SCAR_CUR1	FLASH_SCAR_CUR2	Bank 1	Bank 2	Bank 2	Bank 1
0x034	0x134	FLASH_SCAR_PRG1	FLASH_SCAR_PRG2	Bank 1	Bank 2	Bank 2	Bank 1
0x038	0x138	FLASH_WPSGN_CUR1	FLASH_WPSGN_CUR2	Bank 1	Bank 2	Bank 2	Bank 1
0x03C	0x13C	FLASH_WPSGN_PRG1	FLASH_WPSGN_PRG2	Bank 1	Bank 2	Bank 2	Bank 1
0x040 or 0x140		FLASH_BOOT_CUR		N/A		N/A	
0x044 or 0x144		FLASH_BOOT_PRG		N/A		N/A	
0x050	0x150	FLASH_CRCCR1	FLASH_CRCCR2	Bank 1	Bank 2	Bank 2	Bank 1
0x054	0x154	FLASH_CRCSADD1R	FLASH_CRCSADD2R	Bank 1	Bank 2	Bank 2	Bank 1
0x058	0x158	FLASH_CRCEADD1R	FLASH_CRCEADD2R	Bank 1	Bank 2	Bank 2	Bank 1
0x05C	0x15C	FLASH_CRCDATAR		N/A		N/A	
0x060	0x160	FLASH_ECC_FA1R	FLASH_ECC_FA2R	Bank 1	Bank 2	Bank 2	Bank 1
0x068	N/A	FLASH_OTPBL_CUR	-	N/A		N/A	
0x06C		FLASH_OTPBL_PRG	-	N/A		N/A	

1. As shown above, some registers are not dedicated to a specific bank and can be accessed at two different addresses.
2. Bank swapping is supported only on STM32H7A3/7B3 devices.

4.3.16 FLASH reset and clocks

Reset management

The embedded flash memory can be reset by a core domain reset, driven by the reset and clock control (RCC). The main effects of this reset are the following:

- All registers, except for option byte registers, are cleared, including read and write latencies. If the bank swapping option is changed, it will be applied.
- Most control registers are automatically protected against write operations. To unprotect them, new unlock sequences must be used as described in *Section 4.5.1: FLASH configuration protection*.

The embedded flash memory can be reset by a power-on core domain reset, driven by the reset and clock control (RCC). When the reset falls, all option byte registers are reset. When the reset rises up, the option bytes are loaded, potentially applying new features. During this loading sequence, the device remains under reset and the embedded flash memory is not accessible.

The Reset signal can have a critical impact on the embedded flash memory:

- The contents of the flash memory are not guaranteed if a device reset occurs during a flash memory write or erase operation.
- If a reset occurs while the option byte modification is ongoing, the old option byte values are kept. When it occurs, a new option byte modification sequence is required to program the new values.

Clock management

The embedded flash memory uses the microcontroller system clock (sys_ck), here the AXI interface clock.

Depending on the device clock and internal supply voltage, specific read and write latency settings usually need to be set in the flash access control register (FLASH_ACR), as explained in *Section 4.3.8: FLASH read operations* and *Section 4.3.9: FLASH program operations*.

4.4 FLASH option bytes

4.4.1 About option bytes

The embedded flash memory includes a set of non-volatile option bytes. They are loaded at power-on reset and can be read and modified only through configuration registers.

These option bytes are configured by the end-user depending on the application requirements. Some option bytes might have been initialized by STMicroelectronics during manufacturing stage.

This section documents:

- When option bytes are loaded
- How application software can modify them
- What is the detailed list of option bytes, together with their default factory values (i.e. before the first option byte change).

4.4.2 Option byte loading

There are multiple ways of loading the option bytes into embedded flash memory:

1. **Power-on wake-up**

   When the device is first powered, the embedded flash memory automatically loads all the option bytes. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed.

2. **Wake-up from system Standby**

   When the core power domain, which contains the embedded flash memory, is switched from Standby mode to DRun mode, the embedded flash memory behaves as during a power-on sequence.

3. **Dedicated option byte reloading by the application**

   When the user application successfully modifies the option byte content through the embedded flash memory registers, the non-volatile option bytes are programmed and the embedded flash memory automatically reloads all option bytes to update the option registers.

Note: The option bytes read sequence is enhanced thanks to a specific error correction code.

In case of security issue, the option bytes may be loaded with default values (see Section 4.4.3: Option byte modification).

4.4.3 Option byte modification

Changing user option bytes

A user option byte change operation can be used to modify the configuration and the protection settings saved in the non-volatile option byte area of memory bank 1.

The embedded flash memory features two sets of option byte registers:

- The first register set contains the current values of the option bytes. Their names have the _CUR extension. All “_CUR” registers are read-only. Their values are automatically loaded from the non-volatile memory after power-on reset, wake-up from system standby or after an option byte change operation.
- The second register set allows the modification of the option bytes. Their names contain the _PRG extension. All “_PRG” registers can be accessed in read/write mode.

When the OPTLOCK bit in FLASH_OPTCR register is set, modifying the _PRG registers is not possible.

When OPTSTART bit is set to 1, the embedded flash memory checks if at least one option byte needs to be programmed by comparing the current values (_CUR) with the new ones (_PRG). If this is the case and all the other conditions are met (see *Changing security option bytes*), the embedded flash memory launches the option byte modification in its non-volatile memory and updates the option byte registers with _CUR extension.

If one of the condition described in *Changing security option bytes* is not respected, the embedded flash memory sets the OPTCHANGEERR flag to 1 in the FLASH_OPTSR_CUR register and aborts the option byte change operation. In this case, the _PRG registers are not overwritten by current option value. The user application can check what was wrong in their configuration.

Unlocking the option byte modification

After reset, the OPTLOCK bit is set to 1 and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option bytes. The FLASH_OPTCR unlock sequence is described in *Section 4.5.1: FLASH configuration protection*.

Option byte modification sequence

To modify user option bytes, follow the sequence below:

1. Unlock FLASH_OPTCR register as described in *Section 4.5.1: FLASH configuration protection*, unless the register is already unlocked.
2. Write the desired new option byte values in the corresponding option registers (FLASH_XXX_PRG1/2).
3. Set the option byte start change OPTSTART bit to 1 in the FLASH_OPTCR register.
4. Wait until OPT_BUSY bit is cleared.

Note: If a reset or a power-down occurs while the option byte modification is ongoing, the original option byte value is kept. A new option byte modification sequence is required to program the new value.

Changing security option bytes

On top of OPTLOCK bit, there is a second level of protection for security-sensitive option byte fields. Specific rules must be followed to update them:

- **Readout protection (RDP)**

  A detailed description of RDP option bits is given in *Section 4.5.3*. The following rules must be respected to modify these option bits:

  – When RDP is set to level 2, no changes are allowed (except for the SWAP bit). As a result, if the user application attempts to reduce the RDP level, an option byte change error is raised (OPTCHANGEERR bit in FLASH_OPTSR_CUR register), and all the programmed changes are ignored.

  – When the RDP is set to level 1, requiring a change to level 2 is always allowed. When requiring a regression to level 0, an option byte change error can occur if some of the recommendations provided in this chapter have not been followed.

  – When the RDP is set to level 0, switching to level 1 or level 2 is possible without any restriction.

- **Sector write protection (WRPSGn1/2)**

  These option bytes manage group of sector write protection in FLASH_WPSGN_CUR1/2R registers. They can be changed without any restriction when the RDP protection level is different from level 2.

- **PCROP area size (PROT_AREA_START1/2 and PROT_AREA_END1/2)**

  These option bytes configure the size of the PCROP areas in FLASH_PRAR_CUR1/2 registers. They can be increased without any restriction by the Arm® Cortex®-M7 core. To remove or reduce a PCROP area, an RDP level 1 to 0 regression (see *Section 4.5.3*) or a bank erase with protection removal (see *Section 4.3.10*) must be

requested at the same time. DMEP must be set to 1 in either FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, otherwise an option byte change error is raised.

- **DMEP1/2**

  When this option bit is set, the content of the corresponding PCROP area is erased during a RDP level 1 to 0 regression (see *Section 4.5.3*) or a bank erase with protection removal (see *Section 4.3.10*). It is preserved otherwise.

  There are no restrictions in setting DMEP1/2 bit. Resetting DMEP1/2 bit from 1 to 0 can only be done when an RDP level 1 to 0 regression or a bank erase with protection removal is requested at the same time.

- **Secure access mode (SECURITY)**

  The SECURITY option bit activates the secure access mode described in *Section 4.5.5*. This option bit can be freely set by the application software if such mode is activated on the device. If at least one PCROP or secure-only area is defined as not null, the only way to deactivate the security option bit (from 1 to 0) is to perform an RDP level 1 to 0 regression, when DMEP1/2 is set to 1 in either FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2 registers, and DMES1/2 is set to 1 in either FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2.

  If no valid secure-only area and no valid PCROP area are currently defined, the SECURITY option bit can be freely reset.

Note: It is recommended to have both SEC_AREA_START> SEC_AREA_END and PROT_AREA_START> PROT_AREA_END programmed when deactivating the SECURITY option bit during an RDP level 1 to 0 regression.

- **Secure-only area size (SEC_AREA_START1/2 and SEC_AREA_END1/2)**

  These option bytes configure the size of the secure-only areas in FLASH_SCAR_CUR1/2 registers. They can be changed without any restriction by the user secure application or by the ST secure library running on the device. For user non-secure application, the secure-only area size can be removed by performing a bank erase with protection removal (see *Section 4.3.10*), or an RDP level 1 to 0 regression when DMES1/2 set to 1 in either FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2 (otherwise an option byte change error is raised).

- **DMES1/2**

  When this option bit is set, the content of the corresponding secure-only area is erased during an RDP level 1 to 0 regression or a bank erase with protection removal, it is preserved otherwise.

  DMES1/2 bits can be set without any restriction. Resetting DMES1/2 bit from 1 to 0 can only be performed when an RDP level 1 to 0 regression or a bank erase with protection removal is requested at the same time.

4.4.4 Option bytes overview

Table 21 lists all the user option bytes managed through the embedded flash memory registers, as well as their default values before the first option byte change (default factory value).

1. The option bytes corresponding to bank 2 are only valid for STM32H7A3/7B3 devices.

4.4.5 Description of user and system option bytes

Below the list of the general-purpose option bytes that can be used by the application:

- Watchdog management
  - IWDG_FZ_STOP: independent watchdog IWDG (also known as WDGLS_CD) counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_FZ_SDBY: independent watchdog IWDG (also known as WDGLS_CD) counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_SW: hardware (0) or software (1) IWDG (also known as WDGLS_CD) watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode, respectively. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - BOR: Brownout level option, indicating the supply level threshold that activates/releases the reset (see *Section 6.5.2: Brownout reset (BOR)*)
  - NRST_STDBY: generates a reset when entering Standby mode if cleared to 0,
  - NRST_STOP: generates a reset when entering Stop or Stop2 mode if cleared to 0.

Note: Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STDBY (respectively NRST_STOP) is cleared to 0.

- Bank swapping (STM32H7A3/7B3 only) (see *Section 4.3.15 on page 174*)

  SWAP_BANK_OPT: bank swapping option, set to 1 to swap user sectors and registers after boot.
- Device options
  - VDDIO_HSLV: enables the configuration of pads below 2.7 V for VDDIO power rail if set to 1.
  - VDDMMC_HSLV: enables the configuration of pads below 2.7 V for VDDMMC power rail if set to 1.

When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- Watchdog management
  - IWDG (also known as WDGLS_CD) active in Standby and Stop modes (option value = 0x1)
  - IWDG (also known as WDGLS_CD) not automatically enabled at power-on (option byte value = 0x1)
- Reset management:
  - BOR: brownout level option disabled (option byte value = 0x00)
- No bank swapping (option byte value = 0x0)
- Device working in the full voltage range with I/O speed optimization at low-voltage disabled (VDDIO_HSLV=VDDMMC_HSLV=0)

Refer to *Section 4.9: FLASH registers* for details.

4.4.6 Description of data protection option bytes

Below the list of the option bytes that can be used to enhance data protection:

- RDP[7:0]: Readout protection level (see *Section 4.5.3 on page 190* for details).
- WRPSGn1/2: write protection option of the corresponding group of four consecutive sectors in Bank 1 (respectively Bank 2). It is active low. Refer to *Section on page 194* for details.
  - Bit N: Group embedding sectors 4 x N to 4 x N + 3
- PROT_AREAx: Proprietary code readout protection (refer to *Section 4.5.4 on page 194* for details)
  - PROT_AREA_START1 (respectively PROT_AREA_END1) contains the first (respectively last) 256-byte block of the PCROP zone in Bank 1
  - PROT_AREA_START2 (respectively PROT_AREA_END2) contains the first (respectively last) 256-byte block of the PCROP zone in Bank 2
  - DMEP1/2: when set to 1, the PCROP area in Bank 1 (respectively Bank 2) is erased during a RDP protection level regression (change from level 1 to 0) or a bank erase with protection removal.
- SEC_AREAx: secure access only zones definition (refer to *Section 4.5.5 on page 195* for details).
  - SEC_AREA_START1 (respectively SEC_AREA_END1) contains the first (respectively last) 256-byte block of the secure access only zone in Bank 1
  - SEC_AREA_START2 (respectively SEC_AREA_END2) contains the first (respectively last) 256-byte block of the secure access only zone in Bank 2
  - DMES1/2: when set to 1 the secure access only zone in Bank 1 (respectively Bank 2) is erased during a RDP protection level regression (change from level 1 to 0), or a bank erase with protection removal.

  Secure areas can be set only on STM32H7B0 and STM32H7B3 devices.
- SECURITY: this non-volatile option can be used by the application to manage secure access mode, as described in *Section 4.5.5*.

  This bit cannot be set on STM32H7A3 devices, since the Secure access mode is not supported.
- ST_RAM_SIZE: this non-volatile option defines the amount of DTCM RAM root secure services (RSS) can use during execution when the SECURITY bit is set. The DTCM RAM is always fully available for the application whatever the option byte configuration.

When STMicroelectronics delivers the device, the values programmed in the data protection option bytes are the following:

- RDP level 0 (option byte value = 0xAA)
- Flash bank erase operations do not impact secure-only and PCROP data areas when enabled by the application (DMES1/2=DMEP1/2=0)
- PCROP and secure-only zone protections disabled (start addresses higher than end addresses)
- Write protection enabled (all option byte bits set to 1)
- Secure access mode disabled (SECURITY option byte value = 0)
- RSS can use the full DTCM RAM for executing its services (ST_RAM_SIZE = 11)

Refer to *Section 4.9: FLASH registers* for details.

4.4.7 Description of boot address option bytes

Below the list of option bytes that can be used to configure the appropriate boot address for your application:

- BOOT_ADD0/1: MSB of the Arm® Cortex®-M7 boot address when BOOT pin is low (respectively high)

When STMicroelectronics delivers the device, the values programmed in the BOOT ADDRESS option bytes are the following:

- Arm® Cortex®-M7 boot address (MSB): 0x0800 (BOOT pin low for user flash memory) and system memory 0x1FF0 (BOOT pin high for System flash memory)

Refer to *Section 4.9: FLASH registers* for details.

4.5 FLASH protection mechanisms

Since sensitive information can be stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of protected area, or illegal flash memory erasing.

The embedded flash memory implements the following protection mechanisms that can be used by end-user applications to manage the security of embedded non-volatile storage:

- Configuration protection
- Global device Readout protection (RDP)
- Write protection
- Proprietary code readout protection (PCROP)
- Secure access mode areas
- OTP area locking

This section provides a detailed description of all these security mechanisms.

4.5.1 FLASH configuration protection

The embedded flash memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (e.g. software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

More specifically, write operations to embedded flash memory control registers (FLASH_CR1/2 and FLASH_OPTCR) are not allowed after reset.

The following sequence must be used to unlock FLASH_CR1/2 register:

1. Program KEY1 to 0x45670123 in FLASH_KEYR1/2 key register.
2. Program KEY2 to 0xCDEF89AB in FLASH_KEYR1/2 key register.
3. LOCK1/2 bit is now cleared and FLASH_CR1/2 is unlocked.

The following sequence must be used to unlock FLASH_OPTCR register:

1. Program OPTKEY1 to 0x08192A3B in FLASH_OPTKEYR option key register.
2. Program OPTKEY2 to 0x4C5D6E7F in FLASH_OPTKEYR option key register.
3. OPTLOCK bit is now cleared and FLASH_OPTCR register is unlocked.

Any wrong sequence locks up the corresponding register/bit until the next system reset, and generates a bus error.

The FLASH_CR1/2 (respectively FLASH_OPTCR) register can be locked again by software by setting the LOCK1/2 bit in FLASH_CR1/2 register (respectively OPTLOCK bit in FLASH_OPTCR register).

In addition the FLASH_CR1/2 register remains locked and a bus error is generated when the following operations are executed:

- programming a third key value
- writing to a different register belonging to the same bank than FLASH_KEYR1/2 before FLASH_CR1/2 has been completely unlocked (KEY1 programmed but KEY2 not yet programmed)
- writing less than 32 bits to KEY1 or KEY2.

Similarly the FLASH_OPTCR register remains locked and a bus error is generated when the following operations are executed:

- programming a third key value
- writing to a different register before FLASH_OPTCR has been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- writing less than 32 bits to OPTKEY1 or OPTKEY2.

The embedded flash memory configuration registers protection is summarized in *Table 22*.

Table 22. Flash interface register protection summary

Register name	Unlocking register	Protected asset
FLASH_ACR	N/A	-
FLASH_KEYR1/2	N/A	-
FLASH_OPTKEYR	N/A	-
FLASH_CR1/2	FLASH_KEYR1/2	Write operations Erase commands Interrupt generation masking sources
FLASH_SR1/2	N/A	-

FLASH_CRCDATAR		-
FLASH_ECC_FA1/2R	N/A	-
FLASH_OTPBL_PRG	FLASH_OPTCR(1)	OTP write protection

1. Once set, the OTP Block Lock bits cannot be reset by the application.

4.5.2 Write protection

The purpose of embedded flash memory write protection is to protect the embedded flash memory against unwanted modifications of the non-volatile code and/or data.

Any flash group of four consecutive 8-Kbyte sectors can be independently write-protected or unprotected by clearing/setting the corresponding WRPSGn1/2 bit in the FLASH_WPSGN_CUR1/2R register.

A write-protected group of sectors can neither be erased nor programmed. As a result, a bank erase cannot be performed if one group of sectors is write-protected, unless a bank erase is executed during an RDP level 1 to 0 regression (see *Section : Flash bank erase with automatic protection-removal sequence* for details).

The embedded flash memory write-protection user option bits can be modified without any restriction when the RDP level is set to level 0 or level 1. When it is set to level 2, the write protection bitfield can no more be changed in the option bytes.

Note: PCROP or secure-only areas are write and erase protected.

Write protection errors are documented in *Section 4.7: FLASH error management*.

4.5.3 Readout protection (RDP)

The embedded flash memory readout protection is global as it does not apply only to the embedded flash memory, but also to the other secured regions. This is done by using dedicated security signals.

In this section *other secured regions* are defined as:

- Backup SRAM
- RTC backup registers
- Encrypted regions protected by on-the-fly decryption engine (OTFDEC)

The global readout protection level is set by writing the values given in *Table 23* into the readout protection (RDP) option byte (see *Section 4.4.3: Option byte modification*).

Table 23. RDP value vs readout protection level

RDP option byte value	Global readout protection level
0xAA	Level 0
0xCC	Level 2
Any other value	Level 1(1)

1. Default protection level when RDP option byte is erased.

Definitions of RDP global protection level

RDP Level 0 (no protection)

When the global read protection level 0 is set, all read/program/erase operations from/to the user flash memory are allowed (if no others protections are set). This is true whatever the boot configuration (boot from user or system flash memory, boot from RAM), and whether the debugger is connected to the device or not. Accesses to the *other secured regions* are also allowed.

RDP Level 1 (flash memory content protection)

When the global read protection level 1 is set, the below properties apply:

- The flash memory content is protected against debugger and potential malicious code stored in RAM. Hence as soon as any debugger is connected or has been connected, or a boot is configured in embedded RAM (intrusion), the embedded flash memory prevents any accesses to flash memory.
- When no intrusion is detected (no boot in RAM, no boot in System flash memory and no debugger connected), all read/program/erase operations from/to the user flash memory are allowed (if no others protections are set). Accesses to the *other secured regions* are also allowed.
- When an intrusion is detected, no accesses to the user flash memory can be performed. A bus error is generated when a read access is requested to the flash

memory. In addition, no accesses to *other secured regions* (read or write) can be performed.

- When performing an RDP level regression, i.e. programming the RDP protection to level 0, the user flash memory and the *other secured regions* are erased, as described in *RDP protection transitions*.
- When booting on STM32 bootloader in standard system memory, only the identification services are available (GET_ID_COMMAND, GET_VER_COMMAND and GET_CMD_COMMAND).
- When booting from STMicroelectronics non-secure bootloader, only the identification services are available (GET_ID_COMMAND, GET_VER_COMMAND and GET_CMD_COMMAND).

RDP Level 2 (device protection and intrusion prevention)

When the global read protection level 2 is set, the below rules apply:

- All debugging features are disabled.
- Like level 0, all read/write/erase operations from/to the user flash memory are allowed since the debugger and the boot from RAM and System flash memory are disabled. Accesses to the *other secured regions* are also allowed.
- Booting from RAM is no more allowed.
- The user option bits described in *Section 4.4* can no longer be changed except for the SWAP bit.

Caution: Memory read protection level 2 is an irreversible operation. When level 2 is activated, the level of protection cannot be changed back to level 0 or level 1.

Note: The JTAG port is permanently disabled when level 2 is active (acting as a JTAG fuse). As a consequence. STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Apply a power-on reset if the global read protection level 2 is set while the debugger is still connected.

The above RDP global protection is summarized in *Table 24*.

Table 24. Protection vs RDP Level(1)

Boot area	Inputs		Effects				Comment
	RDP	Debugger connected	User flash memory access(2)	System flash memory access (3)(4)	Other secured regions(5)	Option Bytes access	
User flash memory	**Level 0**	Yes(6)/No	R/W/E	R	R/W	R/W	-
	Level 1	Yes(3)	illegal access(7)	R	no access	R/W	
	Level 1	No	R/W/E	R	R/W	R/W	
	Level 2	No	R/W/E	R	R/W	R	

Table 24. Protection vs RDP Level(1) (continued)

Boot area	Inputs		Effects				Comment
	RDP	Debugger connected	User flash memory access(2)	System flash memory access (3)(4)	Other secured regions(5)	Option Bytes access	
RAM or System flash memory	Level 0	Yes(3)/No	R/W/E	R	R/W	R/W	-
	Level 1	Yes(3)/No	illegal access(7)	R	no access	R/W	When selected, only ST basic bootloader is executed
	Level 2	No	Not applicable				No boot from RAM or ST system flash memory in RDP level 2

1. R = read, W =write, E = erase.
2. PCROP (see *Section 4.5.4)* and secure-only access control (see *Section 4.5.5)* applies.
3. Read accesses to secure boot and secure libraries stored in system flash bank 1 possible only from STMicroelectronics code.
4. Write and erase operations to System flash bank 2 is possible only from STMicroelectronics secure update library.
5. The “other secured regions” are defined at the beginning of this section.
6. JTAG interface disabled while secure libraries are executed.
7. *Read protection error (RDPERR)* with bus error on read operations, *Write protection error (WRPERR)* on write/erase operations.

RDP protection transitions

Figure 13 shows how to switch from one RDP level to another. The transition is effective after successfully writing the option bytes including RDP (refer to *Section 4.4.3* for details on how to change the option bytes).

Figure 13. RDP protection transition scheme

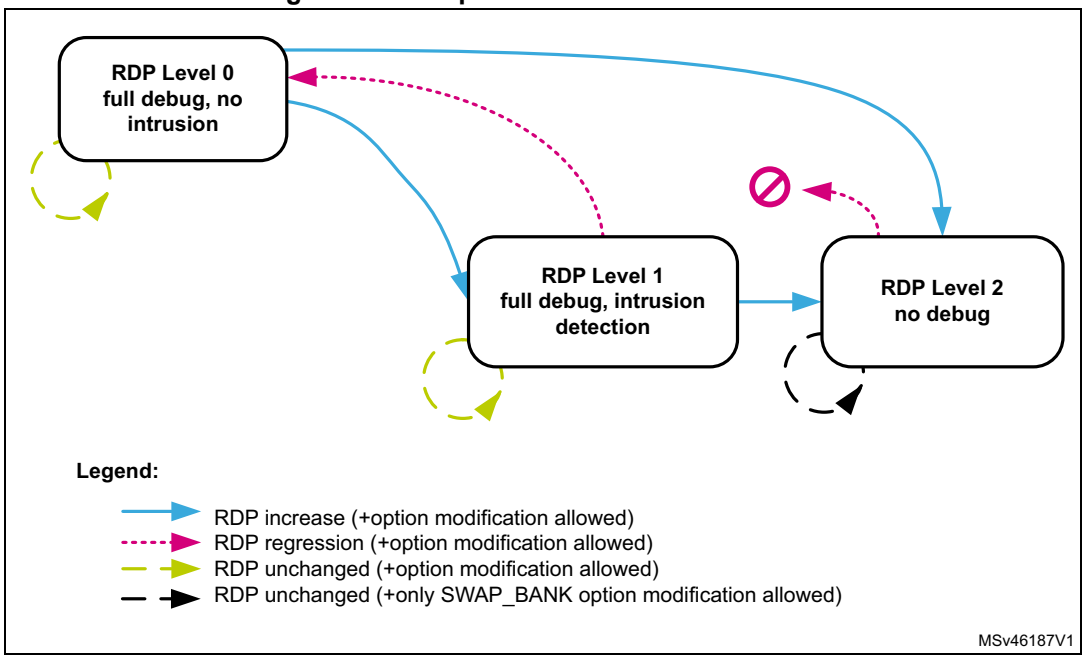

Table 25 details the RDP transitions and their effects on the product.

Table 25. RDP transition and its effects

RDP transition		RDP option update	Effect on device		
Level before change	**Level after change**		**Debugger disconnect**	**Option bytes change (1)**	**Partial/Mass erase**
L0	**L1**	not 0xAA and not 0xCC	No	Allowed	No
	L2	0xCC	**Yes**	**Not allowed**	No
L1	**L2**	0xCC	**Yes**	**Not allowed**	No
	L0	0xAA	No	Allowed	**Yes**
L0	**L0**	0xAA	No	Allowed	No
L1	**L1**	not 0xAA and not 0xCC			

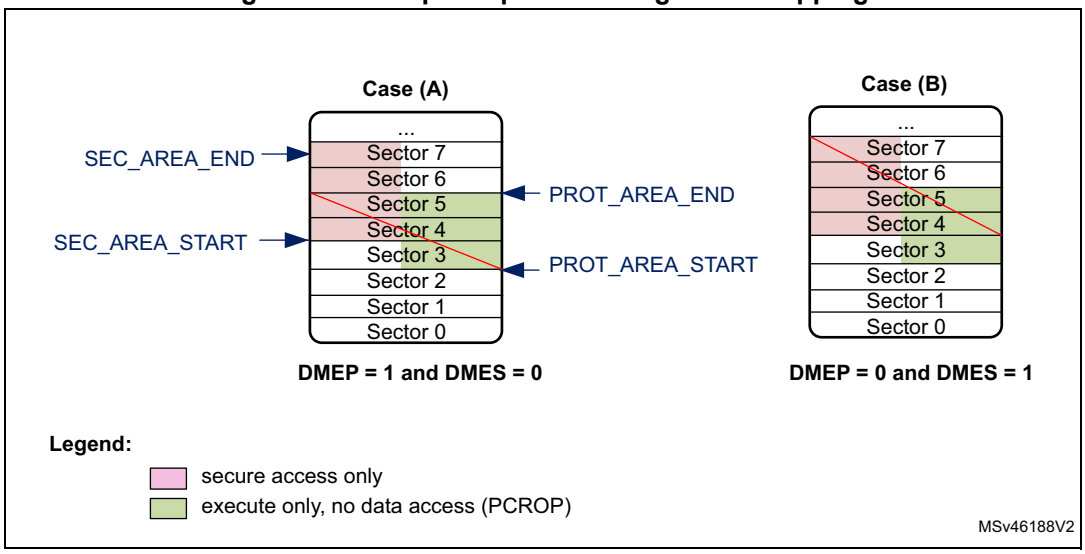
1. Except for bank swapping option bit.

When the current RDP level is RDP level 1, requesting a new RDP level 0 can cause a full or partial erase:

- The user flash memory area of the embedded flash memory is fully or partially erased:
  - A partial sector erase occurs if PCROP (respectively secure-only) areas are preserved by the application. It happens when both DMEP1/2 bits (respectively DMES1/2 bits) are cleared to 0 in FLASH_PRAR_CUR1/2 and FLASH_PRAR_PRG1/2 (respectively FLASH_SCAR_CUR1/2 and FLASH_SCAR_PRG1/2). The sectors belonging to the preserved area(s) are not erased.
  - A full bank erase occurs when at least one DMEP1/2 bit is set to 1 in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, and at least one DMES1/2 bit is set to 1 in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2.

Note: Data in write protection area are not preserved during RDP regression.

- The other secured regions are also erased, i.e.:
  - Backup SRAM and RTC backup registers are fully erased.
  - The content stored in encrypted regions protected by on-the-fly decryption engine (OTFDEC) are no more accessible in the clear, as OTFDEC registers are erased.



OTP and read-only regions are not affected by RDP regression and remain unchanged.

During a level regression, if a PCROP area overlaps with a secure-only area, the embedded flash memory performs the erase operation depending on the DMES/DMEP options bits (see strike-through areas in red in *Figure 14*). More specifically:

- When DMEP is set in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, the PCROP area is erased (overlapped or not with secure-only area).
- When DMES is set in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2, the secure-only area is erased (overlapped or not with PCROP area).

Note: The sector protections (PCROP, secure-only) are removed only if the protected sector boundaries are modified by the user application.

Figure 14. Example of protected region overlapping

About RDP protection errors

Whatever the RDP level, the corresponding error flag is raised when an illegal read or write access is detected (see *Section 4.7: FLASH error management*).

4.5.4 Proprietary code readout protection (PCROP)

The embedded flash memory allows the definition of an “executable-only” area in the user area of each flash memory bank. In this area, only instruction fetch transactions from the system, that is no data access (data or literal pool), are allowed. This protection is particularly efficient to protect third party software intellectual property.

Note: Executable-only area usage requires the native code to be compiled accordingly using “execute-only” option.

PCROP area programming

One PCROP area can be defined in bank 1 (respectively bank 2) by setting the PROT_AREA_END1 and PROT_AREA_START1 (respectively PROT_AREA_END2 and PROT_AREA_START2) option bytes so that the END address is strictly higher than the START address. PROT_AREA_START and PROT_AREA_END are defined with a granularity of 256 bytes. This means that the actual PCROP area size (in bytes) is defined by:

[(PROT_AREA_END - PROT_AREA_START) + 1] x 256

As an example, to set a PCROP area on the first 4 Kbytes of user bank 1 (i.e. from address 0x0800 0000 to address 0x0800 0FFF, both included), the embedded flash memory must be configured as follows:

- PROT_AREA_START1[11:0] = 0x000
- PROT_AREA_END1[11:0] = 0x00F

The protected area size defined above is equal to:

[(PROT_AREA_END - PROT_AREA_START) + 1] x 256 = 16 x 256 bytes = 4 Kbytes.

The minimum execute-only PCROP area that can be set is 32 flash words (or 512 bytes). The maximum area is the whole user flash memory, configured by setting to the same value the PCROP area START and END addresses.

Note: It is recommended to align PCROP area size with 8 Kbytes flash sector granularity in order to avoid access right issues.

PCROP area properties

Each valid PCROP area has the following properties:

- Arm® Cortex®-M7 debug events are ignored while executing code in this area.
- Only the CPU can access it (Master ID filtering), using only instruction fetch transactions. In all other cases, accessing the PCROP area is illegal (see below).
- Illegal transactions to a PCROP area (i.e. data read or write, not fetch) are managed as below:
  - Read operations return a zero, write operations are ignored.
  - No bus error is generated but an error flag is raised (RDPERR for read, WRPERR for write).
- A valid PCROP area is erase-protected. As a result:
  - No erase operations to a sector located in this area is possible (including the sector containing the area start address and the end address)
  - No mass erase can be performed if a single valid PCROP area is defined, except during level regression or erase with protection removal.
- Only the CPU can modify the PCROP area definition and DMEP1/2 bits, as explained in *Changing user option bytes* in *Section 4.4.3*.
- During an RDP level 1 to 0 regression where the PCROP area is not null
  - The PCROP area content is not erased if the corresponding DMEP1/2 bit are both cleared to 0 in FLASH_PRAR_CUR1/2 and FLASH_PRAR_PRG1/2 registers.
  - The PCROP area content is erased if either of the corresponding DMEP1/2 bit is set to 1 in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2 register.

For more information on PCROP protection errors, refer to *Section 4.7: FLASH error management*.

4.5.5 Secure access mode (STM32H7B0 and STM32H7B3 only)

The embedded flash memory allows the definition of a secure-only area in the user area of each flash memory bank. This area can be accessed only while the CPU executes secure application code. This feature is available only if the SECURITY option bit is set to 1.

Secure-only areas help isolating secure user code from application non-secure code. As an example, they can be used to protect a customer secure firmware upgrade code, a custom secure boot library or a third party secure library.

Secure-only area programming

One secure-only area can be defined in bank 1 (respectively bank 2) by setting the SEC_AREA_END1 and SEC_AREA_START1 (respectively SEC_AREA_END2 and SEC_AREA_START2) option bytes so that the END address is strictly higher than the START address. SEC_AREA_START and SEC_AREA_END are defined with a granularity of 256 bytes. This means that the actual secure-only area size (in bytes) is defined by:

[(SEC_AREA_END - SEC_AREA_START) + 1] x 256

As an example, to set a secure-only area on the first 8 Kbytes of user bank 2 (i.e. from address 0x0810 0000 to address 0x0810 1FFF, both included), the embedded flash memory must be configured as follows:

- SEC_AREA_START2[11:0] = 0x000
- SEC_AREA_END2[11:0] = 0x01F

The secure-only area size defined above is equal to:

[(SEC_AREA_END - SEC_AREA_START) + 1] x 256 = 32 x 256 bytes = 8 Kbytes.

Note: These option bytes can be modified only by the CPU running ST security library or application secure code, except during RDP level regression or erase with protection removal.

The minimum secure-only area that can be set is 32 flash words (or 512 bytes). The maximum area is the whole user flash memory bank, configured by setting to the same value the secure-only area START and END addresses.

Note: It is recommended to align the secure-only area size with 8 Kbytes flash sector granularity in order to avoid access right issues.

Secure access-only area properties

- Arm® Cortex®-M7 debug events are ignored while executing code in this area.
- Only the CPU executing ST secure library or user secure application can access it (Master ID filtering). In all other cases, accessing the secure-only area is illegal (see below).
- Illegal transactions to a secure-only area are managed as follows:
  - Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
  - Read instruction transactions generate a bus error and the RDSERR error flag is raised.
- A valid secure-only area is erase-protected. As a result:
  - No erase operations to a sector located in this area are possible (including the sector containing the area start address and the end address), unless the application software is executed from a valid secure-only area.
  - No mass erase can be performed if a single valid secure-only area is defined, except during level regression, erase with protection removal or when the application software is executed from a valid secure-only area.
- Only the CPU can modify the secure-only area definition and DMES1/2 bits, as explained in *Changing user option bytes* in *Section 4.4.3*.
- During an RDP level 1 to 0 regression where the secure-only area is not null:
  - the secure-only area content is not erased if the corresponding DMES1/2 bit are both cleared to 0 in FLASH_SCAR_CUR1/2 and FLASH_SCAR_PRG1/2 registers.
  - the secure-only area content is erased if either of the corresponding DMES1/2 bit is set to 1 in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2 register.

For more information on secure-only protection errors, refer to *Section 4.7: FLASH error management*.

4.6 FLASH low-power modes

4.6.1 Introduction

Table 26 summarizes the behavior of embedded flash memory in STM32 low-power modes. Embedded flash memory belongs to the core domain.

Table 26. Effect of low-power modes on the embedded flash memory

Power mode			Core domain voltage range	Allowed if FLASH Busy	FLASH power mode
System state	Core domain	CPU			
Run	DRun	CRun or CSleep	VOS0/1/2/3	Yes	Run
Autonomous	DStop	CStop		No	Clock gated or Stopped
	DStop2			No	
Stop	DStop	-	SVOS3/4/5	No	
	DStop2	-		No	
Standby			Off	No	Off

When the system state changes or within a given system state, the embedded flash memory might get a different voltage supply range (VOS) according to the application. The procedure to switch the embedded flash memory into various power mode (run, clock gated, stopped, off) is described hereafter.

Note: For more information in the microcontroller power states, refer to the Power control section (PWR).

4.6.2 Managing the FLASH domain switching to DStop or Standby

As explain in *Table 26*, if the embedded flash memory informs the reset and clock controller (RCC) that it is busy (i.e. BSY1/2, QW1/2, WBNE1/2 is set), the microcontroller cannot switch the core domain to DStop, DStop2 or Standby mode.

Note: CRC_BUSY1/2 is not taken into account.

There are two ways to release the embedded flash memory:

- Reset the WBNE1/2 busy flag in FLASH_SR1/2 register by any of the following actions:
  a) Complete the write buffer with missing data.
  b) Force the write operation without filling the missing data by activating the FW1/2 bit in FLASH_CR1/2 register. This forces all missing data “high”.
  c) Reset the PG1/2 bit in FLASH_CR1/2 register. This disables the write buffer and consequently lead to the loss of its content.
- Poll QW1/2 busy bits in FLASH_SR1/2 register until they are cleared. This will indicate that all recorded write, erase and option change operations are complete.

The microcontroller can then switch the domain to DStop, DStop2 or Standby mode.

4.7 FLASH error management

4.7.1 Introduction

The embedded flash memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- *Write protection error (WRPERR)*
- *Programming sequence error (PGSERR)*
- *Strobe error (STRBERR)*
- *Inconsistency error (INCERR)*
- *Error correction code error (SNECCERR/DBECCERR)*
- *Read protection error (RDPERR)*
- *Read secure error (RDSERR)*
- *CRC read error (CRCRDERR)*
- *Option byte change error (OPTCHANGEERR)*

The application software can individually enable the interrupt for each error, as detailed in *Section 4.8: FLASH interrupts*.

Note: For some errors, the application software must clear the error flag before attempting a new operation.

Each bank has a dedicated set of error flags in order to identify which bank generated the error. They are available in flash Status register 1 or 2 (FLASH_SR1/2).

The errors related to bank 2 do not apply to STM32H7B0 devices, since only bank 1 is supported.

4.7.2 Write protection error (WRPERR)

When an illegal erase/program operation is attempted to the non-volatile memory bank 1 (respectively bank 2), the embedded flash memory sets the write protection error flag WRPERR1 (respectively WRPERR2) in FLASH_SR1 register (respectively FLASH_SR2).

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A sector belonging to a valid PCROP area (even partially)
- A sector belonging to a valid secure-only area (even partially) except if the application software is executed from a valid secure-only area
- A sector write-locked with WRPSGn
- The read-only/OTP area

An program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- The system flash memory (bank 2 only) while the device is not executing ST bootloader code
- A user flash sector belonging to a valid PCROP area while the device is not executing an ST secure library
- A user flash sector belonging to a valid secure-only area while the device is not executing user secure code or ST secure library
- A user sector write-locked with WRPSGn
- An OTP block, locked with LOCKBL
- A read-only section
- The bank 1 system flash memory
- The user main flash memory when RDP level is 1 and a debugger has been detected on the device, or the CPU has not booted from user flash memory.
- A reserved area

When WRPERR1/2 flag is raised, the operation is rejected and nothing is changed in the corresponding bank. If a write burst operation was ongoing, WRPERR1/2 is raised each time a flash word write operation is processed by the embedded flash memory.

Note: WRPERR1/2 flag does not block any new erase/program operation.

Not resetting the write protection error flag (WRPERR1/2) does not generate a PGSERR error.

WRPERR1/2 flag is cleared by setting CLR_WRPERR1/2 bit to 1 in FLASH_CCR1/2 register.

If WRPERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when WRPERR1/2 flag is raised (see *Section 4.8: FLASH interrupts* for details).

4.7.3 Programming sequence error (PGSERR)

When the programming sequence to the bank 1 (respectively bank 2) is incorrect, the embedded flash memory sets the programming sequence error flag PGSERR1 (respectively PGSERR2) in FLASH_SR1 register (respectively FLASH_SR2).

More specifically, PGSERR1/2 flag is set if one of below conditions is met:

- A write operation is requested but the program enable bit (PG1/2) has not been set in FLASH_CR1/2 register prior to the request.
- The inconsistency error (INCERR1/2) has not been cleared to 0 before requesting a new write operation.

When PGSERR1/2 flag is raised, the current program operation is aborted and nothing is changed in the corresponding bank. The corresponding write data buffer is also flushed. If a write burst operation was ongoing, PGSERR1/2 is raised at the end of the burst.

Note: When PGSERR1/2 flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERR1/2 flag also blocks any new program operation. This means that PGSERR1 (respectively 2) must be cleared before starting a new program operation on bank 1 (respectively bank 2).

PGSERR1/2 flag is cleared by setting CLR_PGSERR1/2 bit to 1 in FLASH_CCR1/2 register.

If PGSERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when PGSERR1/2 flag is raised. See *Section 4.8: FLASH interrupts* for details.

4.7.4 Strobe error (STRBERR)

When the application software writes several times to the same byte in bank 1 (respectively bank 2) write buffer, the embedded flash memory sets the strobe error flag STRBERR1 (respectively STRBERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When STRBERR1/2 flag is raised, the current program operation is not aborted and new byte data replace the old ones. The application can ignore the error, proceed with the current write operation and request new write operations. If a write burst was ongoing, STRBERR1/2 is raised at the end of the burst.

STRBERR1/2 flag is cleared by setting CLR_STRBERR1/2 bit to 1 in FLASH_CCR1/2 register.

If STRBERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when STRBERR1/2 flag is raised. See *Section 4.8: FLASH interrupts* for details.

4.7.5 Inconsistency error (INCERR)

When a programming inconsistency to bank 1 (respectively bank 2) is detected, the embedded flash memory sets the inconsistency error flag INCERR1 (respectively INCERR2) in register FLASH_SR1 (respectively FLASH_SR2).

More specifically, INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, e.g.
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.

Note: INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

- A wrap burst request issued by a master overlaps two or more 128-bit flash-word addresses, i.e. wrap bursts must be done within 128-bit flash-word address boundaries.

It is recommended to follow the sequence below to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when INCERR1 or INCERR2 flag is raised.
2. Stop all write requests to embedded flash memory.
3. Verify that the write operations that have been requested just before the INCERR event have been successful by reading back the programmed values from the memory.
4. Clear the corresponding INCERR1/2 bit.
5. Restart the write operations where they have been interrupted.

INCERR1/2 flag is cleared by setting CLR_INCERR1/2 bit to 1 in FLASH_CCR1/2 register.

If INCERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when INCERR1/2 flag is raised (see *Section 4.8: FLASH interrupts* for details).

4.7.6 Error correction code error (SNECCERR/DBECCERR)

When a single error correction is detected during a read from bank 1 (respectively bank 2) the embedded flash memory sets the single error correction flag SNECCERR1 (respectively SNECCERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When two ECC errors are detected during a read to bank 1 (respectively bank 2), the embedded flash memory sets the double error detection flag DBECCERR1 (respectively DBECCERR2) in FLASH_SR1 register (respectively FLASH_SR2). When SNECCERR1/2 flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations.

If a read burst operation was ongoing, SNECCERR1/2 or DBECCERR1/2 flag is raised each time a new data is sent back to the requester through the AXI interface.

When SNECCERR1/2 or DBECCERR1/2 flag is raised, the address of the flash word that generated the error is saved in the FLASH_ECC_FA1/2R register. If the address corresponds to a read-only area or to an OTP area, the OTP_FAIL_ECC bit is also set to 1 in the FLASH_ECC_FA1R register. This register is automatically cleared when the associated flag that generated the error is reset.

Note: In case of successive single correction or double detection errors, only the address corresponding to the first error is stored in FLASH_ECC_FA1/2R register.

When DBECCERR1/2 flag is raised, a bus error is generated. In case of successive double error detections, a bus error is generated each time a new data is sent back to the requester through the AXI interface.

Note: It is not mandatory to clear SNECCERR1/2 or DBECCERR1/2 flags before starting a new read operation.

SNECCERR1/2 (respectively DBECCERR1/2) flag is cleared by setting to 1 CLR_SNECCERR1/2 bit (respectively CLR_DBECCERR1/2 bit) in FLASH_CCR1/2 register.

If SNECCERR1/2 (respectively DBECCERR1/2) bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when SNECCERR1/2 (respectively DBECCERR1/2) flag is raised. See *Section 4.8: FLASH interrupts* for details.

4.7.7 Read protection error (RDPERR)

When a read operation to a PCROP, a secure-only or a RDP protected area is attempted in non-volatile memory bank 1 (respectively bank 2), the embedded flash memory sets the

read protection error flag RDPERR1 (respectively RDPERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When RDPERR1/2 flag is raised, the current read operation is aborted but the application can request new read operations. If a read burst was ongoing, RDPERR1/2 is raised each time a data is sent back to the requester through the AXI interface.

Note: A bus error is raised if a standard application attempts to execute on a secure-only or a RDP protected area.

RDPERR1/2 flag is cleared by setting CLR_RDPERR1/2 bit to 1 in FLASH_CCR1/2 register.

If RDPERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when RDPERR1/2 flag is raised (see *Section 4.8: FLASH interrupts* for details).

4.7.8 Read secure error (RDSERR)

When a read operation is attempted to a secure address in bank 1 (respectively bank 2), the embedded flash memory sets the read secure error flag RDSERR1 (respectively RDSERR2) in FLASH_SR1 register (respectively FLASH_SR2). For more information, refer to *Section 4.5.5: Secure access mode (STM32H7B0 and STM32H7B3 only)*.

When RDSERR1/2 flag is raised, the current read operation is aborted and the application can request new read operations. If a read burst was ongoing, RDSERR1/2 is raised each time a data is sent back to the requester through the AXI interface.

Note: The bus error is raised only if the illegal access is due to an instruction fetch.

RDSERR1/2 flag is cleared by setting CLR_RDSERR1/2 bit to 1 in FLASH_CCR1/2 register.

If RDSERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when RDSERR1/2 flag is raised (see *Section 4.8: FLASH interrupts* for details).

4.7.9 CRC read error (CRCRDERR)

After a CRC computation in bank 1 (respectively bank 2), the embedded flash memory sets the CRC read error flag CRCRDERR1 (respectively CRCRDERR2) in FLASH_SR1 register (respectively FLASH_SR2) when one or more address belonging to a protected area was read by the CRC module. A protected area corresponds to a PCROP area (see *Section 4.5.4*) or to a secure-only area (see *Section 4.5.5*).

CRCRDERR1/2 flag is raised when CRCEND1/2 bit is set to 1 (end of CRC calculation). In this case, it is likely that the CRC result is wrong since illegal read operations to protected areas return null values.

CRCRDERR1/2 flag is cleared by setting CLR_CRCRDERR1/2 bit to 1 in FLASH_CCR1/2 register.

If CRCRDERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when CRCRDERR1/2 flag is raised together with CRCEND1/2 bit (see *Section 4.8: FLASH interrupts* for details).

4.7.10 Option byte change error (OPTCHANGEERR)

When the embedded flash memory finds an error during an option change operation, it aborts the operation and sets the option byte change error flag OPTCHANGEERR in FLASH_OPTSR_CUR register.

OPTCHANGEERR flag is cleared by setting CLR_OPTCHANGEERR bit to 1 in FLASH_OPTCCR register.

If OPTCHANGEERRIE bit in FLASH_OPTCR register is set to 1, an interrupt is generated when OPTCHANGEERR flag is raised (see *Section 4.8: FLASH interrupts* for details).

It is mandatory to clean the OPTCHANGEERR flag before starting a new option change. If the OPTCHANGEERR flag is not cleared, the OPTSTART bit cannot be set in the FLASH_OPTCR register.

4.7.11 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On AXI system bus:
  - accesses to user flash memory while RDP is set to 1 and a illegal condition is detected (boot from system flash memory, boot from RAM, or debugger connected)
  - fetching to secure-only user flash memory without the correct access rights
- On AHB configuration or system bus:
  - wrong key input to FLASH_KEYR1/2 or FLASH_OPTKEYR
  - 8-bit accesses to system AHB interface

4.8 FLASH interrupts

The embedded flash memory can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see *Section 4.7: FLASH error management*)
  - Single ECC error correction during read operation
  - Double ECC error detection during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - option change operation error
- Security errors (see *Section 4.7: FLASH error management*)
  - Write protection error
  - Read protection error
  - Read secure error
  - CRC computation on PCROP or secure-only area error
- Miscellaneous events (described below)
  - End of programming
  - CRC computation complete

These multiple sources are combined into a single interrupt signal, **flash_it**, which is the only interrupt signal from the embedded flash memory that drives the NVIC (nested vectored interrupt controller).

You can individually enable or disable embedded flash memory interrupt sources by changing the mask bits in the FLASH_CR1/2 register. Setting the appropriate mask bit to 1 enables the interrupt.

Note: Prior to writing, FLASH_CR1/2 register must be unlocked as explained in Section 4.5.1: FLASH configuration protection

The interrupts corresponding to bank 2 do not apply to STM32H7B0 devices.

Table 27 gives a summary of the available embedded flash memory interrupt features. As mentioned in the table below, some flags need to be cleared before a new operation is triggered.

Table 27. Flash interrupt request

Interrupt event		Event flag	Enable control bit	Clear flag to resume operation	Bus error (1)
End-of-program event	on bank 1	EOP1	EOPIE1	N/A	N/A
	on bank 2	EOP2	EOPIE2		
CRC complete event	on bank 1	CRCEND1	CRCENDIE1	N/A	N/A
	on bank 2	CRCEND2	CRCENDIE2		
Write protection error	on bank 1	WRPERR1	WRPERRIE1	No(2)	No
	on bank 2	WRPERR2	WRPERRIE2		
Programming sequence error	on bank 1	PGSERR1	PGSERRIE1	**Yes**(3)(4)	No
	on bank 2	PGSERR2	PGSERRIE2		
Strobe error	on bank 1	STRBERR1	STRBERRIE1	No	No
	on bank 2	STRBERR2	STRBERRIE2		
Inconsistency error	on bank 1	INCERR1	INCERRIE1	**Yes**(3)(4)	No
	on bank 2	INCERR2	INCERRIE2		
ECC single error correction event	on bank 1	SNECCERR1	SNECCERRIE1	No	No
	on bank 2	SNECCERR2	SNECCERRIE2		
ECC double error detection event	on bank 1	DBECCERR1	DBECCERRIE1	No	**Yes**
	on bank 2	DBECCERR2	DBECCERRIE2		
Read protection error	on bank 1	RDPERR1	RDPERRIE1	No	**Yes**(5)
	on bank 2	RDPERR2	RDPERRIE2		
Read secure error	on bank 1	RDSERR1	RDSERRIE1	No	No (data) **Yes** (fetch)
	on bank 2	RDSERR2	RDSERRIE2		

1. Applies to accesses through AXI bus only
2. Check this flag after every erase and write operation.
3. Programming still possible on the flash bank that does not have the flag bit raised.

4. Check and clear all the error flags (PGSERRx, INCERRx, and STRBERRx) due to the previous write operation.
5. Bus error occurs only when accessing RDP protected area, as defined in *Section 4.5.3: Readout protection (RDP)*

The status of the individual maskable interrupt sources described in *Table 27* (except for option byte error) can be read from the FLASH_SR1/2 register. They can be cleared by setting to 1 the adequate bit in FLASH_CCR1/2 register.

Note: No unlocking mechanism is required to clear an interrupt.

End-of-program event

Setting the end-of-operation interrupt enable bit (EOPIE1/2) in the FLASH_CR1/2 register enables the generation of an interrupt at the end of an erase operation, a program operation or an option byte change on bank 1/2. The EOP1/2 bit in the FLASH_SR1/2 register is also set when one of these events occurs.

Setting CLR_EOP1/2 bit to 1 in FLASH_CCR1/2 register clears EOP1/2 flag.

CRC end of calculation event

Setting the CRC end-of-calculation interrupt enable bit (CRCENDIE1/2) in the FLASH_CR1/2 register enables the generation of an interrupt at the end of a CRC operation on bank 1/2. The CRCEND1/2 bit in the FLASH_SR1/2 register is also set when this event occurs.

Setting CLR_CRCEND1/2 bit to 1 in FLASH_CCR1/2 register clears CRCEND1/2 flag.

4.9 FLASH registers

4.9.1 FLASH access control register (FLASH_ACR)

Address offset: 0x000 or 0x100

Reset value: 0x0000 0013

For more details, refer to *Section 4.3.8: FLASH read operations* and *Section 4.3.9: FLASH program operations*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRHIGHFREQ		LATENCY			
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ**: Flash signal delay

These bits are used to control the delay between non-volatile memory signals during programming operations. Application software has to program them to the correct value depending on the embedded flash memory interface frequency. Please refer to *Table 16* for details.

Note: No check is performed to verify that the configuration is correct.

Two WRHIGHFREQ values can be selected for some frequencies.

Bits 3:0 **LATENCY**: Read latency

These bits are used to control the number of wait states used during read operations on both non-volatile memory banks. The application software has to program them to the correct value depending on the embedded flash memory interface frequency and voltage conditions.

0000: zero wait state used to read a word from non-volatile memory

0001: one wait state used to read a word from non-volatile memory

0010: two wait states used to read a word from non-volatile memory

...

0111: seven wait states used to read a word from non-volatile memory

Note: No check is performed by hardware to verify that the configuration is correct.

4.9.2 FLASH key register for bank 1 (FLASH_KEYR1)

Address offset: 0x004

Reset value: 0x0000 0000

FLASH_KEYR1 is a write-only register. The following values must be programmed consecutively to unlock FLASH_CR1 register:

1. 1^{st} key = 0x4567 0123
2. 2^{nd} key = 0xCDEF 89AB

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY1R

KEY1R															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY1R**: Non-volatile memory bank 1 configuration access unlock key

4.9.3 FLASH option key register (FLASH_OPTKEYR)

Address offset: 0x008 or 0x108

Reset value: 0x0000 0000

FLASH_OPTKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_OPTCR register:

1. 1st key = 0x0819 2A3B
2. 2nd key = 0x4C5D 6E7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPTKEYR

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPTKEYR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OPTKEYR**: FLASH option bytes control access unlock key

4.9.4 FLASH control register for bank 1 (FLASH_CR1)

Address offset: 0x00C

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	CRCRDERRIE1	CRCENDIE1	DBECCERRIE1	SNECCERRIE1	RDSERRIE1	RDPERRIE1	Res.	INCERRIE1	Res.	STRBERRIE1	PGSERRIE1	WRPERRIE1	EOPIE1
			rw	rw	rw	rw	rw	rw		rw		rw	rw	rw	rw

CRC_EN	Res.	Res.	SSN1							START1	FW1	BER1	SER1	PG1	LOCK1
rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rs

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRIE1**: Bank 1 CRC read error interrupt enable bit

When CRCRDERRIE1 bit is set to 1, an interrupt is generated when a protected area (PCROP or secure-only) has been detected during the last CRC computation on bank 1. CRCRDERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a CRC read error occurs on bank 1

1: interrupt generated when a CRC read error occurs on bank 1

Bit 27 **CRCENDIE1**: Bank 1 CRC end of calculation interrupt enable bit

When CRCENDIE1 bit is set to 1, an interrupt is generated when the CRC computation has completed on bank 1. CRCENDIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when CRC computation complete on bank 1

1: interrupt generated when CRC computation complete on bank 1

Bit 26 **DBECCERRIE1**: Bank 1 ECC double detection error interrupt enable bit

When DBECCERRIE1 bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from bank 1. DBECCERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when an ECC double detection error occurs on bank 1

1: interrupt generated if an ECC double detection error occurs on bank 1

Bit 25 **SNECCERRIE1**: Bank 1 ECC single correction error interrupt enable bit

When SNECCERRIE1 bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation from bank 1. SNECCERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when an ECC single correction error occurs on bank 1

1: interrupt generated when an ECC single correction error occurs on bank 1

Bit 24 **RDSERRIE1**: Bank 1 secure error interrupt enable bit

When RDSERRIE1 bit is set to 1, an interrupt is generated when a secure error (access to a secure-only protected address) occurs during a read operation from bank 1. RDSERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a secure error occurs on bank 1

1: an interrupt is generated when a secure error occurs on bank 1

Bit 23 **RDPERRIE1**: Bank 1 read protection error interrupt enable bit

When RDPERRIE1 bit is set to 1, an interrupt is generated when a read protection error occurs (access to an address protected by PCROP or by RDP level 1) during a read operation from bank 1. RDPERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a read protection error occurs on bank 1

1: an interrupt is generated when a read protection error occurs on bank 1

Bit 22 Reserved, must be kept at reset value.

Bit 21 **INCERRIE1**: Bank 1 inconsistency error interrupt enable bit

When INCERRIE1 bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation to bank 1. INCERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a inconsistency error occurs on bank 1

1: interrupt generated when a inconsistency error occurs on bank 1.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **STRBERRIE1**: Bank 1 strobe error interrupt enable bit

When STRBERRIE1 bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 1. STRBERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a strobe error occurs on bank 1

1: interrupt generated when strobe error occurs on bank 1.

Bit 18 **PGSERRIE1**: Bank 1 programming sequence error interrupt enable bit

When PGSERRIE1 bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation to bank 1. PGSERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a sequence error occurs on bank 1

1: interrupt generated when sequence error occurs on bank 1.

Bit 17 **WRPERRIE1**: Bank 1 write protection error interrupt enable bit

When WRPERRIE1 bit is set to 1, an interrupt is generated when a protection error occurs during a program operation to bank 1. WRPERRIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated when a protection error occurs on bank 1

1: interrupt generated when a protection error occurs on bank 1.

Bit 16 **EOPIE1**: Bank 1 end-of-program interrupt control bit

Setting EOPIE1 bit to 1 enables the generation of an interrupt at the end of a program operation to bank 1. EOPIE1 can be programmed only when LOCK1 is cleared to 0.

0: no interrupt generated at the end of a program operation to bank 1.

1: interrupt enabled when at the end of a program operation to bank 1.

Bit 15 **CRC_EN**: Bank 1 CRC control bit

Setting CRC_EN bit to 1 enables the CRC calculation on bank 1. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCCR1 register.

When CRC calculation is performed on bank 1, it can only be disabled by setting CRC_EN bit to 0. Resetting CRC_EN clears CRC configuration and resets the content of FLASH_CRCDATAR register.

Clearing CRC_EN to 0 sets CRCDATA to 0x0.

CRC_EN can be programmed only when LOCK1 is cleared to 0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 Reserved, must be kept at reset value.

Bits 12:6 **SSN1**: Bank 1 sector erase selection number

These bits are used to select the target sector for an erase operation (they are unused otherwise). SSN1 can be programmed only when LOCK1 is cleared to 0.

0x00: Sector 0 of user flash bank 1 selected

0x01: Sector 1 of user flash bank 1 selected

..

0x0F: Sector 15 of user flash bank 1 selected

...

0x3F: Sector 63 of user flash bank 1 selected

...

0x7F: Sector 127 of user flash bank 1 selected

Note: Bank 1 is limited to 16 and 64 sectors on STM32H7B0 and STM32H7A3xG devices, respectively.

Bit 5 **START1**: Bank 1 erase start control bit

START1 bit is used to start a sector erase or a bank erase operation. START1 can be programmed only when LOCK1 is cleared to 0.

The embedded flash memory resets START1 when the corresponding operation has been acknowledged. The user application cannot access any embedded flash memory register until the operation is acknowledged.

Bit 4 **FW1:** Bank 1 write forcing control bit

FW1 forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW1 can be programmed only when LOCK1 is cleared to 0.

The embedded flash memory resets FW1 when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it will lead to permanent ECC error.

Write forcing is effective only if the write buffer is not empty (in particular, FW1 does not start several write operations when the force-write operations are performed consecutively).

Bit 3 **BER1**: Bank 1 erase request

Setting BER1 bit to 1 requests a bank erase operation on bank 1 (user flash memory only). BER1 can be programmed only when LOCK1 is cleared to 0.

BER1 has a higher priority than SER1: if both are set, the embedded flash memory executes a bank erase.

0: bank erase not requested on bank 1

1: bank erase requested on bank 1

Note: Write protection error is triggered when a bank erase is required and some sectors are protected.

Bit 2 **SER1**: Bank 1 sector erase request

Setting SER1 bit to 1 requests a sector erase on bank 1. SER1 can be programmed only when LOCK1 is cleared to 0.

BER1 has a higher priority than SER1: if both bits are set, the embedded flash memory executes a bank erase.

0: sector erase not requested on bank 1

1: sector erase requested on bank 1

Note: Write protection error is triggered when a sector erase is required on a protected sector.

Bit 1 **PG1**: Bank 1 internal buffer control bit

Setting PG1 bit to 1 enables internal buffer for write operations to bank 1. This allows preparing program operations even if a sector or bank erase is ongoing.

PG1 can be programmed only when LOCK1 is cleared to 0. When PG1 is reset, the internal buffer is disabled for write operations to bank 1, and all the data stored in the buffer but not sent to the operation queue are lost.

0: Internal buffer disabled for write operations to bank 1

1: Internal buffer enabled for write operations to bank 1

Bit 0 **LOCK1**: Bank 1 configuration lock bit

This bit locks the FLASH_CR1 register. The correct write sequence to FLASH_KEYR1 register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_KEYR1 is performed twice, this bit remains locked until the next system reset.

LOCK1 can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK1 changes from 0 to 1, the other bits of FLASH_CR1 register do not change.

0: FLASH_CR1 register unlocked

1: FLASH_CR1 register locked

4.9.5 FLASH status register for bank 1 (FLASH_SR1)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	CRCRDERR1	CRCEND1	DBECCERR1	SNECCERR1	RDSERR1	RDPERR1	Res.	INCERR1	Res.	STRBERR1	PGSERR1	WRPERR1	EOP1
			r	r	r	r	r	r		r		r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BUSY1	QW1	WBNE1	BSY1
												r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERR1**: Bank 1 CRC read error flag

CRCRDERR1 flag is raised when a word is found read protected during a CRC operation on bank 1. An interrupt is generated if CRCRDIE1 and CRCEND1 are set to 1. Writing 1 to CLR_CRCRDERR1 bit in FLASH_CCR1 register clears CRCRDERR1.

0: no protected area detected inside address read by CRC on bank 1

1: a protected area has been detected inside address read by CRC on bank 1. CRC result is very likely incorrect.

Note: This flag is valid only when CRCEND1 bit is set to 1

Bit 27 **CRCEND1**: Bank 1 CRC end of calculation flag

CRCEND1 bit is raised when the CRC computation has completed on bank 1. An interrupt is generated if CRCENDIE1 is set to 1. It is not necessary to reset CRCEND1 before restarting CRC computation. Writing 1 to CLR_CRCEND1 bit in FLASH_CCR1 register clears CRCEND1.

0: CRC computation not complete on bank 1

1: CRC computation complete on bank 1

Bit 26 **DBECCERR1**: Bank 1 ECC double detection error flag

DBECCERR1 flag is raised when an ECC double detection error occurs during a read operation from bank 1. An interrupt is generated if DBECCERRIE1 is set to 1. Writing 1 to CLR_DBECCERR1 bit in FLASH_CCR1 register clears DBECCERR1.

0: no ECC double detection error occurred on bank 1

1: ECC double detection error occurred on bank 1

Bit 25 **SNECCERR1**: Bank 1 single correction error flag

SNECCERR1 flag is raised when an ECC single correction error occurs during a read operation from bank 1. An interrupt is generated if SNECCERRIE1 is set to 1. Writing 1 to CLR_SNECCERR1 bit in FLASH_CCR1 register clears SNECCERR1.

0: no ECC single correction error occurs on bank 1

1: ECC single correction error occurs on bank 1

Bit 24 **RDSERR1**: Bank 1 secure error flag

RDSERR1 flag is raised when a read secure error (read access to a secure-only protected word) occurs on bank 1. An interrupt is generated if RDSERRIE1 is set to 1. Writing 1 to CLR_RDSERR1 bit in FLASH_CCR1 register clears RDSERR1.

0: no secure error occurs on bank 1

1: a secure error occurs on bank 1

Bit 23 **RDPERR1: Bank 1** read protection error flag

RDPERR1 flag is raised when an read protection error (read access to a PCROP-protected or a RDP-protected area) occurs on bank 1. An interrupt is generated if RDPERRIE1 is set to 1. Writing 1 to CLR_RDPERR1 bit in FLASH_CCR1 register clears RDPERR1.

0: no read protection error occurs on bank 1

1: a read protection error occurs on bank 1

Bit 22 Reserved, must be kept at reset value.

Bit 21 **INCERR1:** Bank 1 inconsistency error flag

INCERR1 flag is raised when a inconsistency error occurs on bank 1. An interrupt is generated if INCERRIE1 is set to 1. Writing 1 to CLR_INCERR1 bit in the FLASH_CCR1 register clears INCERR1.

0: no inconsistency error occurs on bank 1

1: a inconsistency error occurs on bank 1

Bit 20 Reserved, must be kept at reset value.

Bit 19 **STRBERR1:** Bank 1 strobe error flag

STRBERR1 flag is raised when a strobe error occurs on bank 1 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE1 bit is set to 1. Writing 1 to CLR_STRBERR1 bit in FLASH_CCR1 register clears STRBERR1.

0: no strobe error occurs on bank 1

1: a strobe error occurs on bank 1

Bit 18 **PGSERR1:** Bank 1 programming sequence error flag

PGSERR1 flag is raised when a sequence error occurs on bank 1. An interrupt is generated if the PGSERRIE1 bit is set to 1. Writing 1 to CLR_PGSERR1 bit in FLASH_CCR1 register clears PGSERR1.

0: no sequence error occurs on bank 1

1: a sequence error occurs on bank 1

Bit 17 **WRPERR1**: Bank 1 write protection error flag

WRPERR1 flag is raised when a protection error occurs during a program operation to bank 1. An interrupt is also generated if the WRPERRIE1 is set to 1. Writing 1 to CLR_WRPERR1 bit in FLASH_CCR1 register clears WRPERR1.

0: no write protection error occurs on bank 1

1: a write protection error occurs on bank 1

Bit 16 **EOP1**: Bank 1 end-of-program flag

EOP1 flag is set when a programming operation to bank 1 completes. An interrupt is generated if the EOPIE1 is set to 1. It is not necessary to reset EOP1 before starting a new operation. EOP1 bit is cleared by writing 1 to CLR_EOP1 bit in FLASH_CCR1 register.

0: no programming operation completed on bank 1

1: a programming operation completed on bank 1

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CRC_BUSY1**: Bank 1 CRC busy flag

CRC_BUSY1 flag is set when a CRC calculation is ongoing on bank 1. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation on bank 1.

0: no CRC calculation ongoing on bank 1

1: CRC calculation ongoing on bank 1

Bit 2 **QW1**: Bank 1 wait queue flag

QW1 flag is set when a write, erase or option byte change operation is pending in the command queue buffer of bank 1. It is not possible to know what type of programming operation is present in the queue.

This flag is reset by hardware when all write, erase or option byte change operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

0: no write, erase or option byte change operations waiting in the operation queues of bank 1

1: at least one write, erase or option byte change operation is waiting in the operation queue of bank 1

Bit 1 **WBNE1**: Bank 1 write buffer not empty flag

WBNE1 flag is set when the embedded flash memory is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE1 is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW1 bit in FLASH_CR1
- the embedded flash memory detects an error that involves data loss
- the application software has disabled write operations in this bank

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer of bank 1 empty or full

1: write buffer of bank 1 waiting data to complete

Bit 0 **BSY1**: Bank 1 busy flag

BSY1 flag is set when an effective write, erase or option byte change operation is ongoing on bank 1. It is not possible to know what type of operation is being executed.

BSY1 cannot be forced to 0. It is automatically reset by hardware every time a step in a write, erase or option byte change operation completes.

0: no programming, erase or option byte change operation being executed on bank 1

1: programming, erase or option byte change operation being executed on bank 1

4.9.6 FLASH clear control register for bank 1 (FLASH_CCR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CLR_CRCRDERR1**: Bank 1 CRCRDERR1 flag clear bit
Setting this bit to 1 resets to 0 CRCRDERR1 flag in FLASH_SR1 register.

Bit 27 **CLR_CRCEND1**: Bank 1 CRCEND1 flag clear bit
Setting this bit to 1 resets to 0 CRCEND1 flag in FLASH_SR1 register.

Bit 26 **CLR_DBECCERR1**: Bank 1 DBECCERR1 flag clear bit
Setting this bit to 1 resets to 0 DBECCERR1 flag in FLASH_SR1 register. If the SNECCERR1 flag of FLASH_SR1 register is cleared to 0, FLASH_ECC_FA1R register is reset to 0 as well.

Bit 25 **CLR_SNECCERR1**: Bank 1 SNECCERR1 flag clear bit
Setting this bit to 1 resets to 0 SNECCERR1 flag in FLASH_SR1 register. If the DBECCERR1 flag of FLASH_SR1 register is cleared to 0, FLASH_ECC_FA1R register is reset to 0 as well.

Bit 24 **CLR_RDSERR1**: Bank 1 RDSERR1 flag clear bit
Setting this bit to 1 resets to 0 RDSERR1 flag in FLASH_SR1 register.

Bit 23 **CLR_RDPERR1**: Bank 1 RDPERR1 flag clear bit
Setting this bit to 1 resets to 0 RDPERR1 flag in FLASH_SR1 register.

Bit 22 Reserved, must be kept at reset value.

Bit 21 **CLR_INCERR1**: Bank 1 INCERR1 flag clear bit
Setting this bit to 1 resets to 0 INCERR1 flag in FLASH_SR1 register.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CLR_STRBERR1**: Bank 1 STRBERR1 flag clear bit
Setting this bit to 1 resets to 0 STRBERR1 flag in FLASH_SR1 register.

Bit 18 **CLR_PGSERR1**: Bank 1 PGSERR1 flag clear bit
Setting this bit to 1 resets to 0 PGSERR1 flag in FLASH_SR1 register.

Bit 17 **CLR_WRPERR1**: Bank 1 WRPERR1 flag clear bit
Setting this bit to 1 resets to 0 WRPERR1 flag in FLASH_SR1 register.

Bit 16 **CLR_EOP1**: Bank 1 EOP1 flag clear bit
Setting this bit to 1 resets to 0 EOP1 flag in FLASH_SR1 register.

Bits 15:0 Reserved, must be kept at reset value.

4.9.7 FLASH option control register (FLASH_OPTCR)

Address offset: 0x018 or 0x118

Reset value: 0xX000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	OPTCHANGEERRIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	rw														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PG_OTP	MER	Res.	Res.	OPTSTART	OPTLOCK
										rw	w			w	rs

Bit 31 **SWAP_BANK**: Bank swapping option configuration bit
SWAP_BANK controls whether bank 1 and bank 2 are swapped or not. This bit is loaded with the SWAP_BANK_OPT bit of FLASH_OPTSR_CUR register only after reset or POR.
0: bank 1 and bank 2 not swapped
1: bank 1 and bank 2 swapped

Note: The flash bank swapping is not available on STM32H7B0 devices. The SWAP_BANK option bit must be kept at '0'.

Bit 30 **OPTCHANGEERRIE**: Option byte change error interrupt enable bit
OPTCHANGEERRIE bit controls if an interrupt has to be generated when an error occurs during an option byte change.
0: no interrupt is generated when an error occurs during an option byte change
1: an interrupt is generated when and error occurs during an option byte change.

Bits 29: Reserved, must be kept at reset value.

Bit 5 **PG_OTP**: OTP program control bit
Setting PG_OTP bit enables write operations to the OTP area. This bit can be programmed only when OPTLOCK bit is cleared to 0.
No error sequence and no inconsistency error are generated during OTP write operations. Write operations do not start if PG_OTP is cleared to 0.

Bit 4 **MER**: mass erase request
Setting this bit launches a non-volatile memory bank erase on both banks (i.e. mass erase). FLASH_OPTCR, FLASH_CR1 and FLASH_CR2 must be unlocked prior to setting MER high.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **OPTSTART**: Option byte start change option configuration bit

OPTSTART triggers an option byte change operation. The user can set OPTSTART only when the OPTLOCK bit is cleared to 0. The embedded flash memory resets OPTSTART when the option byte change operation has been acknowledged.

The user application cannot modify any embedded flash memory register until the option change operation has been completed.

Before setting this bit, the user has to write the required values in the FLASH_XXX_PRG registers. The FLASH_XXX_PRG registers will be locked until the option byte change operation has been executed in non-volatile memory.

It is not possible to start an option byte change operation if a CRC calculation is ongoing on bank 1 or bank 2. Trying to set OPTSTART when CRC_BUSY1/2 of FLASH_SR1/2 register is set has not effect; the option byte change does not start and no error is generated.

Bit 0 **OPTLOCK**: FLASH_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH_OPTCR register as well as all _PRG registers. The correct write sequence to FLASH_OPTKEYR register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_OPTKEYR is performed twice, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from 0 to 1, the others bits of FLASH_OPTCR register do not change.

0: FLASH_OPTCR register unlocked

1: FLASH_OPTCR register locked.

4.9.8 FLASH option status register (FLASH_OPTSR_CUR)

Address offset: 0x01C or 0x11C

Reset value: 0xXXXX XXXX (see *Table 21: Option byte organization*)

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK_OPT	OPTCHANGEERR	VDDIO_HSLV	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SECURITY	ST_RAM_SIZE[1:0]		IWDG_FZ_SDBY	IWDG_FZ_STOP	VDDMMC_HSLV
r	r	r								r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDP								NRST_STDY	NRST_STOP	Res.	IWDG_SW	BOR_LEV		Res.	OPT_BUSY
r	r	r	r	r	r	r	r	r	r		r	r	r		r

Bit 31 **SWAP_BANK_OPT**: Bank swapping option status bit

SWAP_BANK_OPT reflects whether bank 1 and bank 2 are swapped or not. SWAP_BANK_OPT is loaded to SWAP_BANK of FLASH_OPTCR after a reset.

0: bank 1 and bank 2 not swapped

1: bank 1 and bank 2 swapped

Note: The flash bank swapping is not available on STM32H7B0 devices. The SWAP_BANK option bit must be kept at '0'.

Bit 30 **OPTCHANGEERR**: Option byte change error flag

OPTCHANGEERR flag indicates that an error occurred during an option byte change operation. When OPTCHANGEERR is set to 1, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTCHANGEERRIE bit of FLASH_OPTCR register is set to 1.

Writing 1 to CLR_OPTCHANGEERR of register FLASH_OPTCCR clears OPTCHANGEERR.

0: no option byte change errors occurred

1: one or more errors occurred during an option byte change operation.

Note: The OPTSTART bit in FLASH_OPTCR cannot be set while OPTCHANGEERR is set.

Bit 29 **VDDIO_HSLV**: VDD I/O high-speed at low-voltage status bit

This bit indicates that the VDDIO power rail operates below 2.7 V.

0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled

1: VDD I/O below 2.7 V, I/O speed optimization at low-voltage feature allowed

Bits 28:26 Reserved, must be kept at reset value.

Bits 25: 22 Reserved, must be kept at reset value.

Bit 21 **SECURITY**: Security enable option status bit

0: Security feature disabled

1: Security feature enabled.

Bits 20:19 **ST_RAM_SIZE[1:0]**: ST RAM size option status

00: 2 Kbytes reserved to ST code

01: 4 Kbytes reserved to ST code

10: 8 Kbytes reserved to ST code

11: 16 Kbytes reserved to ST code

Note: This bitfield is effective only when the security is enabled (SECURITY = 1).

The whole DTCM RAM is always available for the application whatever ST_RAM_SIZE option byte configuration.

Bit 18 **IWDG_FZ_SDBY**: IWDG Standby mode freeze option status bit

When set the independent watchdog IWDG is frozen in system Standby mode.

0: Independent watchdog frozen in Standby mode

1: Independent watchdog keep running in Standby mode.

Bit 17 **IWDG_FZ_STOP**: IWDG Stop mode freeze option status bit

When set the independent watchdog IWDG is in system Stop mode.

0: Independent watchdog frozen in system Stop mode

1: Independent watchdog keep running in system Stop mode.

Bit 16 **VDDMMC_HSLV**: VDDMMC I/O high-speed at low-voltage status bit
This bit indicates that the VDDMMC power rail operates below 2.7 V.
0: I/O speed optimization at low-voltage disabled
1: VDDMMC power rail operating below 2.7 V, I/O speed optimization at low-voltage feature allowed

Bits 15:8 **RDP**: Readout protection level option status byte
0xAA: global readout protection level 0
0xCC: global readout protection level 2
others values: global readout protection level 1.

Bit 7 **NRST_STDY**: Core domain Standby entry reset option status bit
0: a reset is generated when entering Standby mode on core domain
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain DStop entry reset option status bit
0: a reset is generated when entering DStop or DStop2 mode on core domain
1: no reset generated when entering DStop or DStop2 mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_SW**: IWDG control mode option status bit
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bits 3:2 **BOR_LEV**: Brownout level option status bit
These bits reflects the power level that generates a system reset.
00: BOR OFF
01: BOR Level 1, the threshold level is low (around 2.1 V)
10: BOR Level 2, the threshold level is medium (around 2.4 V)
11: BOR Level 3, the threshold level is high (around 2.7 V)

Bit 1 Reserved, must be kept at reset value.

Bit 0 **OPT_BUSY**: Option byte change ongoing flag
OPT_BUSY indicates if an option byte change is ongoing. When this bit is set to 1, the embedded flash memory is performing an option change and it is not possible to modify any embedded flash memory register.
0: no option byte change ongoing
1: an option byte change ongoing and all write accesses to flash registers are blocked until the option byte change completes.

4.9.9 FLASH option status register (FLASH_OPTSR_PRG)

Address offset: 0x020 or 0x120

Reset value: 0xXXXX XXXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK_OPT	Res.	VDDIO_HSLV	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SECURITY	ST_RAM_SIZE[1:0]		IWDG_FZ_SDBY	IWDG_FZ_STOP	VDDMMC_HSLV
rw		rw								rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDP								NRST_STDY	NRST_STOP	Res.	IWDG_SW	BOR_LEV		Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw		

Bit 31 **SWAP_BANK_OPT**: Bank swapping option configuration bit

SWAP_BANK_OPT option bit is used to configure whether the bank 1 and bank 2 are swapped or not. This bit is loaded with the SWAP_BANK_OPT bit of FLASH_OPTSR_CUR register after a reset.

0: bank 1 and bank 2 not swapped

1: bank 1 and bank 2 swapped

Note: The flash bank swapping is not available on STM32H7B0 devices. The SWAP_BANK option bit must be kept at '0'.

Bit 30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: VDD I/O high-speed at low-voltage configuration bit

This bit indicates that the VDD power rail operates below 2.7 V.

0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled

1: VDD I/O below 2.7 V, I/O speed optimization at low-voltage feature allowed

Bits 28:26 Reserved, must be kept at reset value.

Bits 25: 22 Reserved, must be kept at reset value.

Bit 21 **SECURITY**: Security enable option configuration bit

The SECURITY option bit enables the secure access mode of the device during an option byte change. The change will be taken into account at next reset (next boot sequence). Once it is enabled, the security feature can be disabled if no areas are protected by PCROP or Secure access mode. If there are secure-only or PCROP protected areas, perform a level regression (from level 1 to 0) and set all the bits to unprotect secure-only areas and PCROP areas.

0: Security feature disabled

1: Security feature enabled.

Bits 20:19 **ST_RAM_SIZE[1:0]**: ST RAM size option configuration bits
00: 2 Kbytes reserved to ST code
01: 4 Kbytes reserved to ST code
10: 8 Kbytes reserved to ST code
11: 16 Kbytes reserved to ST code
Note: This bitfield is effective only when the security is enabled (SECURITY = 1).
The whole DTCM RAM is always available for the application whatever ST_RAM_SIZE option byte configuration.

Bit 18 **IWDG_FZ_SDBY**: IWDG Standby mode freeze option configuration bit
This option bit is used to freeze or not the independent watchdog IWDG in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode.

Bit 17 **IWDG_FZ_STOP**: IWDG Stop mode freeze option configuration bit
This option bit is used to freeze or not the independent watchdog IWDG in system Stop mode.
0: Independent watchdog frozen in system Stop mode
1: Independent watchdog keep running in system Stop mode.

Bit 16 **VDDMMC_HSLV**: VDDMMC I/O high-speed at low-voltage configuration bit
This bit indicates that the VDDMMC power rail operates below 2.7 V.
0: I/O speed optimization at low-voltage disabled
1: VDDMMC power rail operating below 2.7 V, I/O speed optimization at low-voltage feature allowed

Bits 15:8 **RDP**: Readout protection level option configuration bits
RDP bits are used to change the readout protection level. This change is possible only when the current protection level is different from level 2. The possible configurations are:
0xAA: global readout protection level 0
0xCC: global readout protection level 2
others values: global readout protection level 1.

Bit 7 **NRST_STDY**: Core domain Standby entry reset option configuration bit
0: a reset is generated when entering Standby mode on core domain.
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain DStop entry reset option configuration bit
0: a reset is generated when entering DStop or DStop2 mode on core domain.
1: no reset generated when entering DStop or DStop2 mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_SW**: IWDG control mode option configuration bit
IWDG_SW option bit is used to select if IWDG independent watchdog is controlled by hardware or by software.
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bits 3:2 **BOR_LEV**: Brownout level option status bit
These bits reflects the power level that generates a system reset.
00: BOR OFF
01: BOR Level 1, the threshold level is low (around 2.1 V)
10: BOR Level 2, the threshold level is medium (around 2.4 V)
11: BOR Level 3, the threshold level is high (around 2.7 V)

Bits 1:0 Reserved, must be kept at reset value.

4.9.10 FLASH option clear control register (FLASH_OPTCCR)

Address offset: 0x024 or 0x124

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CLR_OPTCHANGEERR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	w

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CLR_OPTCHANGEERR**: OPTCHANGEERR reset bit
This bit is used to reset the OPTCHANGEERR flag in FLASH_OPTSR_CUR register.
FLASH_OPTCCR is write-only.
It is reset by programming it to 1.

Bits 29:0 Reserved, must be kept at reset value.

4.9.11 FLASH protection address for bank 1 (FLASH_PRAR_CUR1)

Address offset: 0x028

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP1	Res.	Res.	Res.	PROT_AREA_END1											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PROT_AREA_START1											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMEP1**: Bank 1 PCROP protected erase enable option status bit
If DMEP1 is set to 1, the PCROP protected area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **PROT_AREA_END1**: Bank 1 PCROP area end status bits
These bits contain the last 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_START1, the whole bank 1 is PCROP protected.
If this address is lower than PROT_AREA_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PROT_AREA_START1**: Bank 1 PCROP area start status bits
These bits contain the first 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_END1, the whole bank 1 is PCROP protected.
If this address is higher than PROT_AREA_END1, no protection is set on bank 1.

4.9.12 FLASH protection address for bank 1 (FLASH_PRAR_PRG1)

Address offset: 0x02C

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP1	Res.	Res.	Res.	PROT_AREA_END1

Res.	Res.	Res.	Res.	PROT_AREA_START1											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DMEP1**: Bank 1 PCROP protected erase enable option configuration bit
If DMEP1 is set to 1, the PCROP protected area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **PROT_AREA_END1**: Bank 1 PCROP area end configuration bits
These bits contain the last 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_START1, the whole bank 1 is PCROP protected.
If this address is lower than PROT_AREA_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PROT_AREA_START1**: Bank 1 PCROP area start configuration bits
These bits contain the first 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_END1, the whole bank 1 is PCROP protected.
If this address is higher than PROT_AREA_END1, no protection is set on bank 1.

4.9.13 FLASH secure address for bank 1 (FLASH_SCAR_CUR1)

Address offset: 0x030

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES1	Res.	Res.	Res.	SEC_AREA_END1

Res.	Res.	Res.	Res.	SEC_AREA_START1											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMES1**: Bank 1 secure access protected erase enable option status bit
If DMES1 is set to 1, the secure access only area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **SEC_AREA_END1**: Bank 1 secure-only area end status bits
These bits contain the last 256-byte block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_START1, the whole bank 1 is secure access only.
If this address is lower than SEC_AREA_START1, no protection is set on bank 1.
Note: The non-secure flash area starts at address 0x(SEC_AREA_END1 + 1)00.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SEC_AREA_START1**: Bank 1 secure-only area start status bits
These bits contain the first 256 bytes of block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_END1, the whole bank 1 is secure access only.
If this address is higher than SEC_AREA_END1, no protection is set on bank 1.

4.9.14 FLASH secure address for bank 1 (FLASH_SCAR_PRG1)

Address offset: 0x034

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES1	Res.	Res.	Res.	SEC_AREA_END1

Res.	Res.	Res.	Res.	SEC_AREA_START1											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DMES1**: Bank 1 secure access protected erase enable option configuration bit
If DMES1 is set to 1, the secure access only area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **SEC_AREA_END1**: Bank 1 secure-only area end configuration bits
These bits contain the last block of 256 bytes of the secure-only area in bank 1.
If this address is equal to SEC_AREA_START1, the whole bank 1 is secure access only.
If this address is lower than SEC_AREA_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SEC_AREA_START1**: Bank 1 secure-only area start configuration bits
These bits contain the first block of 256 bytes of the secure-only area in bank 1.
If this address is equal to SEC_AREA_END1, the whole bank 1 is secure access only.
If this address is higher than SEC_AREA_END1, no protection is set on bank 1.

4.9.15 FLASH write sector group protection for bank 1 (FLASH_WPSGN_CUR1R)

Address offset: 0x038

Reset value: 0xXXXX XXXX

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSGn1															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSGn1															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRPSGn1**: Bank 1 sector group protection option status byte

Each FLASH_WPSGN_CUR1R bit reflects the write protection status of the corresponding group of four consecutive sectors in bank 1 (0: the group is write protected; 1: the group is not write protected)

Bit 0: Group embedding sectors 0 to 3

Bit 1: Group embedding sectors 4 to 7

Bit N: Group embedding sectors 4 x N to 4 x N + 3

Bit 31: Group embedding sectors 124 to 127

Note: Bank 1 is limited to 16 and 64 sectors on STM32H7B0 and STM32H7A3xG devices, respectively.

4.9.16 FLASH write sector group protection for bank 1 (FLASH_WPSGN_PRG1R)

Address offset: 0x03C

Reset value: 0xXXXX XXXX

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSGn1															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRPSGn1															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRPSGn1**: Bank 1 sector group protection option status byte

Setting WRPSGn1 bits to 0 write protects the corresponding group of four consecutive sectors in bank 1 (0: the group is write protected; 1: the group is not write protected)

Bit 0: Group embedding sectors 0 to 3

Bit 1: Group embedding sectors 4 to 7

Bit N: Group embedding sectors 4 x N to 4 x N + 3

Bit 31: Group embedding sectors 124 to 127

Note: Bank 1 is limited to 16 and 64 sectors on STM32H7B0 and STM32H7A3xG devices, respectively.

4.9.17 FLASH register boot address (FLASH_BOOT_CURR)

Address offset: 0x040 or 0x140

Reset value: 0xXXXX XXXX (see *Table 21: Option byte organization*)

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOT_ADD1															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT_ADD0															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **BOOT_ADD1**: Arm® Cortex®-M7 boot address 1
These bits reflect the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is high.

Bits 15:0 **BOOT_ADD0**: Arm® Cortex®-M7 boot address 0
These bits reflect the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is low.

4.9.18 FLASH register boot address FLASH_BOOT_PRGR)

Address offset: 0x044 or 0x144

Reset value: 0xXXXX XXXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOT_ADD1															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT_ADD0															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BOOT_ADD1**: Arm® Cortex®-M7 boot address 1 configuration
These bits allow configuring the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is high.

Bits 15:0 **BOOT_ADD0**: Arm® Cortex®-M7 boot address 0 configuration
These bits allow configuring the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is low.

4.9.19 FLASH CRC control register for bank 1 (FLASH_CRCCR1)

Address offset: 0x050

Reset value: 0x001C 0000

This register can be modified only if CRC_EN bit is set to 1 in FLASH_CR1 register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALL_BANK	CRC_BURST		Res.	Res.	CLEAN_CRC	START_CRC
									w	rw	rw			w	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CLEAN_SECT	ADD_SECT	CRC_BY_SECT	Res.	CRC_SECT						
					w	w	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **ALL_BANK**: Bank 1 CRC select bit

When ALL_BANK is set to 1, all bank 1 user sectors are added to list of sectors on which the CRC is calculated.

Bits 21:20 **CRC_BURST**: Bank 1 CRC burst size

CRC_BURST bits set the size of the bursts that are generated by the CRC calculation unit.
00: every burst has a size of 4 flash words (128-bit)
01: every burst has a size of 16 flash words (128-bit)
10: every burst has a size of 64 flash words (128-bit)
11: every burst has a size of 256 flash words (128-bit)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CLEAN_CRC**: Bank 1 CRC clear bit

Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDATAR register.

Bit 16 **START_CRC**: Bank 1 CRC start bit

START_CRC bit triggers a CRC calculation on bank 1 using the current configuration. No CRC calculation can launched when an option byte change operation is ongoing because all write accesses to embedded flash memory registers are put on hold until the option byte change operation has completed.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CLEAN_SECT**: Bank 1 CRC sector list clear bit

Setting CLEAN_SECT to 1 clears the list of sectors on which the CRC is calculated.

Bit 9 **ADD_SECT**: Bank 1 CRC sector select bit

Setting ADD_SECT to 1 adds the sector whose number is CRC_SECT to the list of sectors on which the CRC is calculated.

Bit 8 **CRC_BY_SECT**: Bank 1 CRC sector mode select bit

When CRC_BY_SECT is set to 1, the CRC calculation is performed at sector level, on the sectors present in the list of sectors. To add a sector to this list, use ADD_SECT and CRC_SECT bits. To clean the list, use CLEAN_SECT bit.

When CRC_BY_SECT is reset to 0, the CRC calculation is performed on all addresses between CRC_START_ADDR and CRC_END_ADDR.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **CRC_SECT**: Bank 1 CRC sector number

CRC_SECT is used to select one user flash sectors to be added to the list of sectors on which the CRC is calculated. The CRC can be computed either between two addresses (using registers FLASH_CRCSADD1R and FLASH_CRCEADD1R) or on a list of sectors using this register. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC_SECT and then setting to 1 ADD_SECT. The list of sectors can be erased either by setting CLEAN_SECT bit or by disabling the CRC computation. CRC_SECT can be set only when CRC_EN of FLASH_CR register is set to 1.

0b0000000: sector 0 of bank 1 for CRC

0b0000001: sector 1 of bank 1 for CRC

...

0b0001111: sector 15 of bank 1 for CRC

...

0b0111111: sector 63 of bank 1 for CRC

...

0b1111111: sector 127 of bank 1 for CRC

Note: Bank 1 is limited to 16 and 64 sectors on STM32H7B0 and STM32H7AxG devices, respectively.

4.9.20 FLASH CRC start address register for bank 1 (FLASH_CRCSADD1R)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_START_ADDR[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_START_ADDR[19:2]**: CRC start address on bank 1

CRC_START_ADDR is used when CRC_BY_SECT is cleared to 0. It must be programmed to the start address of the bank 1 memory area on which the CRC calculation is performed.

Bits 1:0 Reserved, must be kept at reset value.

4.9.21 FLASH CRC end address register for bank 1 (FLASH_CRCEADD1R)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_END_ADDR[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_END_ADDR[19:2]**: CRC end address on bank 1

CRC_END_ADDR is used when CRC_BY_SECT is cleared to 0. It must be programmed to the end address of the bank 1 memory area on which the CRC calculation is performed

Bits 1:0 Reserved, must be kept at reset value.

4.9.22 FLASH CRC data register (FLASH_CRCDATAR)

Address offset: 0x05C or 0x15C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAIL_ECC_ADDR1															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **OTP_FAIL_ECC**: OTP ECC error bit

This bit is set to 1 when one single ECC correction or double ECC detection occurred during the last successful read operation from the read-only/ OTP area. The address of the ECC error is available in FAIL_ECC_ADDR1 bitfield.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **FAIL_ECC_ADDR1**: Bank 1 ECC error address

When an ECC error occurs (both for single correction or double detection) during a read operation from bank 1, the FAIL_ECC_ADDR1 bitfield indicates the address that generated the error:

Fail address = FAIL_ECC_ADDR1 * 32 + flash memory Bank 1 address offset

FAIL_ECC_ADDR1 is reset when the flag error in the FLASH_SR1 register (CLR_SNECCERR1 or CLR_DBECCERR1) is reset.

The embedded flash memory programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

The address in FAIL_ECC_ADDR1 is relative to the flash memory area where the error occurred (user flash memory, system flash memory, read-only/OTP area).

4.9.24 FLASH OTP block lock (FLASH_OTPBL_CUR)

Address offset: 0x068

Reset value: 0xXXXX XXXX

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKBL**: OTP Block Lock

Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and can no longer be programmed.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked and can still be modified.

4.9.25 FLASH OTP block lock (FLASH_OTPBL_PRG)

Address offset: 0x06C

Reset value: 0xXXXX XXXX

This register is used to program values in corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LOCKBL															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKBL**: OTP Block Lock

Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
LOCKBL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and can no longer be programmed.
LOCKBL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked and can still be modified.
LOCKBL bits can be set if the corresponding bit in FLASH_OTPBL_CUR is cleared.

4.9.26 FLASH key register for bank 2 (FLASH_KEYR2)

Address offset: 0x104

Reset value: 0x0000 0000

FLASH_KEYR2 is a write-only register. The following values must be programmed consecutively to unlock FLASH_CR2 register and allow programming/erasing it:

1. 1st key = 0x4567 0123
2. 2nd key = 0xCDEF 89AB

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_EN	Res.	Res.	SSN2							START2	FW2	BER2	SER2	PG2	LOCK2
rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rs

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRIE2**: Bank 2 CRC read error interrupt enable bit

When CRCRDERRIE2 bit is set to 1, an interrupt is generated when a protected area (PCROP or secure-only) has been detected during the last CRC computation on bank 2. CRCRDERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a CRC read error occurs on bank 2

1: interrupt generated when a CRC read error occurs on bank 2

Bit 27 **CRCENDIE2**: Bank 2 CRC end of calculation interrupt enable bit

When CRCENDIE2 bit is set to 1, an interrupt is generated when the CRC computation has completed on bank 2. CRCENDIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when CRC computation complete on bank 2

1: interrupt generated when CRC computation complete on bank 2

Bit 26 **DBECCERRIE2**: Bank 2 ECC double detection error interrupt enable bit

When DBECCERRIE2 bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from bank 2. DBECCERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when an ECC double detection error occurs on bank 2

1: interrupt generated if an ECC double detection error occurs on bank 2

Bit 25 **SNECCERRIE2**: Bank 2 ECC single correction error interrupt enable bit

When SNECCERRIE2 bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation from bank 2. SNECCERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when an ECC single correction error occurs on bank 2

1: interrupt generated when an ECC single correction error occurs on bank 2

Bit 24 **RDSERRIE2**: Bank 2 secure error interrupt enable bit

When RDSERRIE2 bit is set to 1, an interrupt is generated when a secure error (access to a secure-only protected address) occurs during a read operation from bank 2. RDSERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a secure error occurs on bank 2

1: an interrupt is generated when a secure error occurs on bank 2

Bit 23 **RDPERRIE2**: Bank 2 read protection error interrupt enable bit

When RDPERRIE2 bit is set to 1, an interrupt is generated when a read protection error occurs (access to an address protected by PCROP or by RDP level 1) during a read operation from bank 2. RDPERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a read protection error occurs on bank 2

1: an interrupt is generated when a read protection error occurs on bank 2

Bit 22 Reserved, must be kept at reset value.

Bit 21 **INCERRIE2**: Bank 2 inconsistency error interrupt enable bit

When INCERRIE2 bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation to bank 2. INCERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a inconsistency error occurs on bank 2

1: interrupt generated when a inconsistency error occurs on bank 2.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **STRBERRIE2**: Bank 2 strobe error interrupt enable bit

When STRBERRIE2 bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 2. STRBERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a strobe error occurs on bank 2

1: interrupt generated when strobe error occurs on bank 2.

Bit 18 **PGSERRIE2**: Bank 2 programming sequence error interrupt enable bit

When PGSERRIE2 bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation to bank 2. PGSERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a sequence error occurs on bank 2

1: interrupt generated when sequence error occurs on bank 2.

Bit 17 **WRPERRIE2**: Bank 2 write protection error interrupt enable bit

When WRPERRIE2 bit is set to 1, an interrupt is generated when a protection error occurs during a program operation to bank 2. WRPERRIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated when a protection error occurs on bank 2

1: interrupt generated when a protection error occurs on bank 2.

Bit 16 **EOPIE2**: Bank 2 end-of-program interrupt control bit

Setting EOPIE2 bit to 1 enables the generation of an interrupt at the end of a program operation to bank 2. EOPIE2 can be programmed only when LOCK2 is cleared to 0.

0: no interrupt generated at the end of a program operation to bank 2.

1: interrupt enabled when at the end of a program operation to bank 2.

Bit 15 **CRC_EN**: Bank 2 CRC control bit

Setting CRC_EN bit to 1 enables the CRC calculation on bank 2. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCCR2 register.

When CRC calculation is performed on bank 2, it can only be disabled by setting CRC_EN bit to 0. Resetting CRC_EN clears CRC configuration and resets the content of FLASH_CRCDATAR register.

CRC_EN can be programmed only when LOCK2 is cleared to 0.

Bits 14:13 Reserved, must be kept at reset value.

Bits 12:6 **SSN2**: Bank 2 sector erase selection number

These bits are used to select the target sector for an erase operation (they are unused otherwise). SSN2 can be programmed only when LOCK2 is cleared to 0.

0x0: Sector 0 of user flash bank 2 selected

0x1: Sector 1of user flash bank 2 selected

...

0x3F: Sector 63 of user flash bank 2 selected

...

0x7F: Sector 127 of user flash bank 2 selected

Note: Bank 2 is limited to 64 sectors on STM32H7A3xG devices.

Bit 5 **START2**: Bank 2 erase start control bit

START2 bit is used to start a sector erase or a bank erase operation. START2 can be programmed only when LOCK2 is cleared to 0.

The embedded flash memory resets START2 when the corresponding operation has been acknowledged. The user application cannot access any embedded flash memory register until the operation is acknowledged.

Bit 4 **FW2**: Bank 2 write forcing control bit

FW2 forces a write operation even if the write buffer is not full. FW2 can be programmed only when LOCK2 is cleared to 0.

The embedded flash memory resets FW2 when the corresponding operation has been acknowledged.

Write forcing is effective only if the write buffer is not empty. In particular, FW2 does not start several write operations when the write operations are performed consecutively.

Bit 3 **BER2**: Bank 2 erase request

Setting BER2 bit to 1 requests a bank erase operation on bank 2 (user flash memory only). BER2 can be programmed only when LOCK2 is cleared to 0.

BER2 has a higher priority than SER2: if both are set, the embedded flash memory executes a bank erase.

0: bank erase not requested on bank 2

1: bank erase requested on bank 2

Note: Write protection error is triggered when a bank erase is required and some sectors are protected.

Bit 2 **SER2**: Bank 2 sector erase request

Setting SER2 bit to 1 requests a sector erase on bank 2. SER2 can be programmed only when LOCK2 is cleared to 0.

BER2 has a higher priority than SER2: if both are set, the embedded flash memory executes a bank erase.

0: sector erase not requested on bank 2

1: sector erase requested on bank 2

Note: Write protection error is triggered when a sector erase is required on protected sector(s).

Bit 1 **PG2**: Bank 2 internal buffer control bit

Setting PG2 bit to 1 enables internal buffer for write operations to bank 2. This allows the preparation of program operations even if a sector or bank erase is ongoing.

PG2 can be programmed only when LOCK2 is cleared to 0. When PG2 is reset, the internal buffer is disabled for write operations to bank 2 and all the data stored in the buffer but not sent to the operation queue are lost.

Bit 0 **LOCK2**: Bank 2 configuration lock bit

This bit locks the FLASH_CR2 register. The correct write sequence to FLASH_KEYR2 register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_KEYR2 is performed twice, this bit remains locked until next system reset.

LOCK2 can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK2 changes from 0 to 1, the other bits of FLASH_CR2 register do not change.

0: FLASH_CR2 register unlocked

1: FLASH_CR2 register locked

4.9.28 FLASH status register for bank 2 (FLASH_SR2)

Address offset: 0x110

Reset value: 0x0000 0000

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	CRCRDERR2	CRCEND2	DBECCERR2	SNECCERR2	RDSERR2	RDPERR2	Res.	INCERR2	Res.	STRBERR2	PGSERR2	WRPERR2	EOP2
			r	r	r	r	r	r		r		r	r	r	r

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BUSY2	QW2	WBNE2	BSY2
												r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERR2**: Bank 2 CRC read error flag

CRCRDERR2 flag is raised when a word is found read protected during a CRC operation on bank 2. An interrupt is generated if CRCRDIE2 and CRCEND2 are set to 1. Writing 1 to CLR_CRCRDERR2 bit in FLASH_CCR2 register clears CRCRDERR2.

0: no protected area inside the address read by CRC on bank 2

1: a protected area inside the address read by CRC on bank 2. CRC result is very likely incorrect.

Note: This flag is valid only when CRCEND2 bit is set to 1.

Bit 27 **CRCEND2**: Bank 2 CRC end of calculation flag

CRCEND2 bit is raised when the CRC computation has completed on bank 2. An interrupt is generated if CRCENDIE2 is set to 1. It is not necessary to reset CRCEND2 before restarting CRC computation. Writing 1 to CLR_CRCEND2 bit in FLASH_CCR2 register clears CRCEND2.

0: CRC computation not complete on bank 2

1: CRC computation complete on bank 2

Bit 26 **DBECCERR2**: Bank 2 ECC double detection error flag

DBECCERR2 flag is raised when an ECC double detection error occurs during a read operation from bank 2. An interrupt is generated if DBECCERRIE2 is set to 1. Writing 1 to CLR_DBECCERR2 bit in FLASH_CCR2 register clears DBECCERR2.

0: no ECC double detection error occurs on bank 2

1: ECC double detection error occurs on bank 2

Bit 25 **SNECCERR2**: Bank 2 single correction error flag

SNECCERR2 flag is raised when an ECC single correction error occurs during a read operation from bank 2. An interrupt is generated if SNECCERRIE2 is set to 1. Writing 1 to CLR_SNECCERR2 bit in FLASH_CCR2 register clears SNECCERR2.

0: no ECC single correction error occurs on bank 2

1: ECC single correction error occurs on bank 2

Bit 24 **RDSERR2**: Bank 2 secure error flag

RDSERR2 flag is raised when a read secure error (read access to a secure-only protected word) occurs on bank 2. An interrupt is generated if RDSERRIE2 is set to 1. Writing 1 to CLR_RDSERR2 bit in FLASH_CCR2 register clears RDSERR2.

0: no secure error occurs on bank 2

1: a secure error occurs on bank 2

Bit 23 **RDPERR2**: Bank 2 read protection error flag

RDPERR2 flag is raised when a read protection error (read access to a PCROP-protected word or a RDP-protected area) occurs on bank 2. An interrupt is generated if RDPERRIE2 is set to 1. Writing 1 to CLR_RDPERR2 bit in FLASH_CCR2 register clears RDPERR2.

0: no read protection error occurs on bank 2

1: a read protection error occurs on bank 2

Bit 22 Reserved, must be kept at reset value.

Bit 21 **INCERR2**: Bank 2 inconsistency error flag

INCERR2 flag is raised when a inconsistency error occurs on bank 2. An interrupt is generated if INCERRIE2 is set to 1. Writing 1 to CLR_INCERR2 bit in the FLASH_CCR2 register clears INCERR2.

0: no inconsistency error occurred on bank 2

1: an inconsistency error occurred on bank 2.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **STRBERR2**: Bank 2 strobe error flag

STRBERR2 flag is raised when a strobe error occurs on bank 2 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE2 bit is set to 1. Writing 1 to CLR_STRBERR2 bit in FLASH_CCR2 register clears STRBERR2.

0: no strobe error occurred on bank 2

1: a strobe error occurred on bank 2.

Bit 18 **PGSERR2**: Bank 2 programming sequence error flag

PGSERR2 flag is raised when a sequence error occurs on bank 2. An interrupt is generated if the PGSERRIE2 bit is set to 1. Writing 1 to CLR_PGSERR2 bit in FLASH_CCR2 register clears PGSERR2.

0: no sequence error occurred on bank 2

1: a sequence error occurred on bank 2.

Bit 17 **WRPERR2**: Bank 2 write protection error flag

WRPERR2 flag is raised when a protection error occurs during a program operation to bank 2. An interrupt is also generated if the WRPERRIE2 is set to 1. Writing 1 to CLR_WRPERR2 bit in FLASH_CCR2 register clears WRPERR2.

0: no write protection error occurred on bank 2

1: a write protection error occurred on bank 2

Bit 16 **EOP2**: Bank 2 end-of-program flag

EOP2 flag is set when a programming operation to bank 2 completes. An interrupt is generated if the EOPIE2 is set to 1. It is not necessary to reset EOP2 before starting a new operation. EOP2 bit is cleared by writing 1 to CLR_EOP2 bit in FLASH_CCR2 register.

0: no programming operation completed on bank 2

1: a programming operation completed on bank 2

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CRC_BUSY2**: Bank 2 CRC busy flag

CRC_BUSY2 flag is set when a CRC calculation is ongoing on bank 2. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation on bank 2.

0: no CRC calculation ongoing on bank 2

1: CRC calculation ongoing on bank 2.

Bit 2 **QW2**: Bank 2 wait queue flag

QW2 flag is set when a write or erase operation is pending in the command queue buffer of bank 2. It is not possible to know what type of operation is present in the queue. This flag is reset by hardware when all write/erase operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

0: no write or erase operation is waiting in the operation queues of bank 2

1: at least one write or erase operation is pending in the operation queues of bank 2

Bit 1 **WBNE2**: Bank 2 write buffer not empty flag

WBNE2 flag is set when embedded flash memory is waiting for new data to complete the write buffer. In this state the write buffer is not empty. WBNE2 is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW2 bit in FLASH_CR2
- the embedded flash memory detects an error that involves data loss
- the application software has disabled write operations in this bank

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions or send the missing data.

0: write buffer of bank 2 empty or full

1: write buffer of bank 2 waiting data to complete

Bit 0 **BSY2**: Bank 2 busy flag

BSY2 flag is set when an effective write or erase operation is ongoing to bank 2. It is not possible to know what type of operation is being executed.

BSY2 cannot be forced to 0. It is automatically reset by hardware every time a step in a write, or erase operation completes.

0: no write or erase operation is executed on bank 2

1: a write or an erase operation is being executed on bank 2.

4.9.29 FLASH clear control register for bank 2 (FLASH_CCR2)

Address offset: 0x114

Reset value: 0x0000 0000

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CLR_CRCRDERR2**: Bank 2 CRCRDERR2 flag clear bit
Setting this bit to 1 resets to 0 CRCRDERR2 flag in FLASH_SR2 register.

Bit 27 **CLR_CRCEND2**: Bank 2 CRCEND2 flag clear bit
Setting this bit to 1 resets to 0 CRCEND2 flag in FLASH_SR2 register.

Bit 26 **CLR_DBECCERR2**: Bank 2 DBECCERR2 flag clear bit
Setting this bit to 1 resets to 0 DBECCERR2 flag in FLASH_SR2 register. If the SNECCERR2 flag of FLASH_SR2 register is cleared to 0, FLASH_ECC_FA2R register is reset to 0 as well.

Bit 25 **CLR_SNECCERR2**: Bank 2 SNECCERR2 flag clear bit
Setting this bit to 1 resets to 0 SNECCERR2 flag in FLASH_SR2 register. If the DBECCERR2 flag of FLASH_SR2 register is cleared to 0, FLASH_ECC_FA2R register is reset to 0 as well.

Bit 24 **CLR_RDSERR2**: Bank 2 RDSERR2 flag clear bit
Setting this bit to 1 resets to 0 RDSERR2 flag in FLASH_SR2 register.

Bit 23 **CLR_RDPERR2**: Bank 2 RDPERR2 flag clear bit
Setting this bit to 1 resets to 0 RDPERR2 flag in FLASH_SR2 register.

Bit 22 Reserved, must be kept at reset value.

Bit 21 **CLR_INCERR2**: Bank 2 INCERR2 flag clear bit
Setting this bit to 1 resets to 0 INCERR2 flag in FLASH_SR2 register.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CLR_STRBERR2**: Bank 2 STRBERR2 flag clear bit
Setting this bit to 1 resets to 0 STRBERR2 flag in FLASH_SR2 register.

Bit 18 **CLR_PGSERR2**: Bank 2 PGSERR2 flag clear bit
Setting this bit to 1 resets to 0 PGSERR2 flag in FLASH_SR2 register.

Bit 17 **CLR_WRPERR2**: Bank 2 WRPERR2 flag clear bit
Setting this bit to 1 resets to 0 WRPERR2 flag in FLASH_SR2 register.

Bit 16 **CLR_EOP2**: Bank 2 EOP2 flag clear bit
Setting this bit to 1 resets to 0 EOP2 flag in FLASH_SR2 register.

Bits 15:0 Reserved, must be kept at reset value.

4.9.30 FLASH protection address for bank 2 (FLASH_PRAR_CUR2)

Address offset: 0x128

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This read-only register reflects the current values of corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP2	Res.	Res.	Res.	PROT_AREA_END2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PROT_AREA_START2											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMEP2**: Bank 2 PCROP protected erase enable option status bit
If DMEP2 is set to 1, the PCROP protected area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **PROT_AREA_END2**: Bank 2 PCROP area end status bits
These bits contain the last 256-byte block of the PCROP area in bank 2.
If this address is equal to PROT_AREA_START2, the whole bank 2 is PCROP protected.
If this address is lower than PROT_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PROT_AREA_START2**: Bank 2 PCROP area start status bits
These bits contain the first 256-byte block of the PCROP area in bank 2.
If this address is equal to PROT_AREA_END2, the whole bank 2 is PCROP protected.
If this address is higher than PROT_AREA_END2, no protection is set on bank 2.

4.9.31 FLASH protection address for bank 2 (FLASH_PRAR_PRG2)

Address offset: 0x12C

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP2	Res.	Res.	Res.	PROT_AREA_END2

Res.	Res.	Res.	Res.	PROT_AREA_START2											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DMEP2**: Bank 2 PCROP protected erase enable option configuration bit
If DMEP2 is set to 1, the PCROP protected area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **PROT_AREA_END2**: Bank 2 PCROP area end configuration bits
These bits contain the last 256-byte block of the PCROP area in bank 2.
If this address is equal to PROT_AREA_START2, the whole bank 2 is PCROP protected.
If this address is lower than PROT_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PROT_AREA_START2**: Bank 2 PCROP area start configuration bits
These bits contain the first 256-byte block of the PCROP area in bank 2.
If this address is equal to PROT_AREA_END2, the whole bank 2 is PCROP protected.
If this address is higher than PROT_AREA_END2, no protection is set on bank 2.

4.9.32 FLASH secure address for bank 2 (FLASH_SCAR_CUR2)

Address offset: 0x130

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This read-only register reflects the current values of corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES2	Res.	Res.	Res.	SEC_AREA_END2

Res.	Res.	Res.	Res.	SEC_AREA_START2											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMES2**: Bank 2 secure protected erase enable option status bit
If DMES2 is set to 1, the secure protected area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **SEC_AREA_END2**: Bank 2 secure-only area end status bits
These bits contain the last 256-byte block of the secure-only area in bank 2.
If this address is equal to SEC_AREA_START2, the whole bank 2 is secure protected.
If this address is lower than SEC_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SEC_AREA_START2**: Bank 2 secure-only area start status bits
These bits contain the first 256-byte block of the secure-only area in bank 2.
If this address is equal to SEC_AREA_END2, the whole bank 2 is secure protected.
If this address is higher than SEC_AREA_END2, no protection is set on bank 2.

4.9.33 FLASH secure address for bank 2 (FLASH_SCAR_PRG2)

Address offset: 0x134

Reset value: 0xXXXX 0XXX (see *Table 21: Option byte organization*)

This register is used to program values in corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES2	Res.	Res.	Res.	SEC_AREA_END2											
rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	SEC_AREA_START2											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DMES2**: Bank 2 secure access protected erase enable option configuration bit
If DMES2 is set to 1, the secure access only area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **SEC_AREA_END2**: Bank 2 secure-only area end configuration bits
These bits contain the last of 256 bytes block of the secure-only area in bank 2.
If this address is equal to SEC_AREA_START2, the whole bank 2 is secure access only.
If this address is lower than SEC_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SEC_AREA_START2**: Bank 2 secure-only area start configuration bits
These bits contain the first of 256 bytes block of the secure-only area in bank 2.
If this address is equal to SEC_AREA_END2, the whole bank 2 is secure access only.
If this address is higher than SEC_AREA_END2, no protection is set on bank 2.

4.9.34 FLASH write sector group protection for bank 2 (FLASH_WPSGN_CUR2R)

Address offset: 0x138

Reset value: 0xXXXX XXXX

This read-only register reflects the current values of corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WRPSGn2															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **WRPSGn2**: Bank 2 sector group protection option status byte

Each FLASH_WPSGN_CUR2R bit reflects the write protection status of the corresponding group of 4 consecutive sectors in bank 2 (0: group is write protected; 1: group is not write protected)

Bit 0: Group embedding sectors 0 to 3

Bit 1: Group embedding sectors 4 to 7

Bit N: Group embedding sectors 4 x N to 4 x N + 3

Bit 31: Group embedding sectors 124 to 127

Note: Bank 2 is limited to 64 sectors on STM32H7A3xG devices.

4.9.35 FLASH write sector group protection for bank 2 (FLASH_WPSGN_PRG2R)

Address offset: 0x13C

Reset value: 0xXXXX XXXX

This register is used to program values in corresponding option bits. It is available only on STM32H7A3/7B3 devices and reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRPSGn2

WRPSGn2															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRPSGn2**: Bank 2 sector group protection option status byte

Setting WRPSGn2 bits to 0 write protects the corresponding group of 4 consecutive sectors in bank 2 (0: group is write protected; 1: group is not write protected)

Bit 0: Group embedding sectors 0 to 3

Bit 1: Group embedding sectors 4 to 7

Bit N: Group embedding sectors 4 x N to 4 x N + 3

Bit 31: Group embedding sectors 124 to 127

Note: Bank 2 is limited to 64 sectors on STM32H7A3xG devices.

4.9.36 FLASH CRC control register for bank 2 (FLASH_CRCCR2)

Address offset: 0x150

Reset value: 0x001C 0000

The values in this register can be changed only if CRC_EN bit is set to 1 in FLASH_CR2 register.

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALL_BANK	CRC_BURST		Res.	Res.	CLEAN_CRC	START_CRC
									w	rw	rw			w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CLEAN_SECT	ADD_SECT	CRC_BY_SECT	Res.	CRC_SECT						
					w	w	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **ALL_BANK**: Bank 2 CRC select bit

When ALL_BANK is set to 1, all bank 2 user sectors are added to the list of sectors on which the CRC is calculated.

Bits 21:20 **CRC_BURST**: Bank 2 CRC burst size

CRC_BURST bits set the size of the bursts that are generated by the CRC calculation unit.

00: every burst has a size of 4 flash words (128 bit)

01: every burst has a size of 16 flash words (128-bit)

10: every burst has a size of 64 flash words (128-bit)

11: every burst has a size of 256 flash words (128-bit)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CLEAN_CRC**: Bank 2 CRC clear bit

Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDATAR register.

Bit 16 **START_CRC**: Bank 2 CRC start bit

START_CRC bit triggers a CRC calculation on bank 2 using the current configuration. It is not possible to start a CRC calculation when an option byte change operation is ongoing because all write accesses to embedded flash memory registers are put on hold until the option byte change operation has completed.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CLEAN_SECT**: Bank 2 CRC sector list clear bit

Setting CLEAN_SECT to 1 clears the list of sectors on which the CRC is calculated.

Bit 9 **ADD_SECT**: Bank 2 CRC sector select bit

Setting ADD_SECT to 1 adds the sector whose number is CRC_SECT to the list of sectors on which the CRC is calculated.

Bit 8 **CRC_BY_SECT**: Bank 2 CRC sector mode select bit

When CRC_BY_SECT is set to 1, the CRC calculation is performed at sector level, on the sectors selected by CRC_SECT.

When CRC_BY_SECT is reset to 0, the CRC calculation is performed on all addresses between CRC_START_ADDR and CRC_END_ADDR.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **CRC_SECT**: Bank 2 CRC sector number

CRC_SECT is used to select one or more user flash sectors to be added to CRC calculation. The CRC can be computed either between two addresses (using registers FLASH_CRCSADD2R and FLASH_CRCEADD2R) or on a list of sectors using this register. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC_SECT and then setting ADD_SECT to 1.

The list of sectors can be erased either by setting CLEAN_SECT bit or by disabling the CRC computation. CRC_SECT can be set only when CRC_EN of FLASH_CR register is set to 1.

0b0000000: sector 0 of bank 2 for CRC

0b0000001: sector 1 of bank 2 for CRC

...

0b0111111: sector 63 of bank 2 for CRC

...

0b1111111: sector 127 of bank 2 for CRC

Note: Bank 2 is limited to 64 sectors on STM32H7AxG devices.

4.9.37 FLASH CRC start address register for bank 2 (FLASH_CRCSADD2R)

Address offset: 0x154

Reset value: 0x0000 0000

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

CRC_START_ADDR[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_START_ADDR[19:2]**: CRC start address on bank 2

CRC_START_ADDR is used when CRC_BY_SECT is cleared to 0. It must be programmed to the start address of the bank 2 memory area on which the CRC calculation is performed.

Bits 1:0 Reserved, must be kept at reset value.

4.9.38 FLASH CRC end address register for bank 2 (FLASH_CRCEADD2R)

Address offset: 0x158

Reset value: 0x0000 0000

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

CRC_END_ADDR[15:2]														Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:2 **CRC_END_ADDR[19:2]**: CRC end address on bank 2

CRC_END_ADDR is used when CRC_BY_SECT is cleared to 0. It must be programmed to the end address of the bank 2 memory area on which the CRC calculation is performed.

Bits 1:0 Reserved, must be kept at reset value.

4.9.39 FLASH ECC fail address for bank 2 (FLASH_ECC_FA2R)

Address offset: 0x160

Reset value: 0x0000 0000

This register is available only on STM32H7A3/7B3 devices. It is reserved on STM32H7B0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAIL_ECC_ADDR2															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **FAIL_ECC_ADDR2**: Bank 2 ECC error address

When an ECC error occurs (both for single error correction or double detection) during a read operation from bank 2, the FAIL_ECC_ADDR2 bitfield indicates the address that generated the error:

Fail address = FAIL_ECC_ADDR2 * 32 + flash memory Bank 2 address offset

FAIL_ECC_ADDR2 is reset when the flag error in the FLASH_SR2 register (CLR_SNECCERR2 or CLR_DBECCERR2) is reset.

The embedded flash memory programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

5 Secure memory management (SMM)

5.1 SMM introduction

STM32H7A3/7B3 and STM32H7B0 microcontrollers offer a first set of protection mechanisms, which are similar to other STM32 Series:

- Global readout device protection (RDP)
- Write protection (WRP)
- Proprietary code readout protection (PCROP)

A detailed description of these protection mechanisms is given in *Section 4: Embedded flash memory (FLASH)*.

STM32H7B3 and STM32H7B0 also offer an additional enhanced protection mode, the Secure access mode, that makes possible the development of user-defined secure services (e.g. secure firmware update or secure boot) and guarantees of a safe execution and protection of both code and data. This mechanism is described in details in *Section 5.3: Secure access mode*, *Section 5.4: Root secure services (RSS)* and *Section 5.5: Secure user software*.

The secure memory management unit is contained inside the CD domain.

5.2 Glossary

The following terms will be used in herein:

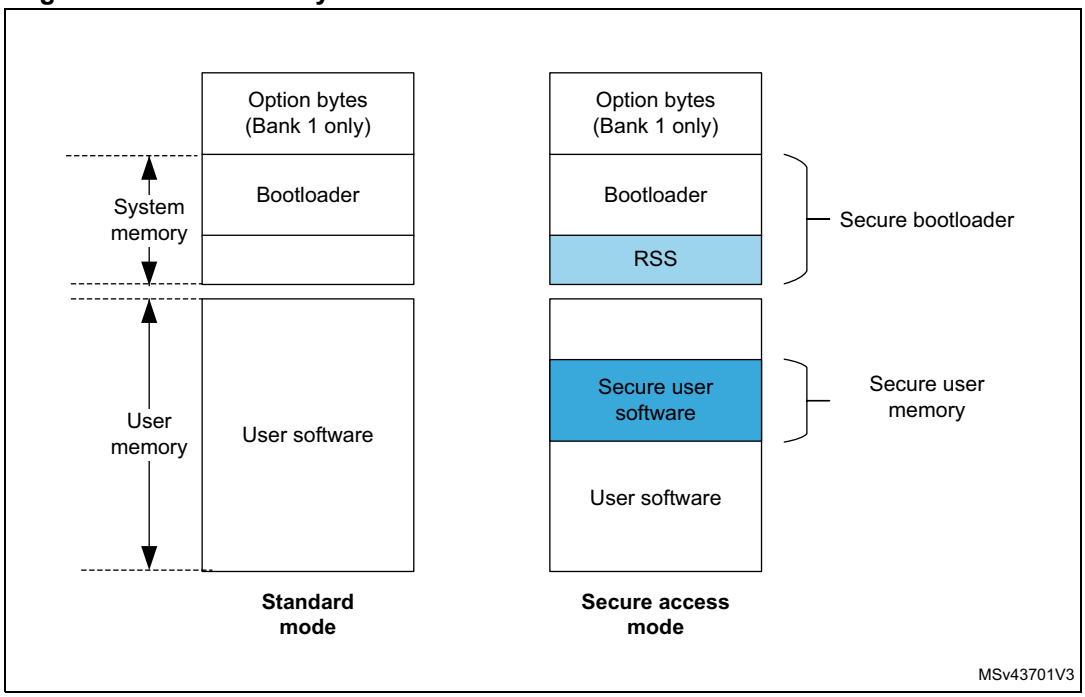
Table 29. List of preferred terms

Term	Description
Device Security Level	
Standard mode	Device state which allows the access to the user Flash memory, the option bytes and the bootloader area.
Secure access mode	Device state which allows the access to all the memory areas of the device.
Memory areas	
System memory	ST reserved memory area used to store ST ROM code.
User flash memory	Flash memory area used to store user code and data.
Secure user memory/area(1)	This area can be configured to be accessed once after reset and be hidden for the firmware stored in the user flash memory after the code stored in this area is executed.

Table 29. List of preferred terms (continued)

Term	Description
Software services	
Bootloader	STMicroelectronics software executed at reset which allows the download of firmware from regular communication ports.
Root secure services (RSS)	STMicroelectronics software which allows the access to secure services.
Secure user software	User software executed once after reset, which can be used to implement secure boot and secure firmware update (SFU). Secure user software is located in secure user memory.

1. Secure user memory/areas are also named secure-hide protected (HDP) memory/areas.



5.3 Secure access mode

Some sensitive functions require safe execution from potential malicious software attacks. Secure firmware update (SFU) software is a good example of code that requires a high level of protection since it handles secret data (such as cryptographic keys) that shall not be retrieved by other processes.

STM32H7B3 and STM32H7B0 microcontrollers feature secure memory areas with restricted access. They allow building secure services that will be executed prior to any user application. These secure areas, together with the software they contain, are only accessible when configuring the device in Secure access mode.

Figure 15 gives an overview of flash memory areas and services in Standard and Secure access modes.

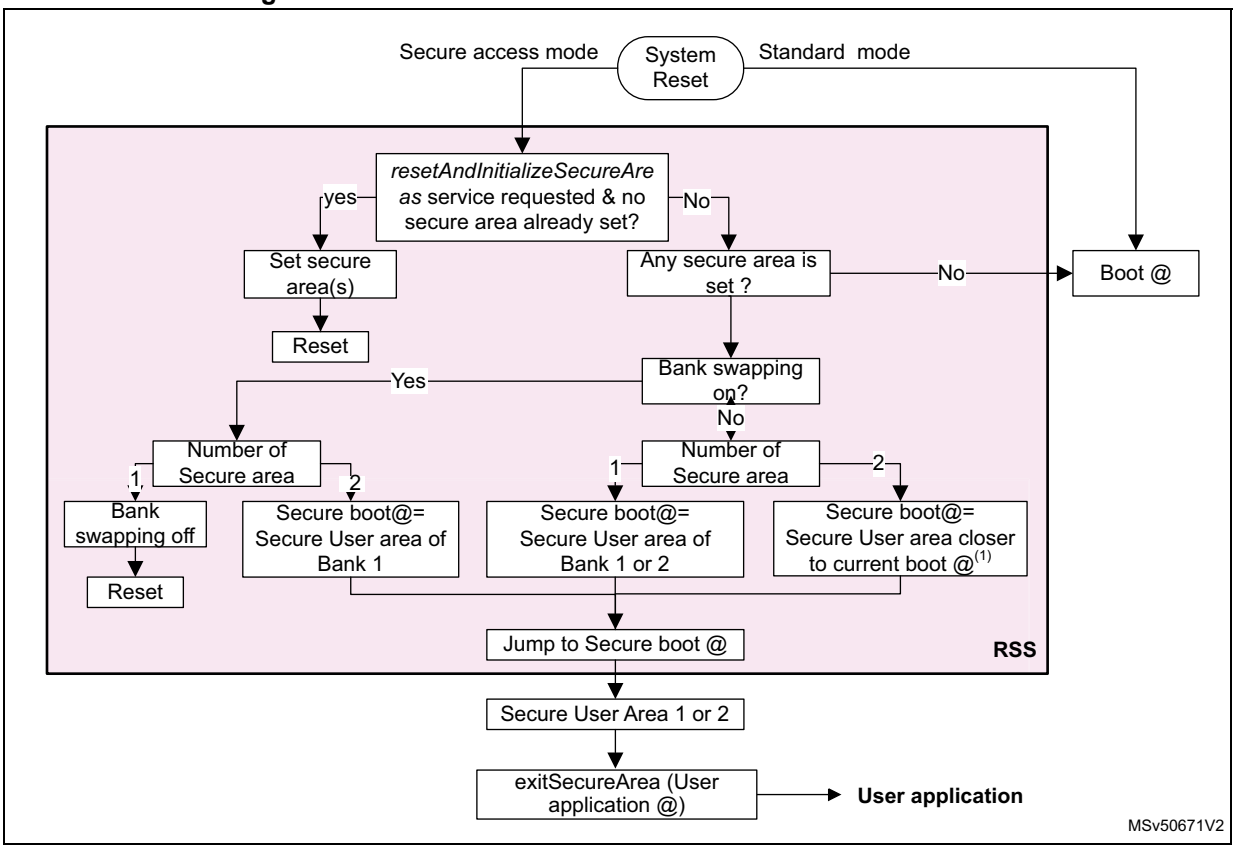
Figure 15. Flash memory areas and services in Standard and Secure access modes

1. The protected areas that can only be accessed in Secure access mode are shown in blue.
2. A single secure user area can be defined for each bank.
3. Only one bank (bank1) is supported on STM32H7B0 devices.

5.3.1 Associated features

The Secure access mode can be configured through option bytes. When it is set, it enables access to:

- STMicroelectronics root secure services to set secure user areas (see *Section 5.4: Root secure services (RSS)*)
- Secure user memory which embeds secure user code and data.



For a summary of access rights for each core, refer to *Section 5.6: Summary of flash protection mechanisms*.

5.3.2 Boot state machine

In Secure access mode, booting is forced in the RSS whatever the boot configuration (boot pins and boot addresses). The RSS can either set a secure user memory area if one has been requested (see *Section 5.5.2: Setting secure user memory areas*) or jump directly to the existing secure user memory. The code located in secure user memory is executed before the main user application and the bootloader. If no service is required and no secure area is defined, the RSS jumps to the boot address selected by BOOT0 pin value.

Figure 16 shows the boot state machine.

Figure 16. Bootloader state machine in Secure access mode

1. Only bank 1 secure user area is available on STM32H7B0 devices. Bank swapping is not supported.

5.3.3 Secure access mode configuration

Enabling Secure access mode

There is no restriction on how to activate Secure access mode on the device. It is configured through the SECURITY option bit in FLASH_OPTSR_CUR register (see *Section 4.9.8: FLASH option status register (FLASH_OPTSR_CUR)*).

The Secure access mode becomes active after a system reset.

Disabling Secure access mode

Disabling Secure access mode is a more sensitive task as it can only be done if no more protected code exists on the device. As a result, to come back to Standard mode, secure user memories and PCROP/execute-only areas shall be removed before clearing the SECURITY option bit in the FLASH_OPTSR_CUR register.

Protected areas can be removed by performing a flash mass erase (refer to *Section 4.3.10: FLASH erase operations* for more details on mass erase sequence).

5.4 Root secure services (RSS)

The root secure services (RSS) are STMicroelectronics ROM code stored on the device. They are part of the security features. These firmware services are available in Secure access mode (see *Section 4.5.5: Secure access mode (STM32H7B0 and STM32H7B3 only)*.

Table 30 gives the addresses of the application programming interface (API) described in the following sections.

Table 30. RSS API addresses

RSS	RSS API address
RSS_getVersion	0x1FF0 9500
RSS_exitSecureArea	0x1FF0 9514
RSS_resetAndInitializeSecureAreas	0x1FF0 9518

5.4.1 Secure area setting service

STMicroelectronics provides a service to perform the initialization of secure areas. This service can be called only once. It is executed after a system reset in Secure access mode prior to any other software stored in the device.

Caution: RSS software cannot be accessed (read, write, execute and debug) when the STM32H7B3 and STM32H7B0 operate in Standard mode. The service can be automatically accessed with ST programming tool, STM32CubeProgrammer, or called through a direct call to the *resetAndInitializeSecureAreas* function defined below.

Warning: It is mandatory to have a functioning software programmed in the flash memory secure area before initializing the secure area. Setting a secure area on an empty flash memory region blocks the device.

resetAndInitializeSecureAreas

Prototype	void *resetAndInitializeSecureAreas*(RSS_SecureArea_t area)
Arguments	Secure user areas start and end addresses. One or two secure user areas can be set.
Description	This service sets secure user area boundaries, following the values stored in the option byte registers: – SEC_AREA_START1 and SEC_AREA_END1 for bank 1 – SEC_AREA_START2 and SEC_AREA_END2 for bank 2 This service can be used only when a secure area is set for the first time. A system reset is triggered after service completion.

5.4.2 Secure area exiting service

The RSS also provides the *exitSecureArea* service. This service must be called to jump to user application. It allows closing safely the secure user area to guarantee that its content can no more be accessed.

Contrary to the *resetAndInitializeSecureAreas* service, it does not trigger any system reset.

exitSecureArea function is defined below:

exitSecureArea

Prototype	void *exitSecureArea*(unsigned int vectors, unsigned int jtagState)
Arguments	Address of application vectors where to jump after exit and state of JTAG after exit: RSS_ENABLE_JTAG_AT_EXIT: JTAG enabled after exiting the secure area RSS_KEEP_JTAG_DISABLED_AT_EXIT: JTAG disabled after exiting the secure area
Description	This service is used to exit from secure user software and jump to user main application. There is no system reset triggered by this service

5.4.3 OTFDEC encryption service

The RSS includes the *RSS_OTFD_resetAndEncrypt* service to perform in-place encryption of the provided payload in RAM. Refer to AN5281 *"How to use OTFDEC for encryption/decryption in trusted environment on STM32 MCUs* " for more details.

5.5 Secure user software

A secure user software is a trusted piece of code that is executed after device power-on or after a system reset. It allows building secure applications such as:

- code signature or integrity checking (user secure boot).
- software license checking
- secure firmware update
- secure initialization

5.5.1 Access rules

Only accessible in Secure access mode, the secure user software is stored in the secure memory areas.

Only one user secure area can be configured per bank. If two secure areas are defined, the secure software that is executed is the one closer to current boot address.

After secure user software execution, the code shall jump to the main user application and prevent access to the secure user area. This is done by calling *exitSecureArea*s secure service with the application code address given as parameter.

Once in the application code, any access to the secure user area triggers a flash error.

5.5.2 Setting secure user memory areas

One secure area of configurable size can be set in each bank. The size of each area can be set from 512 bytes to full bank with a granularity of 256 bytes:

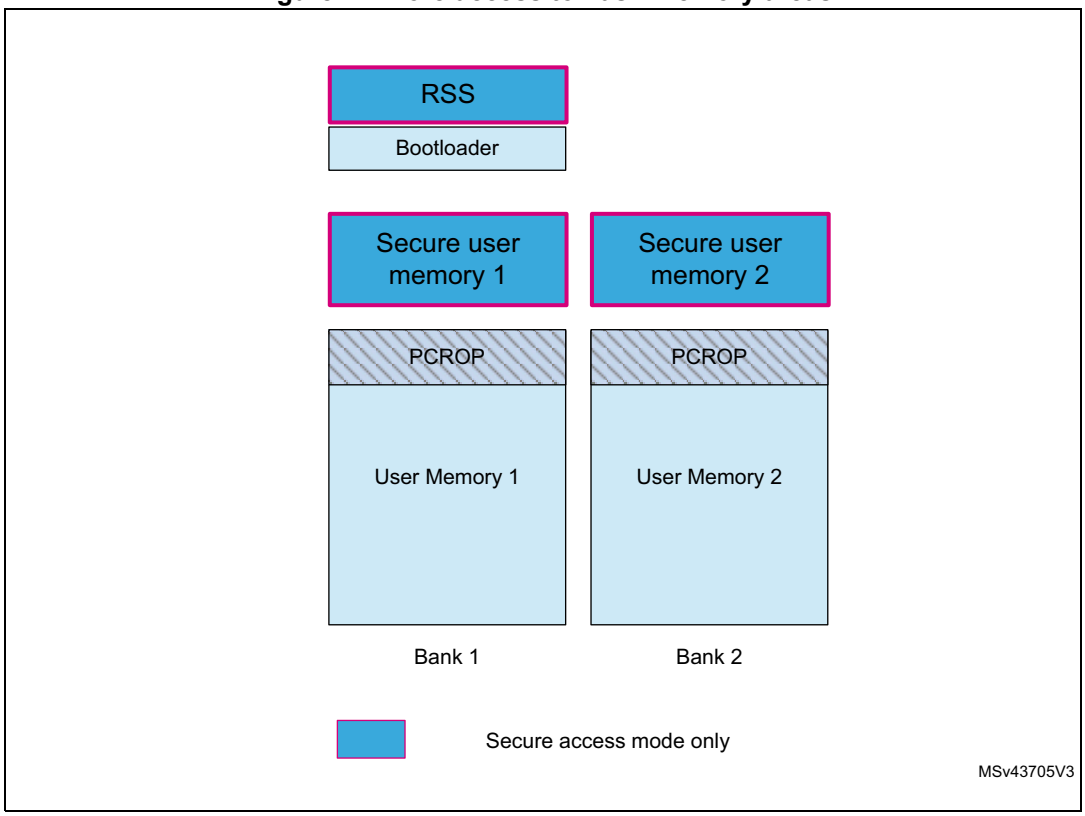
- Secure area in bank 1

  Boundaries are configured through SEC_AREA_START1 and SEC_AREA_END1 option bits in FLASH_SCAR_CUR1 (see *Section 4.9.13: FLASH secure address for bank 1 (FLASH_SCAR_CUR1)*).
- Secure area in bank 2

  Boundaries are configured through SEC_AREA_START2 and SEC_AREA_END2 option bits in FLASH_SCAR_CUR2 (see *Section 4.9.32: FLASH secure address for bank 2 (FLASH_SCAR_CUR2)*).

Note: If the secure area start address is equal to the secure area end address, the whole bank is considered as secure protected.

Flash memory bank 2 is not available on STM32H7B0 devices.



The above option bits can only be initialized through *resetAndInitializeSecureAreas* service.

If a secure area already exists, the secure user area code can update its own secure user area size or create a new one in the other bank.

5.6 Summary of flash protection mechanisms

Figure 17 and *Table 31* summarize the access rights of the different flash memory areas, both in Secure access and Standard modes.

Figure 17. Core access to flash memory areas

1. Flash memory bank 2 is not available on STM32H7B0 devices.

Table 31. Summary of flash protected areas access rights

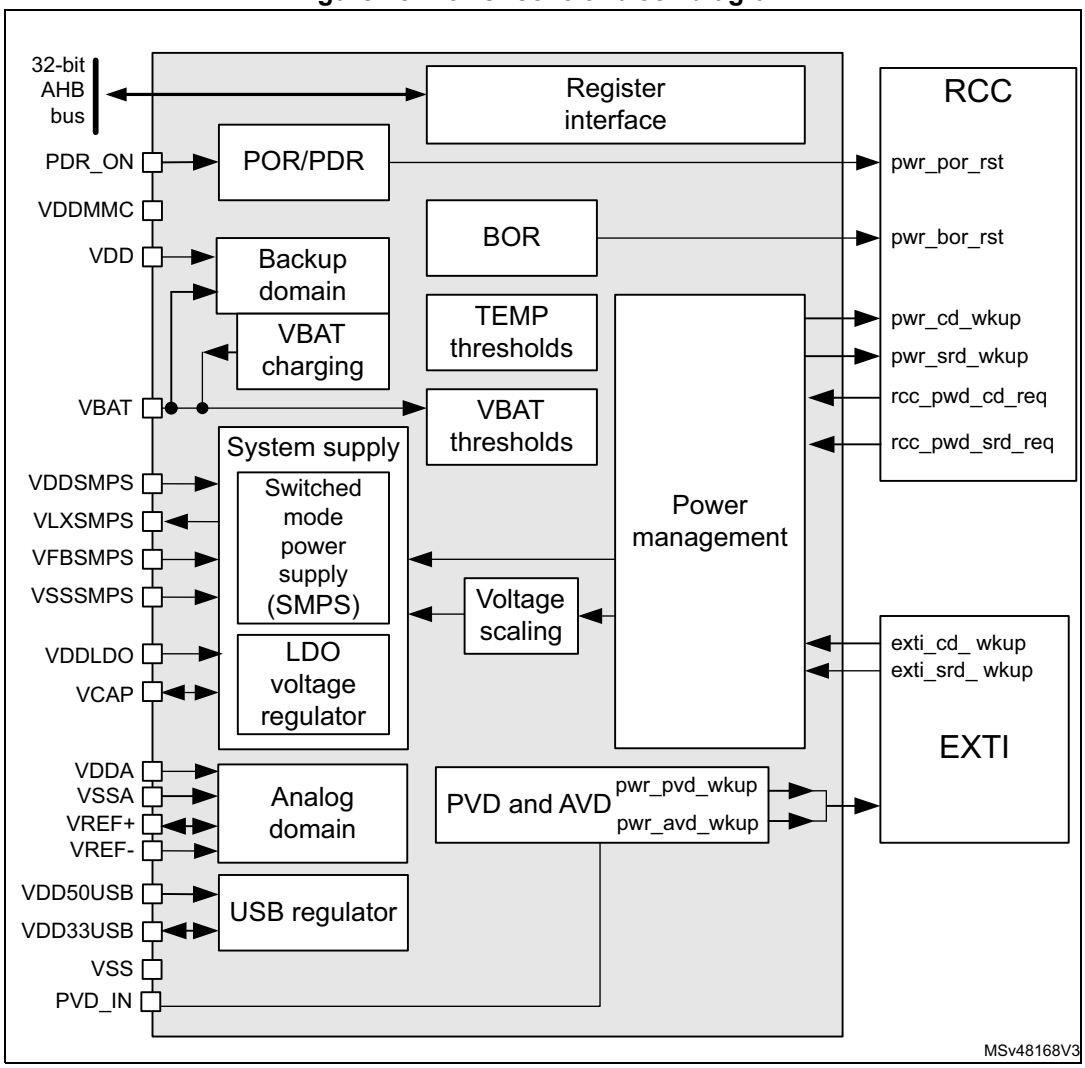
Access type	Software area	Security mode	Access
Execution	PCROP	Any	✓
	Secure user software	Secure access	✓ (1)
	Root secure services	Secure access	✓ (1)
Read access	PCROP	Any	No
	Secure user software	Secure access	✓(1)
	Root secure services	Secure access	✓ (1)
Debug access	PCROP	Any	No
	Secure user software	Secure access	No
	Root secure services	Secure access	No

1. Access rights granted after reset until code completion only.

6 Power control (PWR)

6.1 Introduction

The power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.



It also describes the features of the power supply supervisors and explains how the V_{CORE} supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

6.2 PWR main features

- Power supplies and supply domains
  - Core domains (V_{CORE})
  - V_{DD} domain
  - External VDD_MMC I/O domain
  - Backup domain (V_{SW}, V_{BKP})
  - Analog domain (V_{DDA})
- System supply voltage regulation
  - SMPS step-down converter
  - Voltage regulator (LDO)
- Peripheral supply regulation
  - USB regulator
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - V_{BAT} thresholds
  - Temperature thresholds (embedded dedicated temperature monitoring cell)
- Power management
  - V_{BAT} battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

6.3 PWR block diagram

Figure 18. Power control block diagram

PWR pins and internal signals

Table 32 lists the PWR inputs and output signals connected to package pins or balls, while *Table 33* shows the internal PWR signals.

Table 32. PWR input/output signals connected to package pins or balls

Pin name	Signal type	Description
VDD	Supply input	Main I/O and V_{DD} domain supply input
VDDA	Supply input	External analog power supply for analog peripherals
VBAT	Supply input/output	Backup battery supply input or battery charging output
VDDMMC	Supply input	External power supply for independent I/Os
VDDSMPS	Supply input	Switched mode power supply input

Table 32. PWR input/output signals connected to package pins or balls (continued)

Pin name	Signal type	Description
VLXSMPS	Supply output	Switched mode power supply output
VFBSMPS	Supply input	Switched mode power supply feedback voltage sense
VSSSMPS	Supply input	Switched mode power supply ground
VDDLDO	Supply input	Voltage regulator supply input
VCAP	Supply input/output	Digital core domain supply, generated internally or externally provided
VREF+	Supply input/output	Reference voltage for ADCs and DACs Generated internally or externally provided
VREF-	Supply input	Reference voltage for ADCs and DACs
VDD50USB	Supply input	USB regulator supply input
VDD33USB	Supply input/output	USB regulator supply output or external USB supply input
VSS	Supply input	Main ground
PDR_ON	Digital input	Power-down reset enable
PVD_IN	Analog input	Monitoring of the voltage level applied to this pin

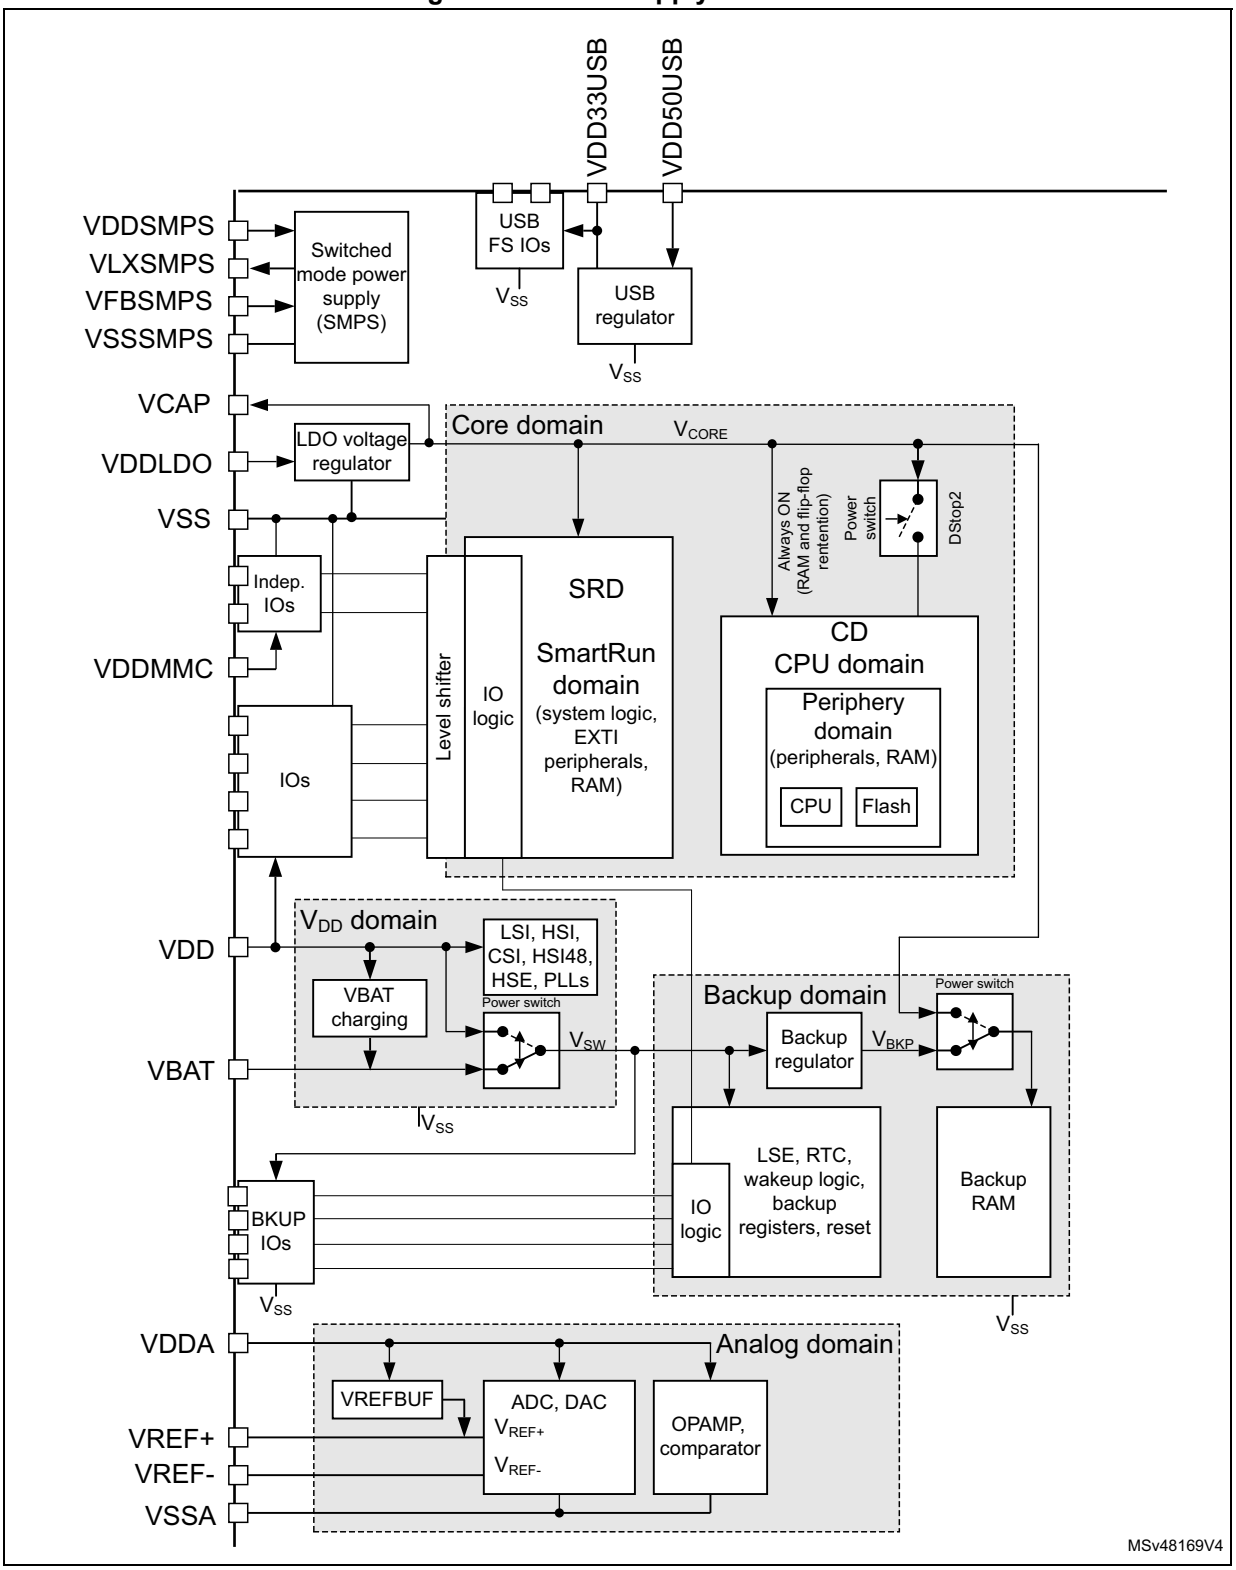
Table 33. PWR internal input/output signals

Signal name	Signal type	Description
AHB	Digital I/O	AHB register interface
pwr_pvd_wkup pwr_avd_wkup	Digital output	Programmable voltage detector output Analog voltage detector output Combined as one signal provided to the EXTI
pwr_por_rst	Digital output	Power-on reset
pwr_bor_rst	Digital output	Brownout reset
exti_c_wkup	Digital input	CPU wake-up request
exti_srd_wkup	Digital input	SmartRun domain wake-up request
pwr_cd_wkup	Digital output	CPU bus matrix and CPU peripherals clock wake-up request
pwr_srd_wkup	Digital output	SmartRun domain bus matrix clock wake-up request
rcc_pwd_srd_req	Digital input	SmartRun domain low-power request generated by the RCC
rcc_pwd_cd_req	Digital input	CPU domain low-power request generated by the RCC

6.4 Power supplies

The device requires V_{DD}, V_{DDLDO}, V_{DDA} and V_{BAT} power supplies. Depending on the use case and when available from the package, V_{DDSMPS}, V_{DDMMC}, V_{DDUSB}, V_{REF+} and V_{CAP} independent power supplies can also be required.

The device provides regulated supplies for specific functions (SMPS step-down converter, LDO voltage regulator, USB regulator, voltage reference buffer):



- V_{DD} external power supply for I/Os and system analog blocks such as reset, power management and oscillators
- V_{DDMMC} external power supply for some independent I/Os (available from some specific packages only), must be tied to V_{DD} when an independent supply is not required
- V_{BAT} optional external power supply for Backup domain when V_{DD} is not present (V_{BAT} mode), must be connected to V_{DD} when this feature is not used
- V_{DDSMPS} external power supply for the switched mode power supply. This power supply must be connected to V_{DD} or tied to V_{SS} when the SMPS is not used.
- V_{LXSMPS} switched mode power supply output
- V_{FBSMPS} is the switched mode power supply sense feedback, must be tied to V_{SS} when the SMPS is not used
- V_{SSSMPS} separate switched mode power supply ground
- V_{DDLDO} external power supply for the voltage regulator
- V_{CAP} digital core domain supply

  This power supply is independent from all the other power supplies:
  - When the voltage regulator is enabled, V_{CORE} is delivered by the internal voltage regulator.
  - When the voltage regulator is disabled, V_{CORE} is delivered by an external power supply through V_{CAP} pin, or by the switched mode power supply.
- V_{DDA} external analog power supply for ADCs, DACs, OPAMPs, comparators and voltage reference buffers

  This power supply is independent from all the other power supplies.
- V_{REF+} external reference voltage for ADC and DAC
  - When the voltage reference buffer is enabled, V_{REF+} is delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled, V_{REF+} is delivered by an independent external reference supply (**Do not** enable the V_{REF} buffer in this case).
- V_{SSA} separate analog and reference voltage ground
- $V_{DD50USB}$ external power supply for USB regulator
- $V_{DD33USB}$ USB regulator supply output for USB interface
  - When the USB regulator is enabled, $V_{DD33USB}$ is delivered by the internal USB regulator.
  - When the USB regulator is disabled, $V_{DD33USB}$ is delivered by an independent external supply input (**Do not** enable the USB regulator in this case).
- V_{SS} common ground for all supplies except for SMPS and analog blocks

Note: Depending on the operating power supply range, some peripherals may be used with limited features and performance. For more details, refer to section “General operating conditions” of the device datasheets.

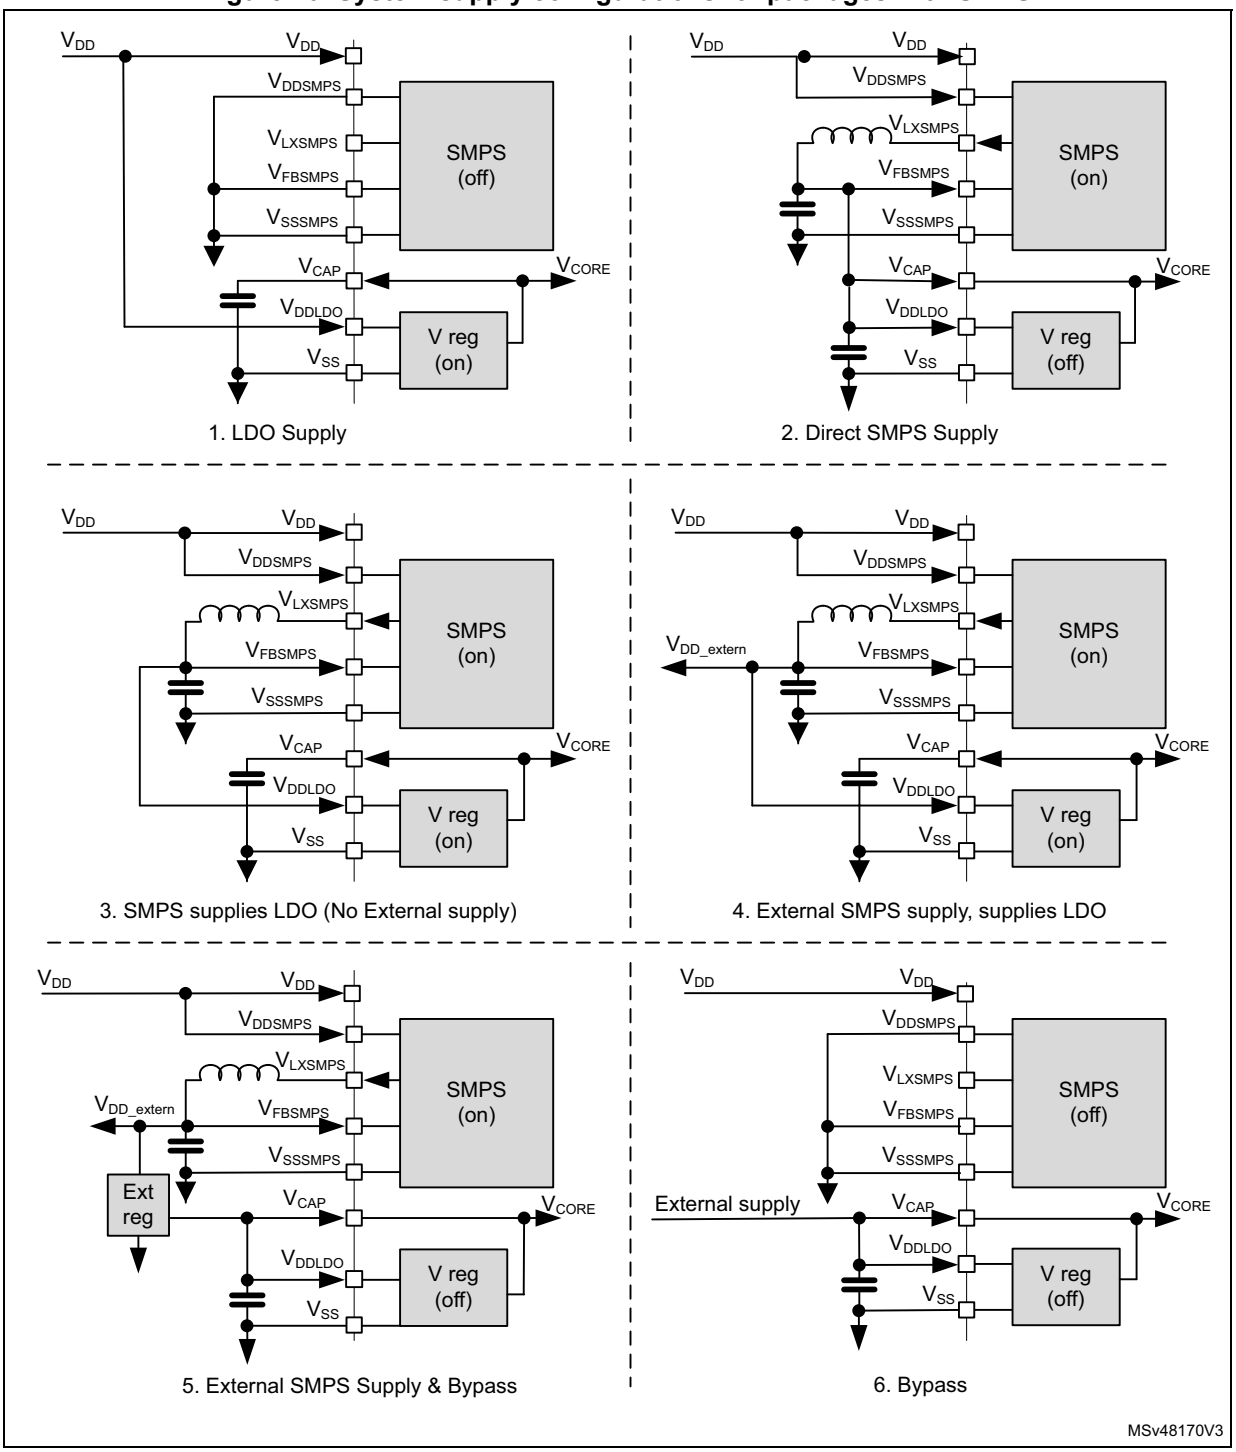


Figure 19. Power supply overview

By configuring the switched mode power supply (SMPS step-down converter) and the LDO voltage regulator, the supply configurations shown in *Figure 20* and *Figure 21* are supported for the V_{CORE} core domain and an external supply.

Note: The SMPS is not available on all packages.

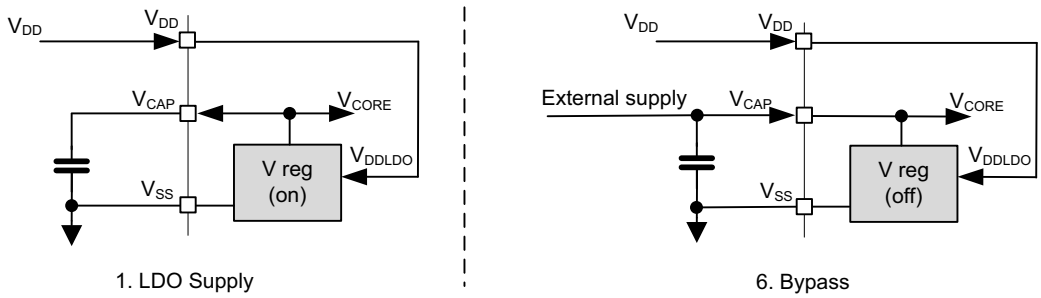

Figure 20. System supply configurations for packages with SMPS

1. The numbers mentioned above correspond to steps described in *Table 34: Supply configuration control*.

Note: For cases 3 to 5, the SMPS output is set to 1.2 V during the startup phase and to 1.8 V or 2.5 V at code execution start (refer to PWR control register 3 (PWR_CR3)).
The different supply configurations are controlled through the LDOEN, SMPSEN, SMPSEXTHP, SMPSLEVEL and BYPASS bits in the PWR control register 3 (PWR_CR3), according to Table 34.

Figure 21. System supply configurations for packages without SMPS

1. The numbers mentioned above correspond to steps described in *Table 34: Supply configuration control*.

Table 34. Supply configuration control

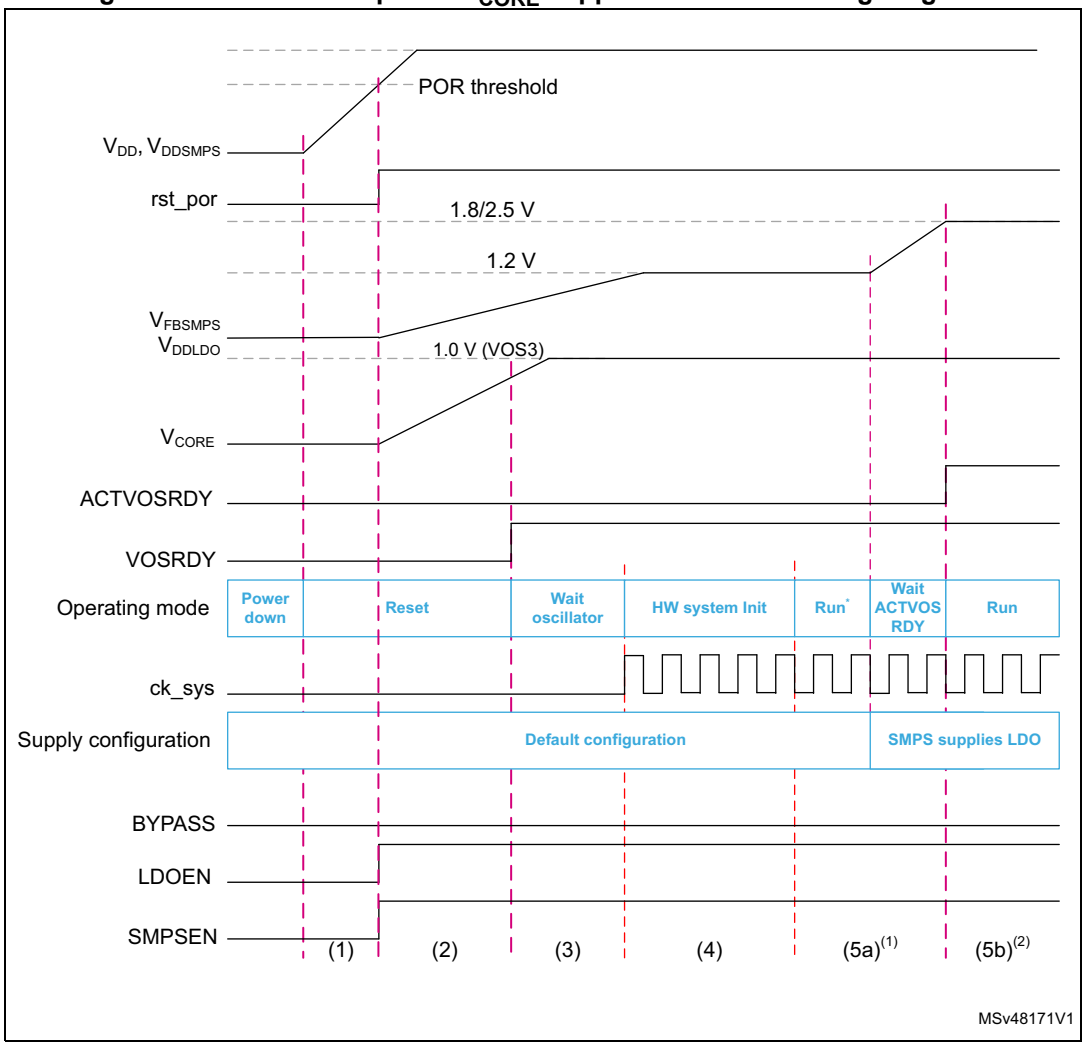
ID	Supply configuration	SMPSLEVEL	SMPSEXTHP	SMPSEN	LDOEN	BYPASS	Description
0	Startup configuration	00	0	1	1	0	– Configuration during power-up phase (not a user config) – V_{CORE} power domains supplied from the LDO (VOS3, 1 V) – SMPS enabled at 1.2 V
1	LDO supply	x	x	0	1	0	– V_{CORE} power domains are supplied from the LDO according to VOS. – LDO power mode (Main, LP, Off) follows system low-power modes. – SMPS disabled
2	Direct SMPS step-down converter supply	x	0	1	0	0	– V_{CORE} power domains are supplied from the SMPS according to VOS. – LDO bypassed – SMPS step-down converter power mode (MR, LP, Off) follows system low-power modes.

Table 34. Supply configuration control (continued)

ID	Supply configuration	SMPSLEVEL	SMPSEXTHP	SMPSEN	LDOEN	BYPASS	Description
3	SMPS step-down converter supplies LDO	01 or 10	0	1	1	0	– V_{CORE} power domains are supplied from the LDO according to VOS. – LDO power mode (Main, LP, Off) follows system low-power modes. – SMPS step-down converter is enabled according to SMPSLEVEL and supplies the LDO. – SMPS power mode (MR, LP or Off) follows the system low-power mode.
4	SMPS step-down converter supplies external and LDO	01 or 10	1	1	1	0	– V_{CORE} power domains are supplied from voltage regulator according to VOS – LDO power mode (Main, LP, Off) follows system low-power modes. – SMPS step-down converter is enabled according to SMPSLEVEL. It is used to supply external circuits and may supply the LDO. – SMPS step-down converter is forced ON in MR mode
5	SMPS step-down converter supplies external and LDO Bypass	01 or 10	1	1	0	1	– V_{CORE} supplied from external source – SMPS step-down converter is enabled according to SMPSLEVEL. It is used to supply external circuits and may supply the external source for V_{CORE}. – SMPS step-down converter is forced ON in MR mode
6	SMPS step-down converter disabled and LDO Bypass	x	x	0	0	1	– V_{CORE} supplied from external source – SMPS step-down converter is disabled and LDO bypassed, voltage monitoring is still active
NA	Illegal	xx	x	0	0	0	If an illegal combination is written, the default configuration is kept (startup configuration, writing ignored) and a power-on reset (POR) is required before writing a new combination.
		xx	x	x	1	1	
		xx	0	1	0	1	
		00	x	1	1	0	
		xx	1	1	0	0	
		00	1	1	0	1	

6.4.1 System supply startup

The system startup sequence from power-on in different supply configurations is the following (see *Figure 22* for LDO supply and *Figure 25* for direct SMPS supply):



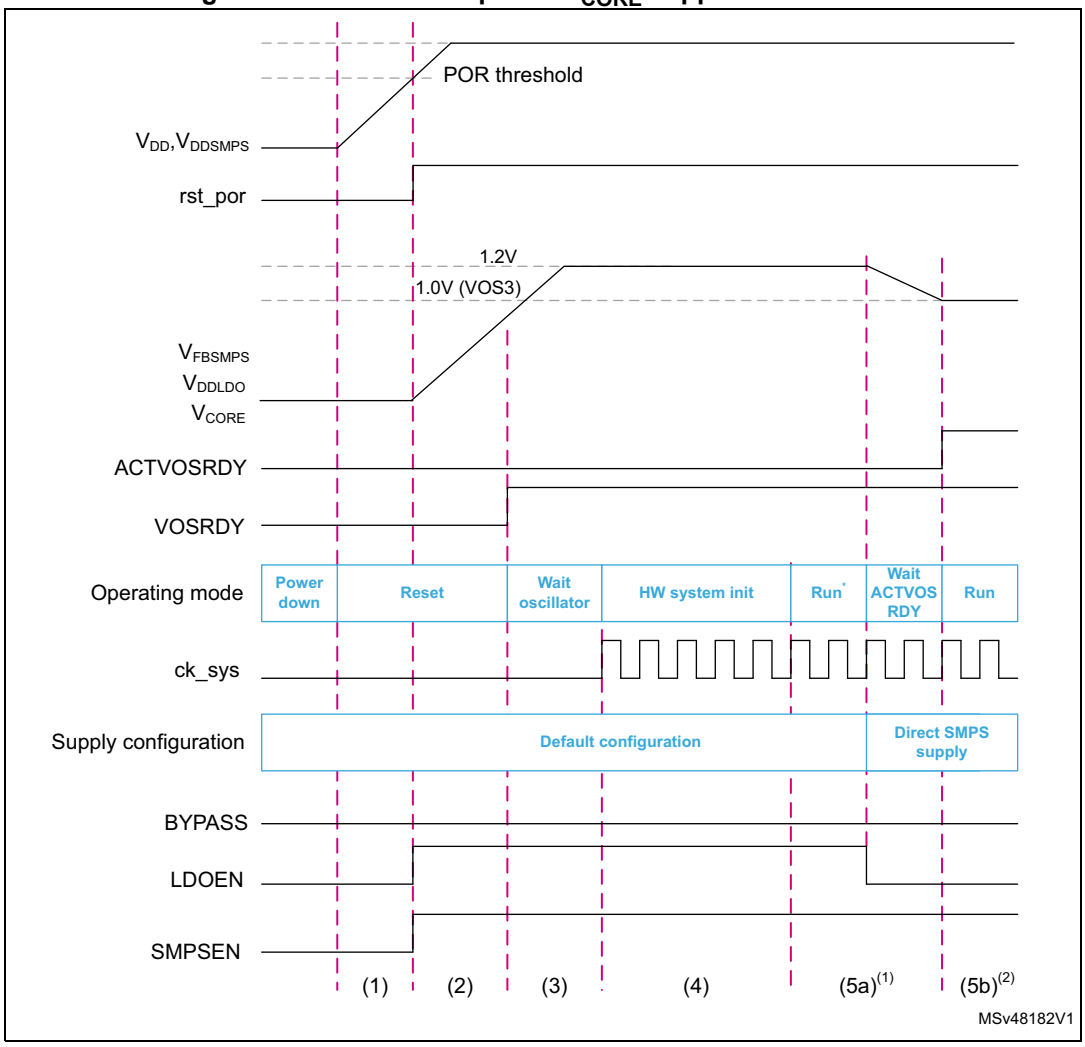
1. When the system is powered on, the POR monitors the V_{DD} supply. Once V_{DD} is above the POR threshold level, the SMPS step-down converter and the LDO voltage regulator are enabled in the default supply configuration:
   – The SMPS step-down converter output level is set at 1.2 V.
   – The voltage converter output level is set at 1.0 V in accordance with the three levels configured in *PWR SmartRun domain control register (PWR_SRDCR)*.
2. The system is kept in reset mode as long as V_{CORE} is not correct.
3. Once V_{CORE} is correct, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: flash memory and option bytes are loaded and the CPU starts in limited run mode (Run*).
5. The software must then initialize the system including supply configuration programming in *PWR control register 3 (PWR_CR3)*. Once the supply configuration has been configured, the ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* must be checked to guarantee valid voltage levels:
   a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run* mode: write accesses to the RAMs are not permitted and VOS must not be changed.
   b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode. Write accesses to RAMs are allowed and VOS can be changed.

Startup with V_{CORE} supplied from the LDO voltage regulator

When V_{CORE} is supplied from the voltage regulator (LDO), the V_{CORE} voltage settles directly at VOS3 level. However the SMPS V_{FBSMPS} output voltage is set at 1.2 V. The ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* indicates that the voltage levels are invalid.

The software must program the supply configuration in *PWR control register 3 (PWR_CR3)*. In addition, the V_{FBSMPS} voltage level must reach the programmed SMPSLEVEL so that ACTVOSRDY indicates a valid voltage level (see *Figure 22*).

Figure 22. Device startup with V_{CORE} supplied from LDO voltage regulator



1. In Run* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.

When exiting from Standby mode, the supply configuration is known by the system since the content of the *PWR control register 3 (PWR_CR3)* is retained. However the software must still wait for the ACTVOSRDY bit to be set in *PWR control status register 1 (PWR_CSR1)* to indicate V_{CORE} voltage levels are valid, before performing write accesses to RAM or changing VOS.

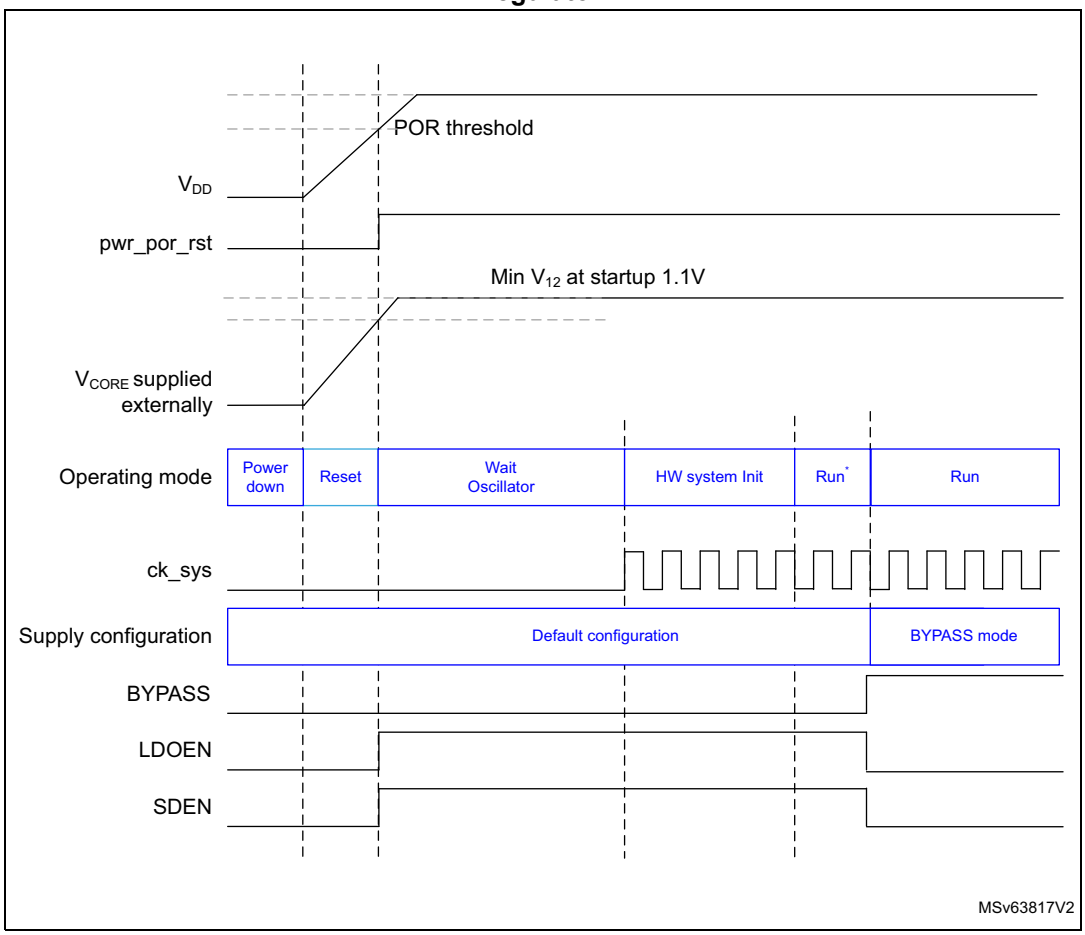
Startup with V_{CORE} supplied directly from the SMPS step-down converter

When V_{CORE} is supplied directly from the SMPS step-down converter, the V_{CORE} voltage first settles at the SMPS V_{FBSMPS} default level (1.2 V). Due to a too high supply compared to the VOS3 level, the ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* indicates an invalid voltage levels. V_{CORE} settles at 1.0 V (VOS3 level) and ACTVODSRDY indicates a valid voltage levels only when the supply configuration has been programmed in *PWR control register 3 (PWR_CR3)* (see Figure 5).

Figure 23. Device startup with V_{CORE} supplied from SMPS

1. In Run* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.

Startup with V_{CORE} provided from an external supply (Bypass)



Once V_{DD} is above the POR threshold level, the voltage regulator is enabled and sets the output level provided to the core domain to 1.0 V.

For this reason, the external supply provided to the core domain needs to be available before the internal voltage converter starts, to insure the voltage converter output stays switched off.

At code execution start, the voltage converter is switched off.

When the LDO is disabled, the external V_{CORE} voltage can be adjusted according to the user application needs (refer to section *General operating conditions* of the datasheet for details on V_{CORE} level versus the maximum operating frequency).

Figure 24. Device startup with V_{CORE} supplied in Bypass mode from external regulator

How to exit from Run* mode

As the Run* mode does not allow accessing RAM, PWR configuration must be done in the startup file. Below an example of code for SMPS supply that can be adapted for any other mode:

6.4.2 Core domain

The V_{CORE} core domain supply can be provided by the SMPS step-down converter, by the LDO voltage regulator or by an external supply (through the VCAP pads). V_{CORE} supplies all the digital circuitries except for the Backup domain and the Standby circuitry. The V_{CORE} domain is split into two sections:

- CPU domain (CD) containing the CPU (Cortex®-M7), flash memory and peripherals
- SmartRun domain (SRD) containing the system control, I/O logic and low-power peripherals

When a power-on reset occurs, the voltage regulator is enabled and supplies V_{CORE}. The SMPS is also enabled to deliver 1.2 V. This allows the system to start up in any supply configurations (see *Figure 20*).

After a power-on reset, the software must configure the used supply configuration in the *PWR control register 3 (PWR_CR3)* before changing VOS in the *PWR SmartRun domain control register (PWR_SRDCR)* or the RCC **ck_sys** frequency. The different system supply configurations are controlled as shown in *Table 34*.

Note: The SMPS is not available on all packages.

6.4.3 Voltage regulators

Embedded LDO voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to VCAP pins.

The LDO voltage regulator provides three different operating modes: Main (MR), Low-power (LP) or Off. These modes are used depending on the system operating modes (Run, Stop and Standby). They are configured through the associated VOS and SVOS levels.

Embedded SMPS step-down converter

The switched mode power supply (SMPS) requires an external coil to be connected between the dedicated VLXSMPS pin and VSS via a capacitor.

The SMPS step-down converter can be used in internal supply mode or external supply mode. The internal supply mode is used to directly supply the V_{CORE} domain, while the external supply mode is used to generate an intermediate supply level (V_{DD_extern} at 1.8 or 2.5 V) that can supply the voltage regulator and optionally an external circuitry.

The SMPS works in three different power modes: Main (MR), Low-power (LP) or Off.

When the SMPS is used in internal supply mode, the converter operating modes depend on the system modes (Run, Stop, Standby) and are configured through the associated VOS and SVOS levels.

When the SMPS supplies an external circuitry by generating an intermediate voltage level, the converter is forced ON and operates in MR mode. The intermediate voltage level is selected through SMPSLEVEL bits in the *PWR control register 3 (PWR_CR3)*. V_{DD_extern} is supplied at all times with full power whatever the system modes (Run, Stop, Standby).

Embedded voltage regulator operating modes

There are three different power modes:

- Run and Autonomous modes

  The voltage regulator (LDO or SMPS) operates in MR mode and provides full power to the V_{CORE} domain (core, memories and digital peripherals). The regulator output voltage (LDO or SMPS) can be scaled by software to different voltage levels (VOS0, VOS1, VOS2, and VOS3) that are configured through the VOS bits in the *PWR SmartRun domain control register (PWR_SRDCR)*. The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS3 is selected after system reset. VOSx bits can be changed on-the-fly to adapt to the required system performance (see *Table 35: Operating mode summary*).

- Stop mode

  The voltage regulator (LDO or SMPS) supplies the V_{CORE} domain to retain the content of registers and internal memories. The regulator can be kept in MR mode to allow fast exit from Stop mode or can be set in LP mode to achieve a lower V_{CORE} supply level but an extend exit-from-Stop latency.

  The regulator mode is selected through the SVOS and LPDS bits in the *PWR control register 1 (PWR_CR1)*. MR mode or LP mode are allowed if SVOS3 voltage scaling is selected, while only LP mode is possible for SVOS4 and SVOS5 scaling.

  Stop mode power consumption can be further reduced using SVO4 (lower voltage level than VOS3) and even further with SVOS5.

- Standby mode

  The regulator (LDO or SMPS) is OFF and the V_{CORE} domains are powered down. The content of the registers and memories are lost except for the Standby circuitry and the Backup domain.

Note: For more details, refer to the Voltage regulator section of the product datasheets.

6.4.4 PWR external supply

When V_{CORE} is supplied from an external source (Bypass mode), different operating modes can be used depending on the system operating modes (Run, Autonomous, Stop or Standby):

- In Run and Autonomous modes

  The external source supplies full power to the V_{CORE} domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS0, VOS1, VOS2 and VOS3). The externally applied voltage level must be reflected in the VOSx bits in the *PWR SmartRun domain control register (PWR_SRDCR)*. The RAMs must only be accessed for write operations and the flash memory for read operations when the external applied voltage level matches VOS settings.

- In Stop mode

  The external source supplies V_{CORE} domain to retain the content of registers and internal memories. The regulator can select a lower V_{CORE} supply level to reduce the consumption in Stop mode.

- In Standby mode

  The external source must be switched OFF and the V_{CORE} domains powered down. The content of registers and memories is lost except for the Standby circuitry and the Backup domain. The external source must be switched ON when exiting Standby mode.

  Care must be taken that all the current operations and transfers are completed before entering Standby and switching OFF the external source.

6.4.5 Backup domain

To retain the content of the Backup domain (RTC, backup registers and backup RAM) when V_{DD} is turned off, VBAT pin can be connected to an optional voltage that is supplied from a battery or from another source.

The switching to V_{BAT} is controlled by the power-down reset embedded in the reset block that monitors the V_{DD} supply.

Warning: **During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR is detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.**
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (see the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into VBAT pin through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

When the V_{DD} supply is present, the Backup domain is supplied from V_{DD}. This allows saving V_{BAT} power supply battery life time.

If no external battery is used in the application, it is recommended to connect VBAT externally to V_{DD} through a 100 nF external ceramic capacitor.

When the V_{DD} supply is present and higher than the PDR threshold, the Backup domain is supplied by V_{DD} and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 or TAMP_OUT3 pin assuming they have been configured by the RTC or the TAMPER.
- PI8 can be used either as GPIO or as RTC_OUT2, TAMP_IN2 or TAMP_OUT3 pin assuming they have been configured by the RTC or the TAMPER.
- PC1 can be used as TAMP_IN3 assuming it has been configured by the TAMPER.

Note: Since the switch only sinks a limited amount of current, the use of PC13 to PC15 and PI8 GPIOs is restricted: only one I/O can be used as an output at a time, at a speed limited to 2 MHz with a maximum load of 30 pF. These I/Os must not be used as current sources (e.g. to drive an LED).

In V_{BAT} mode, when the V_{DD} supply is absent and a supply is present on VBAT, the Backup domain is supplied by V_{BAT} and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 or TAMP_OUT3 pin assuming they have been configured by the RTC or the TAMPTER.
- PI8 can be used as RTC_OUT2, TAMP_IN2 or TAMP_OUT3 pin assuming they have been configured by the RTC or the TAMPER.

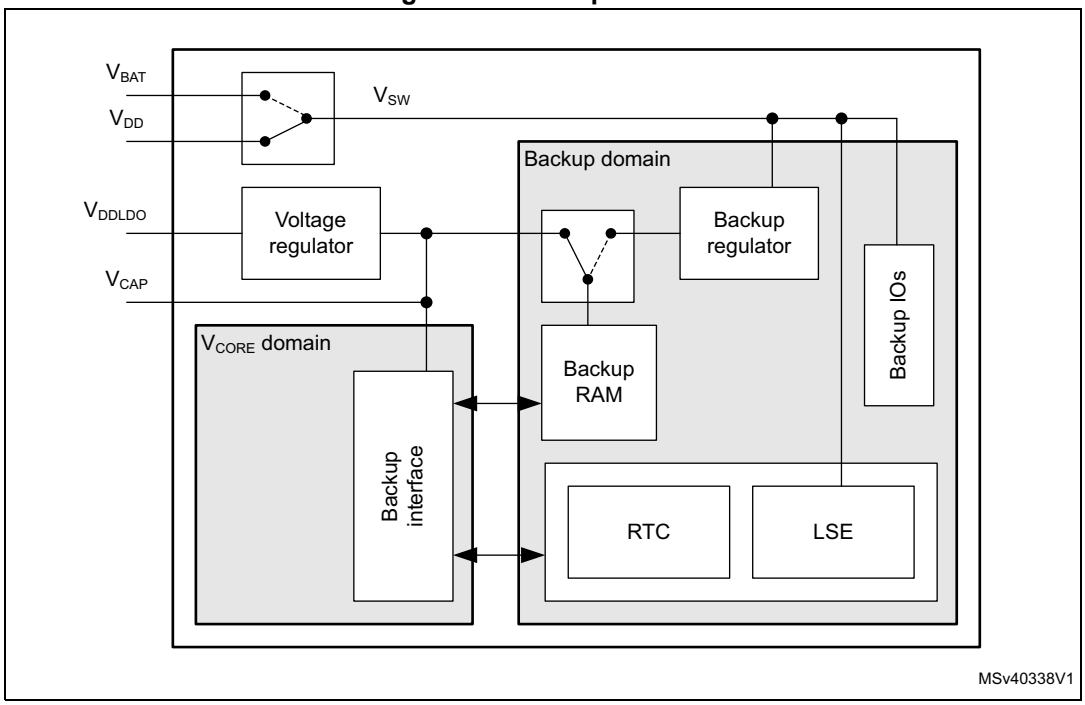
Accessing the Backup domain

After reset, the Backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the Backup domain, set the DBP bit in the *PWR control register 1 (PWR_CR1)*.

For more detail on RTC and backup RAM access, refer to *Section 8: Reset and clock control (RCC)*.

Backup RAM

The Backup domain includes 4 Kbytes of backup RAM accessible in 32-, 16- or 8-bit data mode. The backup RAM is supplied from the backup regulator in the Backup domain. When the backup regulator is enabled through BREN bit in the *PWR control register 2 (PWR_CR2)*, the backup RAM content is retained even in Standby and/or V_{BAT} mode (it can be considered as an internal EEPROM if V_{BAT} is always present).



The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or V_{BAT} modes.

The backup RAM is not mass erased by an tamper event, instead it is read protected to prevent confidential data, such as cryptographic private key, from being accessed. To re-

gain access to the backup RAM after a tamper event, the memory area needs to be first erased. The backup RAM can be erased in the two following ways:

- through the flash interface when a protection level change from level 1 to level 0 is requested (refer to the description of read protection (RDP) in the flash programming manual).
- after a tamper event, by filling the backup RAM with zeros upon the first attempt to write access it

Figure 25. Backup domain

6.4.6 V_{BAT} battery charging

When V_{DD} is present, the external battery connected to VBAT can be charged through an internal resistance.

V_{BAT} charging can be performed either through a 5 kΩ resistor or through a 1.5 kΩ resistor, depending on the VBRS bit value in *PWR control register 3 (PWR_CR3)*.

The battery charging is enabled by setting the VBE bit in *PWR control register 3 (PWR_CR3)*. It is automatically disabled in V_{BAT} mode.

6.4.7 Analog supply

Separate V_{DDA} analog supply

The analog supply domain is powered by dedicated VDDA and VSSA pads that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC and DAC conversion accuracy:

- The analog supply voltage input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

Analog reference voltage V_{REF+}/V_{REF-}

To achieve better accuracy low-voltage signals, the ADC and DAC have a separate reference voltage, available on VREF+ pin. The user can connect a separate external reference voltage on VREF+ pin.

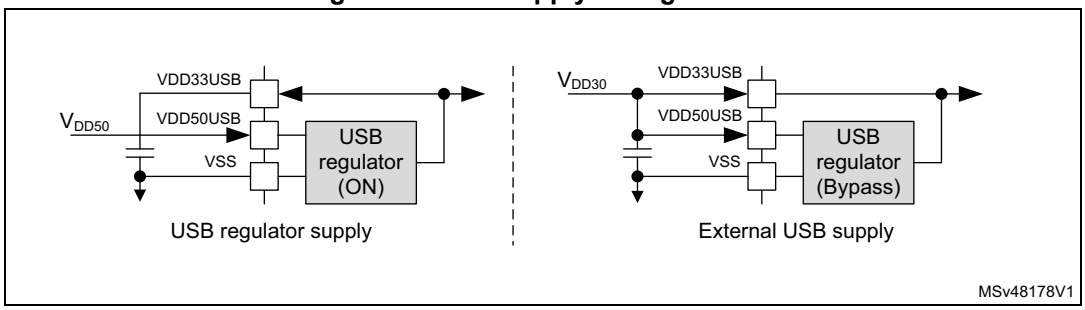
The V_{REF+} controls the highest voltage, represented by the full scale value, the lower voltage reference (V_{REF-}) being connected to VSSA pin.

When enabled by ENVR bit in the VREFBUF control and status register (see *Section 30: Voltage reference buffer (VREFBUF)*), V_{REF+} is provided from the internal voltage reference buffer. The internal voltage reference buffer can also deliver a reference voltage to external components through VREF+ pin.

When the internal voltage reference buffer is disabled by ENVR, V_{REF+} needs to be delivered by an independent external reference supply voltage or connected with V_{DDA}.

Note: The VREF+ and VREF- pins are not available on all packages (connected internally respectively to VDDA and VSSA).
***Do not** enable the internal voltage reference buffer when an external power supply is applied to the VREF+ pin.*

6.4.8 USB regulator



The USB transceiver is supplied from a dedicated $V_{DD33USB}$ supply that can be provided either by the integrated USB regulator or by an external USB supply.

When enabled by USBREGEN bit in *PWR control register 3 (PWR_CR3)*, the $V_{DD33USB}$ is provided from the USB regulator. Before using $V_{DD33USB}$, check that it is available by monitoring USB33RDY bit in *PWR control register 3 (PWR_CR3)*. The $V_{DD33USB}$ supply level detector must be enabled through USB33DEN bit in *PWR control register 3 (PWR_CR3)*.

When the USB regulator is disabled through USBREGEN bit, $V_{DD33USB}$ can be provided from an external supply. In this case $V_{DD33USB}$ and $V_{DD50USB}$ must be connected together.

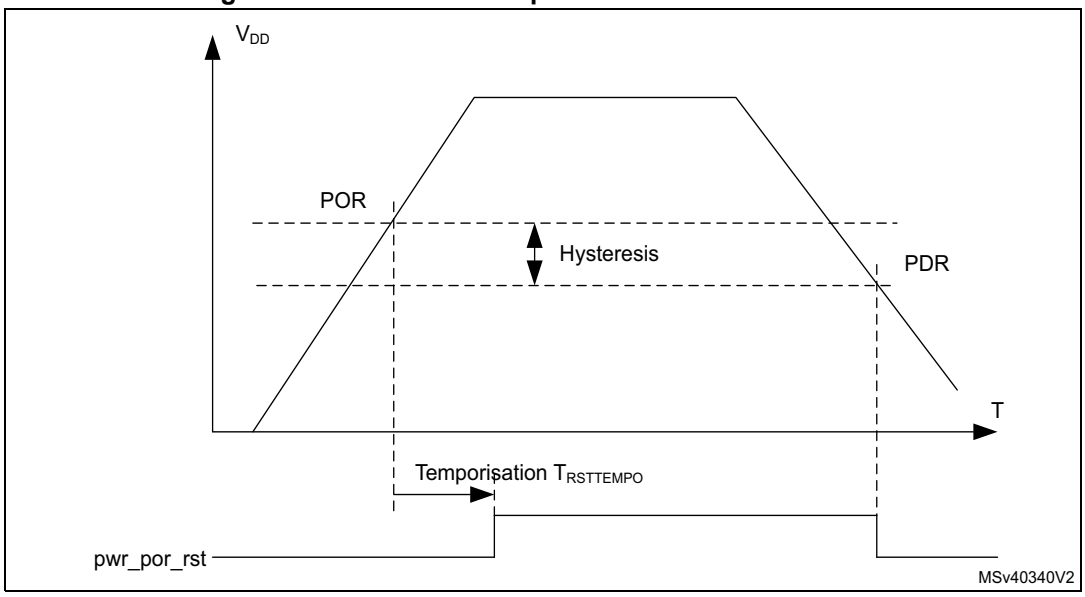
For more information on the USB regulator (see *Section 62: USB on-the-go high-speed (OTG_HS)*).

Figure 26. USB supply configurations

6.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- V_{DD} (V_{DDSMPS}) via POR/PDR (see *Section 6.5.1*), BOR (see *Section 6.5.2*) and PVD monitor (see *Section 6.5.3*)
- V_{DDA} via AVD monitor (see *Section 6.5.4*)
- V_{BAT} via V_{BAT} threshold (see *Section 6.5.5*)
- V_{CORE} over-voltage protection (See *Section 6.5.7*)
- V_{SW} via **rst_vsw**, keeping V_{SW} domain in Reset mode as long as the level is not OK
- V_{BKP} via a BRRDY bit in *PWR control register 2 (PWR_CR2)*
- V_{FBSMPS} via a SMPSEXTRDY bit in *PWR control register 3 (PWR_CR3)*
- $V_{DD33USB}$ via USB33RDY bit in *PWR control register 3 (PWR_CR3)*
- V_{DDMMC} via MMCVDO bit in *PWR control status register 1 (PWR_CSR1)*



6.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in Reset mode when V_{DD} is below a specified V_{POR} threshold, without the need for an external reset circuit. Once the V_{DD} supply level is above the V_{POR} threshold, the system is taken out of reset (see *Figure 27*). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

The POR/PDR can be enabled/disabled by the device PDR_ON input pin.

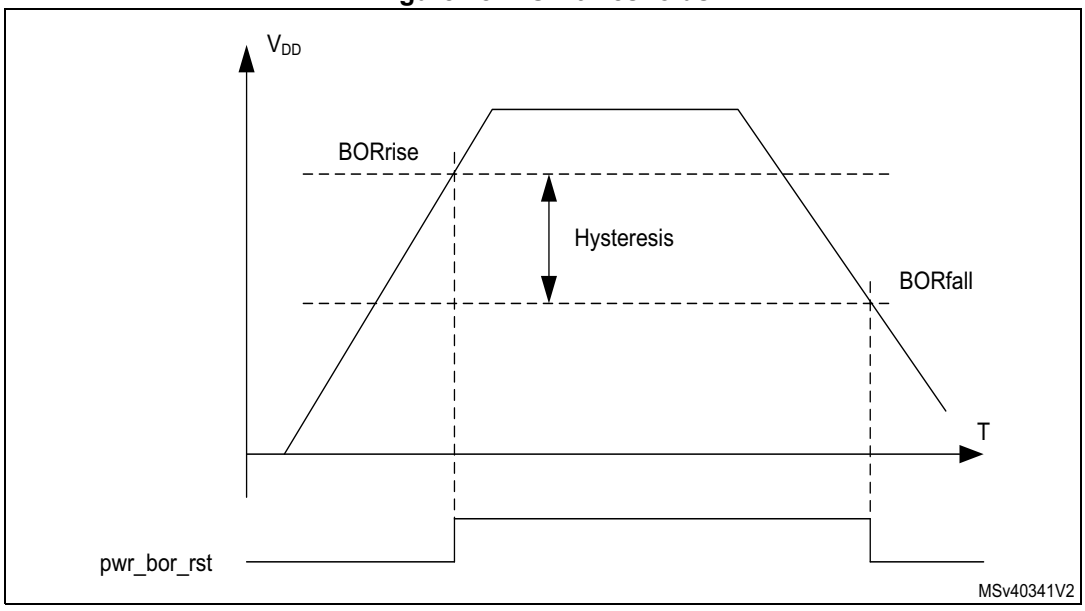
Figure 27. Power-on reset/power-down reset waveform

1. For thresholds and hysteresis values, refer to the datasheets.

6.5.2 Brownout reset (BOR)

During power-on, the brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through system option bytes. By default, BOR is OFF. The following programmable V_{BOR} thresholds can be selected:



- BOR off
- BOR level 1 (V_{BOR1})
- BOR level 2 (V_{BOR2})
- BOR level 3 (V_{BOR3})

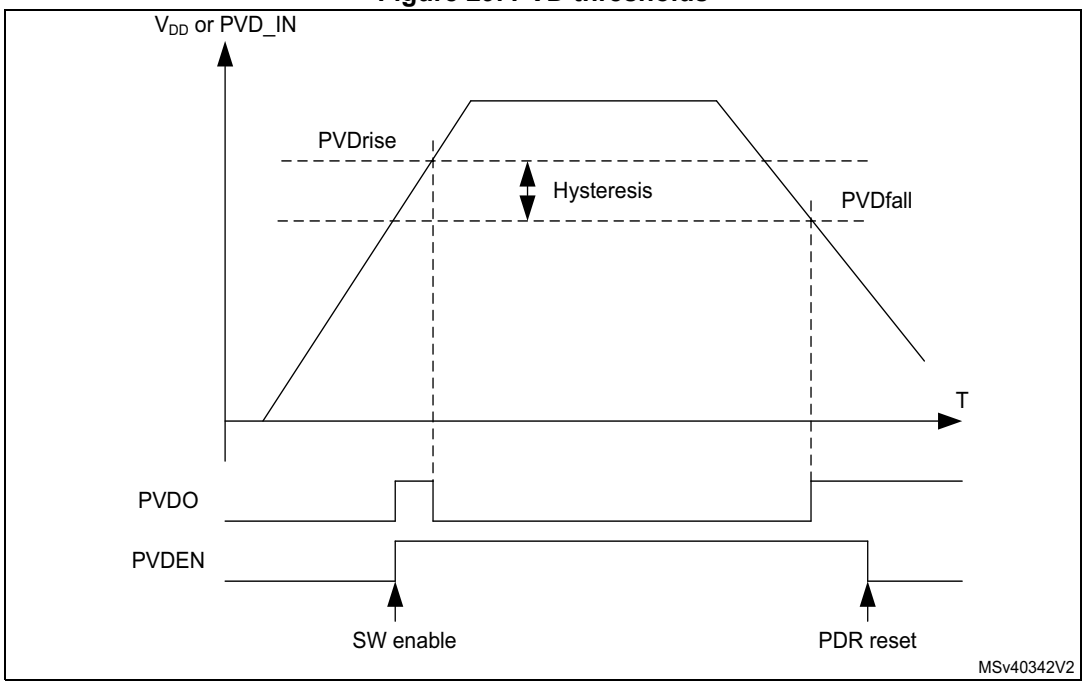
For more details on the brownout reset thresholds, refer to the section “Electrical characteristics” of the product datasheets.

A system reset is generated when the BOR is enabled and V_{DD} supply voltage drops below the selected V_{BOR} threshold.

BOR can be disabled by programming the system option bytes. To disable the BOR function, V_{DD} must have been higher than the POR threshold to start the system option byte programming sequence. The power-down is then monitored by the PDR (see *Section 6.5.1*).

Figure 28. BOR thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.3 Programmable voltage detector (PVD)

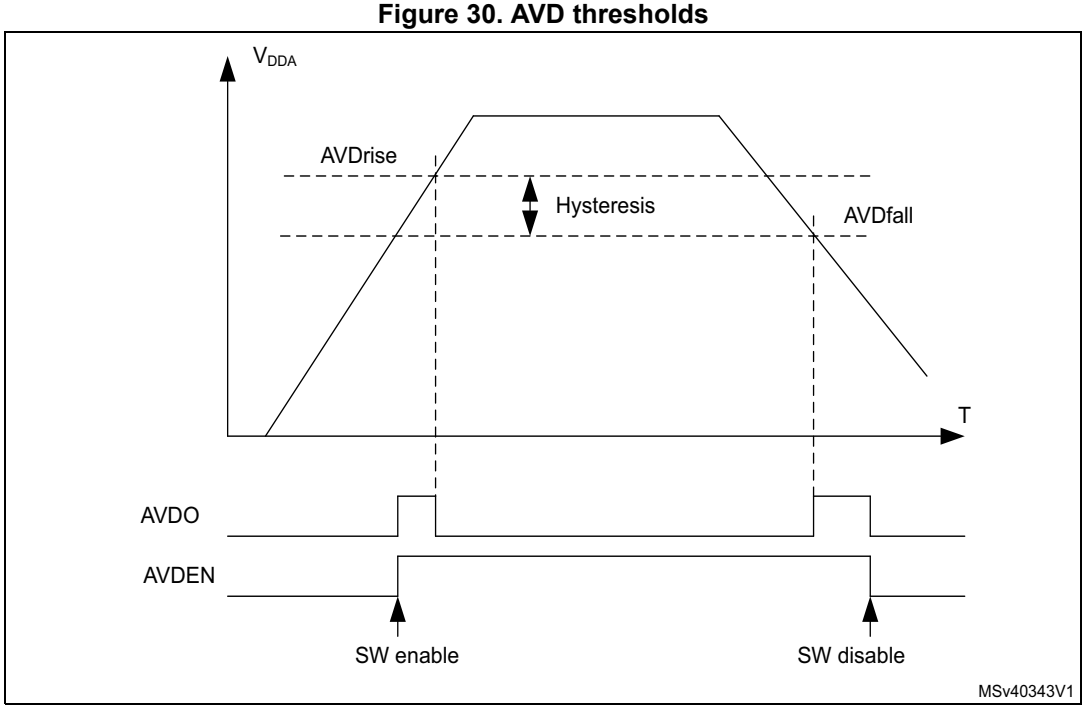
The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[2:0] bits in the *PWR control register 1 (PWR_CR1)*. The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case PVD_IN voltage is compared to the internal VREFINT level.

The PVD is enabled by setting the PVDE bit in *PWR control register 1 (PWR_CR1)*.

A PVDO flag is available in the *PWR control status register 1 (PWR_CSR1)* to indicate if V_{DD} or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, provided it has been enabled through the EXTI registers. The rising/falling edge sensitivity of the EXTI line must be configured according to PVD output behavior, i.e. if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when V_{DD} or PVD_IN voltage drops below the PVD threshold. As an example, the service routine could perform emergency shutdown.

Figure 29. PVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



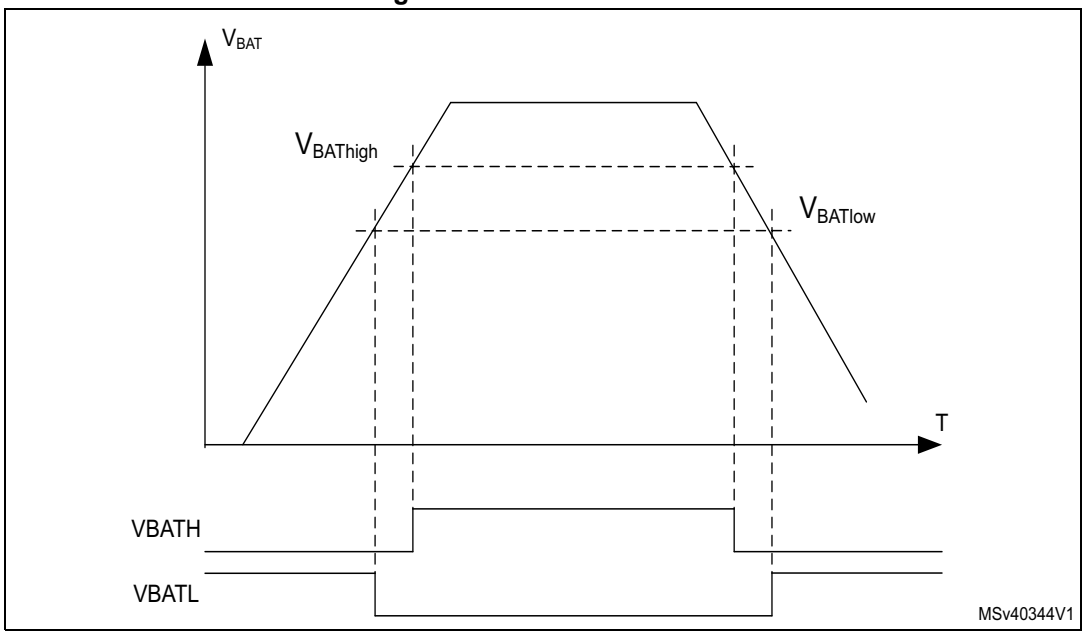
6.5.4 Analog voltage detector (AVD)

The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in *PWR control register 1 (PWR_CR1)*.

An AVDO flag is available in the *PWR control status register 1 (PWR_CSR1)* to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could indicate when the V_{DDA} supply drops below a minimum level.

Figure 30. AVD thresholds



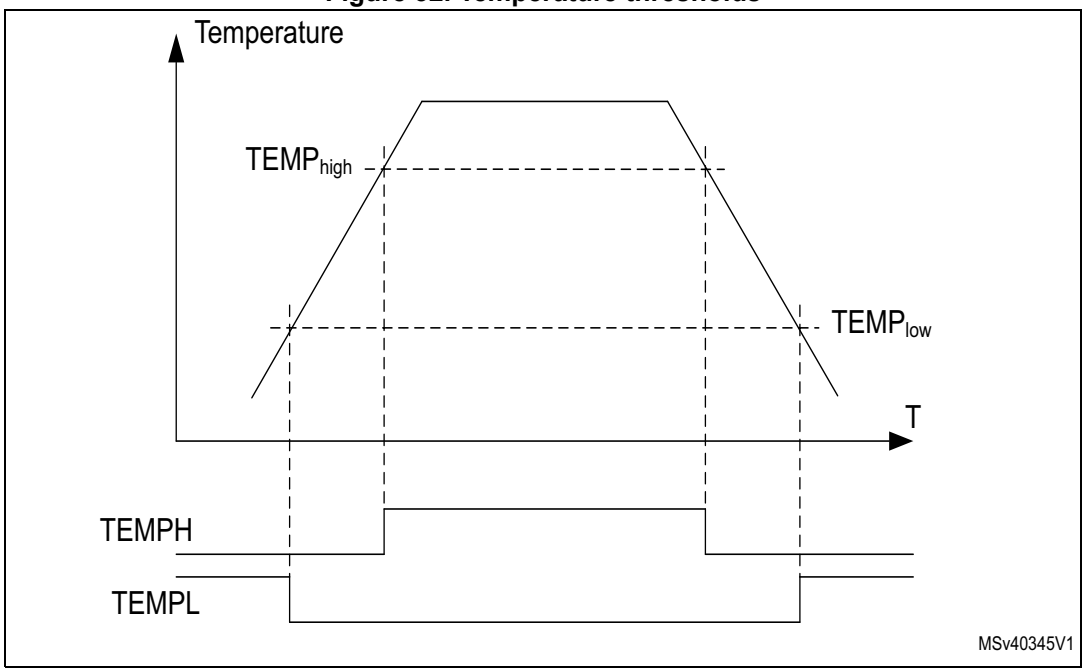
1. For thresholds and hysteresis values, refer to the datasheets.

6.5.5 Battery voltage thresholds

In V_{BAT} mode, the battery voltage supply (RTC domain) can be monitored by comparing it with two threshold levels: $V_{BAThigh}$ and V_{BATlow}. The V_{BAT} supply monitoring can be enabled/disabled via MONEN bit in *PWR control register 2 (PWR_CR2)*. When it is enabled, the battery voltage thresholds increase power consumption.

VBATH and VBATL can trigger an internal tamper event (see *Section 51: Tamper and backup registers (TAMP)*).

Figure 31. VBAT thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

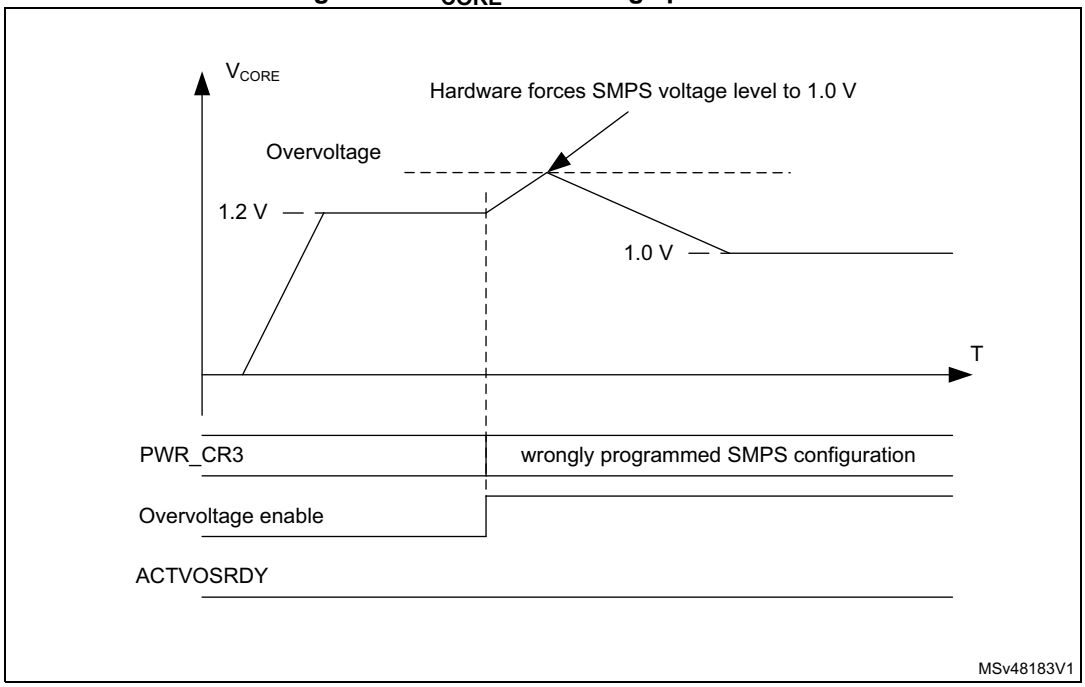
6.5.6 Temperature thresholds

A dedicated temperature sensor cell is embedded in the power control. The junction temperature can be monitored by comparing it with two threshold levels, $TEMP_{high}$ and $TEMP_{low}$.TEMPH and TEMPL flags in the *PWR control register 2 (PWR_CR2)*, indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in *PWR control register 2 (PWR_CR2)*. When enabled, the temperature thresholds increase power consumption. As an example the levels may be used to trigger a routine to perform temperature control tasks.

TEMPH and TEMPL wake-up interrupts are available on the RTC tamper signals (see *Section 51: Tamper and backup registers (TAMP)*).

Figure 32. Temperature thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.7 V_{CORE} maximum voltage level detector

V_{CORE} is protected against too high voltages in the direct SMPS step-down converter configuration. V_{CORE} overvoltage protection is enabled at startup by hardware once the SMPS step-down converter configuration has been programmed into *PWR control register 3 (PWR_CR3)*. The two following configurations exist:

- V_{CORE} voltage level stays within range:
  - The ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* indicates valid voltage levels.
  - The system operates normally and V_{CORE} overvoltage protection is disabled.
- V_{CORE} overvoltages (due to a wrongly programmed SMPS step-down converter):
  - The hardware forces the SMPS step-down converter voltage level to 1.0 V.
  - ACTVOSRDY indicates invalid voltage levels. In this case the software must be corrected and re-loaded to program a correct SMPS step-down converter

configuration that matches the application supply connections. The system must be power cycled.

Figure 33. V_{CORE} overvoltage protection

6.6 Power management

The power management block controls the V_{CORE} supply in accordance with the system operation modes (see *Section 6.6.1*).

The V_{CORE} domain is split into the following power domains.

- CPU domain (CD) containing most peripherals and the Cortex®-M7 Core (CPU)
- SmartRun domain (SRD) containing some peripherals and the system control

The CPU and SmartRun domains can operate in one of the following operating modes (see *Table 35: Operating mode summary*):

- Run (power ON, clock ON)
- Autonomous (power ON, SRD domain clock ON)
- Stop (power ON, clock OFF)
- Standby (power OFF, clock OFF).

The CPU domain is a power domain that is common to the CPU, DMAs and most of the AXI, AHB and APB peripherals.

The SRD domain includes one DMA, an AHB bus matrix and some APB peripherals. The SDR domain power modes can either follow CPU subsystem modes or remain in Run mode

regardless of CPU subsystem modes. This is done by setting the RUN_SRD bit in the PWR_CPUCR register.

- If RUN_SRD is set to 1, the SmartRun domain remains in DRun mode, independently from the CPU modes (see *Section 6.8.5: PWR CPU control register (PWR_CPUCR)*
- If RUN_SRD is set to 0, the SmartRun domain enters DStop mode when the CPU enters CStop mode (see *Table 35: Operating mode summary*).

The CPU and system SmartRun domains are supplied from a single regulator at a common V_{CORE} level. The V_{CORE} supply level follows the system operating mode (Run, Stop, Standby). The CPU domain can be set in a specific retention level, known as DStop2, whereby the logic is switched off and the register contents are retained. Selection between Dstop or DStop2 is made through the RETDS_CD bit of *PWR CPU control register (PWR_CPUCR)*.

The content of all memories is retained in DStop and DStop2. Further power saving can be made by selectively switching off individual memory blocks. This is done by means of bits xxxSO bits of *PWR control register 1 (PWR_CR1)*.

The following voltage scaling features allow controlling the power with respect to the required system performance (see *Section 6.6.2: Voltage scaling*):

- The corresponding voltage scaling must be set in accordance with the system clock frequency. To do this, configure the VOS bits to get the Run mode voltage scaling.
- In Stop mode, to obtain the best trade-off between static power consumption and exit-from-Stop mode latency, configure the SVOS bits to get Stop mode voltage scaling.

6.6.1 System operating modes

Several system operating modes are available to tune the system according to the performance required, means when the CPU does not need to execute code and is waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low-power consumption, short startup time and available wake-up sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them. The system operating mode is driven by the CPU subsystem and system SmartRun autonomous wake-up. The CPU subsystem can span different configurations depending on its peripheral allocation (see *Section 8.5.11: Peripheral clock gating control*).

The operating modes described below are available for the different system blocks (see *Table 35*).

Description of the operating mode

System Run modes

Any Run mode voltage scaling can be selected (VOS0, VOS1, VOS2 or VOS3).

- **SRD domain**

  The system clock and the SmartRun domain bus matrix clock are running.

- **CPU domain**

  The domain bus matrix is clocked. The CPU subsystem operates in CRun or CSleep mode:

  – CRun

    The CPU and CPU subsystem peripheral allocated via PERxEN bits in the RCC registers are clocked.

  – CSleep

    The CPU clock is stalled and the CPU subsystem allocated peripheral clock operates according to PERxLPEN bit setting in the RCC registers.

System Autonomous modes

Any Run mode voltage scaling can be selected (VOS0/1/2/3).

- **SRD domain**

  The system clock and the SmartRun domain bus matrix clocks are running.

- **CPU domain**

  The CPU and CPU subsystem peripheral clocks are stalled.

  The domain bus matrix clock is stalled.

  When the CPU subsystem is in CStop mode, the CPU domain is either in DStop or Dstop2.

  The CPU domain mode selection between DStop and DStop2 is configured via RETDS_CD bit in PWR CPU control register (PWR_CPUCR).

  The CPU domain Autonomous modes are the following:

  – Dstop

    The CPU domain peripherals able to operate in Stop mode are still operational.

  – Dstop2

    The CPU domain peripherals able to operate in Stop mode are no longer operational.

System Stop

Any Stop mode voltage scaling can be selected (SVOS3/4/5).

- **SRD domain**

  The system clock and the SmartRun domain bus matrix clock are stalled.

- **CPU domain**

  The CPU and CPU subsystem peripheral clocks are stalled.

  The domain bus matrix clock is stalled.

  When the CPU subsystem is in CStop mode, the CPU domain is either in DStop or Dstop2.

  The CPU domain mode selection between DStop and DStop2 is configured via RETDS_CD bit in PWR CPU control register (PWR_CPUCR).

  The CPU domain peripherals able to operate in Stop mode are no longer operational. This means that no peripherals in CPU domain are operational.

System Standby

Both SRD and CPU domain supplies are powered down.All internal wake-up signals are inactive.

The Standby mode is selected through the PDDS_SRD bit in PWR CPU control register (PWR_CPUCR).

DStop vs DStop2 mode

DStop2 and DStop modes are very similar from user point of view. In DStop2 mode the asynchronous logic is switched off while RAM and register contents are maintained. This allows further leakage current consumption reduction compared to DStop mode. When exiting DStop2, the CPU domain resumes normal execution at the cost of a slightly higher startup time.

The main differences between DStop and DStop2 are given below:

- In DStop mode, the entire logic is still supplied.
- In DStop2 mode, memories and registers are maintained, while asynchronous logic is switched off. This allows further leakage current reduction. Upon exiting DStop2, the CPU domain can resume normal execution.

The system state is retained in DStop and DStop2.

Table 35. Operating mode summary

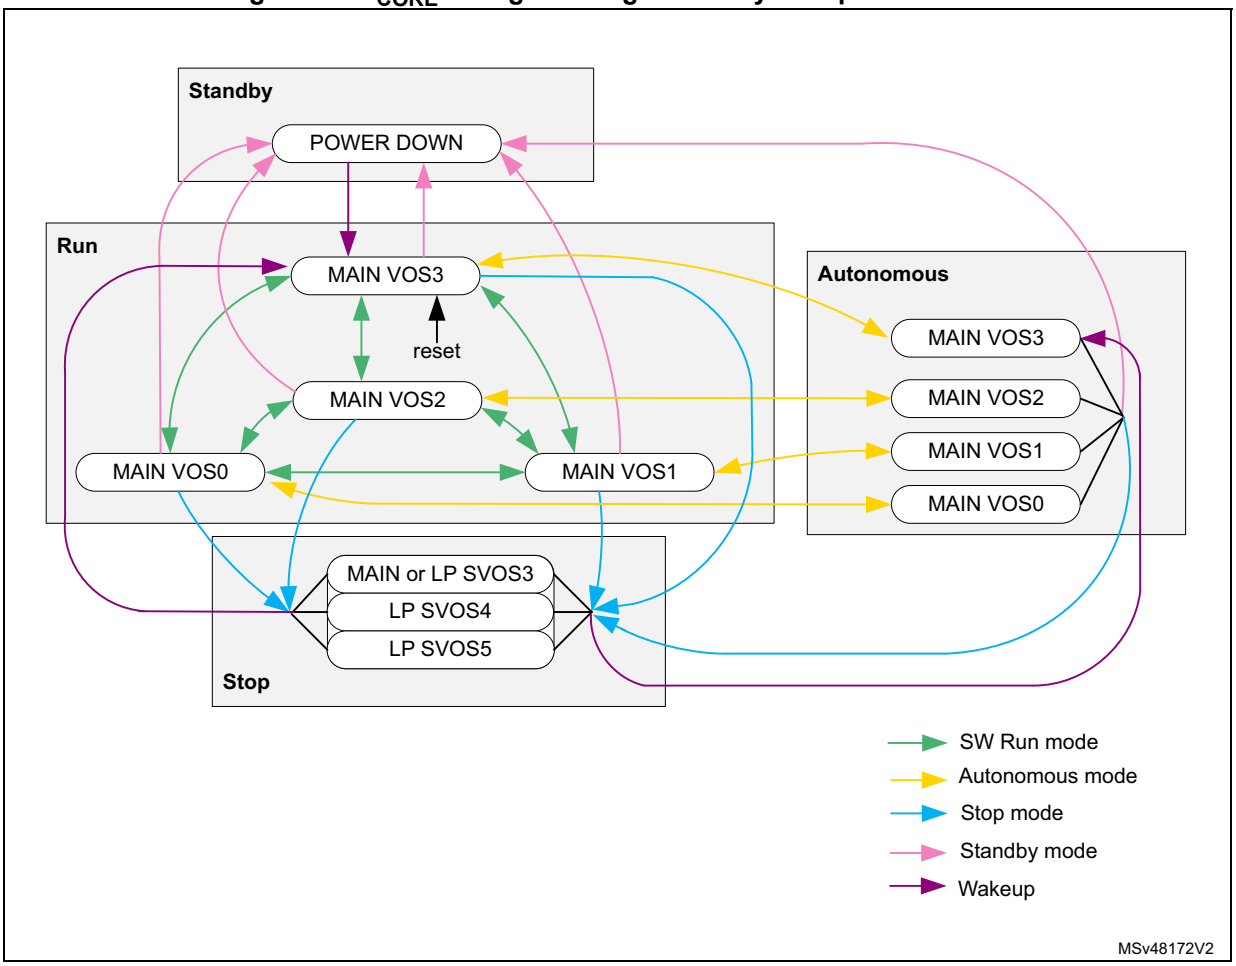
System	SRD domain	CPU domain	CPU	Entry	wake-up	System oscillator	System clock	Domain bus matrix clock	Peripheral clock	CPU clock	Voltage regulator	Domain supply	Voltage scaling
Run	SRDRun	DRun	CRun	-	-	ON	ON	ON	ON	ON	ON	ON	VOS0/1/2/3
			CSleep	WFI or return from ISR or WFE	Any interrupt or event				ON/OFF[1]	OFF			
Autono-mous		DStop[2]	CStop	SLEEPDEEP bit + WFI or return from ISR or WFE	Any EXTI interrupt or event			OFF	ON/OFF[3]			RET[9]	
		DStop2[4]											
Stop[5]	SRDStop	DStop[2]		SLEEPDEEP bit + WFI or return from ISR or WFE or wake-up source cleared[6]		ON/OFF[7]	OFF		OFF[8]			ON	SVOS3/4/5
		DStop2[4]										RET[9]	
Standby[10]				PDDS_SRD bit + SLEEPDEEP bit + WFI or return from ISR or WFE or wake-up source cleared[6]	WKUP pins rising or falling edge, RTC alarm (Alarm A or Alarm B), RTC wake-up event, RTC tamper events, RTC timestamp event, external reset in NRST pin, IWDG reset	OFF			OFF		OFF	OFF	OFF

1. The peripherals that have a PERxLPEN bit, operate accordingly.
2. The CPU subsystem is in CStop and RETDS_CD selects DStop.
3. SmartRun domain peripherals having a PERxAMEN bit, operate accordingly.
4. The CPU subsystem is in CStop and RETDS_CD selects DStop2.
5. The CPU domain needs to be in DStop or DStop2 mode, no wake-up signal is active in SmartRun domain and PDDS_SRD bit selects the Stop mode.
6. When the CPU is in CStop and SmartRun domain in Autonomous mode, the last EXTI wake-up source must be cleared to enter System Stop or Standby mode.

7. When the system oscillator HSI or CSI is used, the state is controlled by HSIKERON and CSIKERON, otherwise the system oscillator is OFF.
8. When the system is in Stop mode, all the peripheral bus interface clocks are OFF. But peripherals in the SmartRun domain having a kernel clock request can stay active by programming their PERxAMEN bit (RCC_SRDAMEN).
9. Supply level is in retention: content is kept (memories, registers) but domain is not operational.
10. PDDS_SRD selects the Standby mode. The whole core domain is switched off.

6.6.2 Voltage scaling

The CPU and SmartRun domains are supplied from a single voltage regulator supporting voltage scaling with the following features:



- Run mode voltage scaling
  - VOS0: scale 0
  - VOS1: scale 1
  - VOS2: scale 2
  - VOS3: scale 3
- Stop mode voltage scaling
  - SVOS3: scale 3
  - LP-SVOS4: scale 4
  - LP-SVOS5: scale 5

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS3). The voltage scaling can then be changed on-the-fly by software by programming VOS bits in *PWR SmartRun domain control register (PWR_SRDCR)* according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS3 value.

Before entering Stop mode, the software can preselect the SVOS level in *PWR control register 1 (PWR_CR1)*. The Stop mode voltage scaling for SVOS4 and SVOS5 also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption. When preselecting SVOS3, the use of the voltage regulator low-power mode (LP) can be selected by LPDS bit in *PWR control register 1 (PWR_CR1)*.

Figure 34. V_{CORE} voltage scaling versus system power modes

6.6.3 Power control modes

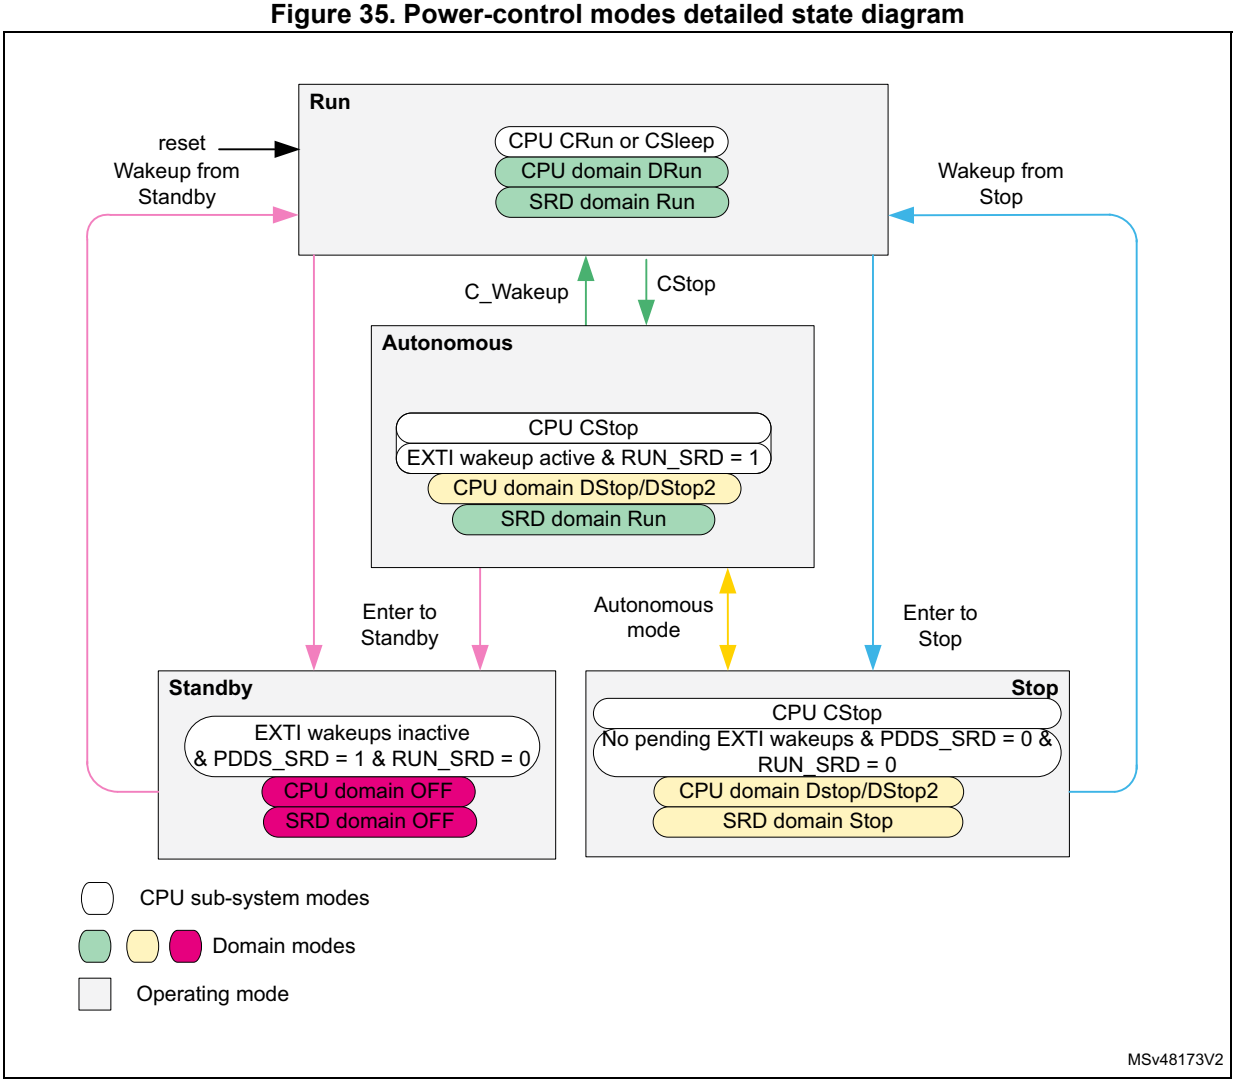
The power control block handles the V_{CORE} supply for system Run, Stop and Standby modes.

The system operating mode depends on the CPU subsystem modes (CRun, CSleep, CStop), on the domain modes (DRun, DStop, DStop2) and on the system SmartRun autonomous wake-up:

- In Run and Autonomous modes, V_{CORE} is defined by the VOS voltage scaling.
  The CPU subsystem is either in CRun or CSleep, or an EXTI wake-up is active.
- In Stop mode, V_{CORE} is defined by the SVOS voltage scaling.
  The CPU subsystem is in CStop mode and no EXTI wake-ups are pending. The CPU domain is either in DStop or DStop2 mode.
- In Standby mode, V_{CORE} supply is switched off.
  The CPU domain and CPU subsystem are powered off and all EXTI wake-ups are inactive, except wake-up pins, Tamper and RTC.

The CPU domain mode selection between DStop and DStop2 is configured via RETDS_CD bit in *PWR CPU control register (PWR_CPUCR)*. The system/SmartRun mode selection

between Stop and Standby is configured via PDDS_SRD bit in *PWR CPU control register (PWR_CPUCR)*.



The system enters Standby when PDDS_SRD bit allows it and stays otherwise in Stop mode (CPU domain in DStop or Dstop2).

Table 36 describes all possible low-power mode states.

Table 36. PDDS_SRD and RETDS_CD low-power mode control

PWR_CPUCR		CPU domain mode	SmartRun domain mode
RETDS_CD	PDDS_SRD		
0	0	DStop	SDRun or SDStop
1		DStop2	
0	1	Standby	Standby
1			

Figure 35. Power-control modes detailed state diagram

After a system reset, the CPU is in CRun mode.

Power control state transitions are initiated by the following events:

- The CPU goes to CStop mode or wakes up from CStop mode (state transitions in Run mode are marked in green).
- The system enters or exits Stop mode (state transitions marked in blue)
  - blue transitions: the system enters Stop mode with the CPU domain in DStop or Dstop2 and the CPU in CStop. The system wakes up from Stop. The CPU and CPU domain are restarted. When exiting system Stop mode, the STOPF bit is set.
  - yellow transitions: the system toggles between SRDRun and SRDStop, while the CPU domain remains in DStop or DStop2 without waking up (Autonomous mode).
- The system enters or exits from Standby mode (state transitions are marked in pink).
  - When exiting from Standby mode, the SBF bit is set.

Table 37 shows the flags indicating from which mode the domain/system exits. The CPU features a set of flags that can be read from *PWR CPU control register (PWR_CPUCR)*.

Table 37. Low-power exit mode flags

System mode	CPU domain mode	SBF	STOPF	Comment
Run	DRun	0	0	-
Autonomous	DStop or DStop2	0	0	CPU domain and system contents retained
Stop	DStop or DStop2	0	1	CPU domain and system contents retained, clock system reset.
Standby	OFF	1	0	CPU domain and system contents lost

6.6.4 Power management examples

Figure 36 shows V_{CORE} voltage scaling behavior in Run mode.

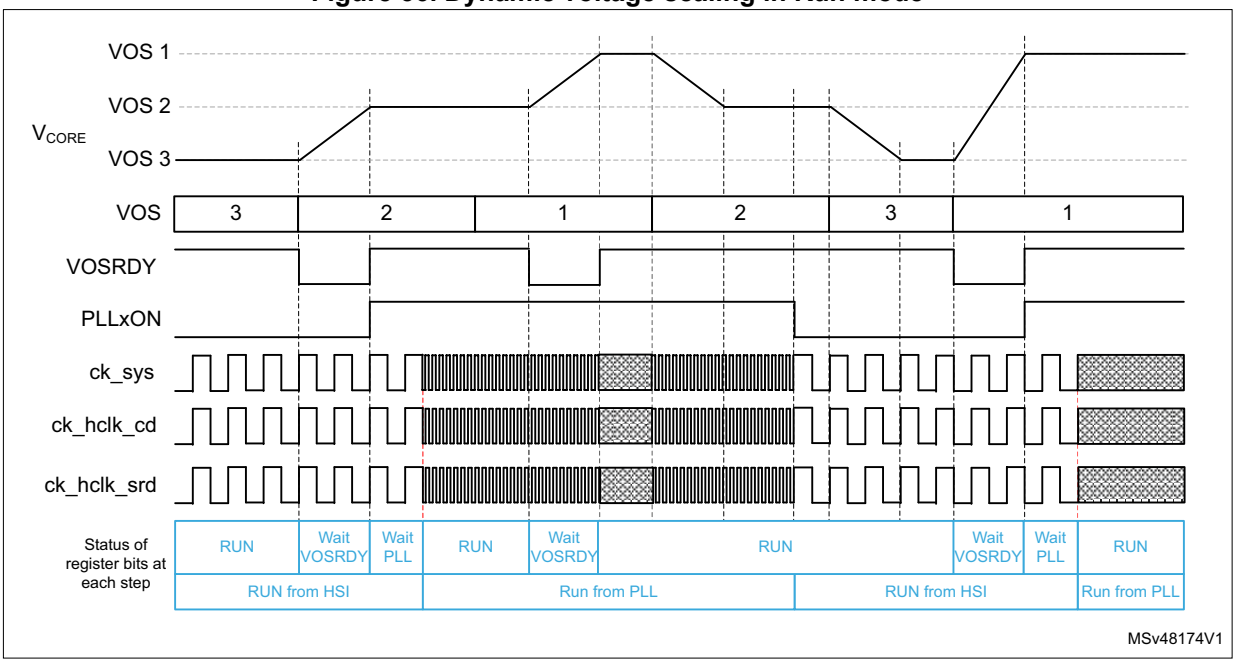
Figure 37 shows V_{CORE} voltage scaling behavior in Stop mode.

Figure 38 shows V_{CORE} voltage regulator and voltage scaling behavior in Standby mode.

Figure 39 shows V_{CORE} voltage scaling behavior in Run mode with CPU domain in DStop or DStop2 mode.

Example of V_{CORE} voltage scaling behavior in Run mode

Figure 36 illustrates the following system operation sequence example:



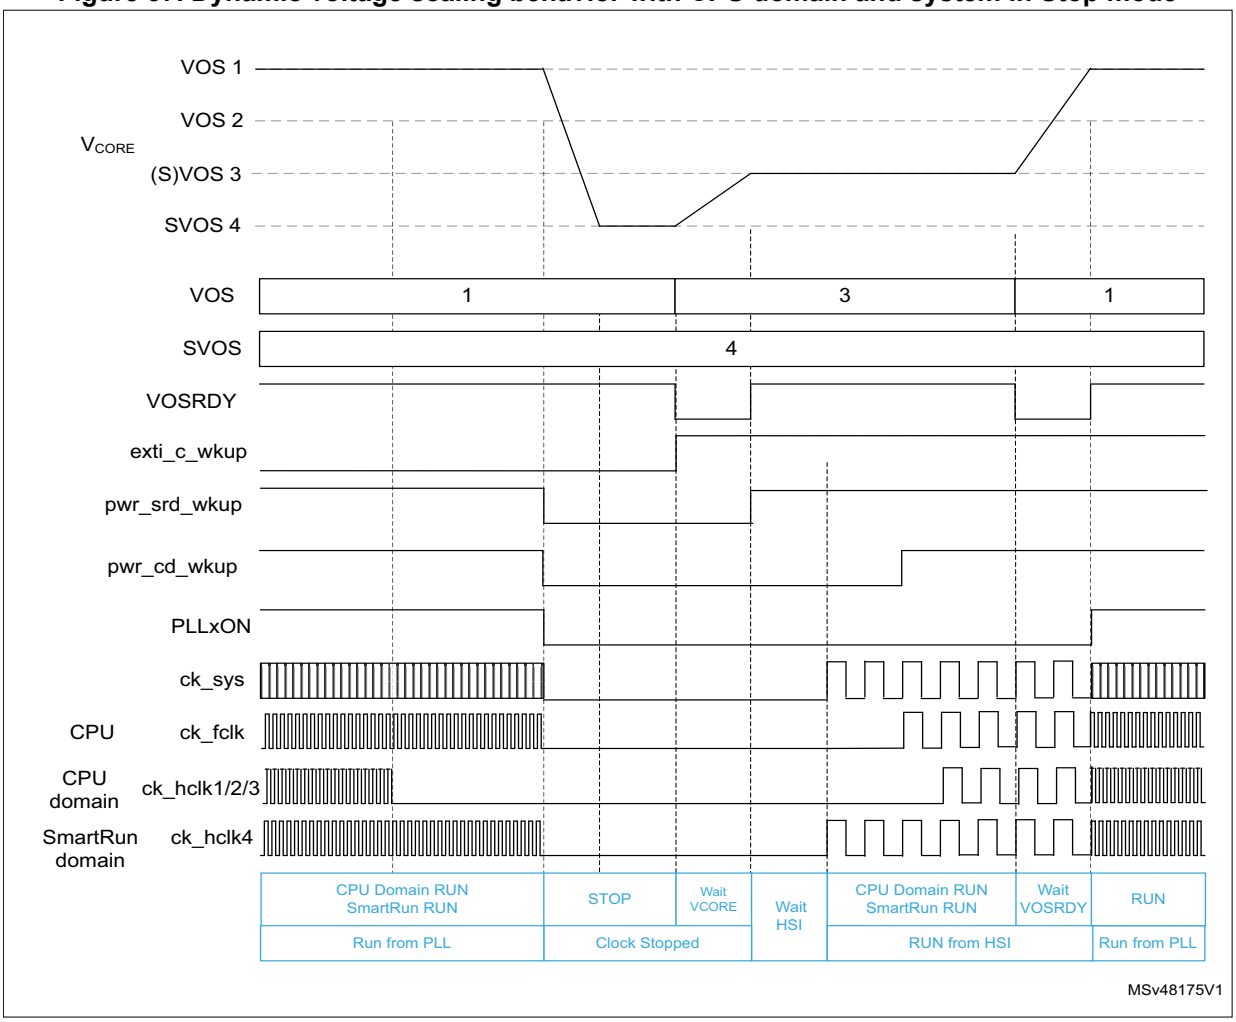
1. After reset, the system starts from HSI with VOS3.
2. The system performance is first increased to a medium-speed clock from the PLL with voltage scaling VOS2. To do this:
   a) Program the voltage scaling to VOS2.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The system performance is then increased to high-speed clock from the PLL with voltage scaling VOS1. To do this:
   a) Program the voltage scaling to VOS1.

b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency.

4. The system performance is then reduced to a medium-speed clock with voltage scaling VOS2. To do this:
   a) First decrease the system frequency.
   b) Then decrease the voltage scaling to VOS2.
5. The next step is to reduce the system performance to HSI clock with voltage scaling VOS3. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS3.
6. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly. otherwise the system might be unreliable.

Figure 36. Dynamic voltage scaling in Run mode

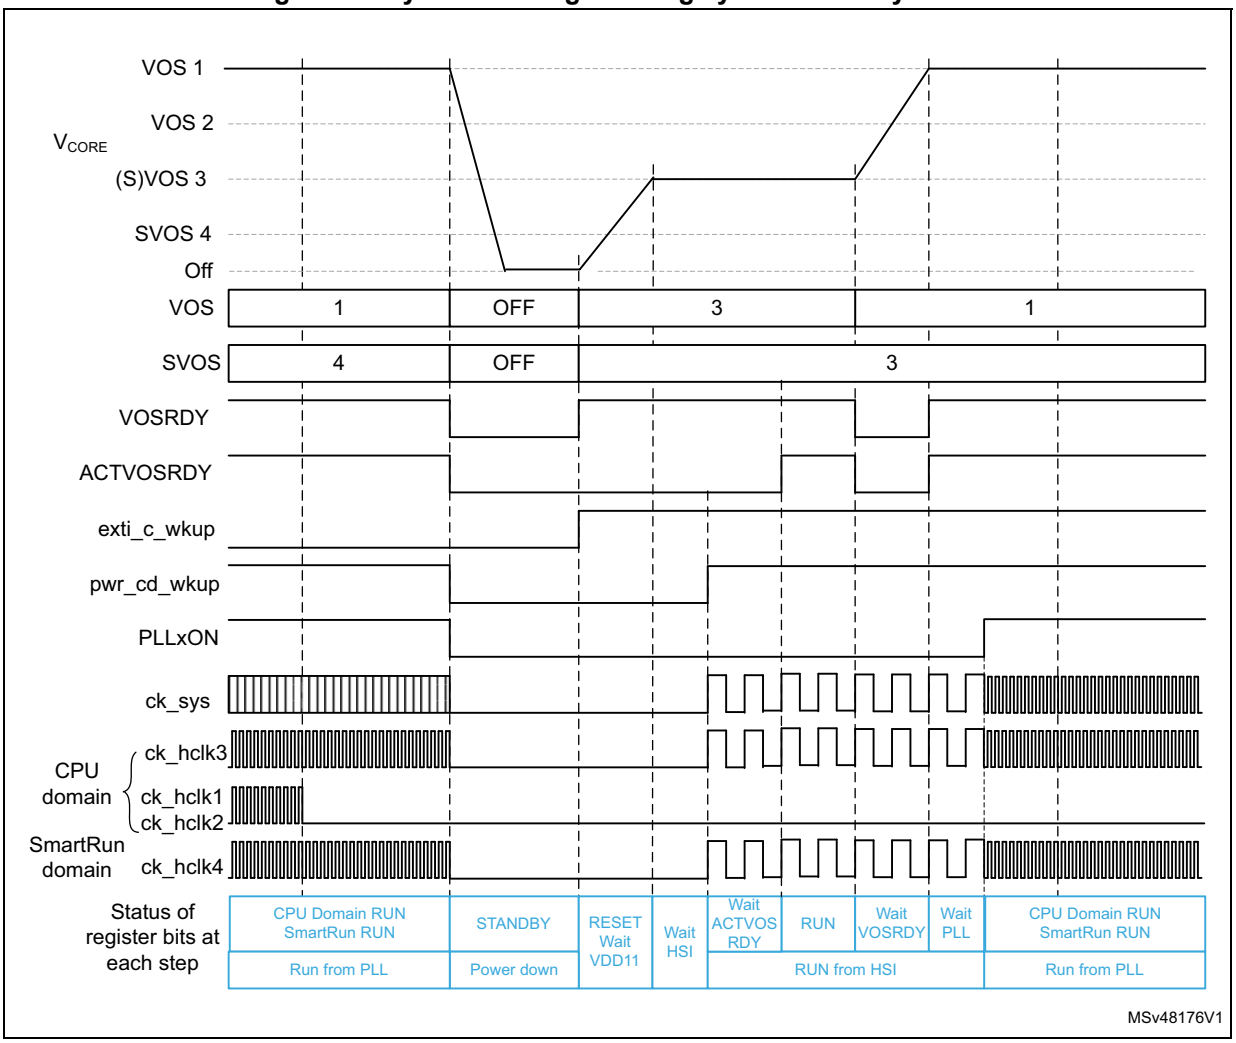


Example of V_{CORE} voltage scaling behavior in Stop mode

Figure 37 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all peripherals related to AHB1 and AHB2. As a consequence, the clocks hclk[2:1] and the related APB1 and APB2 peripherals clocks (pclk1 and pclk2) are stopped. The system still provides the high-performance system clock, hence the voltage scaling must stay at VOS1 level.
3. In a second step, the CPU subsystem enters CStop mode, the CPU domain enters DStop or DStop2 mode (Dstop or Dstop2 is selected by RETDS_CD bit in *PWR CPU control register (PWR_CPUCR)*) and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.
4. The CPU subsystem is then woken up. The system exits Stop mode, the CPU domain exits DStop or DStop2 mode and the CPU subsystem exits CStop mode. The hardware then sets the voltage scaling to VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock, the CPU domain clock and the CPU subsystem clock are enabled. Several system clock cycles are needed before the bus clocks are activated according to the xxxEN bits in the RCC.
5. The CPU subsystem allocates a peripheral in the APB1/APB2 domain. The related hclk and pclk peripheral clocks are enabled.
6. The system performance is then increased. To do this:
   a) The software first sets the voltage scaling to VOS1.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
   c) Once the PLL is locked, the system clock can be switched.

Figure 37. Dynamic voltage scaling behavior with CPU domain and system in Stop mode

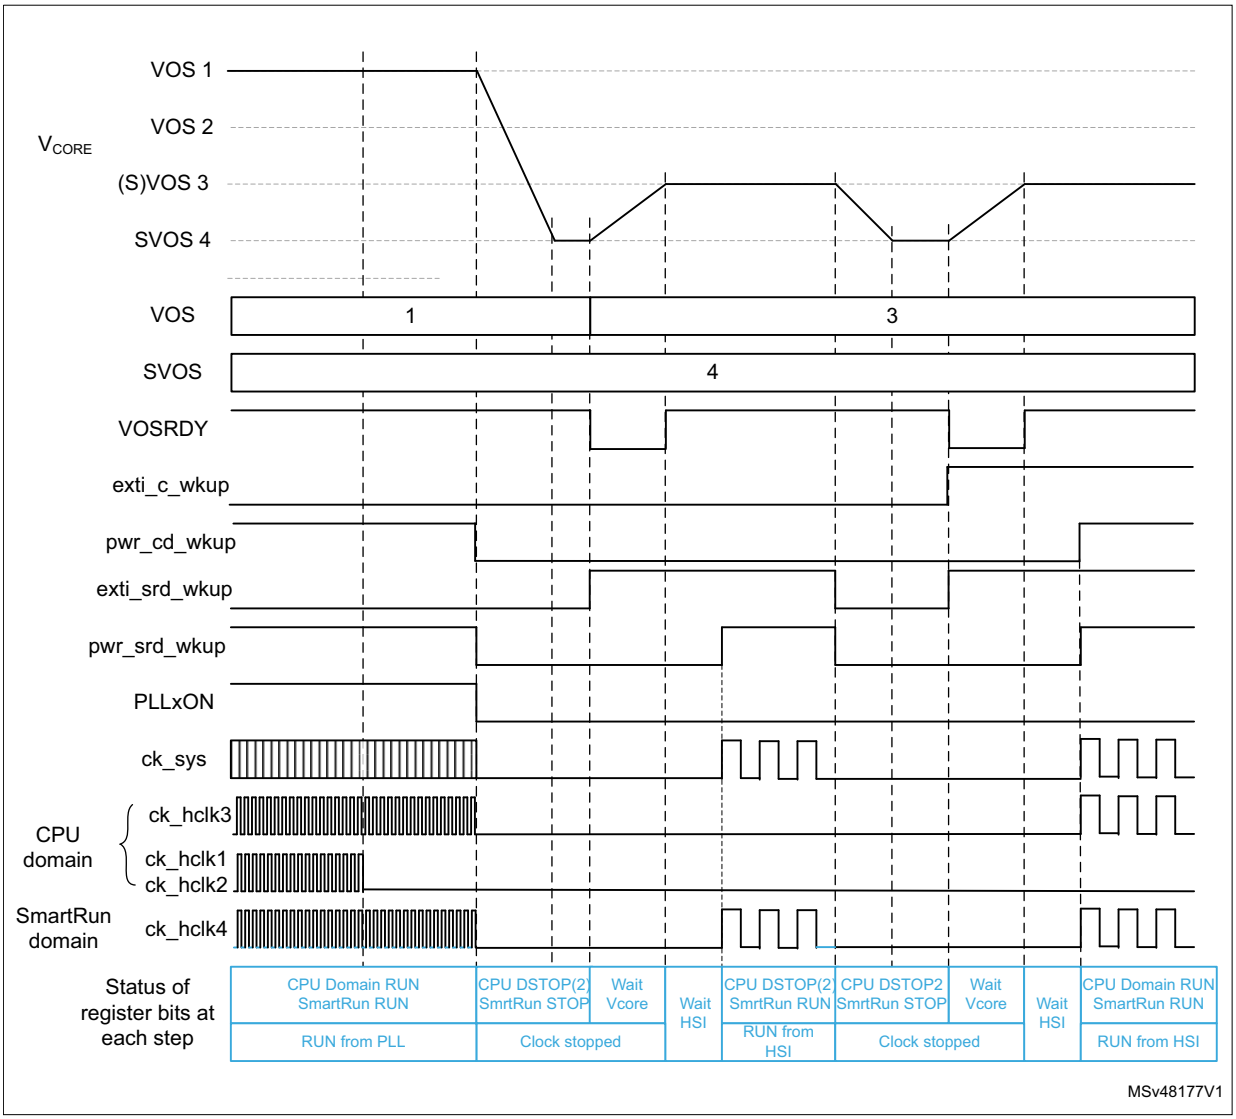


Example of V_{CORE} voltage regulator/voltage scaling behavior in Standby mode

Figure 38 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all peripherals related to AHB1 and AHB2. As a consequence the clocks hclk[2:1] and the related APB1 and APB2 peripherals clocks (pclk1 and pclk2) are stopped. The system performance is unchanged hence the voltage scaling does not change.
3. The CPU subsystem and the system enters Standby mode (selection through PDDS_SRD bit). The system clock is stopped and the voltage regulator is switched off.
4. The system is then woken up by a wake-up source. The system exits Standby mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and the CPU subsystem clock are enabled. The software must then check the ACTVOSRDY is valid before changing the system performance.
5. The CPU subsystem allocates a peripheral in the APB1/APB2 domain. The related hclk and pclk peripheral clocks are enabled.
6. In a next step, increase the system performance. To do this:
   a) The software first increases the voltage scaling to VOS1 level.
   b) Before enabling the PLL, the software waits for the requested supply level to be reached by monitoring VOSRDY bit.
   c) Once the PLL is locked, the system clock can be switched.

Figure 38. Dynamic voltage scaling system Standby mode



Example of V_{CORE} voltage scaling behavior in Run mode with CPU domain in DStop or DStop2 mode

Figure 39 illustrates the following system operation sequence example:

1. The system is running from the PLL with system in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all peripherals related to AHB1 and AHB2. As a consequence the clocks hclk[2:1] and the related APB1 and APB2 peripherals clocks (pclk1 and pclk2) are stopped. The system performance is unchanged hence the voltage scaling does not change.
3. The CPU subsystem then enters CStop mode and the CPU domain enters DStop or DStop2 mode (selected by RETDS_CD bit in *PWR CPU control register (PWR_CPUCR)*. The CPU AXI bus matrix clock is stopped. At the same time the system/SmartRun domain enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.
4. The system is then woken up by a SmartRun Autonomous mode wake-up event. The system exits Stop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled. The system is running in SmartRun Autonomous mode.
5. The SmartRun Autonomous mode wake-up source is then cleared, causing the system to enter Stop mode. The system clock is stopped and the voltage scaling is lowered to the software preselected SVOS4 level.
6. The CPU subsystem is then woken up. The system exits Stop mode, the CPU domain exits DStop/DStop2 mode and the CPU subsystem exits CStop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and the CPU subsystem clock are enabled.

Figure 39. Dynamic voltage scaling behavior with CPU domain in DStop or DStop2 mode and SmartRun domain in Autonomous mode

6.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to execute code (when waiting for an external event). It is up to the user application to select the mode that gives the best compromise between low-power consumption, short startup time and available wake-up sources:

- Slowdown of system clocks: see *Section 8.5.6: System clock (sys_ck)*
- Control of individual peripheral clocks, see *Section 8.5.11: Peripheral clock gating control*
- Available low-power modes (see *Table 35: Operating mode summary* and *Figure 35: Power-control modes detailed state diagram*):
  - System Run, SRDRun, DRun and CSleep modes
    Only the Arm® Cortex®-M7 (CPU subsystem) clock is stopped (CSleep).
  - System Autonomous, SRDRun, DStop/DStop2 and CStop modes
    The SRD domain is running (SRDRun).
    All the clocks in the CPU domain are stopped (CStop).
    The CPU domain is in DStop or Retention mode (DStop2).
  - System Stop, SRDStop, DStop /DStop2 and CStop modes
    All clocks stopped for all domains
    Some clocks can remain active on demand (see *Section 6.7.7: Stop mode*).
    The CPU domain is in DStop or DStop2 (Retention mode).
  - System Standby
    The system is powered down.

6.7.1 Slowing down system clocks

In Run mode the speed of the system clock ck_sys can be reduced. For more details refer to *Section 8.5.6: System clock (sys_ck)*.

6.7.2 Controlling peripheral clocks

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bits in RCC_C1_xxxxENR or RCC_DnxxxxENR to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bits in RCC_C1_xxxxLPENR or RCC_DnxxxxLPENR. For the peripherals still receiving a clock in CSleep mode, their clock can be slowed down before entering CSleep mode and clock gating can be enabled (RCC_CKGAENR register).

In Autonomous mode, the individual peripheral clocks can remain active by setting the corresponding PERxAMEN bit of RCC_SRDAMR register.

6.7.3 Entering low-power modes

The MCU enters one of the power mode listed in *Section 6.7: Low-power modes* when executing the WFI (wait for interrupt) or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M system control register is set on Return from ISR.

The system can enter Stop or Standby low-power mode when all EXTI wake-up sources are cleared (see *Figure 35*).

6.7.4 Exiting from low-power modes

The CPU subsystem exits CSleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits low-power mode as soon as an event occurs. The wake-up event can be generated by one of the followings:
  - an NVIC IRQ interrupt

    When SEVONPEND = 0 in the Cortex®-M7 system control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

    When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared. Only NVIC interrupts with sufficient priority wake up and interrupt the MCU.

    When SEVONPEND = 1 in the Cortex®-M7 system control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

    All NVIC interrupts wake up the MCU, even the disabled ones.

    Only enabled NVIC interrupts with sufficient priority wake up and interrupt the MCU.
  - an event

    An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit, as the pending bits corresponding to the event line are not set. It might be necessary to clear the interrupt flag in the peripheral.

The MCU exits the Autonomous mode (SRDRun, DStop/DStop2, CStop) or Stop mode (SRDStop, DStop/DStop2, CStop) by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

In Autonomous mode the system can wake up from Stop mode by enabling an EXTI wake-up, without waking up the CPU subsystem.

The MCU exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).

6.7.5 System Run and CSleep modes

The system remains in Run mode with both the SRD and CPU domains are in Run mode (see *Table 35: Operating mode summary*).

The CSleep mode applies only to the CPU subsystem. In this mode, the CPU clock is stopped and the CPU subsystem peripheral clocks operate according to the configuration defined in PERxLPEN bits of RCC_xxxxLPENR registers.

Entering CSleep mode

The CSleep mode is entered according to *Section 6.7.3: Entering low-power modes* when the SLEEPDEEP bit in the Cortex®-M System Control register is cleared.

Refer to *Table 38* for details on how to enter CSleep mode.

Exiting from CSleep mode

The CSleep mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 38* for more details on how to exit from CSleep mode.

Table 38. CSleep mode

CSleep mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 0 (Refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
Mode exit	If WFI or return from ISR was used for entry: – Any Interrupt enabled in NVIC: Refer to *Table 125: NVIC* If WFE was used for entry and SEVONPEND = 0: – Any event: Refer to *Section 20.5.3: EXTI CPU wakeup procedure* If WFE was used for entry and SEVONPEND = 1: – Any Interrupt even when disabled in NVIC: refer to *Table 125: NVIC* or any event: refer to *Section 20.5.3: EXTI CPU wakeup procedure*
wake-up latency	None

6.7.6 System Autonomous mode

In Autonomous mode the SRD domain remains in Run mode while the CPU domain is in DStop or DStop2.

The whole CPU domain is in low-power mode and all the clocks of this domain are stopped. The CPU subsystem included in the CPU domain is in the same mode.

The CPU clock is stopped as well as the peripheral clocks of the CPU domain.

Only the SmartRun domain peripherals associated to a PERxAMEN bit operate according to this bit configuration and can request a kernel clock, if relevant.

The flash memory can be in low-power mode when it is enabled through the FLPS bit of the PWR_CR1 register. This allows a trade-off between CPU domain DStop/DStop2 restart time and low-power consumption.

Entering Autonomous mode

The Autonomous mode is entered according to *Section 6.7.3: Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M System Control register is set.

The CPU domain enters DStop or DStop2 depending on the configuration of RETDS_CD bit of PWR_CPUCR register.

Before entering DStop2 mode, it is mandatory to configure the flash memory in low-power mode by setting the FLPS bit of PWR_CR1.

Before entering DStop2, all the peripherals belonging to the CPU domain and having a kernel clock must be either disabled by clearing the enable bit in the peripheral itself, or reset by setting the corresponding bit in the associated AHB peripheral reset register (RCC_AHBxRSTR) or APB peripheral reset register (RCC_APBxRSTR).

Warning: The user must ensure that no allocated peripheral in the CPU domain has an active kernel clock, or are still clocked by LSI LSE, HSI or CSI. The flash memory must be configured in low-power mode (FLPS bit set in PWR_CR1 register) before entering DStop2.

Refer to *Table 39* for details on how to enter Automous mode.

Exiting Autonomous mode

The Autonomous mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 39* for more details on how to exit from Autonomous mode.

Table 39. Autonomous mode

Autonomous mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 1 (Refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wake-up sources are cleared.
	On return from ISR while: – SLEEPDEEP = 1 and – SLEEPONEXIT = 1 (Refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wake-up sources are cleared. – The RETDS_CD bit selects DStop or DStop2 – No CPU domain peripherals with kernel clocks or cadenced by LSI, LSE, HSI or CSI

Table 39. Autonomous mode

Autonomous mode	Description
Mode exit	If WFI or return from ISR was used for entry: – EXTI Interrupt enabled in NVIC: Refer to *Table 125: NVIC*, for peripheral which are not stopped. If WFE was used for entry and SEVONPEND = 0: – EXTI event: Refer to *Section 20.5.3: EXTI CPU wakeup procedure*, for peripheral which are not stopped. If WFE was used for entry and SEVONPEND = 1: – EXTI Interrupt even when disabled in NVIC: refer to *Table 125: NVIC* or EXTI event: refer to *Section 20.5.3: EXTI CPU wakeup procedure*, for peripheral which are not stopped.
Wake-up latency	EXTI and RCC wake-up synchronization (see *Section 8.4.7: Power-on and wake-up sequences*)

I/O states in Autonomous mode

The I/O pin configuration remains unchanged in Autonomous mode.

6.7.7 Stop mode

In system Stop mode, the SRD domain is in Stop mode with the CPU domain in DStop or DStop2. The system clock including a PLL and the SmartRun domain bus matrix clocks are stopped.

The HSI or CSI can remain enabled in system Stop mode (HSIKERON and CSIKERON set in RCC_CR register). After exiting Stop mode, the clock is quickly available as kernel clock for peripherals. Other system oscillator sources are stopped and require a starting time after exiting Stop mode.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 49: Independent watchdog (IWDG)*).
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the RCC Backup Domain Control Register (RCC_BDCR).
- Internal RC oscillator (LSI RC)

  This is configured via the LSION bit in the RCC Clock Control and Status Register (RCC_CSR).
- External 32.768 kHz oscillator (LSE OSC)

This is configured via the LSEON bit in the RCC Backup Domain Control Register (RCC_BDCR).

- Peripherals in SmartRun domain capable of running on the LSI or LSE clock
- Peripherals in SmartRun domain having a kernel clock request

  In this case the PERxAMEN bit of these peripherals must be set to request the kernel clock (in the RCC_SRDAMR register)
- Peripherals in CPU domain capable of running on the LSI or LSE clock, if CPU domain is in DStop mode (as opposed to DStop2)
- Peripherals in the CPU domain having a kernel clock request, if the CPU domain is in DStop mode (as opposed to DStop2)
- Internal RC oscillators (HSI and CSI)

  This is configured via the HSIKERON and CSIKERON bits in the RCC Clock Control and Status Register (RCC_CSR).
- The ADC or DAC can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, the ADON bit in the ADC_CR2 register and the ENx bit in the DAC_CR register must both be written to 0.

The selected SVOS4 and SVOS5 levels add an additional startup delay when exiting from system Stop mode (see *Table 40*). An extra latency is added upon entering and exiting DStop2 mode as well.

Table 40. Stop mode operation

SVOS	LPDS	Stop mode voltage regulator operation	Wake-up latency
SVOS3	0	Main	No additional wake-up time
	1	LP	Voltage regulator wake-up time from Low-power mode
SVOS4 or SVOS5	x	LP	Voltage regulator wake-up time from Low-power mode + voltage level wake-up time for SVOS4 or SVOS5 level to VOS3 level

The flash memory can be in Stop mode when it is enabled through the FLPS bit of the PWR_CR1 register. This allows a trade-off between CPU domain DStop/DStop2 restart time and low-power consumption.

RAM memory shut-off

In DStop or DStop2 mode, the content of the memory blocks is maintained. Further power optimization can be obtained by switching off some memory blocks. This optimization implies loss of the memory content. The user can select which memory is discarded during Stop mode by means of xxSO bits in *PWR control register 1 (PWR_CR1)* as indicated in *Table 42*.

Table 41. Memory shut-off block selection

Selection bit	Shut-off block during Stop mode (DStop or DStop2)
AXIRAM1SO	AXI SRAM1 shut-off control
AXIRAM2SO	AXI SRAM2 shut-off control

Table 41. Memory shut-off block selection

Selection bit	Shut-off block during Stop mode (DStop or DStop2)
AXIRAM3SO	AXI SRAM3 shut-off control
AHBRAM1SO	AHB SRAM1 shut-off control
AHBRAM2SO	AHB SRAM2 shut-off control
ITCMSO	ITCM and ETM memories shut-off control
GFXSO	GFXMMU and JPEG memory shut-off control
HSITFSO	High-speed interface USB and FDCAN memories shut-off control
SRDRAMSO	SmartRun AHB SRAM shut-off control

Entering Stop mode

The Stop mode is entered according to *Section 6.7.3: Entering low-power modes*.

Refer to *Table 42* for details on how to enter Stop mode.

If the flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to a bus matrix is ongoing, the Stop mode entry is delayed until the bus matrix access is finished.

Warning: The user must ensure that no peripherals allocated in the CPU domain have an active kernel clock or are still clocked by LSI, LSE, HSI or CSI.
The flash memory must be configured in low-power mode (FLPS bit set in PWR_CR1 register) before entering DStop2.

Exiting from Stop mode

The Stop mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 42* for more details on how to exit from Stop mode.

When exiting Stop mode, the system clock, the SmartRun domain bus matrix clocks and voltage scaling are reset.

STOPF status flag in *PWR CPU control register (PWR_CPUCR)* indicates that the system has exited Stop mode (see *Table 37*).

Table 42. Stop mode

Stop mode	Description
Mode entry	When the CPU is in CStop mode and there is no active EXTI wake-up source and RUN_SRD = 0 (in PWR_CPUCR register)
Mode exit	On a EXTI wake-up
Wake-up latency	System oscillator startup (when disabled) + EXTI and RCC wake-up synchronization + Voltage scaling refer to *Table 40* (see *Section 6.6.2: Voltage scaling*) + Exiting DStop2

I/O states in Stop mode

The I/O pin configuration remains unchanged in Stop mode.

6.7.8 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem CStop mode. However the V_{CORE} supply regulator is powered off.

The system SmartRun domain enters Standby mode only when the CPU domain is in DStop or DStop2, no EXTI is pending and PDDS_SRD bit selects Standby. When the system/SmartRun domain enters Standby mode, the voltage regulator is disabled. The complete V_{CORE} domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and HSE oscillator are also switched off. The content of SRAM and registers is lost except for Backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see *Section 6.4.5: Backup domain*).

In system Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by programming its key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 49: Independent watchdog (IWDG)*).
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the Backup domain control register (RCC_BDCR).
- Internal RC oscillator (LSI RC)

  This is configured by the LSION bit in the control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE OSC)

  This is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

Entering Standby mode

The Standby mode is entered according to *Section 6.7.3: Entering low-power modes*, when the PDDS_SRD bit requests Standby (in *PWR CPU control register (PWR_CPUCR)*).

Refer to *Table 44* for more details on how to enter Standby mode.

Exiting from Standby mode

The Standby mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 44* for more details on how to exit from Standby mode.

The system exits from Standby mode when an external reset (NRST pin), an IWDG reset, a WKUP pin event, a RTC alarm, a tamper event, or a timestamp event is detected. All registers are reset after waking up from Standby except for power control and status registers (PWR control register 2 (PWR_CR2), PWR control register 3 (PWR_CR3)), SBF bit in PWR CPU control register (PWR_CPUCR), PWR wake-up flag register (PWR_WKUPFR), and PWR wake-up enable and polarity register (PWR_WKUPEPR).

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched). The SBF status flag in *PWR CPU control register (PWR_CPUCR)* indicates from which mode the system has exited (see *Table 43*).

Table 43. Standby and Stop flags

SBF	STOPF	Description
0	1	System has been in or exits from Stop.
1	0	System exits from Standby.

Table 44. Standby mode

Standby mode	Description
Mode entry	– The CPU subsystem is in CStop mode and there is no active EXTI wake-up source and RUN_SRD = 0. – PDDS_SRD bit selects Standby. – All WKUPFx bits in power control/status register (PWR_WKUPFR) are cleared.
Mode exit	WKUP pins rising or falling edge, RTC alarm (Alarm A and Alarm B), RTC wake-up, tamper event, timestamp event, external reset in NRST pin, IWDG reset
Wake-up latency	System reset phase (see *Section 8.4.2: System reset*)

I/O states in Standby mode

In Standby mode, all I/O pins are high impedance without pull, except for:

- Reset pad (still available)
- PC14 and PC15 pins if configured for LSE oscillator
- PC13 pin if configured as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 or TAMP_OUT3, assuming they have been configured by the RTC or the TAMPER
- PI8 pin if configured as RTC_OUT2, TAMP_IN2 or TAMP_OUT3, assuming they have been configured by the RTC or the TAMPER
- PC1 pin if configured as TAMP_IN3, assuming it has been configured by the TAMPER
- WKUP pins (if enabled).
  The WKUP pin pull configuration can be defined through WKUPPUPDx[1:0] bits in *PWR wake-up enable and polarity register (PWR_WKUPEPR)*.

6.7.9 Monitoring low-power modes

The devices feature state monitoring pins that monitor the CPU and Domain state transitions to low-power mode (refer to *Table 45* for the list of pins and their description). The GPIO pin corresponding to each monitoring signal has to be programmed in alternate function mode.

This feature is not available in Standby mode since these I/O pins are switched to high impedance.

Table 45. Overview of low-power mode monitoring pins

Power state monitoring pins	Description	Pin assignment
CSLEEP	CPU clock OFF	PC3
CSTOP	CPU domain in low-power mode	PC2
NDSTOP2	CPU domain Retention mode selection	PA5

The state of the monitoring pins reflect the mode of the CPUs and domains. Refer to *Table 46* for a description of the GPIO state depending on the CPU and domain state.

Table 46. GPIO state according to CPU and domain state

CSLEEP	CSTOP	NDSTOP2	CPU domain power state	SRD domain power state	CPU state
0	0	1	DRun	SRDRun	CRun
1	0	1	DRun	SRDRun	CSleep
1	1	1	DStop	SRDRun or SRDStop	CStop
1	1	0	DStop2	SRDRun or SRDStop	CStop

6.8 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

6.8.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0xF000 C000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SRDRAMSO	HSITFSO	GFXSO	ITCMSO	AHBRAM2SO	AHBRAM1SO	AXIRAM3SO	AXIRAM2SO	AXIRAM1SO	ALS[1:0]		AVDEN
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SVOS[1:0]		AVD_READY	BOOSTE	Res.	Res.	FLPS	DBP	PLS[2:0]			PVDE	Res.	Res.	Res.	LPDS
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw				rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **SRDRAMSO**: SmartRun domain AHB memory shut-off in DStop/DStop2 low-power mode
0: SmartRun domain AHB memory content is kept in DStop or DStop2 mode
1: SmartRun domain AHB memory content is lost in DStop or DStop2 mode

Bit 26 **HSITFSO**: high-speed interfaces USB and FDCAN memory shut-off in DStop/DStop2 mode
0: USB and FDCAN memories content is kept in DStop or DStop2 mode
1: USB and FDCAN memories content is lost in DStop or DStop2 mode

Bit 25 **GFXSO**: GFXMMU and JPEG memory shut-off in DStop/DStop2 mode
0: GFXMMU and JPEG memory content is kept in DStop or DStop2 mode
1: GFXMMU and JPEG memory content is lost in DStop or DStop2 mode

Bit 24 **ITCMSO**: instruction TCM and ETM memory shut-off in DStop/DStop2 mode
0: ITCM and ETM memories content is kept in DStop or DStop2 mode
1: ITCM and ETM memories content is lost in DStop or DStop2 mode

Bit 23 **AHBRAM2SO**: AHB SRAM2 shut-off in DStop/DStop2 mode
0: AHB SRAM2 content is kept in DStop or DStop2 mode
1: AHB SRAM2 content is lost in DStop or DStop2 mode

Bit 22 **AHBRAM1SO**: AHB SRAM1 shut-off in DStop/DStop2 mode
0: AHB SRAM1 content is kept in DStop or DStop2 mode
1: AHB SRAM1 content is lost in DStop or DStop2 mode

Bit 21 **AXIRAM3SO**: AXI SRAM3 shut-off in DStop/DStop2 mode
0: AXI SRAM3 content is kept in DStop or DStop2 mode
1: AXI SRAM3 content is lost in DStop or DStop2 mode

Bit 20 **AXIRAM2SO**: AXI SRAM2 shut-off in DStop/DStop2 mode
0: AXI SRAM2 content is kept in DStop or DStop2 mode
1: AXI SRAM2 content is lost in DStop or DStop2 mode

Bit 19 **AXIRAM1SO**: AXI SRAM1 shut-off in DStop/DStop2 mode
0: AXI SRAM1 content is kept in DStop or DStop2 mode
1: AXI SRAM1 content is lost in DStop or DStop2 mode

Bits 18:17 **ALS[1:0]:** analog voltage detector level selection
These bits select the voltage threshold detected by the AVD.
00: 1.7 V
01: 2.1 V
10: 2.5 V
11: 2.8 V

Bit 16 **AVDEN:** peripheral voltage monitor on V_{DDA} enable
0: peripheral voltage monitor on V_{DDA} disabled
1: peripheral voltage monitor on V_{DDA} enabled

Bits 15:14 **SVOS[1:0]:** system stop mode voltage scaling selection
These bits control the V_{CORE} voltage level in system Stop mode, to obtain the best trade-off between power consumption and performance.
00: reserved
01: SVOS5 scale 5
10: SVOS4 scale 4
11: SVOS3 scale 3 (default)

Bit 13 **AVD_READY**: analog voltage ready
This bit is only used when the analog switch boost needs to be enabled (see BOOSTE bit).
It must be set by software when the expected V_{DDA} analog supply level is available.
The correct analog supply level is indicated by the AVDO bit (PWR_CSR1 register) after setting the AVDEN bit and selecting the supply level to be monitored (ALS bits).
0: peripheral analog voltage V_{DDA} not ready (default)
1: peripheral analog voltage V_{DDA} ready

Bit 12 **BOOSTE**: analog switch VBoost control
This bit enables the booster to guarantee the analog switch AC performance when the V_{DD} supply voltage is below 2.7 V (reduction of the total harmonic distortion to have the same switch performance over the full supply voltage range)
The V_{DD} supply voltage can be monitored through the PVD and the PLS bits.
0: booster disabled (default)
1: booster enabled if analog voltage ready (AVD_READY = 1)

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **FLPS:** Flash memory low-power mode in DStop or DStop2 mode
When it is set, the flash memory enters Low-power mode when the CPU domain is in DStop/DStop2 mode.
The power consumption is improved with a slightly longer wake-up time.
It is mandatory to set FLPS before entering DStop2 mode.
0: Flash memory remains in normal mode when the CPU domain enters DStop (quick restart time).
1: Flash memory enters Low-power mode when the CPU domain enters DStop/DStop2 (low-power consumption).

Bit 8 **DBP:** disable Backup domain write protection

In reset state, the RCC_BDCR register, the RTC registers (including the backup registers), BREN and MOEN bits in PWR_CR2 register, are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: access to RTC, RTC backup registers and backup SRAM disabled

1: access to RTC, RTC backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]:** programmable voltage detector level selection

These bits select the voltage threshold detected by the PVD.

000: 1.95 V

001: 2.1 V

010: 2.25 V

011: 2.4 V

100: 2.55 V

101: 2.7 V

110: 2.85 V

111: PVD_IN pin

Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bit 4 **PVDE:** programmable voltage detector enable

0: programmable voltage detector disabled

1: programmable voltage detector enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **LPDS:** low-power Deepsleep with SVOS3 (SVOS4 and SVOS5 always use low-power, regardless of the setting of this bit)

0: LDO voltage regulator or SMPS step-down converter in Main mode (MR) when SVOS3 selects Stop

1: LDO voltage regulator or SMPS step-down converter in Low-power mode (LPR) when SVOS3 selects Stop

6.8.2 PWR control status register 1 (PWR_CSR1)

Address offset: 0x004

Reset value: 0x0000 4000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MMCVDO	AVDO
														r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACTVOS[1:0]		ACTVOSRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	Res.	Res.
r	r	r									r				

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **MMCVDO**: voltage detector output on V_{DDMMC}
This bit is set and cleared by hardware.
0: V_{DDMMC} is below 1.2 V.
1: V_{DDMMC} is above or equal to 1.2 V.

Bit 16 **AVDO**: analog voltage detector output on V_{DDA}
This bit is set and cleared by hardware. It is valid only if AVD on V_{DDA} is enabled by the AVDEN bit.
0: V_{DDA} is equal or higher than the AVD threshold selected with the ALS[2:0] bits.
1: V_{DDA} is lower than the AVD threshold selected with the ALS[2:0] bits.
Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the AVDEN bit is set.

Bits 15:14 **ACTVOS[1:0]**: VOS currently applied for V_{CORE} voltage scaling selection.
These bits reflect the last VOS value applied to the voltage regulator.

Bit 13 **ACTVOSRDY:** Voltage levels ready bit for currently used VOS
This bit is set to 1 by hardware when the voltage regulator and the SMPS step-down converter are both disabled and Bypass mode is selected in PWR control register 3 (PWR_CR3).
0: voltage level invalid, above or below current VOS selected level
1: voltage level valid, at current VOS selected level

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: programmable voltage detect output
This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.
0: V_{DD} is equal or higher than the PVD threshold selected through the PLS[2:0] bits.
1: V_{DD} is lower than the PVD threshold selected through the PLS[2:0] bits.
Note: since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bits 3:0 Reserved, must be kept at reset value.

6.8.3 PWR control register 2 (PWR_CR2)

Address offset: 0x008

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, RESET signal and V_{DD} POR. It is only reset by V_{SW} POR and VSWRST reset.

This register must not be accessed when VSWRST bit in RCC_BDCR register resets the V_{SW} domain.

After reset, PWR_CR2 register is write-protected. Prior to modifying its content, the DBP bit in PWR_CR1 register must be set to disable the write protection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	Res.	Res.	Res.	Res.	Res.	BRRDY
								r	r						r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.	Res.	Res.	BREN
											rw				rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: temperature level monitoring versus high threshold
0: temperature below high threshold level
1: temperature equal or above high threshold level

Bit 22 **TEMPL**: temperature level monitoring versus low threshold
0: temperature above low threshold level
1: temperature equal or below low threshold level

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **BRRDY**: backup regulator ready
This bit is set by hardware to indicate that the backup regulator is ready.
0: backup regulator not ready
1: backup regulator ready

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MONEN:** V_{BAT} and temperature monitoring enable
This feature is available only when the backup regulator is enabled (BREN = 1).
0: V_{BAT} and temperature monitoring disabled
1: V_{BAT} and temperature monitoring enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN:** backup regulator enable
When this bit set, the backup regulator (used to maintain the backup RAM content in Standby and V_{BAT} modes) is enabled.
If BREN is cleared, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However its content is lost in Standby and V_{BAT} modes.
If BREN is set, the application must wait till the backup regulator ready flag (BRRDY) is set to indicate that the data written into the SRAM is maintained in Standby and V_{BAT} modes.
0: backup regulator disabled
1: backup regulator enabled

6.8.4 PWR control register 3 (PWR_CR3)

Address offset: 0x00C

Reset value: 0x0000 0006

Reset by POR only, not reset by wake-up from Standby mode and RESET pad.

The lower byte of this register is written once after POR and must be written before changing VOS level or ck_sys clock frequency. No limitation applies to the upper bytes.

Programming data corresponding to an invalid combination of SMPSLEVEL, SMPSEXTHP SMPSEN, LDOEN and BYPASS bits (see *Table 34*) are ignored: data are not written, the written-once mechanism locks the register and any further write access is ignored. The default supply configuration is kept and the ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* goes on indicating invalid voltage levels. The system must be power cycled before writing a new value.

Illegal combinations of SMPSLEVEL, SMPSEXTHP, SMPSEN, LDOEN and BYPASS are described in *Table 34*.

The SMPS step-down converter is not available on all packages.In this case, the SMPS step-down converter is disabled.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **USB33RDY**: USB supply ready
- 0: USB33 supply not ready
- 1: USB33 supply ready

Bit 25 **USBREGEN**: USB regulator enable
- 0: USB regulator disabled
- 1: USB regulator enabled

Bit 24 **USB33DEN**: $V_{DD33USB}$ voltage level detector enable
- 0: $V_{DD33USB}$ voltage level detector disabled
- 1: $V_{DD33USB}$ voltage level detector enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **SMPSEXTRDY**: SMPS step-down converter external supply ready
This bit is set by hardware to indicate that the external supply from the SMPS step-down converter is ready.
0: external supply not ready
1: external supply ready

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **VBRS**: V_{BAT} charging resistor selection
0: charge V_{BAT} through a 5 kΩ resistor
1: charge V_{BAT} through a 1.5 kΩ resistor

Bit 8 **VBE**: V_{BAT} charging enable
0: V_{BAT} battery charging disabled
1: V_{BAT} battery charging enabled

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SMPSLEVEL[1:0]**: SMPS step-down converter voltage output level selection
This bitfield is used when both the LDO and SMPS step-down converter are enabled with SMPSEN and LDOEN enabled or when SMPSEXTHP is enabled. In this case SMPSLEVEL must be written with a value different than 00 at system startup.
00: reset value
01: 1.8 V
10: 2.5 V
11: 2.5 V
Note: This bitfield is written once after POR and must be written before changing VOS level or ck_sys clock frequency.

Bit 3 **SMPSEXTHP**: SMPS step-down converter external power delivery selection
0: SMPS normal operating mode, no power delivery to external circuits
1: SMPS external operating mode, power delivery to external circuits
Note: This bit is written once after POR and must be written before changing VOS level or ck_sys clock frequency.

Bit 2 **SMPSEN**: SMPS step-down converter enable
0: SMPS disabled
1: SMPS enabled (default)
Note: This bit is written once after POR and must be written before changing VOS level or ck_sys clock frequency.

Bit 1 **LDOEN**: low drop-out regulator enable
0: low drop-out regulator disabled
1: low drop-out regulator enabled (default)
Note: This bit is written once after POR and must be written before changing VOS level or ck_sys clock frequency.

Bit 0 **BYPASS**: power management unit bypass
0: power management unit normal operation
1: power management unit bypassed, voltage monitoring still active
Note: This bit is written once after POR and must be written before changing VOS level or ck_sys clock frequency.

6.8.5 PWR CPU control register (PWR_CPUCR)

This register allows controlling CPU domain power.

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RUN_SRD	Res.	CSSF	Res.	Res.	SBF	STOPF	Res.	Res.	PDDS_SRD	Res.	RETDS_CD
				rw		rw			r	r			rw		rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RUN_SRD:** prevent the SmartRun Domain (SRD) to enter Stop mode
0: SmartRun domain follows CPU subsystem modes.
1: SmartRun domain remains in Run mode regardless of CPU subsystem modes.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CSSF:** clear Standby and Stop flags (always read as 0)
This bit is cleared to 0 by hardware.
0: no effect
1: STOPF and SBF flags cleared

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **SBF:** system Standby flag
This bit is set by hardware and cleared only by a POR or by setting the CSSF bit.
0: system has not been in Standby mode.
1: system has been in Standby mode.

Bit 5 **STOPF:** STOP flag
This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.
0: system has not been in Stop mode.
1: system has been in Stop mode.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **PDDS_SRD:** system SmartRun domain power down Deepsleep
This bit allows defining the Deepsleep mode for system SmartRun domain.
0: Keeps Stop mode when CPU domain enters Deepsleep.
1: Allows Standby mode when CPU domain enters Deepsleep.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **RETDS_CD**: CPU domain power down Deepsleep selection.
This bit defines the Deepsleep mode for CPU domain.
0: Go to DStop mode when CPU domain enters Deepsleep.
1: Go to DStop2 mode (Retention mode) when CPU domain enters Deepsleep.

6.8.6 PWR SmartRun domain control register (PWR_SRDCR)

This register allows controlling SmartRun domain power.

Address offset: 0x018

Reset value: 0x0000 2000

Following reset, VOSRDY is read 1 by software.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VOS[1:0]		VOSRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	r													

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **VOS[1:0]:** voltage scaling selection according to performance

These bits control the V_{CORE} voltage level and allow to obtain the best trade-off between power consumption and performance:

- In Bypass mode, these bits must also be set according to the external provided core voltage level and related performance.
- When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
- When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.

00: scale 3 (default)
01: scale 2
10: scale 1
11: scale 0

Note: VOS[1:0] can be changed only when ACTVOSRDY is valid (PWR_CSR1 register)

Bit 13 **VOSRDY:** VOS ready bit for V_{CORE} voltage scaling output selection

This bit is set to 1 by hardware when Bypass mode is selected in PWR_CR3 register.
0: not ready, voltage level below VOS selected level
1: ready, voltage level at or above VOS selected level

Bits 12:0 Reserved, must be kept at reset value.

6.8.7 PWR wake-up clear register (PWR_WKUPCR)

Address offset: 0x020

Reset value: 0x0000 0000

Reset only by system reset, not reset by wake-up from Standby mode.

Five wait states are required when writing this register. The AHB write access completes after the WKUPFx has been cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPCn:** clear wake-up pin flag for WKUPn (n = 6 to 1)

These bits are always read as 0.

0: no effect

1: writing 1 clears the WKUPFn wake-up pin flag (bit is cleared to 0 by hardware).

6.8.8 PWR wake-up flag register (PWR_WKUPFR)

Address offset: 0x024

Reset value: 0x0000 0000

Reset only by system reset, not reset by wake-up from Standby mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPF6	WKUPF5	WKUPF4	WKUPF3	WKUPF2	WKUPF1
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPFn:** wake-up pin WKUPn flag (n = 6 to 0)

This bit is set by hardware and cleared only by a RESET pin or by setting the WKUPCn bit in PWR_WKUPCR register.

0: no wake-up event occurred

1: a wake-up event received from WKUPn pin

6.8.9 PWR wake-up enable and polarity register (PWR_WKUPEPR)

Address offset: 0x028

Reset value: 0x0000 0000

Reset only by system reset, not reset by wake-up from Standby mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	WKUPPUPD6[1:0]		WKUPPUPD5[1:0]		WKUPPUPD4[1:0]		WKUPPUPD3[1:0]		WKUPPUPD2[1:0]		WKUPPUPD1[1:0]

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **WKUPPUPD(truncate(n/2)-7)[1:0]**: wake-up pin pull configuration for WKUP(truncate(n/2)-7)

These bits define the I/O pad pull configuration used when WKUPEN(truncate(n/2)-7) = 1. The associated GPIO port pull configuration must be set to the same value or to 00.

The wake-up pin pull configuration is kept in Standby mode.

00: no pull-up

01: pull-up

10: pull-down

11: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **WKUPPn-7**: wake-up pin polarity bit for WKUPn-7

These bits define the polarity used for event detection on WKUPn-7 external wake-up pin.

0: detection on high level (rising edge)

1: detection on low level (falling edge)

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPENn+1**: enable wake-up pin WKUPn+1

These bit are set and cleared by software.

0: An event on WKUPn+1 pin does not wake-up the system from Standby mode.

1: A rising or falling edge on WKUPn+1 pin wakes up the system from Standby mode.

Note: An additional wake-up event is detected if WKUPn+1 pin is enabled (by setting the WKUPENn+1 bit) when WKUPn+1 pin level is already high when WKUPPn+1 selects rising edge, or low when WKUPPn+1 selects falling edge.

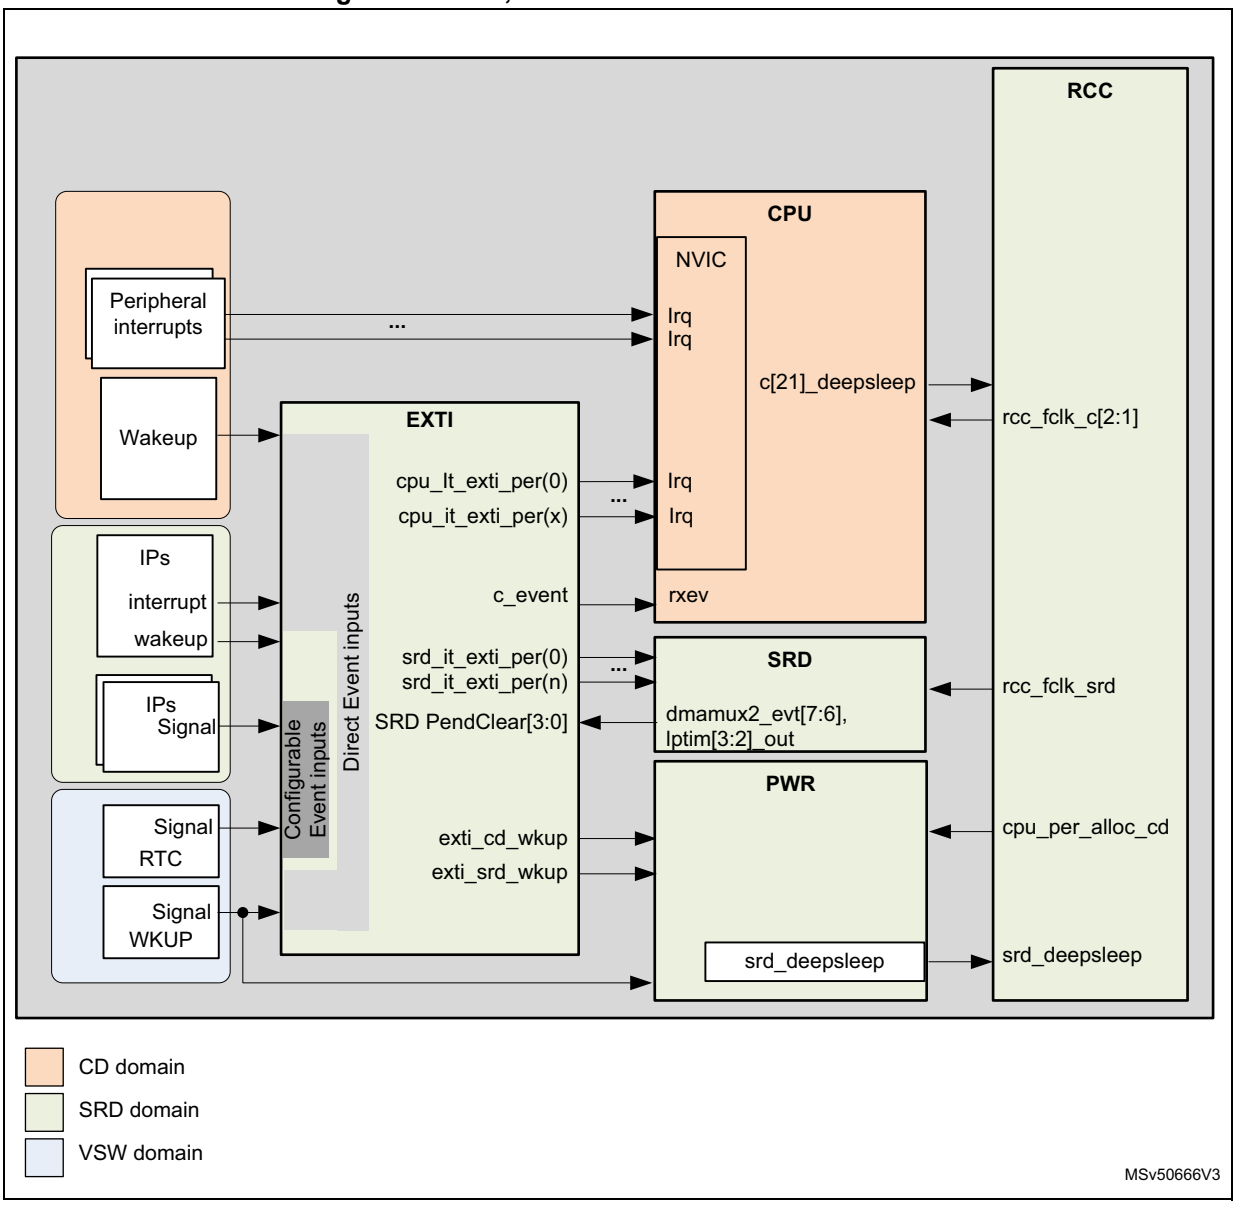
7 Low-power SRD domain application example

This section describes, through an example, how to use the SRD domain to implement low-power applications.

7.1 Introduction

The first part of the description explains how the EXTI, RCC and PWR blocks interact with each other and with the other system blocks. A detailed explanation on how the DMAMUX2 can be used to free the CPU is also provided.



The second part explains how to use the Autonomous mode to perform simple data transfers through an example of LPUART1 transmission.

Register programming is detailed only for the blocks related to the Autonomous mode.

7.2 EXTI, RCC and PWR interconnections

Figure 40 shows the main EXTI, RCC and PWR interconnections.

Figure 40. EXTI, RCC and PWR interconnections

7.2.1 Interrupts and wake-up

Three kinds of signals are exchanged between the peripherals. They can be used to wake up the system from Stop mode:

- **Wake-up events** (or asynchronous interrupts)

  Some peripherals can generate interrupt events, even if their bus interface clock is not present. These interrupt events are called wake-up events (or asynchronous interrupts).

  Example: i2c1_wkup, usart1_wkup and lptim1_wkup.

- **Signals**

  Some peripherals generate a pulse instead of an interrupt signal. These pulses are called signals.

  Examples: lptim2_out and lptim3_out.

- **Interrupts**

  Contrary to signals, the interrupts should be cleared by a CPU or any other bus master, either by clearing the corresponding event bit in the peripheral register or by updating the FIFO interrupt level.

  All the interrupts associated to system peripherals are directly connected to the NVIC, except for the peripherals which are able to wake up the system from Stop mode or the CPU from CStop. In this latter case, the interrupts, signals or wake-up events are connected to the NVIC via the EXTI.

  Example: spi1_it, tim1_brk_it and tim1_upd_it.

The interrupt and wake-up sources that require to be cleared in the peripheral itself are connected to EXTI Direct Event inputs. The EXTI does not manage any CPU status pending bit.

The peripherals signals are connected to EXTI Configurable Event inputs. These EXTI inputs provide a CPU status pending bit which needs to be cleared by the application.

7.2.2 Block interactions

Interaction between EXTI and PWR blocks

The EXTI delivers wake-up requests signals (**exti_cd_wkup, exti_srd_wkup**) to the PWR controller. These signals are activated according to the state of the interrupts, signals or wake-up events connected to the EXTI. These wake-up requests are used by the PWR controller to supply the domain who needs to handle the activated wake-up event generated by the peripherals.

Interaction between PWR and RCC blocks

The PWR block controls the V_{CORE} supply according to the system operating mode (CRun, CSleep or CStop). For DStop2 (Retention mode), the PWR controller also controls the power switch (ePOD) that cuts the supply of part of the CD domain.

The RCC block controls the clock generation in accordance with the system operating mode. It is also responsible for reset generation.

To synchronize the system mode transitions, the RCC block is tightly coupled with the PWR controller:

- The RCC informs the PWR controller when peripherals located in the CD or SRD domain are allocated by the CPU (**c_per_alloc_cd**).
- The RCC also warns the PWR block when a domain clock is activated/deactivated. These signals are used in case of domain transition from DRun to DStop, DStop2 and Standby. In this case, the PWR controller waits until the domain clock has been gated, before switching down this domain.
- Similarly, the PWR controller informs the RCC about the V_{CORE} supply status of each domain (**pwr_srd_wkup and pwr_cd_wkup**). This information is used by the RCC when a domain transition from DStop or DStop2 to DRun occurs.

Interaction between EXTI and SRD domain

All the wake-up event inputs received by the EXTI from the peripherals located in SRD domain can be used to perform operations in Autonomous mode without activating the CPU.

The EXTI **SRD_PenClear[3:0]** inputs received from the SRD domain are used to acknowledge the ongoing wake-up requests generated by peripherals located in the SRD domain. The **SRD_PenClear[3:0]** inputs allow switching the system SRD domain from Run to Stop mode.

7.2.3 Role of DMAMUX2 in SRD domain

The DMAMUX2 implemented in the SRD domain allows chaining BDMA2 transfers. BDMA2 requests are synchronized thanks to trigger events (**dmamux2_evtx**) which can be generated when the expected amount of data has been transferred.

These events can also trigger DMAMUX2 request generators (REQ_GEN[3:0]), and thus chain several BDMA2 transfers. In fact REQ_GEN[3:0] can be triggered indirectly by all the wake-up events generated by all SRD domain peripherals.

Like LPTIM3 and LPTIM2 outputs, dmamux2_evt7 and dmamux2_evt6 events are connected to the EXTI. They can be used to switch the SRD domain from DRun to DStop or DStop2 mode when the task requested by the wake-up event is complete.

7.3 Low-power application example based on LPUART1 transmission

This section illustrates, through an example, the benefit of the SRD domain usage on power consumption. To help the user program the device, only the key register settings are given herein.

Refer to Sections *Reset and clock control (RCC)* and *Power control (PWR)* for additional details.

7.3.1 Memory retention

The SRD domain features 32 Kbytes of SRAM (SRD SRAM). When the CD domain is in DStop or DStop2 mode while the system is in Run mode, data can be transferred between this RAM area and to/from a peripheral located in the SRD domain.

DStop2 and DStop are very similar from user point of view. In DStop2 mode the asynchronous logic is switched off while RAM and register contents are maintained. This allows further leakage current consumption reduction compared to DStop mode. When exiting DStop2, the CPU domain resumes normal execution at the cost of a slightly higher startup time.

In DStop/DStop2 modes, all the CD domain clocks are OFF but data are retained. The power consumption in DStop/DStop2 mode can be further optimized by choosing to shut off some SRAMs with the consequence to loose their content (see *Section 6: Power control (PWR)*).

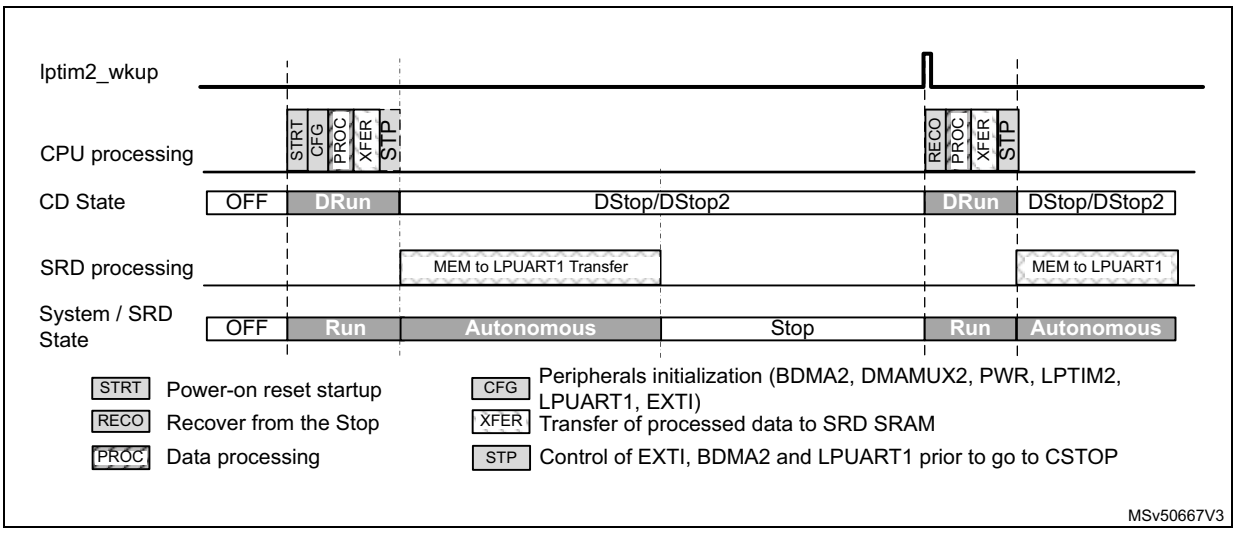
Note: SRD SRAM remains available as long as the system is not in Standby mode.

If the system is in Standby mode, it is still possible to use the BKUP_SRAM. However, its size is limited to 4 Kbytes.

7.3.2 Memory-to-peripheral transfer using LPUART1 interface

Example description

Figure 41 shows the proposed implementation. At a regular time interval given by LPTIM2, the CPU wakes up from CStop mode (which domain is in DStop/DStop2). When the CPU is in Run mode, it prepares the data to be transmitted via LPUART1, transfers them to SRD SRAM, and goes back to CStop. The SRD domain is configured to perform data transfers via LPUART1 and go back to Stop mode when the transfer is complete.



The LPTIM2 interface is used to wake up the system from Stop at regular time intervals. the CPU must then perform the following operations:

1. Recover the application from the system Stop mode (RECO).
2. Process the new data to be sent via LPUART1 (PROC).
3. Transfer the data into SRD SRAM (XFER).
4. Configure the DMAMUX2, the BDMA2, the LPUART1, and the RCC (CFG).
5. Configure the EXTI (CFG).
6. Configure the PWR block to allow the CD domain to go to DStop/DStop2 mode.
7. Set the CPU to Stop mode.

The SRD domain executes the following tasks in Autonomous mode:

1. Transfer the data from SRD SRAM to LPUART1, using BDMA2.
2. When the LPUART1 interface indicates that the last byte has been transferred, the SRD domain is switched to Stop mode.

Figure 41. Timing diagram of SRD SRAM-to-LPUART1 transfer with BDMA2 and SRD domain in Autonomous mode

Note: The RUN_SRD bit can be used to force the SRD domain to remain in Run mode when the CD domain enters DStop or DStop2 mode.

If the CPU is not running, the SRD domain is not able to switch on its own from Run to Stop mode.

The proposed solution is explained in details in the following sections. It consists in setting a wake-up event for the SRD domain before the CD domain enters DStop/DStop2 mode. In this way the SRD domain remains in run mode and enters Stop mode only when this request is cleared.

RCC programming

Before entering Autonomous mode (CD domain in DStop/DStop2 mode with SRD domain in Run mode), the RCC must be programmed to request the needed clocks to remain enabled. In this example, they are required for the SRD SRAM, BDMA2/DMAMUX2, LPTIM2, GPIOs and LPUART1

LPUART1 can use its own APB clock as kernel clock. Since the system will not enter Stop mode before LPUART1 has completed data transfer, PLLx can be used to provide clocks to the peripherals.

PWR programming

In this example, the PWR block must be programmed in order to:

- allow the CD domain to enter DStop/Dstop2 mode when the data transfer is complete,
- define the working voltage according to system modes.

Note: SRD domain could enter Standby as well, but in this case the LPTIM2 could not be used to wake up the system and the AWU should be used instead. In addition, everything must be reprogrammed when the system wakes up.

EXTI programming

The EXTI block must be configured to provide the following services:

- Keep SRD domain running when CD domain is in DStop/DStop2. This will be done by a software event.
- Set the device to Stop mode when the data transfer via LPUART1 is complete.
- Wake up the product from Stop when LPTIM2 time interval has elapsed.

The EXTI block is configured once before performing the first data transfer. For incoming data transfers, the programmed configuration remains unchanged; only some events need to be triggered or acknowledged.

Note: The CPU uses the event input number 0 to generate a software event. LPTIM2 wake-up signal is connected to event input number 48 (direct event input).

All other event inputs must be disabled: EXTI_RTSRx_TRy = '0' and EXTI_FTSRx_TRy = '0'.

To generate a wake-up event for SRD domain, the CPU must write SWIER0 bit of EXTI_SWIER1 to '1'.

BDMA2 and DMAMUX2 programming

Two BDMA2 channels are required to execute data transfers via LPUART1.

- A BDMA2 channel, such as channel 0, is used to transfer data from SRD SRAM to LPUART1, using the TXE flag.
- The second BDMA2 channel role is to switch the SRD domain to Stop mode. For that purpose, DMAMUX2 request generator channel 0 (REQ_GEN0) and DMAMUX2 channel 7 synchronization block (SYNC7) are used in conjunction with BDMA2 channel 7.

BDMA2 channel 0 does not use DMAMUX2 trigger capabilities. Refer to *Table 48* for initialization details.

BDMA2 channel 7 uses REQ_GEN0 to generate BDMA2 requests. The generation of BDMA2 requests is triggered by the LPUART1 transmit interrupt (**lpuart1_tx_it**). The LPUART1 interface generates lpuart1_tx_it interrupt when the transmit complete event is detected. The BDMA2 then clears the pending interrupt by performing a write operation to the LPUART1.

The SYNC7 block is programmed in Free-running mode. It generates a pulse on its **dmamux2_evt7** output when the BDMA2 request generated by the REQ_GEN0 is complete. **dmamux2_evt7** signal is used by the EXTI to switch back the SRD domain to Stop mode.

Figure 42 shows the active signal paths via DMAMUX2. The grayed blocks represent the unused paths.

Figure 42. BDMA2 and DMAMUX2 interconnection

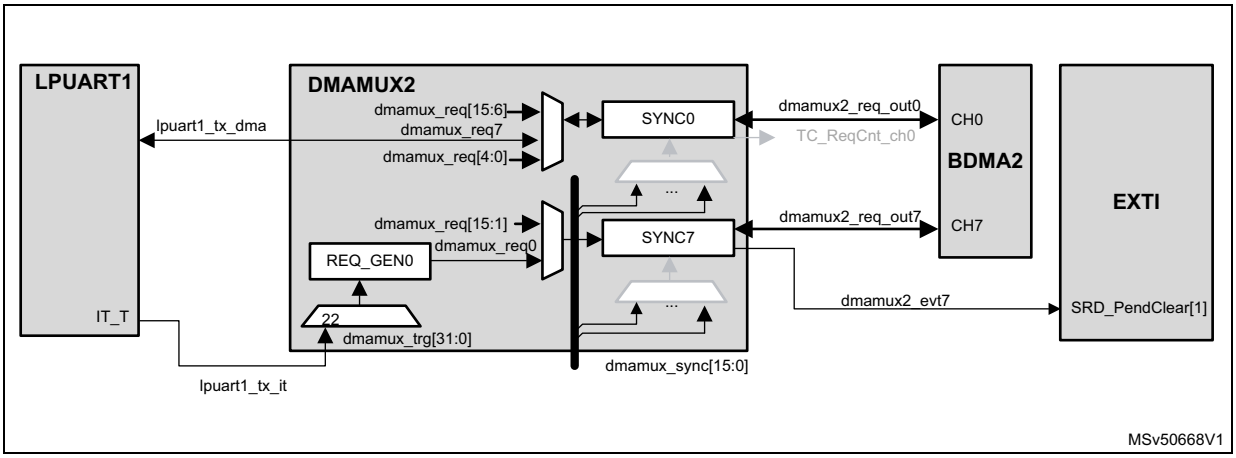


Table 48 explain how to program BDMA2 and DMAMUX2 key functions. The way errors are handled is not described.

Table 48. BDMA2 and DMAMUX2 initialization sequence (DMAMUX2_INIT)

Peripherals	Register content	Related actions
DMAMUX2 SYNC0	DMAREQ_ID of DMAMUX2_C0CR = ‘10’ SE of DMAMUX2_C0CR = ‘0’ EGE of DMAMUX2_C0CR = ‘0’ NBREQ of DMAMUX2_C0CR = ‘0’	Selects LPUART_TX BDMA2 request. Disables block synchronization. No event generation. Generates an event every BDMA2 transfer (Free-running mode).
DMAMUX2 SYNC7	DMAREQ_ID of DMAMUX2_C7CR = ‘0’ SE of DMAMUX2_C7CR = ‘0’ EGE of DMAMUX2_C7CR = ‘1’ NBREQ of DMAMUX2_C7CR = ‘0’	Selects of REQ_GEN0 as BDMA2 request. Disables block synchronization. Enables event generation. Generates an event every BDMA2 transfer (Free-running mode).
DMAMUX2 REQ_GEN0	SIG_ID of DMAMUX2_RG0CR = ‘0d24’ GPOL of DMAMUX2_RG0CR = ‘0b01’ GNBREQ of DMAMUX2_RG0CR = ‘0’ GE of DMAMUX2_RG0CR = ‘1’	Selects LPUART TX interrupt as trigger. Trigger on rising edge of the event. Generates only one BDMA2 request. Enables generator.

Table 48. BDMA2 and DMAMUX2 initialization sequence (DMAMUX2_INIT) (continued)

Peripherals	Register content	Related actions
BDMA2 - CH0	NDT bits of BDMA_CNDTR0 = DatNber	Number of data to transfer.
	PA of BDMA_CPAR0 = &LPUART1_TDR	Address of LPUART1_TDR.
	MA of BDMA_CMAR0 = &DatBuff	Address of memory buffer of SRD SRAM.
	DIR of BDMA_CCR0 = ‘1’	Read from memory.
	CIRC of BDMA_CCR0 = ‘0’	Circular mode disabled.
	PINC of BDMA_CCR0 = ‘0’	Peripheral increment disabled.
	MINC of BDMA_CCR0 = ‘1’	Memory increment enabled.
	PSIZE of BDMA_CCR0 = ‘0’	Peripheral size = 8 bits.
	MSIZE of BDMA_CCR0 = ‘1’	Memory size = 8 bits.
	MEM2MEM of BDMA_CCR0 = ‘0’	Memory to memory disabled.
BDMA2 - CH7	NDT bits of BDMA_CNDTR7 = ‘1’	Only one data transferred.
	PA of BDMA_CPAR7 = &LPUART1_ICR	Address of LPUART1_ICR (Interrupt Flag Clear Reg.).
	MA of BDMA_CMAR7 = &DatClrTC	Address of a variable located into SRD SRAM. This variable must contain 0x0040 in order to clear the TC flag.
	DIR of BDMA_CCR7 = ‘1’	Read from memory.
	CIRC of BDMA_CCR7 = ‘0’	Circular mode disabled.
	PINC of BDMA_CCR7 = ‘0’	Peripheral increment disabled.
	MINC of BDMA_CCR7 = ‘1’	Memory increment disabled.
	PSIZE of BDMA_CCR7 = 2	Peripheral size = 32 bits.
	MSIZE of BDMA_CCR7 = 2	Memory size = 32 bits.
	MEM2MEM of BDMA_CCR7 = ‘0’	Memory to memory disabled.

LPTIM2 programming

When LPTIM2 wake-up event occurs, the CPU reboots and SRD domain mode is also set to Run mode.

An interrupt issued by LPTIM2 is pending on the CPU NVIC. LPTIM2 interrupt handler must acknowledge this LPTIM2 interrupt by writing ARRMCF bit in LPTIM2_ICR register to ‘1’ (LPTIM2_Ack).

LPUART programming

In the use-case described herein, the capability of the LPUART1 to request the kernel clock according to some events is not used.

LPUART1 is programmed so that is generates a BDMA request when its TX-FIFO is not full.

LPUART1 also generates an interrupt when the TX-FIFO and its transmit shift register are empty. This interrupt is used to switch the SRD domain to Stop mode.

Table 49 gives the key settings concerning the handling of Stop mode for LPUART1.

Table 49. LPUART1 Initial programming (LPUART1_INIT)

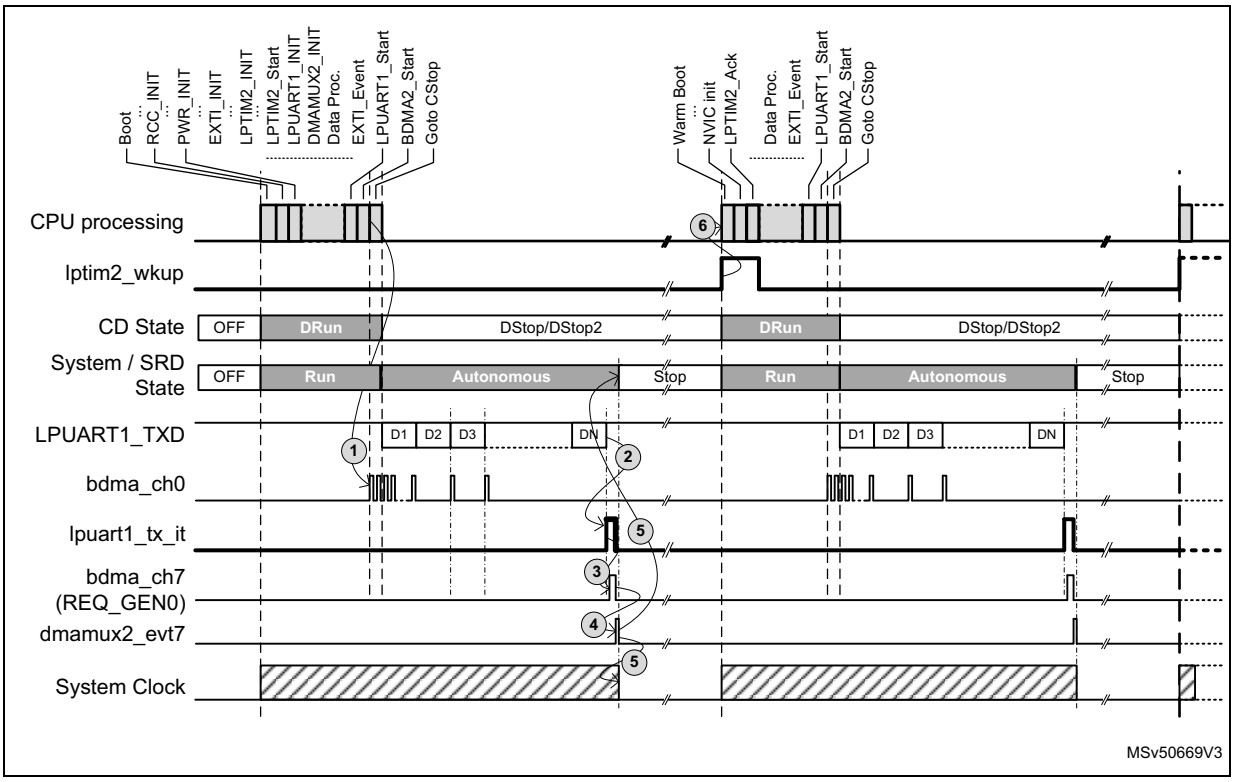
Register content	Related actions
FIFOEN of LPUART1_CR1 = ‘1’	Enables FIFO. BDMA2 will then use TXFNF (TXFIFO Not Full) flag for generating the BDMA2 requests.
TCIE of LPUART1_CR1 = ‘0’	Disables interrupt when the transmit buffer is empty.
UE of LPUART1_CR1 = ‘1’	Enables BDMA2.
TE of LPUART1_CR1 = ‘1’	Enables the LPUART1.
TXE of LPUART1_CR1 = ‘1’	Enables transmission.
DMAT of LPUART1_CR3 = ‘1’	Enables the BDMA2 mode for transmission.

Respect the sequence described in *Table 50* to enable LPUART1.

Table 50. LPUART1 start programming (LPUART1_Start)

Register content	Related actions
TCCF of LPUART1_ICR = ‘1’	Clears the TC flag, to avoid immediate interrupt generation, which would clear the SRD_PendClear[1] in EXTI.
TCIE of LPUART1_CR1 = ‘1’	Enables interrupt when the transmit buffer is empty.

7.3.3 Overall description of the low-power application example based on LPUART1 transmission



After a Power-on reset, the CPU perform the following operations:

1. Boot sequence (not described here).
2. Full initialization of RCC, PWR, EXTI, LPUART1, GPIOs, LPTIM2, DMAMUX2, BDMA2 and NVIC.
   Only the relevant steps of RCC, EXTI, PWR, LPUART1, BDMA2 and DMAMUX2 initialization related to the Autonomous mode are described herein. Refer to the previous sections for additional details.
3. The CPU processes the data to be transferred and copies them to SRD SRAM.
4. The CPU generates a wake-up event (EXTI_Event) to maintain SRD in Run mode when CD enters DStop/DStop2.
5. The CPU enables the BDMA2 to start LPUART transmission and goes to CStop mode. As it is allowed to do so, CD domain enters DStop/DStop2 while SRD remains in Run mode. The data stored in SRD SRAM are retained while the CD domain is in DStop/DStop2 mode.
6. As soon as the BDMA2 is enabled, it serves the request from LPUART1 in order to fill its TX-FIFO. In parallel, serial data transmission can start.
7. When the expected amount of data has been transmitted (NDT bits of BDMA_CNDTR0 set to 0), the BDMA2 no longer provides data to the LPUART1. The LPUART1 generates an interrupt when the TX-FIFO and the transmit buffer are empty.
8. This interrupt triggers DMAMUX2 REQ_GEN0, thus activating a data transfer via BDMA2 channel 7 (BDMA_Ch7). This transfer clears LPUART1 TC flag, and the **lpuart1_tx_it** is reset to ‘0’.
9. The end of this transfer triggers a dmamux2_evt7 signal which is used to clear the wake-up request generated by the CPU.
10. As a consequence, the SRD domain (i.e. the system) enters Stop mode and the system clock is gated. LPTIM2 still operates since it uses **ck_lsi** clock.

11. LPTIM2 **lptim2_wkup** interrupt wakes up the system. The device exits from Stop mode with the HSI clock. The CPU must restore the proper clock configuration during the warm re-boot sequence and perform the following tasks:
    a) Acknowledge LPTIM2 wake-up interrupt,
    b) Process the next data block and transfers them to SRD SRAM,
    c) Generate again a wake-up event for SRD domain,
    d) Start the BDMA2.
    e) Go back to CStop mode.

Note: The CPU does not need to initialize BDMA2, DMAMUX2 and LPUART1 again.

Figure 43. Timing diagram of LPUART1 transmission with SRD domain in Autonomous mode

7.3.4 Alternate implementations

More power efficient implementations are also possible. As an example the system clock can be stopped once the data have been transferred to LPUART1 TX-FIFO, instead of remaining activated during the whole transmission as in the example presented above. In this case, the LPUART1 must use ck_hsi or ck_csi as kernel clock when the system switches from Run to Stop mode. LPUART1 must be programmed to wake up SRD domain when its TX-FIFO in almost empty. This asynchronous interrupt can be used as trigger by the REQ_GENx of the DMAMUX2, which will perform a given number (e.g. 14) of data transfers to LPUART1_TDR and then switch back the SRD domain to Stop mode. This implementation is possible because the LPUART1 can request the kernel clock as long as the TX-FIFO and transmit buffer are not empty.

Further power consumption reduction during DStop/DStop2 mode can be achieved by shutting off the SRAMs located in the CD domain. Their content is then lost (see *Section 6: Power control (PWR)* for more details).

7.4 Other low-power applications

Other peripherals located in SRD domain, such as I2C4, SPI6/I2S6, DFSDM2 or DAC2, can be used to implement low-power applications.

8 Reset and clock control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller.

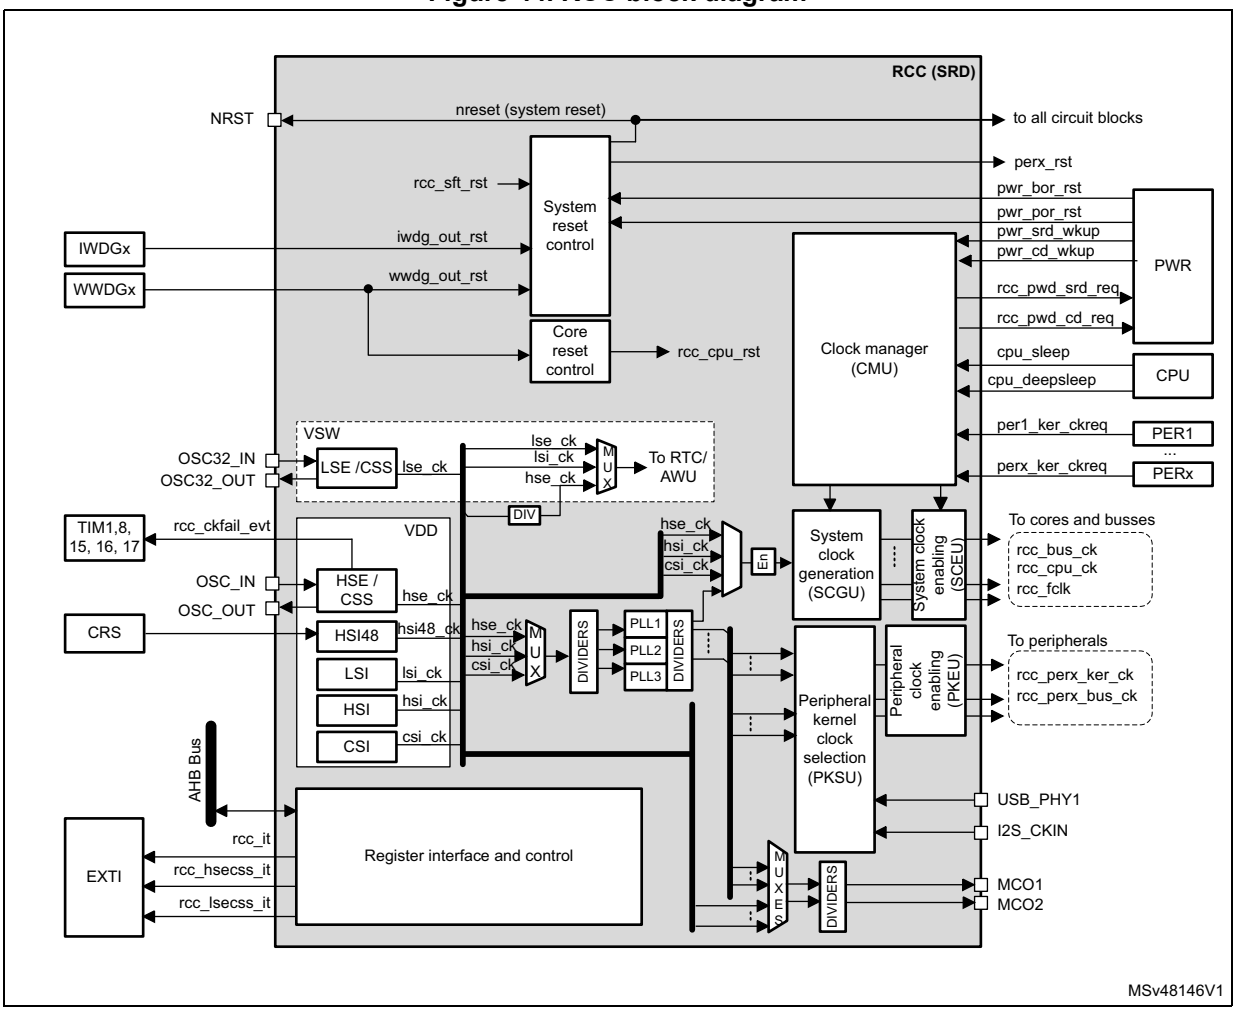
The RCC block is located in the SmartRun domain (refer to *Section 6: Power control (PWR)* for a detailed description).

The operating modes this section refers to are defined in *Section 6.6.1: System operating modes* of the PWR block.

8.1 RCC main features

Reset block

- Generation of local and system reset
- Bidirectional pin reset allowing to reset the microcontroller or external devices
- WWDG and IWDG reset supported
- Power-on (POR) and Brownout (BOR) resets initiated by the power control (PWR)



Clock generation block

- Generation and dispatching of clocks for the complete device
- 3 separate PLLs using integer or fractional ratios
- Possibility to change the PLL fractional ratios on-the-fly
- Smart clock gating to reduce power dissipation
- 2 external oscillators:
  - High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 50 MHz frequency
  - Low-speed external oscillator (LSE) for the 32 kHz crystals
- 4 internal oscillators
  - High-speed internal oscillator (HSI)
  - 48 MHz RC oscillator (HSI48)
  - Low-power internal oscillator (CSI)
  - Low-speed internal oscillator (LSI)
- Buffered clock outputs for external devices
- Generation of two types of interrupts lines:
  - Dedicated interrupt lines for clock security management
  - One general interrupt line for other events
- Clock generation handling in Stop and Standby mode
- SmartRun domain Autonomous mode

8.2 RCC block diagram

Figure 44 shows the RCC block diagram.

Figure 44. RCC block diagram

8.3 RCC pins and internal signals

Table 51 lists the RCC inputs and output signals connected to package pins or balls.

Table 51. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input

Table 51. RCC input/output signals connected to package pins or balls (continued)

Signal name	Signal type	Description
OSC_OUT	O	System oscillator output
MCO1	O	Output clock 1 for external devices
MCO2	O	Output clock 2 for external devices
I2S_CKIN	I	External kernel clock input for digital audio interfaces: SPI/I2S, SAI, and DFSDM
USB_PHY1	I	USB clock input provided by the external USB_PHY

The RCC exchanges a lot of internal signals with all components of the product, for that reason, *Table 52* only shows the most significant internal signals.

Table 52. RCC internal input/output signals

New signal name	Signal type	Description
rcc_it	O	General interrupt request line
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_lsecss_it	O	LSE clock security failure interrupt
rcc_ckfail_evt	O	Event indicating that a HSE clock security failure is detected. This signal is connected to TIMERS.
nreset	I/O	System reset
iwdg_out_rst	I	Reset line driven by the IWDG, indicating that a timeout occurred
wwdg_out_rst	I	Reset line driven by the WWDG, indicating that a timeout occurred
pwr_bor_rst	I	Brownout reset generated by the PWR block
pwr_por_rst	I	Power-on reset generated by the PWR block
pwr_vsw_rst	I	Power-on reset of the VSW domain generated by the PWR block
rcc_perx_rst	O	Reset generated by the RCC for the peripherals
pwr_cd_wkup	I	Wake-up domain request generated by the PWR and used to restore the domain clocks
pwr_srd_wkup	I	Wake-up domain request generated by the PWR and used to restore the domain clocks
rcc_pwd_cd_req	O	Low-power request generated by the RCC and used to set the domain into low-power mode
rcc_pwd_srd_req	O	Low-power request generated by the RCC and used to set the domain into low-power mode
cpu_sleep	I	Signals generated by the CPU, indicating if the CPU is in CRun, CSleep or CStop
cpu_deepsleep	I	
perx_ker_ckreq	I	Signal generated by some peripherals in order to request the activation of their kernel clock
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC, for some peripherals

Table 52. RCC internal input/output signals (continued)

New signal name	Signal type	Description
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals
rcc_bus_ck	O	Clocks for APB, AHB and AXI bridges generated by the RCC
rcc_cpu_ck	O	Clocks for the CPU, generated by the RCC
rcc_fclk_c	O	

8.4 RCC reset block functional description

The following sources can generate a reset:

- an external device via NRST pin
- a failure on the supply voltage applied to VDD
- a watchdog timeout
- a software command

The reset scope depends on the source that generates the reset.

Three reset categories exist:

- power-on/off reset
- system reset
- local resets

8.4.1 Power-on/off reset

The power-on/off reset (**pwr_por_rst**) is generated by the power controller block (PWR). It is activated when the input voltage (V_{DD}) is below a threshold level. This is the most complete reset since it resets the whole circuit, except the Backup domain.

The power-on/off reset function can be disabled through PDR_ON pin (see *Section 6.5: Power supply supervision*).

Refer to *Table 53: Reset distribution summary* for details.

8.4.2 System reset

A system reset (**nreset)** resets all registers to their default values unless otherwise specified in the register description.

A system reset can be generated from one of the following sources:

- a reset from NRST pin (external reset)
- a reset from the power-on/off reset block (**pwr_por_rst**)
- a reset from the brownout reset block (**pwr_bor_rst**)

  Refer to *Section 6.5.2: Brownout reset (BOR)* for a detailed description of the BOR function.
- a reset from the independent watchdogs (**iwdg_out_rst**)
- a software reset from the Cortex®-M7 core

  It is generated via the SYSRESETREQ signal issued by the Cortex®-M7 core. This signal is also named SFTRESET in this document.
- a reset from the window watchdogs depending on WWDG configuration (**wwdg_out_rst**)
- A reset from the low-power mode security reset, depending on option byte configuration (**lpwr_rst**)

Note: The SYSRESETREQ bit in Cortex®-M7 through the FPU application interrupt and reset control register, must be set to force a software reset on the device. Refer to the Cortex®-M7 with FPU technical reference manual for more details (see http://infocenter.arm.com*).*

As shown in *Figure 45*, some internal sources (such as **pwr_por_rst**, **pwr_bor_rst**, **iwdg_out_rst**) perform a system reset of the circuit, which is also propagated to the NRST pin to reset the connected external devices. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

Note: It is not recommended to let the NRST pin unconnected. When it is not used, connect this pin to ground via a 10 to 100 nF*capacitor (C_R in Figure 45*).

Figure 45. System reset circuit

8.4.3 Local resets

Domain reset

When the system exits from Standby mode, a **stby_rst** reset is applied. The **stby_rst** signal generates a reset of the complete V_{CORE} domain as long the V_{CORE} voltage provided by the internal regulator is not valid.

Table 53 gives a detailed overview of reset sources and scopes.

Table 53. Reset distribution summary

Reset source	Reset name	CPU	CD interconnect	CD peripherals	CD debug	CD WWDG	SRD peripherals	CD IWDG	FLASH	RTC domain	Backup RAM	System supply	NRST pin	Comments
Pin	NRST	x	x	x	-	x	x	x	-	-	-	-	x	– Resets CPU domain and all its peripherals – Resets SmartRun domain peripherals – Resets V_{DD} domain: IWDG, LDO – Debug features, RTC and backup RAM are not reset.
PWR	pwr_bor_rst	x	x	x	-	x	x	x	-	-	-	-	x	– Same as pin reset. The pin is asserted as well.
	pwr_por_rst	x	x	x	x	x	x	x	x	-	-	x	x	– Same as **pwr_bor_rst** reset, plus: Reset of the flash memory digital block (including the option byte loading). Reset of the debug block
	lpwr_rst	x	x	x	-	x	x	x	-	-	-	-	x	– The low-power mode security reset has the same scope than **pwr_por_rst.** Refer to *Section 8.4.5: Low-power mode security reset (lpwr_rst)* for additional information.
RCC	VSWRST	-	-	-	-	-	-	-	-	x	-	-	-	– The Backup domain reset can be triggered by software. Refer to *Section 8.4.6: Backup domain reset* for additional information
	stby_rst	x	x	x	x	x	x	-	-	-	-	-	-	– When the device exits Standby mode, a reset of the complete V_{CORE} domain is performed as long the V_{CORE} voltage is not valid. The V_{CORE} is supplied by the internal regulator. NRST signal is not asserted.
CPU	SFTRESET	x	x	x	-	x	x	x	-	-	-	-	x	– This reset is generated by software when writing SYSRESETREQ bit located into AIRCR register of the Cortex®-M7 core. – Same scope as **pwr_bor_rst** reset
Backup domain	pwr_vsw_rst	-	-	-	-	-	-	-	-	x	-	-	-	– This reset is generated by the Backup domain when the V_{SW} supply voltage is outside the operating range.
IWDG	iwdg_out_rst	x	x	x	-	x	x	x	-	-	-	-	x	– Same as **pwr_bor_rst** reset
WWDG	wwdg_out_rst	x	x	x	-	x	x	x	-	-	-	-	x	– Same as **pwr_bor_rst** reset

8.4.4 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC_RSR register.

The CPU can reset the flags by setting RMVF bit.

Table 54 shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs (line #6), if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 54. Reset source identification (RCC_RSR)(1)

#	Situations generating a reset	LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	CDRSTF
1	Power-on reset (pwr_por_rst)	0	0	0	0	1	1	1	1
2	Pin reset (NRST)	0	0	0	0	0	1	0	0
3	Brownout reset (pwr_bor_rst)	0	0	0	0	0	1	1	0
4	System reset generated by CPU (SFTRESET)	0	0	0	1	0	1	0	0
5	WWDG reset (wwdg_out_rst)	0	1	0	0	0	1	0	0
6	IWDG reset (iwdg_out_rst)	0	0	1	0	0	1	0	0
7	CPU domain exits DStop mode and pin reset during DStop	0	0	0	0	0	1	0	0
8	CPU domain exits DStop2 mode and pin reset during DStop2	0	0	0	0	0	1	0	1
9	CPU erroneously enters CStop mode	1	0	0	0	0	1	0	0

1. Grayed cells highlight the register bits that are set.

8.4.5 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST_STOP_CD and nRST_STANDBY option bytes, a system reset is generated if the following conditions are met:

- The CPU domain (CD) accidentally enters Dstop or Dstop2 mode.
  This type of reset is enabled by resetting nRST_STOP_CD user option byte. In this case, whenever the Dstop or Dstop2 mode entry sequence is successfully executed, a system reset is generated.
- CPU and system accidentally enter Standby mode.
  This type of reset is enabled by resetting nRST_Standby user option byte. In this case, whenever a Standby mode entry sequence is successfully executed, a system reset is generated.
  When the Standby mode is entered, a flag is also set in the power controller.

LPWRRSTF bit in the *RCC reset status register (RCC_RSR)* indicates that a low-power mode security reset occurred (see line #9 in *Table 54*).

lpwr_rst is activated when a low-power mode security reset due to CPU occurred.

Refer to *Section 4.4: FLASH option bytes* for additional information.

Refer to *Section 6: Power control (PWR)* for additional information and *Table 35: Operating mode summary* for the overview of the existing power modes

8.4.6 Backup domain reset

A Backup domain reset is generated when one of the following events occurs:

- A software reset, triggered by setting VSWRST bit in the *RCC Backup domain control register (RCC_BDCR)*. All RTC registers and the RCC_BDCR register are reset to their default values. The backup RAM is not affected.
- V_{SW} voltage is outside the operating range. All RTC registers and the RCC_BDCR register are reset to their default values. In this case the content of the backup RAM is no longer valid.

There are two ways to reset the backup RAM:

- through the flash memory interface by requesting a protection level change from 1 to 0
- when a tamper event occurs

Refer to *Section 6.4.5: Backup domain* section of PWR block for additional information.

8.4.7 Power-on and wake-up sequences

For detailed diagrams refer to *Section 6.4.1: System supply startup* in the PWR section.

The time interval between the event that exits the product from a low-power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. *Figure 46* shows the most usual examples.

Power-on wake-up sequence

The power-on wake-up sequence shown in *Figure 46* gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever V_{BAT} was present or not.

Boot from pin reset

When a pin reset occurs, V_{DD} is still present. As a result:

- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The flash memory power recovery delay can also be skipped if the flash memory was enabled when the NRST occurred.

Note: The boot sequence is similar for pwr_bor_rst, lpwr_rst, STFxRESET, iwdg_out_rst and wwdg_out_rst.

Boot from system Standby

When waking up from system Standby, the reference voltage is stable since V_{DD} has not been removed. As a result, the regulator settling time is fast. Since V_{CORE} was not present, the restart delay for the HSI, the flash memory power recovery and the option byte reloading cannot be skipped.

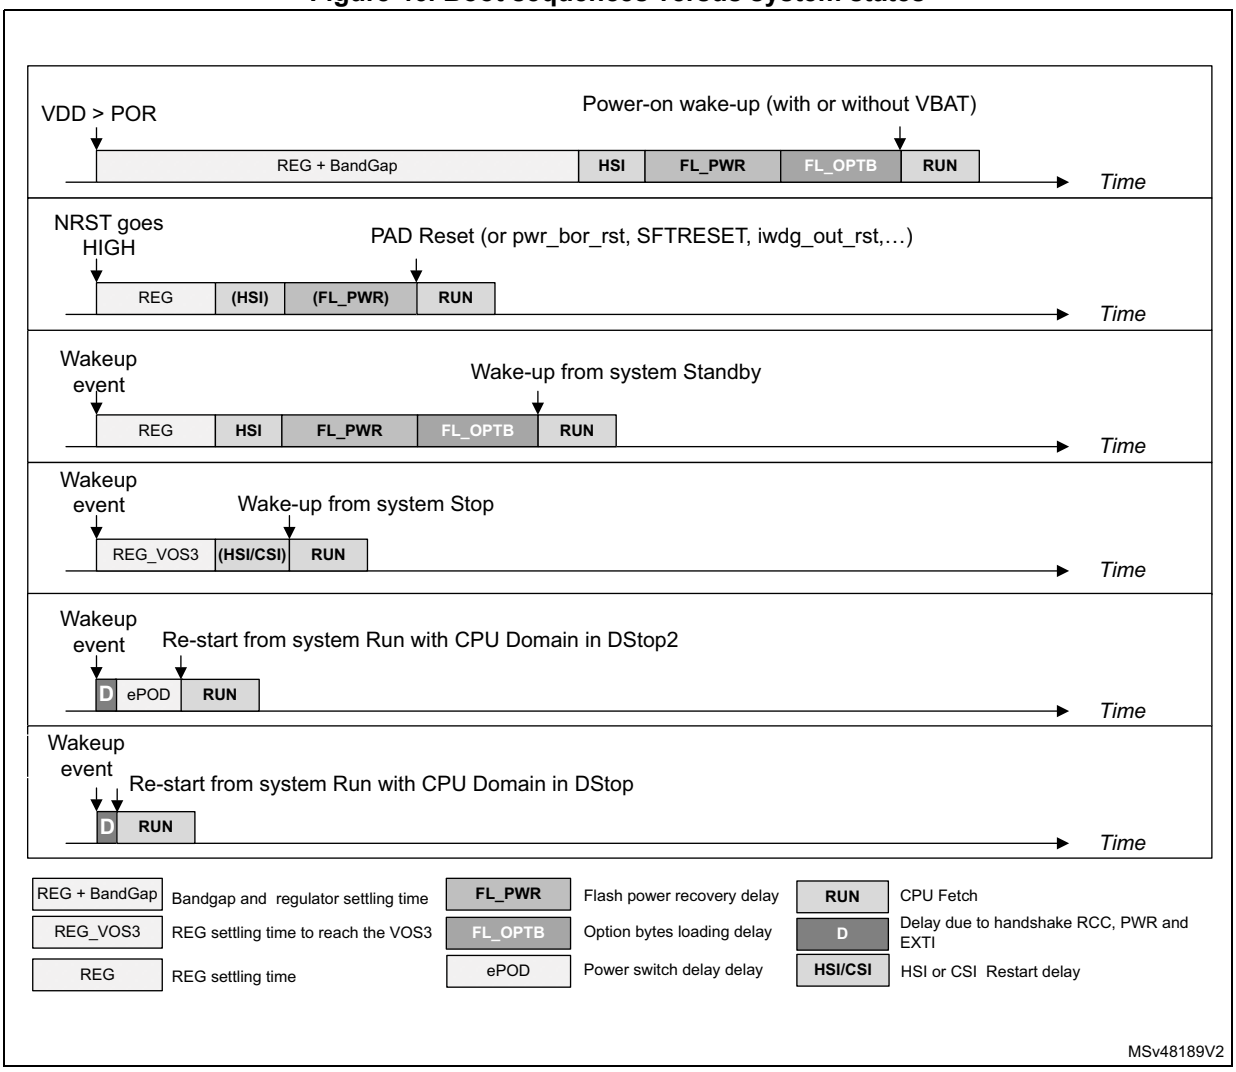
Restart from system Stop

When restarting from system Stop (CPU domain can be in DStop or DStop2), V_{DD} is still present. As a result, the sequence is mainly composed of three steps:

1. Regulator settling time to reach VOS3 (default voltage).
2. Power switch (ePOD) settling time to change from Retention mode to Normal mode in case of DStop2.
3. HSI/CSI restart delay. This step can be skipped if HSIKERON or CSIKERON bit is set to 1 in the *RCC source control register (RCC_CR)*.

Restart from system Autonomous mode with CPU domain in DStop/DStop2

Since the SRD domain is in Run mode, the regulator is already activated.



The restart sequence of the CPU domain in DStop or Dstop2 mode is mainly composed of two steps:

1. Handshake between RCC, EXTI and PWR blocks.
2. The power-switch (ePOD) settling time to change from retention mode to normal mode in case of DStop2.

Restart from domain DStop

The restart sequence of a domain from DStop is mainly composed of the handshake between the RCC, EXTI and PWR blocks.

Figure 46. Boot sequences versus system states

8.5 RCC clock block functional description

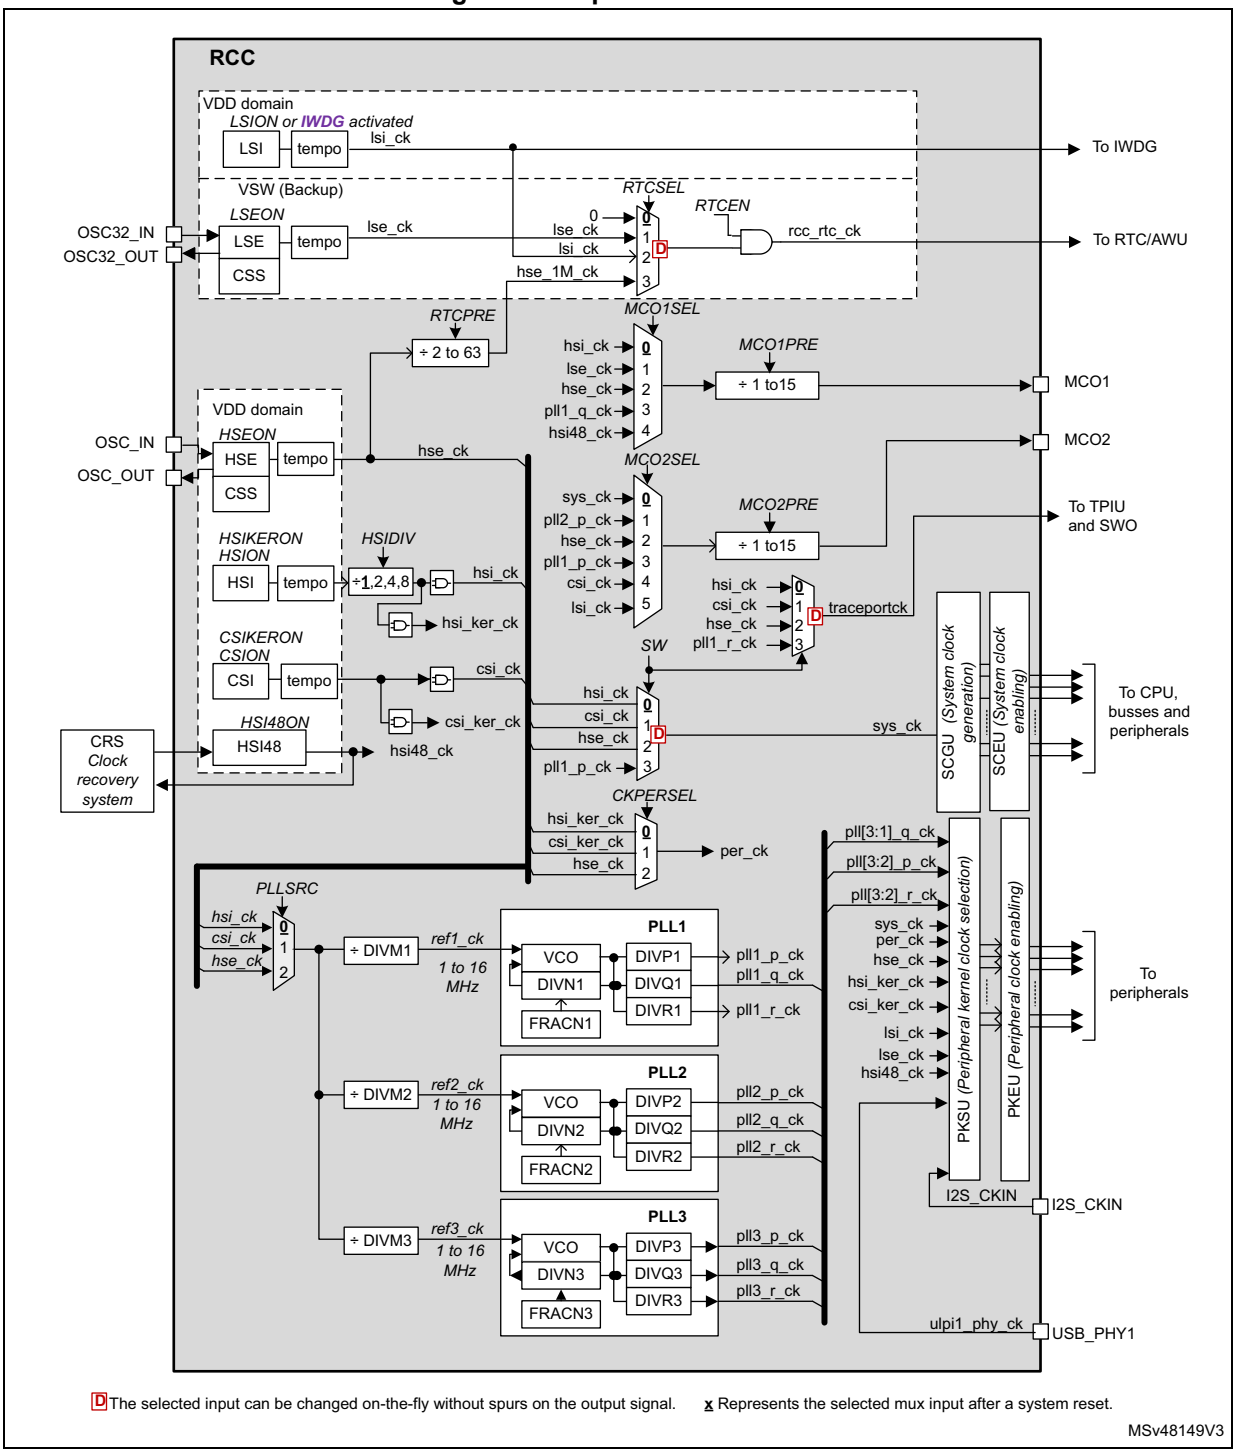
The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (high-speed external oscillator) clock: 4 to 48 MHz
- LSE (low-speed external oscillator) clock: 32 kHz
- LSI (low-speed internal oscillator) clock: ~ 32 kHz
- CSI (low-power internal oscillator) clock: ~4 MHz
- HSI48 (high-speed internal oscillator) clock: ~48 MHz

The RCC offers then a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as USB OTG-FS and HS, SPI/I2S, SAI and SDMMC.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured with integer or fractional ratios.



As shown in the *Figure 47*, the RCC offers two clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

The SCGU block (system clock generation unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (peripheral kernel clock selection unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (peripheral kernel clock enable unit) and SCEU (system clock enable unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.

Figure 47. Top-level clock tree

8.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- **Peripheral clocks**

  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:

  – bus interface clocks

  – kernel clocks

  A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (such as RNG, TIMx).

  Some peripherals also require a dedicated clock to handle the interface function. This clock is named kernel clock. As an example, peripherals such as SAI must generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **CPU clock**

  The CPU clock is the clock provided to the CPU. It is derived from the system clock (**sys_ck**).

- **Bus matrix clocks**

  The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (**sys_ck**).

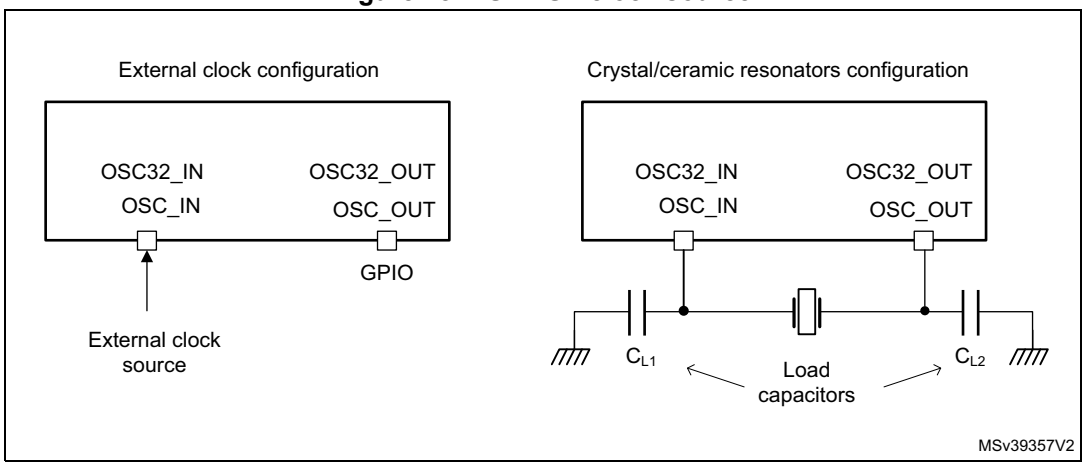
8.5.2 Oscillators description

HSE oscillator

The HSE block can generate a clock from two possible sources:

- external crystal/ceramic resonator
- external clock source

Figure 48. HSE/LSE clock source



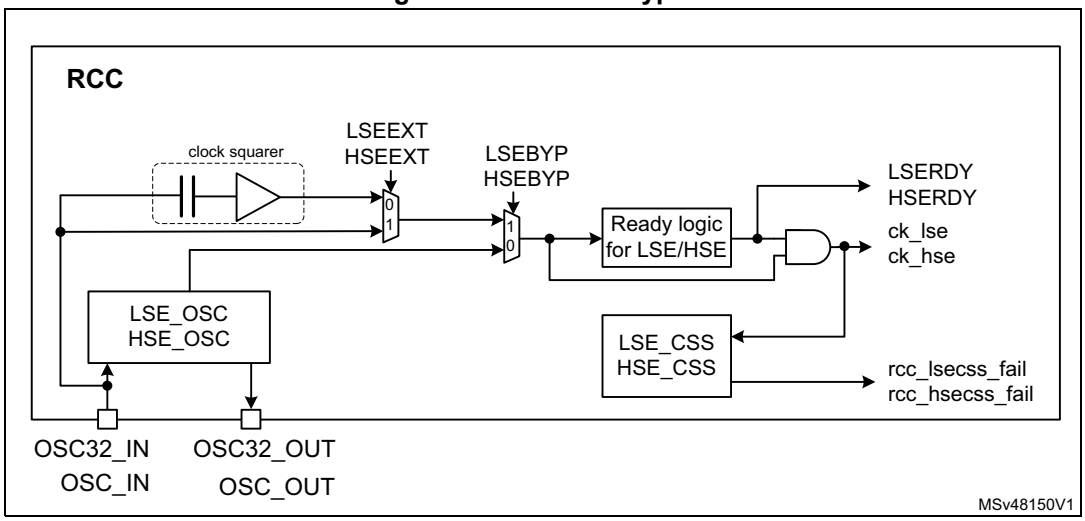


Figure 49. HSE/LSE bypass

External clock source (HSE bypass)

In this mode, an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital.

If this clock is directly used by a peripheral, the duty cycle requirement is defined by this peripheral and the application (refer to datasheet for more details)

This external clock is provided to the OSC_IN pin while the OSC_OUT pin must be left HI-Z (see *Figure 48*).

In case of an analog clock (low swing) the HSEBYP and HSEON bits must be set to 1 in the *RCC source control register (RCC_CR)*.

In case of a digital clock, the HSEBYP and the HSEEXT bits must be set to 1 followed by setting the HSEON bit to 1 in the *RCC source control register (RCC_CR)*.

External crystal/ceramic resonator

The oscillator is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

The HSE can be used when the product requires a very accurate high-speed clock.

The associated hardware configuration is shown in *Figure 48*: the resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag of the *RCC source control register (RCC_CR)* indicates whether the HSE oscillator is stable or not. At startup, the **hse_ck** clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

The HSE can be switched ON and OFF through the HSEON bit. Note that the HSE cannot be switched OFF if one of the two conditions is met:

- The HSE is used directly (via software mux) as system clock.
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSEON bit to 0.

The HSE is automatically disabled by hardware, when the system enters Stop or Standby mode (refer to *Section 8.5.7: Handling clock generators in Stop and Standby modes* for additional information).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

LSE oscillator

The LSE block can generate a clock from two possible sources:

- external crystal/ceramic resonator
- external user clock

External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32_IN pin. The input clock can have a frequency up to 1 MHz and be low swing (analog) or digital. A duty cycle close to 50% is recommended.

This external clock is provided to the OSC32_IN pin while the OSC32_OUT pin must be left HI-Z (see *Figure 48*).

In case of an analog clock (low swing) the LSEBYP and HSEON bits must be set to 1 (*RCC Backup domain control register (RCC_BDCR)*).

In case of a digital clock the LSEBYP and the LSEEXT bits must be set to 1 followed by setting the LSEON bit to 1 (*RCC Backup domain control register (RCC_BDCR)*)

If the RTC is used, the LSE bypass must not be configured in digital mode but in low swing analog mode (default value after reset)

External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions.

The LSERDY flag of the *RCC Backup domain control register (RCC_BDCR)* indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

The LSE oscillator is switched ON and OFF using the LSEON bit. The LSE remains enabled when the system enters Stop or Standby mode.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for other application components.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to insure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

HSI oscillator

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The HSI can be switched ON and OFF using the HSION bit. Note that the HSI cannot be switched OFF if one of the two conditions is met:

- The HSI is used directly (via software mux) as system clock.
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSION bit to 0.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *CSS on HSE on page 354*). The HSI can be disabled or not when the system enters Stop mode. Refer to *Section 8.5.7: Handling clock generators in Stop and Standby modes* for additional information.

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

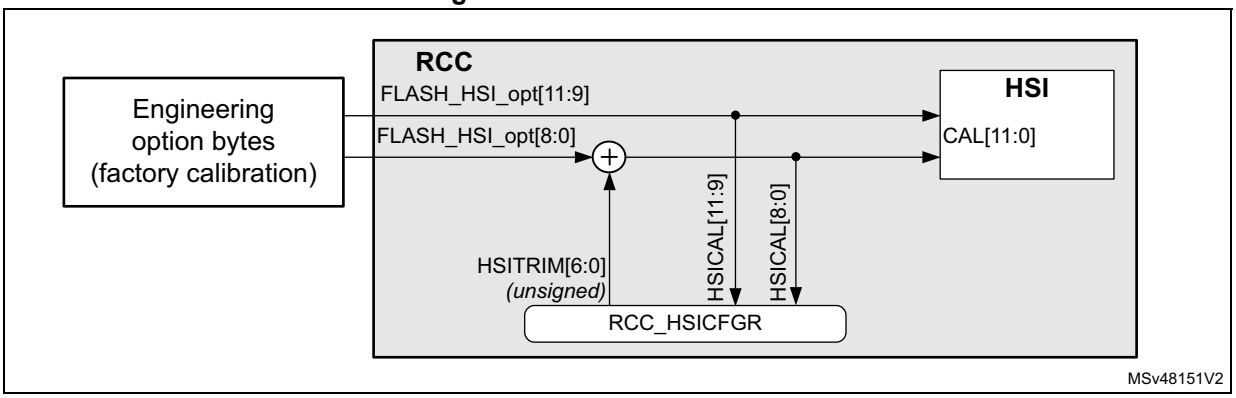
Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

Note: The HSI can remain enabled when the system is in Stop mode (see Section 8.5.7: Handling clock generators in Stop and Standby modes for additional information).

HSION, HSIRDY and HSIDIV bits are located in the RCC source control register (RCC_CR).

HSI calibration



RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI} (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded in the HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

Note: HSICAL[11:0] and HSITRIM[6:0] bits are located in the RCC CSI calibration register (RCC_CSICFGR).

Figure 50. HSI calibration flow

CSI oscillator

The CSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)
- very low-power consumption,

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The CSI cannot be switched OFF if one of the two conditions is met:

- The CSI is used directly (via software mux) as system clock.
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the CSION bit to 0.

The CSI can be disabled or not when the system enters Stop mode (refer to *Section 8.5.7: Handling clock generators in Stop and Standby modes* for additional information).

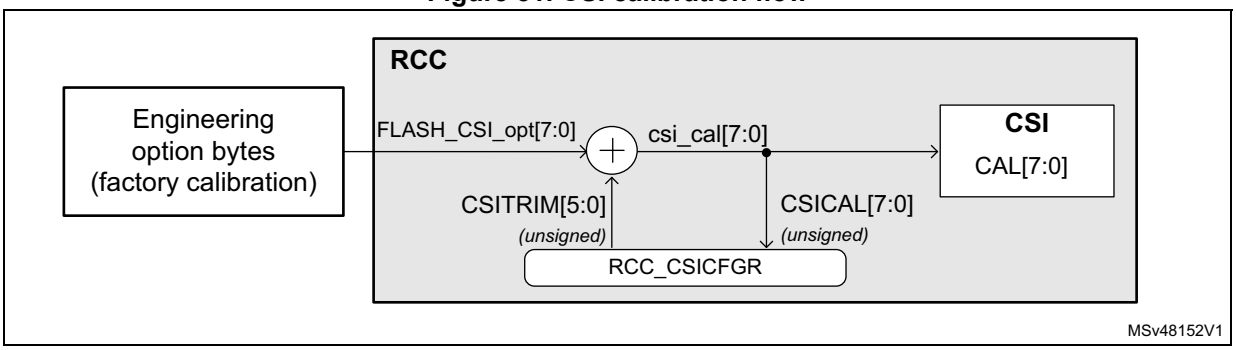
In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

Note: CSION and CSIRDY bits are located in the RCC source control register (RCC_CR).

CSI calibration



RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve accuracy of ACC_{CSI} (refer to the product datasheet for more information).

After reset, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[5:0] bits.

Note: Bits CSICAL[7:0] and CSITRIM[5:0] are located into the RCC CSI calibration register (RCC_CSICFGR)

Figure 51. CSI calibration flow

HSI48 oscillator

The HSI48 is an RC oscillator delivering a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry, that can use the USB SOF signal, the LSE or an external signal to automatically adjust the oscillator frequency on-the-fly, with a very small granularity.

The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free running and thus subject to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI48} (refer to the product datasheet for more information).

For more details on how to configure and use the CRS, refer to *Section 9: Clock recovery system (CRS)*).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by hardware.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

Note: HSI48ON and HSI48RDY bits are located in the RCC source control register (RCC_CR).

LSI oscillator

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wake-up unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (refer to *Section 8.5.7: Handling clock generators in Stop and Standby modes* for additional information).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY bits are located into the RCC clock control and status register (RCC_CSR).

8.5.3 Clock security system (CSS)

CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to 0.

The CSS on HSE is enabled by the hardware when the HSE is enabled and ready, and HSECSSON set to 1.

The CSS on HSE is disabled when the HSE is disabled. As a result, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software.

The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see *Section 8.4.2: System reset*).

If a failure is detected on the HSE clock, the system automatically switches to the HSI in order to provide a safe clock. The HSE is then automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers (TIM1, TIM8, TIM15, TIM16, and TIM17), and an interrupt is generated to inform the software about the failure (CSS interrupt: ***rcc_hsecss_it***), thus allowing the MCU to perform rescue operations. If the HSE output was used as clock source for PLLs when the failure occurred, the PLLs are also disabled.

If an HSE clock failure occurs when the CSS is enabled, the CSS generates an interrupt that causes the automatic generation of an NMI. The HSECSSF flag in *RCC clock source interrupt flag register (RCC_CIFR)* is set to 1 to allow the application to identify the failure

source. The NMI routine is executed indefinitely until the HSECSSF bit is cleared. As a consequence, the application must clear the HSECSSF flag in the NMI ISR by setting the HSECSSC bit in the *RCC clock source interrupt clear register (RCC_CICR)*.

CSS on LSE

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the *RCC Backup domain control register (RCC_BDCR)*.

This bit can be disabled only by hardware one of the following conditions is met:

- after a pwr_vsw_rst (V_{SW} software reset)
- after a failure detection on LSE.

The LSECSSON bit must be written after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

The CSS on LSE works in all modes (Run, Stop and Standby) except VBAT.

If an LSE failure is detected, the LSE clock is no more delivered to the RTC but the values of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.

A wake-up is generated in Standby mode. In other modes an interrupt (**rcc_lsecss_it**) can be sent to wake up the software. The software must then disable the LSECSSON bit, stop the defective LSE (clear LSEON bit) and can change the RTC clock source (no clock or LSI or HSE) through RTCSEL bits, or take any required action to secure the application.

8.5.4 Clock output generation (MCO1/MCO2)

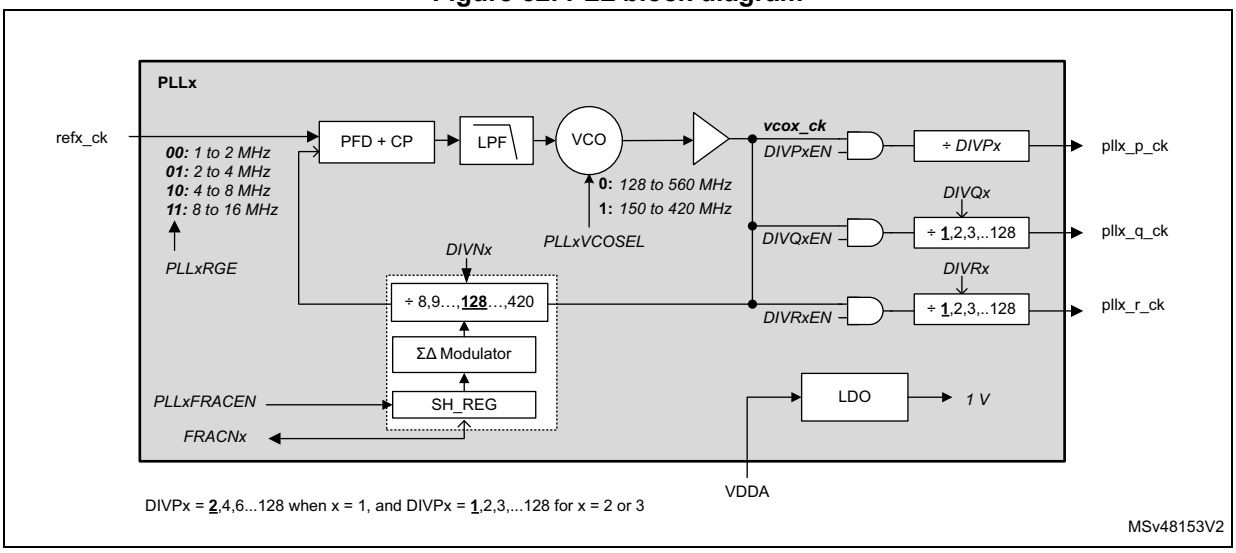
Two microcontroller clock output pins (MCO), MCO1 and MCO2, are available. A clock source can be selected for each output.The selected clock can be divided thanks to configurable prescaler (refer to *Figure 47* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0] and MCO2[2:0] located in the *RCC clock configuration register (RCC_CFGR)*.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the product datasheet for information on the supported pin speed).

8.5.5 PLL description



The RCC features three PLLs:

- a main PLL, PLL1, generally used to provide clocks to the CPU and some peripherals
- two dedicated PLLs, PLL2 and PLL3, used to generate the kernel clock for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

- A VCO supporting two modes:
  - A wide-range
  - A low-range used for instance in audio application cases
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- Capability to work either in integer or fractional mode
- 13-bit sigma-delta modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs.
- Each PLL offers 3 outputs with post-dividers.

Figure 52. PLL block diagram

The PLLs are controlled via RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLCFGR and RCC_CR registers.

The frequency of the reference clock provided to the PLLs (**refx_ck**) must range from 1 to 16 MHz. The DIVMx dividers of the *RCC PLLs clock source selection register (RCC_PLLCKSELR)* must be properly programmed in order to match this condition. In addition, the PLLxRGE[1:0] field of the *RCC PLLs configuration register (RCC_PLLCFGR)* must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO. The smaller range (150-420 MHz) must be chosen when the reference clock frequency is lower to 2 MHz.

To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.

DIVNx loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operate in integer mode when the value of SH_REG bit of the FRACNx shadow register is set to 0. The SH_REG bit is updated with the FRACNx value when PLLxFRACEN bit goes from 0 to 1. The sigma-delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON to 1. The PLLxRDY bits indicate that the PLL is ready (means locked).

*Note: Before enabling the PLLs, make sure that the reference frequency (**refx_ck**) provided to the PLL is stable, so the hardware does not allow changing DIVMx when the PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.*

The hardware prevents writing PLL1ON to 0 if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to HSE oscillator on page 348, HSI oscillator on page 351 and CSI oscillator on page 352).
The following PLL parameters cannot be changed once the PLL is enabled: DIVNx, PLLxRGE, PLLxVCOSEL, DIVPx, DIVQx, DIVRx, DIVPxEN, DIVQxEN and DIVRxEN.

To insure an optimal behavior of the PLL when one of the post-divider (DIVP, DIVQ or DIVR) is not used, the application must set the enable bit (DIVyEN) as well as the corresponding post-divider bits (DIVP, DIVQ or DIVR) to 0.

If the above rules are not respected, the PLL output frequency is not guaranteed.

Output frequency computation

When the PLL is configured in integer mode (SH_REG = 0), the VCO frequency (F_{VCO}) is given by the following expression:

$$F_{VCO} = F_{REF_CK} \times DIVN$$

$$F_{PLL_y_CK} = (F_{VCO} / (DIVy + 1)) \text{ with y = P, Q or R}$$

When the PLL is configured in fractional mode (SH_REG different from 0), the DIVN divider must be initialized before enabling the PLLs. However, it is possible to change the value of FRACNx on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy or to fine-tune the frequency on-the-fly.

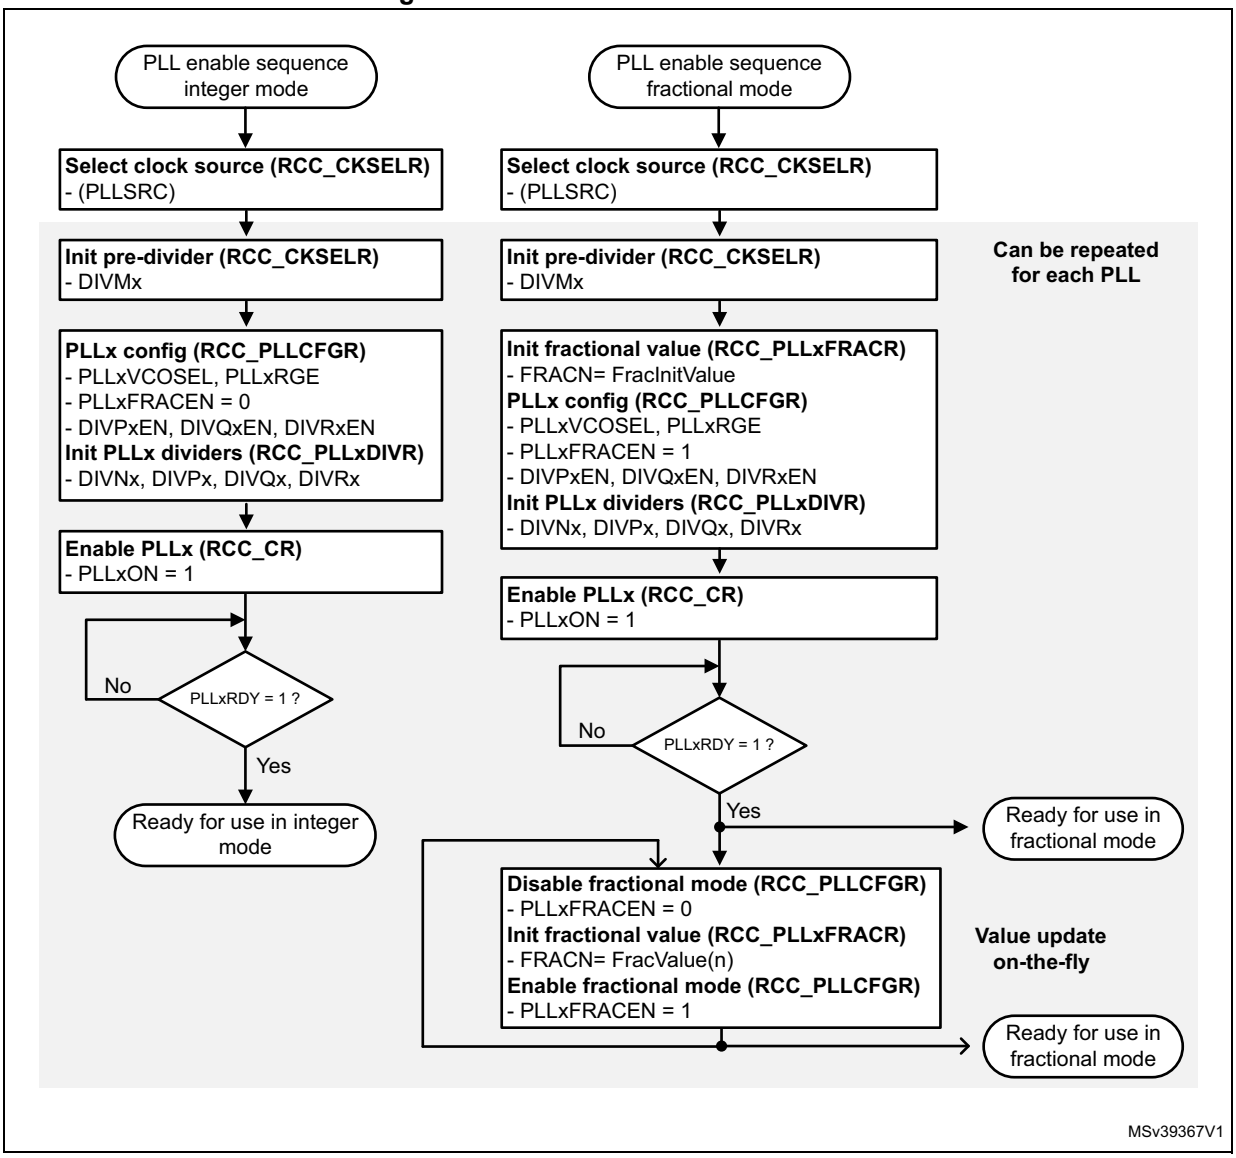
For each PLL, the VCO frequency is given by the following formula:

$$F_{VCO} = F_{ref_ck} \times \left(DIVN + \frac{FRACN}{2^{(13)}} \right)$$

Note: For PLL1, DIVP can only take odd values.

The PLLs are disabled by hardware when:

- the system enters Stop or Standby mode
- an HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock



PLL initialization phase

Figure 53 shows the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLLs registers according to the required frequency.
   - Set PLLxFRACEN of *RCC PLLs configuration register (RCC_PLLCFGR)* to 0 for integer mode.
   - For fractional mode, set FRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to 1.
2. Once the PLLxON bit is set to 1, the user application must wait until PLLxRDY bit is set to 1. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be set back to 0 as long as PLLxRDY = 0.
3. Once the PLLxRDY bit is set to 1, the PLLx is ready to be used.
4. If the application intends to tune the PLLx frequency on-the-fly (possible only in fractional mode), then:
   a) PLLxFRACEN must be set to 0. When PLLxFRACEN = 0, the sigma-eelta modulator is still operating with the value latched into SH_REG.
   b) A new value must be uploaded into PLLxFRACR (FracValue(n)).
   c) PLLxFRACEN must be set to 1, in order to latch the content of PLLxFRACR into its shadow register.

Note: When the PLLxRDY goes to 1, it means that the difference between the PLLx output frequency and the target value is lower than ±2%.

Figure 53. PLLs Initialization flowchart

8.5.6 System clock (sys_ck)

System clock selection

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the system enters Stop or Standby mode.

When the system is running, the user application can select the system clock (**sys_ck**) among the 4 following sources:

- HSE
- HSI
- CSI
- pll1_p_ck

This function is controlled by programming the *RCC clock configuration register (RCC_CFGR)*. A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the *RCC clock configuration register (RCC_CFGR)* indicate which clock is currently used as system clock. The other status bits in the RCC_CR register indicate which clock(s) is (are) ready.

System clock generation

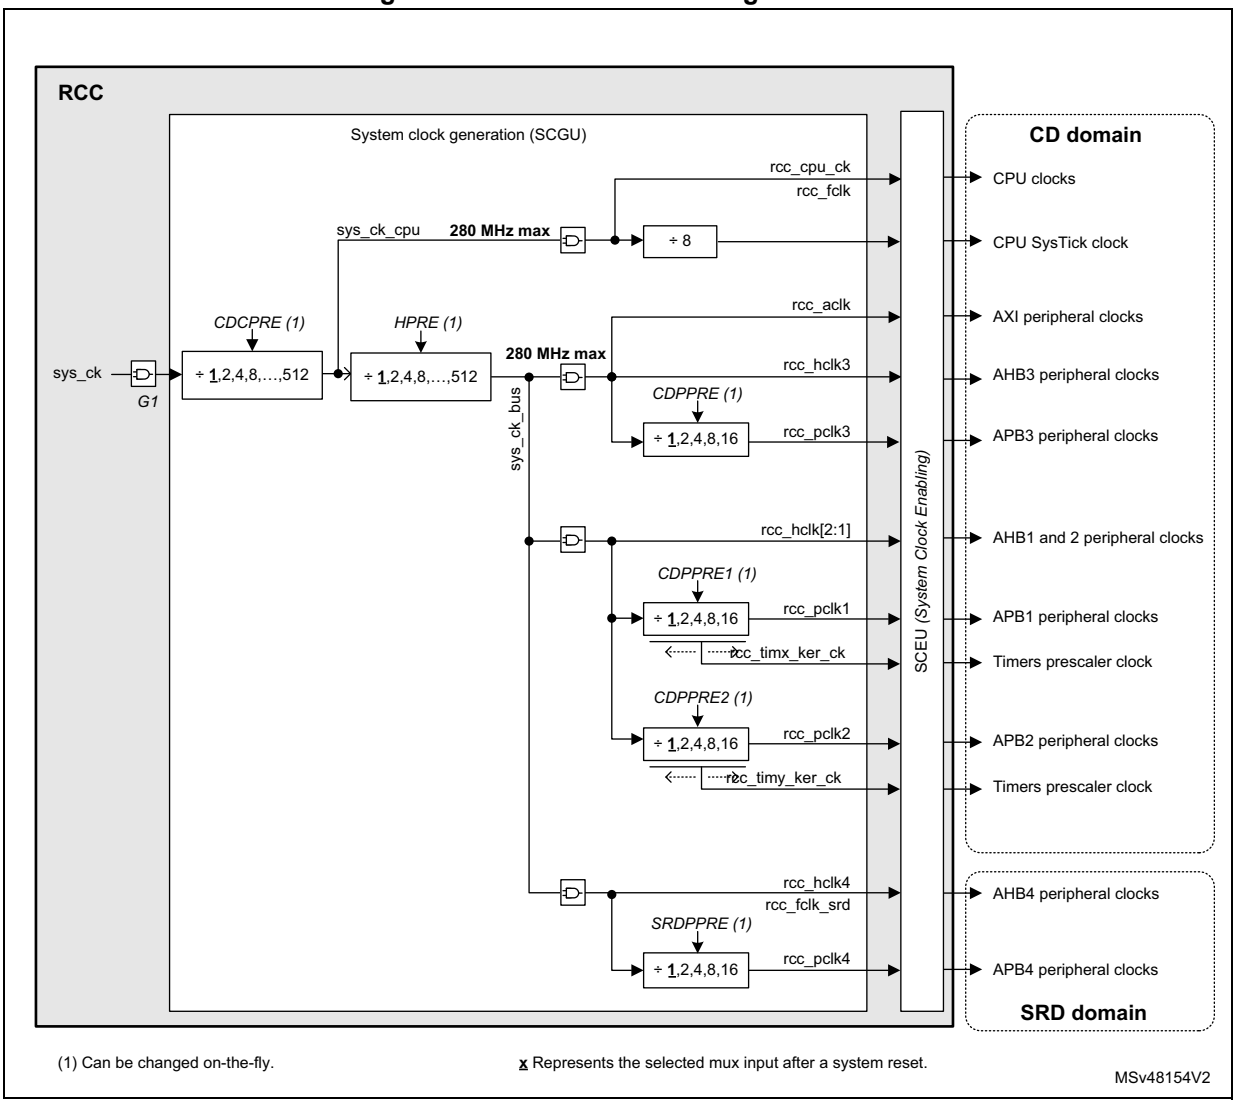


Figure 54 shows a simplified view of the clock distribution for the CPU and busses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simple solution to adapt the busses frequencies to the application needs, thus optimizing the power consumption.

The CDCPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix.

In the same way, HPRE divider can be used to adjust the clock for the CPU domain bus matrix, but this also impacts the clock frequency of bus matrix of SmartRun domain.

Most of the prescalers are controlled via RCC_CDCFGR and RCC_SRDCFGR registers.

Figure 54. Core and bus clock generation

This block also provides the clock for the timers (**rcc_timx_ker_ck** and **rcc_timy_ker_ck**). The frequency of the timers clock depends on the APB prescaler corresponding to the bus to which the timer is connected, and on TIMPRE bit.

Table 55 shows how to select the timer clock frequency.

Table 55. Ratio between clock timer and pclk

CDPPRE1(1) CDPPRE2	TIMPRE (2)	-	$F_{rcc_timx_ker_ck}$ $F_{rcc_timy_ker_ck}$	F_{rcc_pclk1} F_{rcc_pclk2}	Comments
0xx	0	→	F_{rcc_hclk1}	F_{rcc_hclk1}	The timer clock is equal to the bus clock.
100	0	→	F_{rcc_hclk1}	F_{rcc_hclk1} / 2	The timer clock is twice as fast as the bus clock.
101	0	→	F_{rcc_hclk1} / 2	F_{rcc_hclk1} / 4	
110	0	→	F_{rcc_hclk1} / 4	F_{rcc_hclk1} / 8	
111	0	→	F_{rcc_hclk1} / 8	F_{rcc_hclk1} / 16	

Table 55. Ratio between clock timer and pclk (continued)

CDPPRE1[1] CDPPRE2	TIMPRE [2]	-	$F_{rcc_timx_ker_ck}$ $F_{rcc_timy_ker_ck}$	F_{rcc_pclk1} F_{rcc_pclk2}	Comments
0xx	1	→	F_{rcc_hclk1}	F_{rcc_hclk1}	The timer clock is equal to the bus clock.
100	1	→	F_{rcc_hclk1}	F_{rcc_hclk1} / 2	The timer clock is twice as fast as the bus clock.
101	1	→	F_{rcc_hclk1}	F_{rcc_hclk1} / 4	The timer clock is 4 times faster than the bus clock.
110	1	→	F_{rcc_hclk1} / 2	F_{rcc_hclk1} / 8	
111	1	→	F_{rcc_hclk1} / 4	F_{rcc_hclk1} / 16	

1. CDPPRE1 and CDPPRE2 belong to *RCC CPU domain clock configuration register 2 (RCC_CDCFGR2)*.
2. TIMPRE belongs to *RCC clock configuration register (RCC_CFGR)*.

8.5.7 Handling clock generators in Stop and Standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped as well as the following clock sources:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HSI48

The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HSI48ON that are set to 0.

Exiting Stop mode

When the microcontroller exits system Stop mode via a wake-up event, the application can select which oscillator (HSI and/or CSI) is used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop, a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the *RCC clock configuration register (RCC_CFGR)*.

Table 56 gives a detailed description of their behavior.

Table 56. STOPWUCK and STOPKERWUCK description

STOPWUCK	STOPKERWUCK	-	Activated oscillator when system exits Stop mode	Distributed clocks when system exits Stop mode	
				System clock	Kernel clock
0	0	→	HSI	HSI	HSI
	1	→	HSI and CSI		HSI and/or CSI
1	0	→		CSI	
	1	→	CSI		CSI

During Stop mode

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- when a dedicated peripheral requests the kernel clock
  The peripheral receives the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- when the HSIKERON or CSIKERON bits are set
  The HSI and CSI are kept running during Stop mode but the outputs are gated. The clock is then available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see *Table 57* for details).

HSIKERON and CSIKERON bits belong to *RCC source control register (RCC_CR)*. *Table 57* gives a detailed description of their behavior.

Table 57. HSIKERON and CSIKERON behavior

HSIKERON (CSIKERON)	-	HSI (CSI) state during Stop mode	HSI (CSI) setting time
0	→	OFF	$t_{su(HSI)}$ ($t_{su(CSI)}$) (1)
1	→	Running and gated	Immediate

1. $t_{su(HSI)}$ and $t_{su(CSI)}$ are the startup times of the HSI and CSI oscillators (refer to the product datasheet for values of these parameters).

When the microcontroller exists system Standby mode, the HSI is selected as system and kernel clock. The RCC registers are reset to their initial values except for the RCC_RSR and RCC_BDCR registers.

Note that the HSI and CSI outputs provide two clock paths (see *Figure 47*):

- one path for the system clock (**hsi_ck** or **csi_ck**)
- one path for the peripheral kernel clock (**hsi_ker_ck** or **csi_ker_ck**).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the **hsi_ker_ck** or **csi_ker_ck** is activated.

Caution: It is not guaranteed that the CPU gets automatically the same clock frequencies when leaving CStop mode: this mainly depends on the system state. For example If the CPU goes to CStop, while the SmartRun domain is kept in CRun, the clock settings remain unchanged when the CPU exits from CStop. If the SmartRun domain goes to CStop while the CPU is also in CStop, then the CPU operates with HSI or CSI when exiting from CStop mode.

8.5.8 Kernel clock selection

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (**ckg_bus_perx** clock)
- a clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an on-going transfer with UART is not disturbed if its APB clock is changed on-the-fly.

Table 58 shows the kernel clock that the RCC can deliver to the peripherals. Each row of this table represents a mux and the peripherals connected to its output. The columns starting from number 4 represents the clock sources. Column 3 gives the maximum allowed frequency at each mux output. It is up to the user to respect these requirements.

Table 58. Kernel clock distribution overview

Peripherals	Clock mux control bits	Domain	Clock sources(1)																			
			pll1_q_ck	pll2_p_ck	pll2_q_ck	pll2_r_ck	pll3_p_ck	pll3_q_ck	pll3_r_ck	sys_ck	bus clocks(2)	hse_ck	hsi_ker_ck	csi_ker_ck	hsi48_ck	lse_ck	lsi_ck	per_ck (3)	I2S_CKIN	USB_PHY1	spdifrx_symb_ck	Disabled

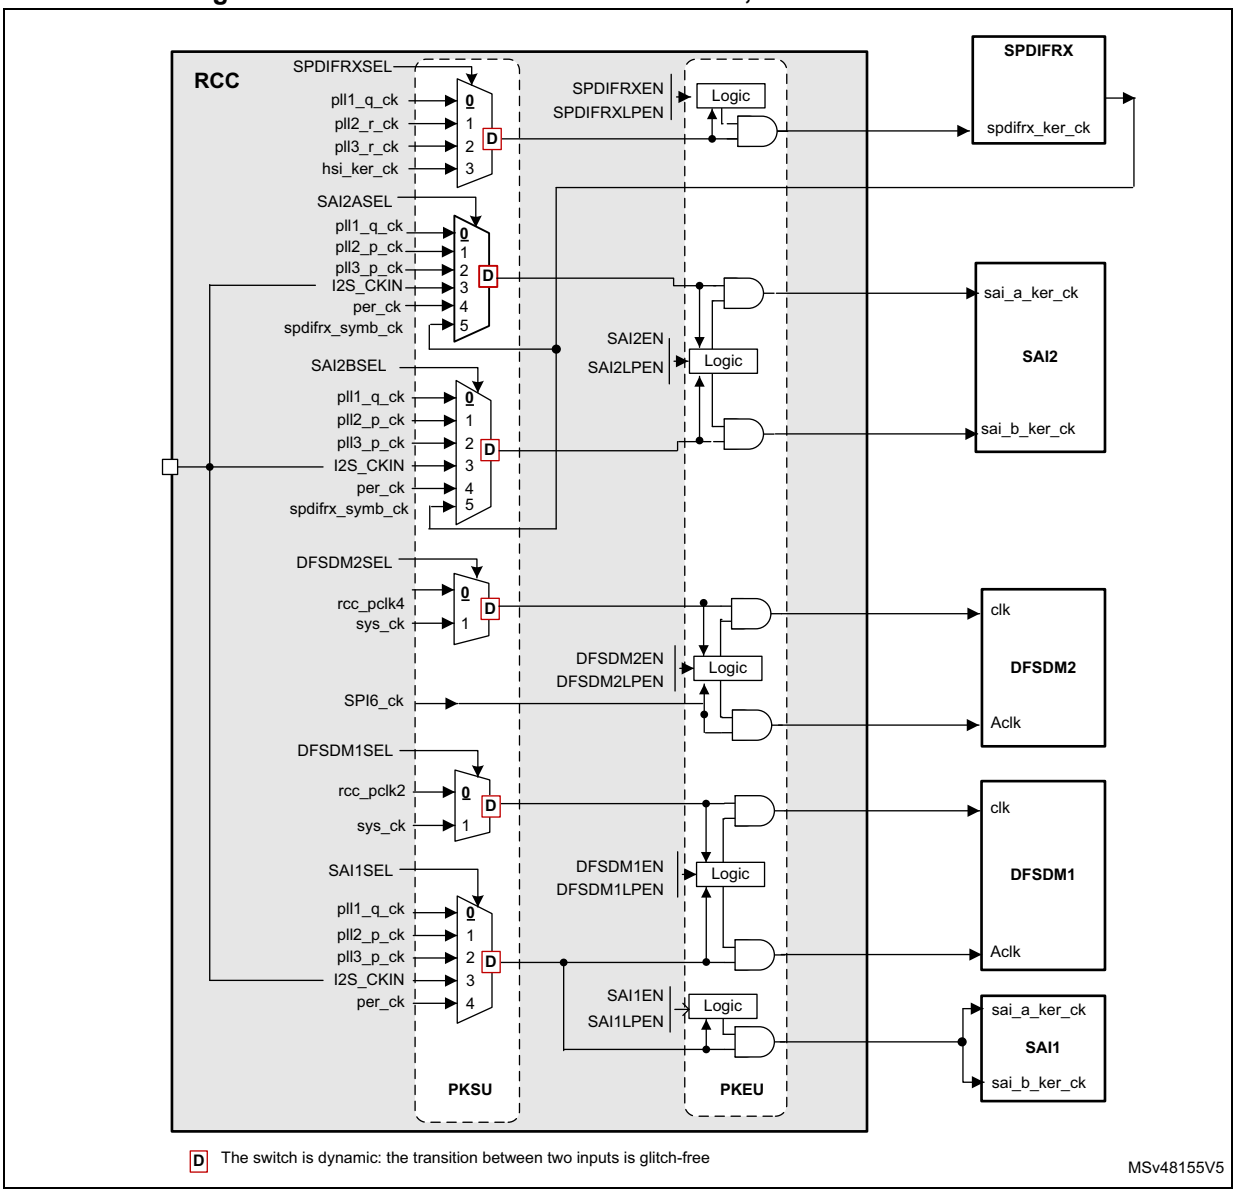
1. **X** represents the selected mux input after a system reset.
2. The bus clocks are the bus interface clocks to which the peripherals are connected. It can be APB, AHB or AXI clocks.
3. The per_ck clock can be hse_ck, hsi_ker_ck or csi_ker_ck according to CKPERSEL selection.
4. Clock CSI divided by 122.
5. The SAI1 max clock frequency can, in some cases, be limited by the constraints on DFSDM1 (see*Figure 55*).
6. With a duty cycle close to 50 %, meaning that DIV[P/Q/R]x values must be even. For SDMMCx, the duty cycle must be 50 % when supporting DDR.
7. The SPI6 maximum clock frequency can, in some cases, be limited by the constraints on DFSDM2 (see *Figure 55* and *Figure 56*).
8. Clock HSE divided by RTCPRE.

Figure 55 to *Figure 63* provide a more detailed description of kernel clock distribution. To simplify the drawings, the bus interface clocks (pclk, hclk) are not represented, even if they are gated with enable signals. Refer to *Section 8.5.11: Peripheral clock gating control* for more details.

To reduce the amount of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

Peripherals dedicated to audio applications

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in *Figure 55* and *Figure 58*, the kernel clock of the SAIs or SPI(I2S)s can be generated by:



- PLL1 when the amount of active PLLs must be reduced (for SAIs and SPI/I2S1 to 3)
- APB2 peripheral clock (for SPI/I2S4 and 5)
- APB4 peripheral clock (for SPI/I2S6)
- PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- I2S_CKIN when an external clock reference needs to be used

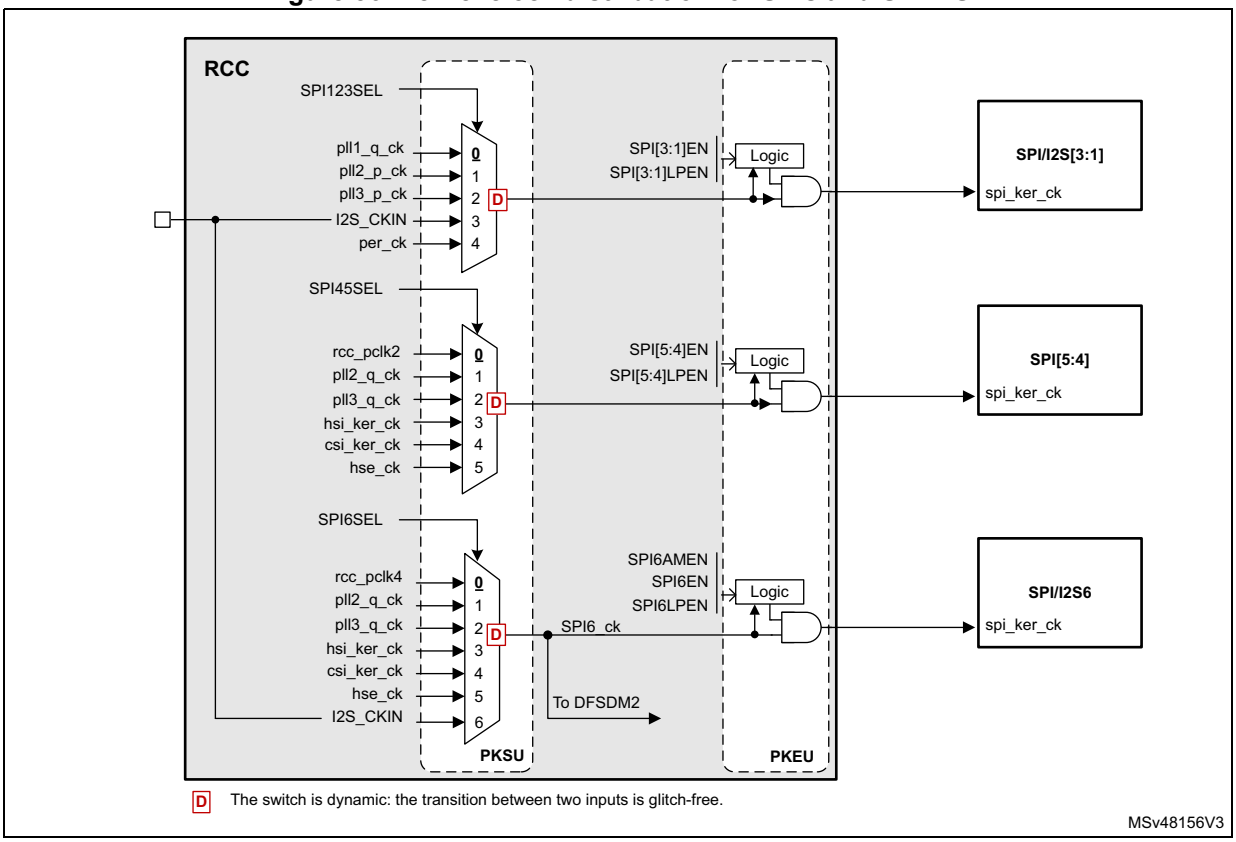
Note: The SPDIFRX does not require a specific frequency but only a kernel clock frequency high enough to make the peripheral work properly. Refer to the SPDIFRX description for more details.

DFSDM1 can use the same clock as SAI1 and DFSDM2 can use the same clock as I2S6. This is useful when DFSDM1 and DFSDM2 are used for audio applications.

The SAI2 can use the symbol clock provided by the SPDIFRX. SPI/I2S1, 2, and 3 share the same kernel clock source. The SPI/I2S4 and 5 share the same kernel clock source (see Figure 56).

Figure 55. Kernel clock distribution for SAIs, DFSDMs and SPDIFRX

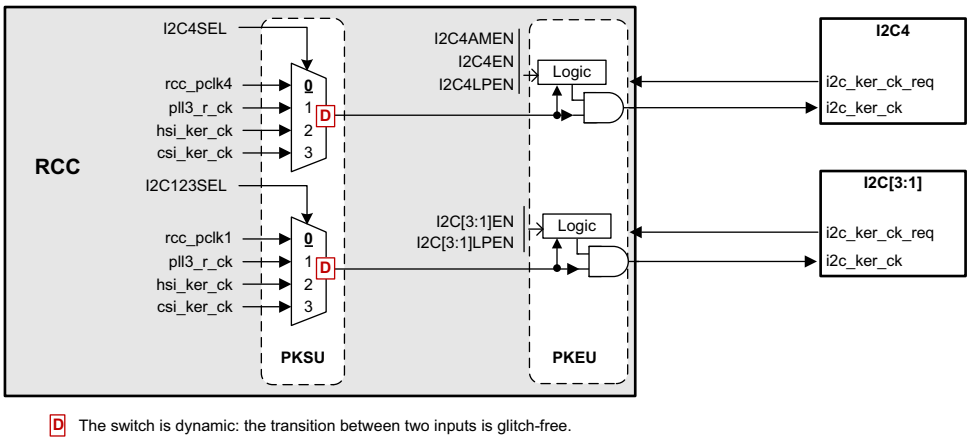
1. **X** represents the selected mux input after a system reset.
2. This figure does not show the connection of the bus interface clock to the peripherals. For details on each enable cell, refer to *Section 8.5.11: Peripheral clock gating control*.



Peripherals dedicated to control and data transfer

Peripherals such as SPIs, I2Cs, UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the required bit clock on the serial interface. For that purpose the source can be selected among the following ones:

- PLL1 when the amount of active PLLs must be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI for low-power use-cases or when the peripheral must quickly wake up from Stop mode (such as UART or I2C)



Note: UARTs also need the LSE clock when high baud rates are not required.

Figure 56. Kernel clock distribution for SPIs and SPI/I2S

2. This figure does not show the connection of the bus interface clock to the peripheral. For details on each enable cell, refer to *Section 8.5.11: Peripheral clock gating control*.

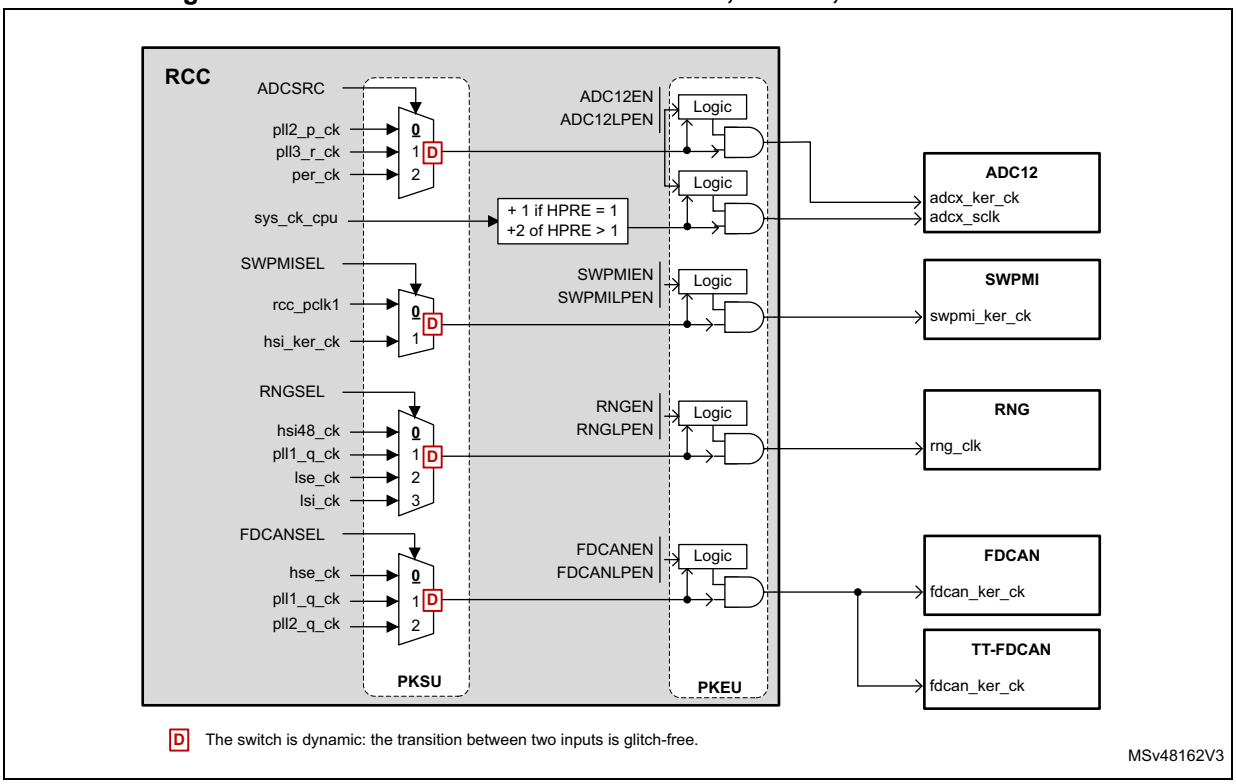
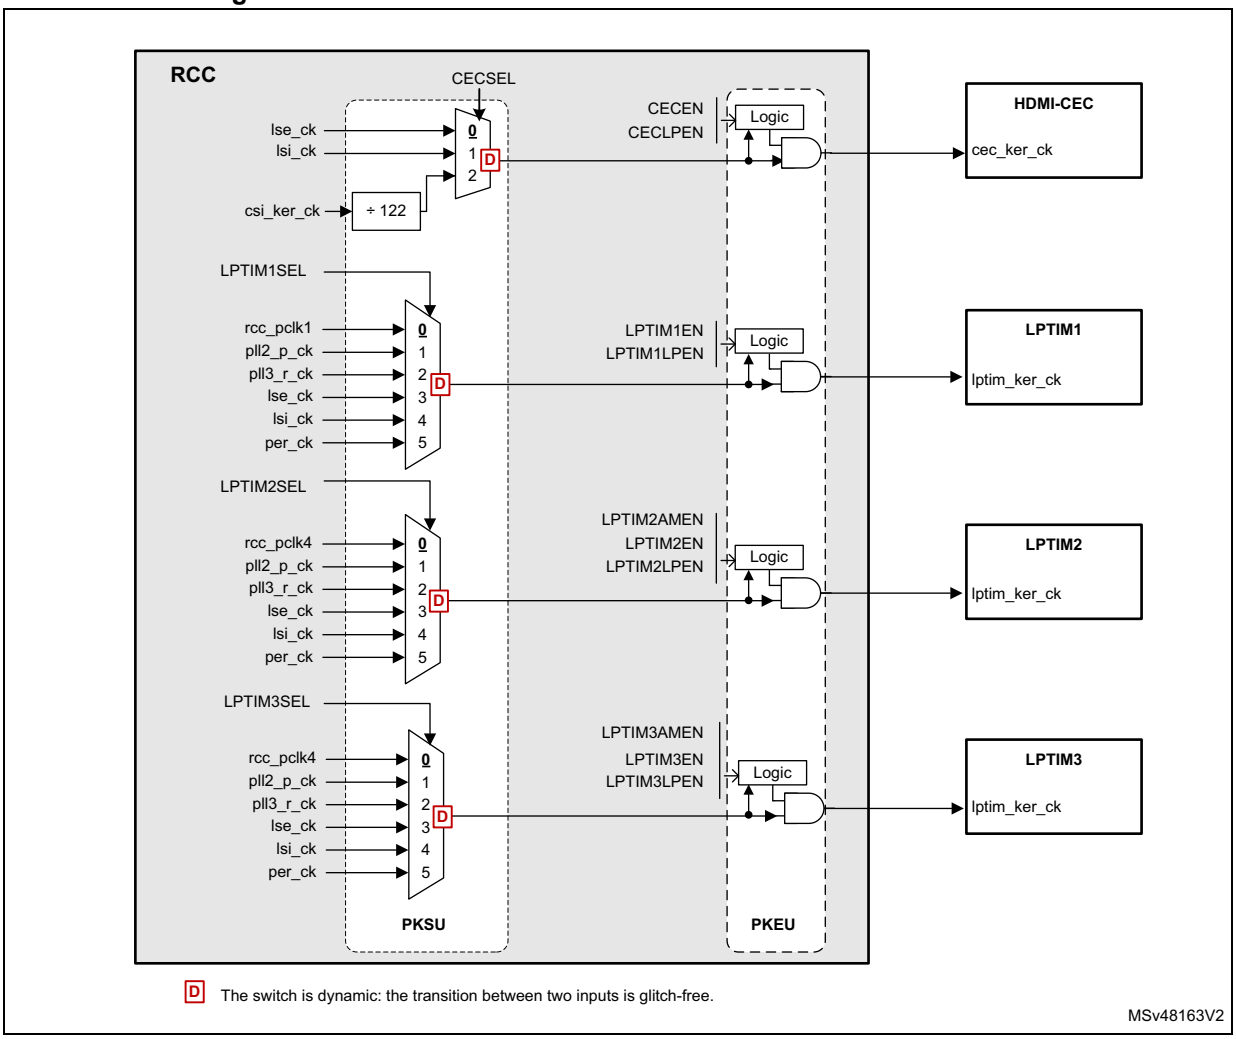
Figure 61 shows the clock distribution for the USB blocks. The USB1ULPI block receives its clock from the external PHY.

The USB1OTG block receives two kind of clocks:



- the clock for USB communications that can be selected among different sources thanks to the MUX controlled by USBSEL
- the **lsi_ck** clock provided to the USB1OTG block in ADP mode on request.

Figure 61. Kernel clock distribution for USB (2)



1. **X** represents the selected mux input after a system reset.
2. This figure does not show the connection of the bus interface clock to the peripheral. For details on each enable cell, refer to *Section 8.5.11: Peripheral clock gating control*.

Figure 62. Kernel clock distribution for ADCs, SWPMI, RNG and FDCANs

2. This figure does not show the connection of the bus interface clock to the peripheral. For details on each enable cell, refer to *Section 8.5.11: Peripheral clock gating control*.

RTC/AWU clock

The **rtc_ck** clock source can be one of the following:

- the **hse_1M_ck** (**hse_ck** divided by a programmable prescaler)
- the **lse_ck**
- the **lsi_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain control register (RCC_BDCR)* and the RTCPRE[5:0] bits in the *RCC clock configuration register (RCC_CFGR)*.

This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_{DD} supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as RTC clock, the RTC continues working even if the V_{DD} supply is switched OFF, provided the V_{BAT} supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_{DD} supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the V_{CORE} supply is powered off.

The **rtc_ck** clock is enabled through RTCEN bit located in the *RCC Backup domain control register (RCC_BDCR)*.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB4ENR/LPENR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

Watchdog clocks

The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

  The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

  The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see *RCC CSI calibration register (RCC_CSICFGR)*). When HSI or CSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

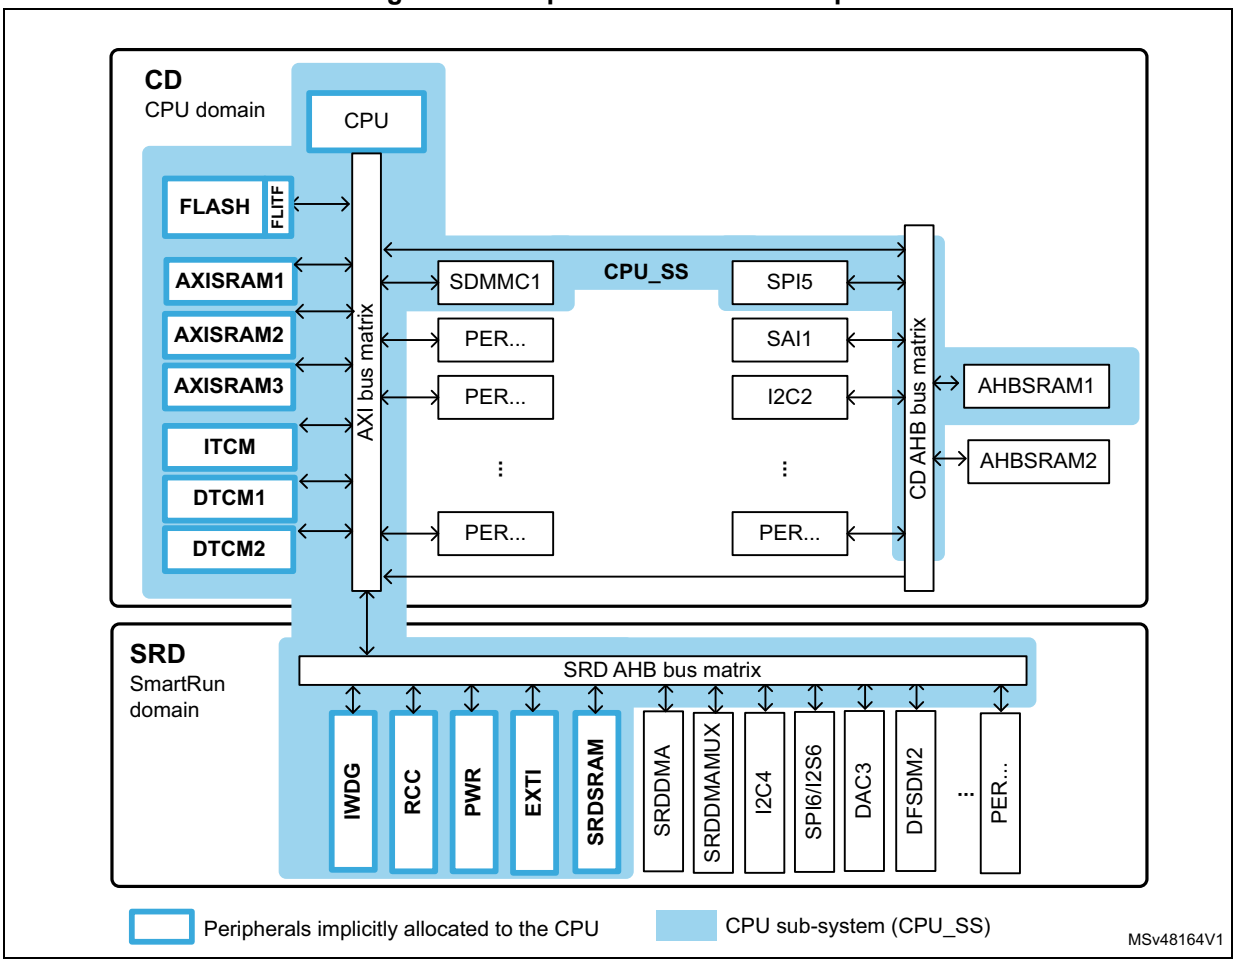
- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process

deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

8.5.9 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system (CPU and SmartRun domains), according to the operating mode of each function (refer to *Section 8.5.1: Clock naming convention* for details on clock definitions).



For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to use a peripheral, the CPU must enable it (by setting PERxEN to 1), and define if this peripheral remains active in CSleep mode (by setting PERxLPEN to 1). This is called ‘allocation’ of a peripheral to the CPU (refer to *Section 8.5.10: Peripheral allocation* for more details).

The peripheral allocation is used by the RCC to automatically control the clock gating according to the CPU and domain modes, and by the PWR to control the supply voltages of CPU and SmartRun domains.

Figure 64 gives an example of peripheral allocation: the CPU enables SDMMC1, SPI5 and AHBSRAM1. The AXISRAMs, ITCM, DTCM1, DTCM2 and SRDSRAM are implicitly allocated to the CPU. The group composed of the CPU, bus matrix 1/2/3 and allocated peripherals makes up a sub-system (CPU_SS).

Note: The FLASH, AXISRAMs, ITCM, DTCM1, DTCM2, SRDSRAM, IWGD, IWGD, PWR, EXTI and RCC are common resources and are implicitly allocated to the CPU.

Figure 64. Peripheral allocation example

Smart Run domain (SRD)

The SmartRun domain can be kept in DRun mode while the CPU is in CStop mode and the CPU domain is in DStop or DStop2 mode. This is done by setting RUN_SRD bit in PWR_CPUCR register.

- If RUN_SRD is set to 1, then SmartRun domain is maintained in DRun mode, independently from the CPU modes (see power control, PWR_CPUCR register)
- If RUN_SRD is set to 0, then the SmartRun domain enters DStop mode when the CPU enters CStop mode (see *Table 59*).

When the CPU domain enters CStop mode, the RCC automatically disables the bus interface and kernel clocks of all the peripherals of the CPU_SS, as well as the CPU clock. The PLLs, if enabled, are not disabled by the RCC since the SmartRun domain is still running.

The CPU can control if the CPU domain is allowed to enter DStop or Dstop2 modes or the SmartRun domain is allowed to enter in DStop when conditions are met, via bits RETDS_CD and PDDS_SRD of PWR control register (PWR_CPUCR).

A wake-up event is able to exit the CPU domain from DStop or Dstop2 and the SmartRun domain from DStop mode.

Autonomous mode

The Autonomous mode allows the delivery of the clocks to peripherals located in the SmartRun domain, even if the CPU is in CStop mode. When a peripheral has its autonomous bit activated, it receives its peripheral clocks according to the SmartRun domain state, if the CPU is in CStop mode:

- If the SmartRun domain is in DRun mode, peripherals with Autonomous mode activated receive their peripheral clocks,
- If the SmartRun domain is in DStop mode, no peripheral clock is provided.

The Autonomous mode does not prevent the SmartRun domain to enter DStop or DStop2 mode.

The autonomous bits are located in *RCC SmartRun domain Autonomous mode register (RCC_SRDAMR)*.

For example, the CPU can enter CStop mode while the I2S6 is filling the SRDSRAM with data received from an external device via BDMA2. When the amount of received data is reached, the CPU can be re-activated by a wake-up event. This can be done by setting the I2S6, the BDMA2, and SRDSRAM in Autonomous mode, while keeping the SmartRun domain in DRun mode (RUN_SRD set to 1). In this example, the RCC does not switch off the PLLs as the SmartRun domain is always in DRun mode.

It is possible to go a step further with power-consumption reduction by combining the Autonomous mode with the capability of some peripherals (UARTs, I2Cs) to request the kernel clock on their own, without waking-up the CPU. For example, if the system is expecting messages via I2C4, the whole system can be put in Stop mode. When the I2C4 peripheral detects a START bit, it generates a “kernel clock request”. This request enables the HSI or CSI, and a kernel clock is provided only to the requester (in our example the I2C4). The I2C4 then decodes the incoming message.

Several cases are then possible:

- If the device address of the message does not match, then I2C4 releases its “kernel clock request” until a new START condition is detected.
- If the device address of the incoming message matches, it must be stored into the SmartRunSmartRun local memory. I2C4 is able to generate a wake-up event on address match to switch the SmartRun domain to DRun mode. The message is then transferred into memory via BDMA2, and the SmartRun domain go back to DStop mode without any CPU activation. Note that if the amount of data transferred into memory reached the transfer count, the BDMA2 can also generate an interrupt to wake-up the CPU.
- If the device address of the incoming message matches and the peripheral is setup to wake up the CPU, then I2C4 generates a wake-up event to activate the CPU.

Refer to the description of EXTI block to see which peripheral is able to perform a wake-up event to which domain.

Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM1, AXISRAM2, AXISRAM3, ITCM, DTCM1, DTCM2 and FLASH
- AHBSRAM1 and AHBSRAM2
- SRDSRAM and BKPRAM

As shown in *Figure 64*, FLASH, AXISRAMs, SRDSRAM, ITCM, DTCM1 and DTCM2 are implicitly allocated to the CPU. As a result, there is no enable bit allowing the CPU to allocate these memories.

The BKPRAM has a dedicated enable in order to gate the bus interface clock. The CPU needs to enable the BKPRAM prior to use it.

Note: The memory interface clocks (flash memory and RAM interfaces) can be stopped by software during CSleep mode (via SRAMyLPEN bits).

Refer to *Section 8.5.11: Peripheral clock gating control* and *Section 8.5.12: CPU and bus matrix clock gating control* sections for details on clock enabling.

System states overview

Table 59 gives an overview of the system states with respect to the CPU and SmartRun domain modes.

- The system remains in Run mode as long as the SmartRun domain is in DRun mode. Several sub-states of system Run exist that are not detailed here (refer *Section 6: Power control (PWR)* for more information).
- The SmartRun domain can run while the CPU domain is in DStop or DStop2 mode thanks to RUN_SRD bits of PWR_CPUCR registers or when the SmartRun domain is in Autonomous mode.
- The system remains in Stop mode as long as the SmartRun domain is in DStop mode. This means implicitly that the CPU domain is in DStop or DStop2 mode. As soon as the CPU domain exits DStop or DStop2, the SmartRun domain switches to DRun mode.
- The system remains in Standby mode as long as CPU and SmartRun domains are in DStandby.
- Domain states versus CPU states:
  - When the CPU domain is in DRun mode, it means that its bus matrix is clocked and the CPU is in CRun mode.
  - When the CPU domain is in DStop mode, it means that its bus matrix is no longer clocked and the CPU is in CStop mode.
  - When a domain is in DStandby mode, it means that the domain including its CPU are powered down.

Table 59. System states overview

System state	CPU domain state	SmartRun domain state
Run	DRun	DRun
Autonomous	DStop/DStop2	
Stop	DStop/DStop2	DStop
Standby	DStandby	DStandby

8.5.10 Peripheral allocation

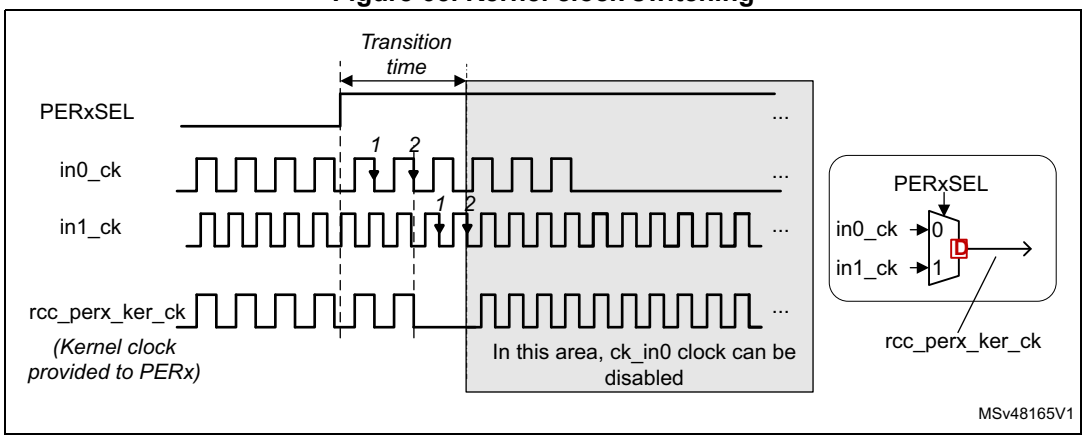
The CPU can allocate a peripheral and hence control its kernel and bus interface clock.

The CPU can allocate a peripheral by setting the dedicated PERxEN bit located into the RCC_xxxxENR registers.

The CPU can control the peripheral clocks gating when it is in CSleep mode via the PERxLPEN bits located into the RCC_xxxxLPENR registers.

Refer to *RCC source control register (RCC_CR)* for additional information.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU (CPU sub-system). In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states. The PWR block also uses this information to control properly the domain states.



Clock switches and gating

- Clock switching delays

  The input selected by the kernel clock switches can be changed dynamically without generating spurs or timing violation. As a consequence, switching from the original to the new input can only be performed if a clock is present on both inputs. If it is not the case, no clock is provided to the peripheral. To recover from this situation, the user must provide a valid clock to both inputs.

  During the transition from one input to another, the kernel clock provided to the peripheral is gated, in the worst case, during 2 clock cycles of the previously selected clock, and 2 clock cycles of the new selected clock. As shown in *Figure 65*, both input clocks must be present during transition time.

Figure 65. Kernel clock switching

- Clock enabling delays

  In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

  – A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can

be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.

– A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

Note: Both the kernel and bus interface clocks are affected by this re-synchronization delay.

8.5.11 Peripheral clock gating control

As mentioned previously, each peripheral requires a bus interface clock, named **rcc_perx_bus_ck** (for peripheral 'x'). This clock can be an APB, AHB or AXI clock, according to which bus the peripheral is connected.

The clocks used as bus interface for peripherals located in the CPU domain, can be **rcc_aclk**, **rcc_hclk3** or **rcc_pclk3**, depending on the bus connected to each peripheral. For simplicity sake, these clocks are named **rcc_bus_cd_ck**.

Similarly, the signal **rcc_bus_srd_ck** represents **rcc_hclk4** or **rcc_pclk4** for peripherals located in the SmartRun domain.

Some peripherals (such as SAI or UART) also require a dedicated clock for their communication interface. This clock is generally asynchronous with respect to the bus interface clock. It is named kernel clock (**perx_ker_ckreq**). Both clocks can be gated according to several conditions detailed hereafter.

As shown in *Figure 66*, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits,

  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to 1 via the RCC_xxxxENR registers.
- PERxAMEN bits belonging to *RCC SmartRun domain Autonomous mode register (RCC_SRDAMR)*.
- CPU state (**cpu_sleep** and **cpu_deepsleep** signals)
- SmartRun domain state (**srd_deepsleep** signal)
- Kernel clock request (**perx_ker_ckreq**) of the peripheral itself, when the feature is available

Refer to *Section 8.5.10: Peripheral allocation* for more details.

Figure 66. Peripheral kernel clock enable logic details

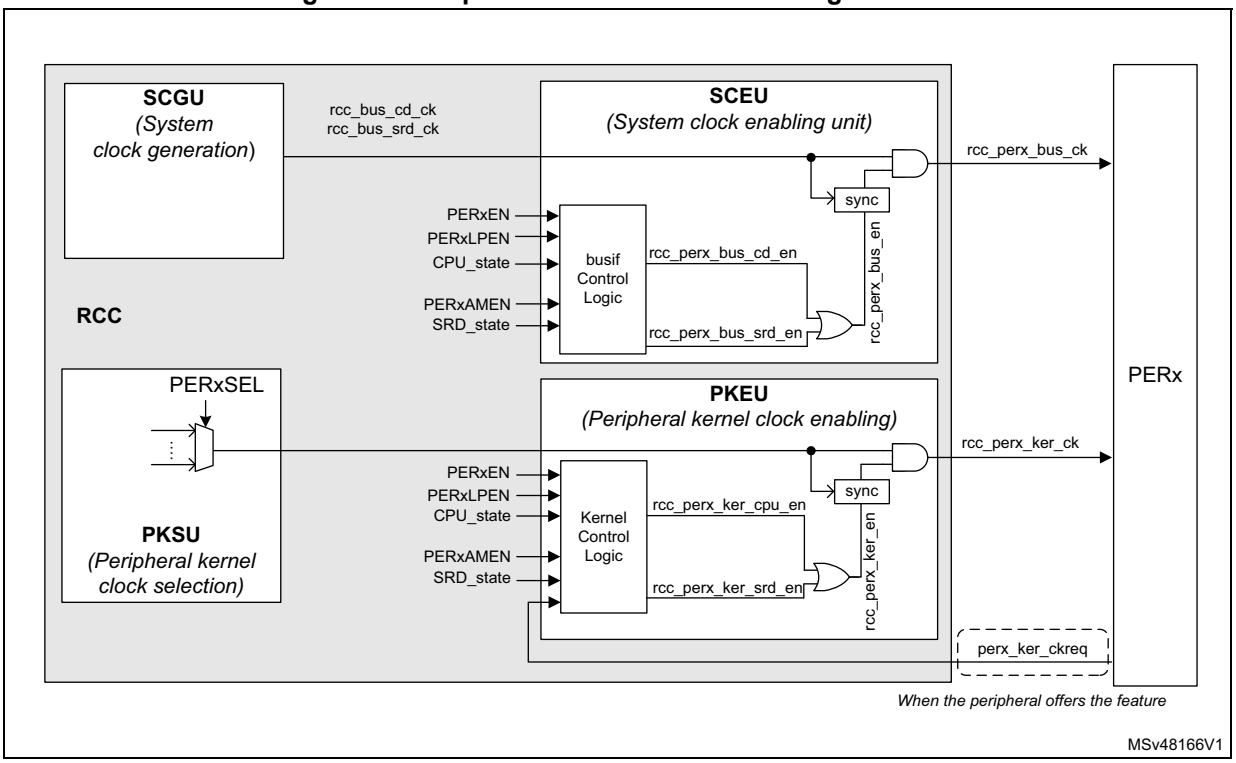


Table 60 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in the CPU domain and allocated by the CPU.

Table 60. Peripheral clock enabling for the CPU domain peripherals

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_cpu_en	rcc_perx_bus_cd_en	Comments
0	X	X	X	X	0	0	No clock provided to the peripheral, because PERxEN=0
1	X	X	X	CRun	1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CRun, and PERxEN = 1.
1	0	X	X	CSleep	0	0	No clock provided to the peripheral, because the CPU is in CSleep and PERxLPEN = 0
1	1	X	X		1	1	Kernel and bus interface clocks are provided to the peripheral, because CPU is in CSleep, and PERxLPEN = 1

Table 60. Peripheral clock enabling for the CPU domain peripherals (continued)

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_cpu_en	rcc_perx_bus_cd_en	Comments
1	0	X	X	CStop	0	0	No clock provided to the peripheral because the PERxLPEN bit is set to 0.
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no csi_ker_ck	X		0	0	No clock provided to the peripheral because CPU is in CStop and **lse_ck** or **lsi_ck** or **hsi_ker_ck** or **csi_ker_ck** are not selected.
1	1	lsi_ck or lse_ck	X		1 (1)	0	Kernel clock is provided to the peripheral because PERxEN = PERxLPEN = 1 and **lsi_ck** or **lse_ck** are selected. The bus interface clock is no provided as the CPU is in CStop.
1	1	hsi_ker_ck or csi_ker_ck	1		1	0	Kernel clock is provided to the peripheral because **req_ker_perx** = 1, and PERxEN = PERxLPEN = 1 and **hsi_ker_ck** or **csi_ker_ck** are selected. The bus interface clock is no provided as the CPU is in CStop.
1	1	hsi_ker_ck or csi_ker_ck	0		0	0	No clock provided to the peripheral because CPU is in CStop, and no kernel clock request pending

1. For RNG block, the kernel clock is not delivered if the CPU to which it is allocated is in CStop mode, even if the clock selected is lsi_ck or lse_ck.

As a summary, we can state that the kernel clock is provided to the peripherals located on the CPU domain when the following conditions are met:

1. The CPU is in CRun mode, and the peripheral is allocated.
2. The CPU is in CSleep mode and the peripheral is allocated with PERxLPEN = 1.
3. The CPU is in CStop mode, the peripheral is allocated with PERxLPEN = 1, the peripheral generates a kernel clock request and the selected clock is **hsi_ker_ck** or **csi_ker_ck**.
4. The CPU is in CStop mode, the peripheral is allocated with PERxLPEN = 1 and the kernel source clock of the peripheral is **lse_ck** or **lsi_ck**.

The bus interface clock is provided to the peripherals only when conditions 1 or 2 are met.

Table 61 gives a detailed description of the enabling logic of the kernel clock for all peripherals located in the SmartRun domain.

Table 61. Peripheral clock enabling for SmartRun domain peripherals

PERxEN	PERxLPEN	PERxAMEN	PERxSEL	perx_ker_ckreq	CPU state	SmartRun domain state	rcc_perx_ker_srd_en	rcc_perx_bus_srd_en	Comments
0	X	X	X	X	Any	Any	0	0	No clock provided to the peripheral, as PERxEN = 0
1	X	X	X	X	CRun	Run	1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CRun, and PERxEN = 1.
1	0	X	X	X	CSleep		0	0	No clock provided to the peripheral, because the CPU is in CSleep, and PERxLPEN = 0
1	1	X	X	X			1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CSleep, and PERxLPEN = 1
1	X	0	X	X	CStop		0	0	As the CPU is in CStop, and PERxEN=1, then the kernel clock gating depends on the SmartRun domain state and PERxAMEN bits. No clock provided to the peripheral because PERxAMEN = 0.
1	X	1	X	X			1	1	The kernel and bus interface clocks are provided because even if the CPU is in CStop mode, the SmartRun domain is in Run mode, with PERxEN and PERxAMEN bits set to 1.
1	X	1	not lse_ck and not lsi_ck	0		Stop	0	0	No clock provided to the peripheral, because the SmartRun domain is in Stop, **req_ker_perx** = 0, and **lse_ck** or **lsi_ck** is not selected

Table 61. Peripheral clock enabling for SmartRun domain peripherals (continued)

PERxEN	PERxLPEN	PERxAMEN	PERxSEL	perx_ker_ckreq	CPU state	SmartRun domain state	rcc_perx_ker_srd_en	rcc_perx_bus_srd_en	Comments
1	X	1	not hsi_ker_ck and not csi_ker_ck and not lse_ck and not lsi_ck	1	CStop	Stop	0	0	No clock provided to the peripheral, because even if **req_ker_perx** = 0, **lse_ck** or **lsi_ck** or **hsi_ker_ck** or **csi_ker_ck** is not selected.
1	X	1	hsi_ker_ck or csi_ker_ck	1			1	0	Kernel clock is provided to the peripheral because **req_ker_perx** = 1, and PERxEN = PERxAMEN = 1, and the selected clock is **hsi_ker_ck** or **csi_ker_ck**. The bus interface clock is not provided as the SmartRun domain is in Stop.
1	X	1	lse_ck or lsi_ck	X			1	0	Kernel clock is provided to the peripheral because PERxEN = PERxAMEN = 1 and **lse_ck** or **lsi_ck** are selected, while the SmartRun domain is in Stop. The bus interface clock is not provided as the SmartRun domain is in Stop.

As a summary, we can state that the kernel clock is provided to the peripherals of the SmartRun domain if the following conditions are met:

1. The CPU is in CRun mode and the peripheral is allocated.
2. The CPU is in CSleep mode and the peripheral is allocated with PERxLPEN = 1.
3. The CPU is in CStop mode, the peripheral is allocated and the SmartRun domain is in Run mode with PERxAMEN = 1.
4. The CPU is in CStop mode, the peripheral is allocated, the SmartRun domain is in Stop mode with PERxAMEN = 1, the peripheral is generating a kernel clock request and the kernel clock source is **hsi_ker_ck** or **csi_ker_ck**.
5. The CPU is in CStop mode, the peripheral is allocated, the SmartRun domain is in Stop mode with PERxAMEN = 1 and the kernel clock source of the peripheral is **lse_ck** or **lsi_ck**.

The bus interface clock is provided to the peripherals only when condition 1, 2 or 3 is met.

Note: When they are set to 1, the autonomous bits indicate that the associated peripheral receives a kernel clock according to the SmartRun domain state and not according to the mode of the CPU.

Only I2C, U(S)ART and LPUART peripherals are able to request the kernel clock. This feature gives to the peripheral the capability to transfer data with an optimal power consumption.

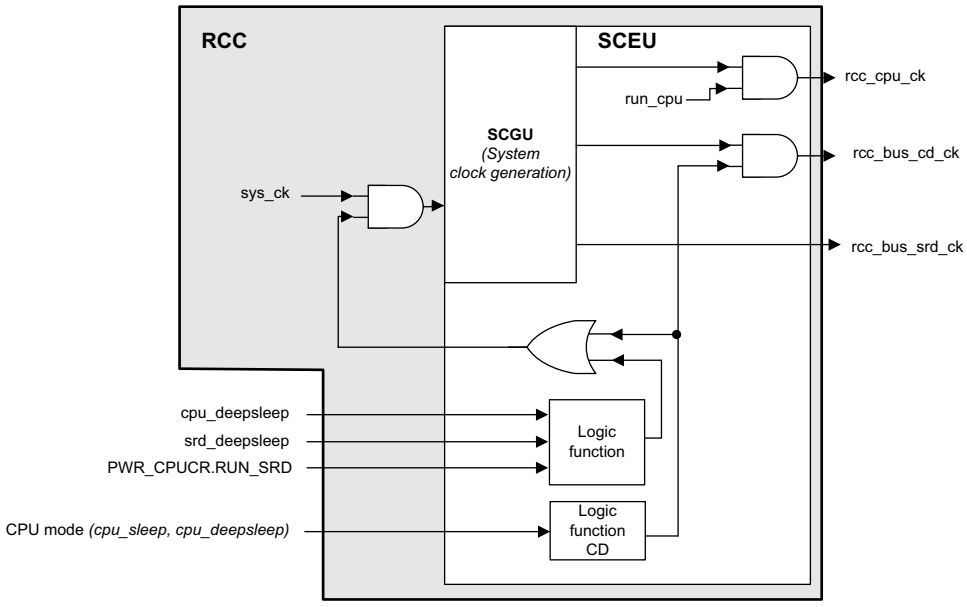
The autonomous bits dedicated to some peripherals located in the SmartRun domain, allow the data transfer with external devices without activating the CPU.

*In order for the LPTIMER to operate with **lse_ck** or **lsi_ck** when the circuit is in Stop mode, the user application must select the **lsi_ck** or **lse_ck** input via LPTIMxSEL fields, and set LPTIMxAMEN and LPTIMxLPEN bits to 1.*

8.5.12 CPU and bus matrix clock gating control

For each domain it is possible to control the activation/deactivation of the CPU clock and bus matrix clock.

For information about convention naming, refer to *Section 8.5.11: Peripheral clock gating control*.



The clocks of the CPU, AHB and AXI bridges and APB busses are enabled according to the rules hereafter:

- The CPU clock **rcc_cpu_ck** is enabled when the CPU is in CRun mode.
- The AXI bridge clock is enabled when the CPU domain is in DRun mode.
- Each AXI master and slave has an independent clock gating that can be activated to further reduce the power consumption (register RCC_CKGAENR). When activated the clock is automatically enabled on bus transaction request.
- The CPU domain AHB bridges clocks are enabled when the CPU domain is in DRun mode.
- The SmartRun domain AHB bridge clock is enabled when one of the following conditions is met:
  - The CPU is in CRun or CSleep mode.
  - When the RUN_SRD bit is set to 1, independently of CPU modes.
  - When the **SRD_deepsleep** signal is inactive (0), independently of CPU modes.
- The APB1,2,3 busses are enabled when one of the following conditions is met:
  - The CPU is in CRun mode.
  - When the CPU is in CSleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.
- The APB4 bus is enabled when the SmartRun domain is in DRun mode.

As shown in the *Figure 67*, the enabling of the core and bus clock of each domain depends on several input signals:

- **cpu_sleep** and **cpu_deepsleep** signals from the CPU
- **srd_sleepdeep** signal
- RCC_xxxxENR.PERxEN bits of peripherals located on the CPU domain

Figure 67. Bus clock enable logic

run_cpu is a combination of NOT cpu_deepsleep and NOT cpu_sleep.

rcc_bus_dx represents the clocks for the bus matrix and the peripheral bus interface for domain x.

MSv48167V1

8.6 RCC interrupts

The RCC provides three interrupt lines:

- **rcc_it**: general interrupt line providing events when the PLLs are ready or when the oscillators are ready
- **rcc_hsecss_it**: interrupt line dedicated to the failure detection of the HSE CSS (clock security system)
- **rcc_lsecss_it**: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled via *RCC clock source interrupt enable register (RCC_CIER)*, except for the HSE CSS failure. When the HSE CSS feature is enabled, it not possible to mask the interrupt generation.

The interrupt flags can be checked via *RCC clock source interrupt flag register (RCC_CIFR)*, and those flags can be cleared via *RCC clock source interrupt clear register (RCC_CICR)*.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Table 62 gives a summary of the interrupt sources and the way to control them.

Table 62. Interrupt sources and control

Interrupt source	Description	Interrupt enable	Action to clear interrupt	Interrupt line
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to 1	rcc_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to 1	
HSIDRYF	HSI ready	HSIDRYIE	Set HSIRDYC to 1	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to 1	
CSIRDYF	CSI ready	CSIRDYIE	Set CSIRDYC to 1	
HSI48RDYF	HSI48 ready	HSI48RDYIE	Set HSI48RDYC to 1	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYC to 1	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYC to 1	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYC to 1	
LSECSSF	LSE CSS failure	LSECSSFIE (1)	Set LSECSSC to 1	rcc_lsecss_it
HSECSSF	HSE CSS failure	-(2)	Set HSECSSC to 1	rcc_hsecss_it

1. The security system feature must also be enabled (LSECSSON = 1), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

8.7 RCC registers

8.7.1 RCC source control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 0025

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	rw			rw	r	rw		r	rw	rw	r	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag
Set by hardware to indicate that the PLL3 is locked.
0: PLL3 unlocked (default after reset)
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable
Set and cleared by software to enable PLL3.
Cleared by hardware when entering Stop or Standby mode.
0: PLL3 OFF (default after reset)
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL2 is locked.
0: PLL2 unlocked (default after reset)
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop or Standby mode.
0: PLL2 OFF (default after reset)
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked (default after reset)
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable PLL1.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock.
0: PLL1 OFF (default after reset)
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: external high speed clock type in Bypass mode
Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the HSEON bit to be used by the device.
The HSEEXT bit can be written only if the HSE oscillator is disabled.
0: HSE in analog mode (default after reset)
1: HSE in digital mode

Bit 19 **HSECSSON**: HSE clock security system enable
Set by software to enable clock security system on HSE.
This bit is “set only” (disabled by a system reset or when the system enters in Standby mode).
When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.
0: CSS on HSE OFF (clock detector OFF) (default after reset)
1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock is not ready (default after reset)

1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE when entering Stop or Standby mode.

This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: HSE is OFF (default after reset)

1: HSE is ON

Bit 15 **CDCKRDY**: CPU domain clocks ready flag

Set by hardware to indicate that the following CPU domain clocks are available: APB1, APB2, AHB bus matrix.

0: CPU domain clocks are not available (default after reset)

1: CPU domain clocks are available

Bit 14 **CPUCKRDY**: CPU related clocks ready flag

Set by hardware to indicate that the CPU related clocks (CPU, APB3, AXI bus matrix and related memories) are available.

0: CPU related clocks are not available (default after reset)

1: CPU related clocks are available

Bit 13 **HSI48RDY**: HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable.

0: HSI48 clock is not ready (default after reset)

1: HSI48 clock is ready

Bit 12 **HSI48ON**: HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.

0: HSI48 is OFF (default after reset)

1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CSIKERON**: CSI clock enable in Stop mode

Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.

0: no effect on CSI (default after reset)

1: CSI is forced to ON even in Stop mode

Bit 8 **CSIRDY**: CSI clock ready flag

Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).

0: CSI clock is not ready (default after reset)

1: CSI clock is ready

Bit 7 **CSION**: CSI clock enable

Set and reset by software to enable/disable CSI clock for system and/or peripheral.

Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.

This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock, or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: CSI is OFF (default after reset)

1: CSI is ON

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag

Set and reset by hardware.

As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV.

0: new division ratio not yet propagated to **hsi(_ker)_ck** (default after reset)

1: **hsi(_ker)_ck** clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed)

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider

Set and reset by software.

These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case, the new HSIDIV value is ignored.

00: division by 1, **hsi(_ker)_ck** = 64 MHz (default after reset)

01: division by 2, **hsi(_ker)_ck** = 32 MHz

10: division by 4, **hsi(_ker)_ck** = 16 MHz

11: division by 8, **hsi(_ker)_ck** = 8 MHz

Bit 2 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

Bit 1 **HSIKERON**: HSI clock enable in Stop mode

Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: no effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

Bit 0 **HSION**: HSI clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = 0 or STOPKERWUCK = 0.

Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SW mux) as system clock, or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: HSI is OFF

1: HSI is ON (default after reset)

8.7.2 RCC HSI calibration register (RCC_HSICFGR)

Address offset: 0x004

Reset value: 0x4000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	HSITRIM[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSITRIM[6:0]**: HSI clock trimming

Set by software to adjust calibration.

HSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_HSI_opt) in order to form the calibration trimming value.

HSICAL = HSITRIM + FLASH_HSI_opt.

Note: The reset value of the field is 0x40.

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Adjusted by software through trimming bits HSITRIM.

This field represents the sum of engineering option byte calibration value and HSITRIM bits value.

8.7.3 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x008

Reset value: 0x0000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Read-only.

8.7.4 RCC CSI calibration register (RCC_CSICFGR)

Address offset: 0x00C

Reset value: 0x2000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	CSITRIM[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
		rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSICAL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **CSITRIM[5:0]**: CSI clock trimming

Set by software to adjust calibration.

CSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_CSI_opt) in order to form the calibration trimming value.

CSICAL = CSITRIM + FLASH_CSI_opt.

Note: The reset value of the field is 0x20.

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:0 **CSICAL[7:0]**: CSI clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Adjusted by software through trimming bits CSITRIM.

This field represents the sum of engineering option byte calibration value and CSITRIM bits value.

8.7.5 RCC clock configuration register (RCC_CFGR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2SEL[2:0]			MCO2PRE[3:0]				MCO1SEL[2:0]			MCO1PRE[3:0]				Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMPRE	Res.	RTCPRE[5:0]						STOPKERWUCK	STOPWUCK	SWS[2:0]			SW[2:0]		
rw		rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	rw	rw	rw

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: system clock selected (**sys_ck**) (default after reset)
001: PLL2 oscillator clock selected (**pll2_p_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_p_ck**)
100: CSI clock selected (**csi_ck**)
101: LSI clock selected (**lsi_ck**)
others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: HSI clock selected (**hsi_ck**) (default after reset)
001: LSE oscillator clock selected (**lse_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_q_ck**)
100: HSI48 clock selected (**hsi48_ck**)
others: reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TIMPRE**: timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.

0: The timers kernel clock is equal to **rcc_hclk1** if CDPPRE1 or CDPPRE2 corresponds to a division by 1 or 2, else it is equal to 2 x $\mathbf{F_{rcc_pclk1}}$ or 2 x $\mathbf{F_{rcc_pclk2}}$ (default after reset)

1: The timers kernel clock is equal to 2 x $\mathbf{F_{rcc_pclk1}}$ or 2 x $\mathbf{F_{rcc_pclk2}}$ if CDPPRE1 or CDPPRE2 corresponds to a division by 1, 2
or 4, else it is equal to 4 x $\mathbf{F_{rcc_pclk1}}$ or 4 x $\mathbf{F_{rcc_pclk2}}$.

Refer to *Table 55: Ratio between clock timer and pclk* for more details.

Bit 14 Reserved, must be kept at reset value.

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.

Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000: no clock (default after reset)
000001: no clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
...
111110: HSE/62
111111: HSE/63

Bit 7 **STOPKERWUCK**: kernel clock selection after a wake up from system Stop

Set and reset by software to select the kernel wake-up clock from system Stop.

0: HSI selected as wake up clock from system Stop (default after reset)
1: CSI selected as wake up clock from system Stop

See *Section 8.5.7: Handling clock generators in Stop and Standby modes* for details.

Bit 6 **STOPWUCK**: system clock selection after a wake up from system Stop

Set and reset by software to select the system wake-up clock from system Stop.

The selected clock is also used as emergency clock for the clock security system (CSS) on HSE.

0: HSI selected as wake up clock from system Stop (default after reset)

1: CSI selected as wake up clock from system Stop

See *Section 8.5.7: Handling clock generators in Stop and Standby modes* for details.

Caution: STOPWUCK must not be modified when CSS is enabled (by HSECSSON bit) and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW =10).

Bits 5:3 **SWS[2:0]**: system clock switch status

Set and reset by hardware to indicate which clock source is used as system clock.

000: HSI used as system clock (**hsi_ck**) (default after reset)

001: CSI used as system clock (**csi_ck**)

010: HSE used as system clock (**hse_ck**)

011: PLL1 used as system clock (**pll1_p_ck**)

others: reserved

Bits 2:0 **SW[2:0]**: system clock and trace clock switch

Set and reset by software to select system clock and trace clock sources (**sys_ck** and **traceportck**).

Set by hardware in order to:

– force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode

– force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock

000: HSI selected as system clock (**hsi_ck**) (default after reset)

001: CSI selected as system clock (**csi_ck**)

010: HSE selected as system clock (**hse_ck**)

011: PLL1 selected as system clock (**pll1_p_ck** for **sys_ck**, **pll1_r_ck** for **traceportck**)

others: reserved

8.7.6 RCC CPU domain clock configuration register 1 (RCC_CDCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	CDCPRE[3:0]				Res.	CDPPRE[2:0]			HPRE[3:0]			
				rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **CDCPRE[3:0]**: CPU domain core prescaler

Set and reset by software to control the CPU domain CPU clock division factor.
Changing this division ratio has an impact on the frequency of the CPU clock and all bus matrix clocks.
After changing this prescaler value, it takes up to 16 periods of the slowest APB clock before the new division ratio is taken into account. The application can check if the new division factor is taken into account by reading back this register.
0xxx: **sys_ck** not divided (default after reset)
1000: **sys_ck** divided by 2
1001: **sys_ck** divided by 4
1010: **sys_ck** divided by 8
1011: **sys_ck** divided by 16
1100: **sys_ck** divided by 64
1101: **sys_ck** divided by 128
1110: **sys_ck** divided by 256
1111: **sys_ck** divided by 512

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CDPPRE[2:0]**: CPU domain APB3 prescaler

Set and reset by software to control the division factor of **rcc_pclk3**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc_hclk3** after CDPPRE write.
0xx: **rcc_pclk3** = **rcc_hclk3** (default after reset)
100: **rcc_pclk3** = **rcc_hclk3** / 2
101: **rcc_pclk3** = **rcc_hclk3** / 4
110: **rcc_pclk3** = **rcc_hclk3** / 8
111: **rcc_pclk3** = **rcc_hclk3** / 16

Bits 3:0 **HPRE[3:0]**:CPU domain AHB prescaler

Set and reset by software to control the division factor of **rcc_hclk3** and **rcc_aclk**. Changing this division ratio has an impact on the frequency of all bus matrix clocks.
0xxx: **rcc_hclk3** = **sys_cdcpre_ck** (default after reset)
1000: **rcc_hclk3** = **sys_cdcpre_ck** / 2
1001: **rcc_hclk3** = **sys_cdcpre_ck** / 4
1010: **rcc_hclk3** = **sys_cdcpre_ck** / 8
1011: **rcc_hclk3** = **sys_cdcpre_ck** / 16
1100: **rcc_hclk3** = **sys_cdcpre_ck** / 64
1101: **rcc_hclk3** = **sys_cdcpre_ck** / 128
1110: **rcc_hclk3** = **sys_cdcpre_ck** / 256
1111: **rcc_hclk3** = **sys_cdcpre_ck** / 512

*Note: The clocks are divided by the new prescaler factor from1 to 16 periods of the slowest APB clock among **rcc_pclk[4:1]** after HPRE update.*

*Note: Note also that **rcc_hclk3** = **rcc_aclk**.*

Caution: Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the V_{CORE} voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application must program a correct value in HPRE to make sure that the system frequency does not exceed the maximum frequency.

8.7.7 RCC CPU domain clock configuration register 2 (RCC_CDCFGR2)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	CDPPRE2[2:0]			Res.	CDPPRE1[2:0]			Res.	Res.	Res.	Res.
					rw	rw	rw		rw	rw	rw				

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **CDPPRE2[2:0]**: CPU domain APB2 prescaler

Set and reset by software to control the CPU domain APB2 clock division factor.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc_hclk1** after CDPPRE2 write.
0xx: **rcc_pclk2** = **rcc_hclk1** (default after reset)
100: **rcc_pclk2** = **rcc_hclk1** / 2
101: **rcc_pclk2** = **rcc_hclk1** / 4
110: **rcc_pclk2** = **rcc_hclk1** / 8
111: **rcc_pclk2** = **rcc_hclk1** / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **CDPPRE1[2:0]**: CPU domain APB1 prescaler

Set and reset by software to control the CPU domain APB1 clock division factor.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc_hclk1** after CDPPRE1 write.
0xx: **rcc_pclk1** = **rcc_hclk1** (default after reset)
100: **rcc_pclk1** = **rcc_hclk1** / 2
101: **rcc_pclk1** = **rcc_hclk1** / 4
110: **rcc_pclk1** = **rcc_hclk1** / 8
111: **rcc_pclk1** = **rcc_hclk1** / 16

Bits 3:0 Reserved, must be kept at reset value.

8.7.8 RCC SmartRun domain clock configuration register (RCC_SRDCFGR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRDPPRE[2:0]			Res.	Res.	Res.	Res.
									rw	rw	rw				

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **SRDPPRE[2:0]**: SmartRun domain APB4 prescaler

Set and reset by software to control the SmartRun domain APB4 clock division factor.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc_hclk4** after SRDPPRE write.
0xx: **rcc_pclk4** = **rcc_hclk4** (default after reset)
100: **rcc_pclk4** = **rcc_hclk4** / 2
101: **rcc_pclk4** = **rcc_hclk4** / 4
110: **rcc_pclk4** = **rcc_hclk4** / 8
111: **rcc_pclk4** = **rcc_hclk4** / 16

Bits 3:0 Reserved, must be kept at reset value.

8.7.9 RCC PLLs clock source selection register (RCC_PLLCKSELR)

Address offset: 0x028

Reset value: 0x0202 0200

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	DIVM3[5:0]						Res.	Res.	DIVM2[5:4]	
						rw	rw	rw	rw	rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIVM2[3:0]				Res.	Res.	DIVM1[5:0]						Res.	Res.	PLLSRC[1:0]	
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **DIVM3[5:0]:** prescaler for PLL3

Set and cleared by software to configure the prescaler of the PLL3.
The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = 1).
In order to save power when PLL3 is not used, the value of DIVM3 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **DIVM2[5:0]**: prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2.
The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = 1).
In order to save power when PLL2 is not used, the value of DIVM2 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:4 **DIVM1[5:0]**: prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = 1).
In order to save power when PLL1 is not used, the value of DIVM1 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSRC[1:0]:** DIVMx and PLLs clock source selection

Set and reset by software to select the PLL clock source.
These bits can be written only when all PLLs are disabled.
In order to save power, when no PLL is used, the value of PLLSRC must be set to ‘11’.
00: HSI selected as PLL clock (**hsi_ck**) (default after reset)
01: CSI selected as PLL clock (**csi_ck**)
10: HSE selected as PLL clock (**hse_ck**)
11: no clock send to DIVMx divider and PLLs

8.7.10 RCC PLLs configuration register (RCC_PLLCFGR)

Address offset: 0x02C

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIVR3EN**: PLL3 DIVR divider output enable
Set and reset by software to enable the **pll3_r_ck** output of the PLL3.
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
This bit can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0: **pll3_r_ck** output disabled
1: **pll3_r_ck** output enabled (default after reset)

Bit 23 **DIVQ3EN**: PLL3 DIVQ divider output enable
Set and reset by software to enable the **pll3_q_ck** output of the PLL3.
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
This bit can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
0: **pll3_q_ck** output disabled
1: **pll3_q_ck** output enabled (default after reset)

Bit 22 **DIVP3EN**: PLL3 DIVP divider output enable
Set and reset by software to enable the **pll3_p_ck** output of the PLL3.
This bit can be written only when the PLL3 is disabled (PLL3ON = 0 and PLL3RDY = 0).
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll3_p_ck** output disabled
1: **pll3_p_ck** output enabled (default after reset)

Bit 21 **DIVR2EN**: PLL2 DIVR divider output enable
Set and reset by software to enable the **pll2_r_ck** output of the PLL2.
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0: **pll2_r_ck** output disabled
1: **pll2_r_ck** output enabled (default after reset)

Bit 20 **DIVQ2EN**: PLL2 DIVQ divider output enable
Set and reset by software to enable the **pll2_q_ck** output of the PLL2.
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0: **pll2_q_ck** output disabled
1: **pll2_q_ck** output enabled (default after reset)

Bit 19 **DIVP2EN**: PLL2 DIVP divider output enable
Set and reset by software to enable the **pll2_p_ck** output of the PLL2.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll2_p_ck** output disabled
1: **pll2_p_ck** output enabled (default after reset)

Bit 18 **DIVR1EN**: PLL1 DIVR divider output enable
Set and reset by software to enable the **pll1_r_ck** output of the PLL1.
To save power, DIVR3EN and DIVR3 bits must be set to 0 when the **pll3_r_ck** is not used.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0: **pll1_r_ck** output disabled
1: **pll1_r_ck** output enabled (default after reset)

Bit 17 **DIVQ1EN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the **pll1_q_ck** output of the PLL1.
In order to save power, when the **pll1_q_ck** output of the PLL1 is not used, the **pll1_q_ck** must be disabled.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0: **pll1_q_ck** output disabled
1: **pll1_q_ck** output enabled (default after reset)

Bit 16 **DIVP1EN**: PLL1 DIVP divider output enable
Set and reset by software to enable the **pll1_p_ck** output of the PLL1.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
In order to save power, when the **pll1_p_ck** output of the PLL1 is not used, the **pll1_p_ck** must be disabled.
0: **pll1_p_ck** output disabled
1: **pll1_p_ck** output enabled (default after reset)

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
These bits must be written before enabling the PLL3.
00: PLL3 input (**ref3_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (**ref3_ck**) clock range frequency between 2 and 4 MHz
10: PLL3 input (**ref3_ck**) clock range frequency between 4 and 8 MHz
11: PLL3 input (**ref3_ck**) clock range frequency between 8 and 16 MHz

Bit 9 **PLL3VCOSEL**: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit must be written before enabling the PLL3.
0: wide VCO range 128 to 560 MHz (default after reset)
1: medium VCO range 150 to 420 MHz

Bit 8 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN3 into the sigma-delta modulator.
In order to latch the FRACN3 value into the sigma-delta modulator, PLL3FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN3 into the modulator.
Refer to *PLL initialization phase on page 358* for additional information.

Bits 7:6 **PLL2RGE[1:0]**: PLL2 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL2.
These bits must be written before enabling the PLL2.
00: PLL2 input (**ref2_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL2 input (**ref2_ck**) clock range frequency between 2 and 4 MHz
10: PLL2 input (**ref2_ck**) clock range frequency between 4 and 8 MHz
11: PLL2 input (**ref2_ck**) clock range frequency between 8 and 16 MHz

Bit 5 **PLL2VCOSEL**: PLL2 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL2.
This bit must be written before enabling the PLL2.
0: wide VCO range 128 to 560 MHz (default after reset)
1: medium VCO range 150 to 420 MHz

Bit 4 **PLL2FRACEN**: PLL2 fractional latch enable
Set and reset by software to latch the content of FRACN2 into the sigma-delta modulator.
In order to latch the FRACN2 value into the sigma-delta modulator, PLL2FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN2 into the modulator.
Refer to *PLL initialization phase on page 358* for additional information.

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL1.
This bit must be written before enabling the PLL1.
00: PLL1 input (**ref1_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL1 input (**ref1_ck**) clock range frequency between 2 and 4 MHz
10: PLL1 input (**ref1_ck**) clock range frequency between 4 and 8 MHz
11: PLL1 input (**ref1_ck**) clock range frequency between 8 and 16 MHz

Bit 1 **PLL1VCOSEL**: PLL1 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL1.
These bits must be written before enabling the PLL1.
0: wide VCO range from 128 to 560 MHz (default after reset)
1: medium VCO range from 150 to 420 MHz

Bit 0 **PLL1FRACEN**: PLL1 fractional latch enable
Set and reset by software to latch the content of FRACN1 into the sigma-delta modulator.
In order to latch the FRACN1 value into the sigma-delta modulator, PLL1FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN1 into the modulator.
Refer to *PLL initialization phase on page 358* for additional information.

8.7.11 RCC PLL1 dividers configuration register (RCC_PLL1DIVR)

Address offset: 0x030

Reset value: 0x0101 0280

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR1[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the **pll1_r_ck** clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: **pll1_r_ck** = **vco1_ck**
0000001: **pll1_r_ck** = **vco1_ck** / 2 (default after reset)
0000010: **pll1_r_ck** = **vco1_ck** / 3
0000011: **pll1_r_ck** = **vco1_ck** / 4
...
1111111: **pll1_r_ck** = **vco1_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ1[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the **pll1_q_ck** clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: **pll1_q_ck** = **vco1_ck**
0000001: **pll1_q_ck** = **vco1_ck** / 2 (default after reset)
0000010: **pll1_q_ck** = **vco1_ck** / 3
0000011: **pll1_q_ck** = **vco1_ck** / 4
...
1111111: **pll1_q_ck** = **vco1_ck** / 128

Bits 15:9 **DIVP1[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the **pll1_p_ck** clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
Note that odd division factors are not allowed.
0000000: not allowed
0000001: **pll1_p_ck** = **vco1_ck** / 2 (default after reset)
0000010: not allowed
0000011: **pll1_p_ck** = **vco1_ck** / 4
...
1111111: **pll1_p_ck** = **vco1_ck** / 128

Bits 8:0 **DIVN1[8:0]**: multiplication factor for PLL1 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = PLL1RDY = 0).
.....: not used
0x006: wrong configuration
0x007: DIVN1 = 8
...
0x080: DIVN1 = 129 (default after reset)
...
0x1A3: DIVN1 = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 560 MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x DIVN1, when fractional value 0 has been loaded into FRACN1, with:

- DIVN1 between 8 and 420
- The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

8.7.12 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

FRACN1[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN1[12:0]**: fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 560 MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x $\left(DIVN1 + (FRACN1 / 2^{13})\right)$, with

- DIVN1 between 8 and 420
- FRACN1 can be between 0 and 2^{13}- 1
- The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into FRACN1.
- Set the bit PLL1FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

8.7.13 RCC PLL2 dividers configuration register (RCC_PLL2DIVR)

Address offset: 0x038

Reset value: 0x0101 0280

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR2[6:0]**: PLL2 DIVR division factor

Set and reset by software to control the frequency of the **pll2_r_ck** clock.
These bits can be written only when the PLL2 is disabled (PLL2ON = PLL2RDY = 0).
0000000: **pll2_r_ck** = **vco2_ck**
0000001: **pll2_r_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_r_ck** = **vco2_ck** / 3
0000011: **pll2_r_ck** = **vco2_ck** / 4
...
1111111: **pll2_r_ck** = **vco2_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ2[6:0]**: PLL2 DIVQ division factor

Set and reset by software to control the frequency of the **pll2_q_ck** clock.
These bits can be written only when the PLL2 is disabled (PLL2ON = PLL2RDY = 0).
0000000: **pll2_q_ck** = **vco2_ck**
0000001: **pll2_q_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_q_ck** = **vco2_ck** / 3
0000011: **pll2_q_ck** = **vco2_ck** / 4
...
1111111: **pll2_q_ck** = **vco2_ck** / 128

Bits 15:9 **DIVP2[6:0]**: PLL2 DIVP division factor

Set and reset by software to control the frequency of the **pll2_p_ck** clock.
These bits can be written only when the PLL2 is disabled (PLL2ON = PLL2RDY = 0).
0000000: **pll2_p_ck** = **vco2_ck**
0000001: **pll2_p_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_p_ck** = **vco2_ck** / 3
0000011: **pll2_p_ck** = **vco2_ck** / 4
...
1111111: **pll2_p_ck** = **vco2_ck** / 128

Bits 8:0 **DIVN2[8:0]**: multiplication factor for PLL2 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL2ON = PLL2RDY = 0).
.....: not used
0x006: wrong configuration
0x007: DIVN2 = 8
...
0x080: DIVN2 = 129 (default after reset)
...
0x1A3: DIVN2 = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 560 MHz if PLL2VCOSEL = 0
- 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = F_{ref2_ck} x DIVN2, when fractional value 0 has been loaded into FRACN2, with

- DIVN2 between 8 and 420
- The input frequency F_{ref2_ck} must be between 1 and 16MHz.

...
0x1A3: DIVN3 = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 560 MHz if PLL3VCOSEL = 0
- 150 to 420 MHz if PLL3VCOSEL = 1

VCO output frequency = F_{ref3_ck} x DIVN3, when fractional value 0 has been loaded into FRACN3, with:

- DIVN3 between 8 and 420
- The input frequency F_{ref3_ck} must be between 1 and 16MHz

8.7.16 RCC PLL3 fractional divider register (RCC_PLL3FRACR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACN3[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN3[12:0]**: fractional part of the multiplication factor for PLL3 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 560 MHz if PLL3VCOSEL = 0
- 150 to 420 MHz if PLL3VCOSEL = 1

VCO output frequency = F_{ref3_ck} x $\left(DIVN3 + (FRACN3 / 2^{13})\right)$, with

- DIVN3 between 8 and 420
- FRACN3 can be between 0 and $2^{13} - 1$
- The input frequency F_{ref3_ck} must be between 1 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into FRACN1.
- Set the bit PLL1FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

8.7.17 RCC CPU domain kernel clock configuration register (RCC_CDCCIPR)

Address offset: 0x04C

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **CKPERSEL[1:0]**: **per_ck** clock source selection
- 00: **hsi_ker_ck** selected as **per_ck** clock (default after reset)
- 01: **csi_ker_ck** selected as **per_ck** clock
- 10: **hse_ck** selected as **per_ck** clock
- 11: reserved, the **per_ck** clock is disabled

Bits 27:17 Reserved, must be kept at reset value.

Bit 16 **SDMMCSEL**: SDMMC kernel clock source selection
- 0: **pll1_q_ck** selected as kernel peripheral clock (default after reset)
- 1: **pll2_r_ck** selected as kernel peripheral clock

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:4 **OCTOSPISEL[1:0]**: OCTOSPI kernel clock source selection
- 00: **rcc_hclk3** selected as kernel peripheral clock (default after reset)
- 01: **pll1_q_ck** selected as kernel peripheral clock
- 10: **pll2_r_ck** selected as kernel peripheral clock
- 11: **per_ck** selected as kernel peripheral clock

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **FMCSEL[1:0]**: FMC kernel clock source selection
- 00: **rcc_hclk3** selected as kernel peripheral clock (default after reset)
- 01: **pll1_q_ck** selected as kernel peripheral clock
- 10: **pll2_r_ck** selected as kernel peripheral clock
- 11: **per_ck** selected as kernel peripheral clock

8.7.18 RCC CPU domain kernel clock configuration register (RCC_CDCCIP1R)

Address offset: 0x050

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bit 31 **SWPMISEL**: SWPMI kernel clock source selection
Set and reset by software.
0: **rcc_pclk1** selected as SWPMI kernel clock (default after reset)
1: **hsi_ker_ck** selected as SWPMI kernel clock

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **FDCANSEL[1:0]**: FDCAN kernel clock source selection
Set and reset by software.
00: **hse_ck** clock selected as FDCAN kernel clock (default after reset)
01: **pll1_q_ck** selected as FDCAN kernel clock
10: **pll2_q_ck** selected as FDCAN kernel clock
11: reserved, the kernel clock is disabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **DFSDM1SEL**: DFSDM1 kernel clock **Clk** source selection
Set and reset by software.
Note: the DFSDM1 Aclk clock source selection is done by SAI1SEL (see Figure 55).
0: **rcc_pclk2** selected as DFSDM1 Clk kernel clock (default after reset)
1: **sys_ck** selected as DFSDM1 Clk kernel clock

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **SPDIFRXSEL[1:0]**: SPDIFRX kernel clock source selection
00: **pll1_q_ck** selected as SPDIFRX kernel clock (default after reset)
01: **pll2_r_ck** selected as SPDIFRX kernel clock
10: **pll3_r_ck** selected as SPDIFRX kernel clock
11: **hsi_ker_ck** selected as SPDIFRX kernel clock

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **SPI45SEL[2:0]**: SPI4 and 5 kernel clock source selection
Set and reset by software.
000: **rcc_pclk2** clock selected as kernel clock (default after reset)
001: **pll2_q_ck** is selected as kernel clock
010: **pll3_q_ck** is selected as kernel clock
011: **hsi_ker_ck** is selected as kernel clock
100: **csi_ker_ck** is selected as kernel clock
101: **hse_ck** is selected as kernel clock
others: reserved, the kernel clock is disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **SPI123SEL[2:0]**: SPI/I2S1,2 and 3 kernel clock source selection

Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 379* for additional information.

000: **pll1_q_ck** selected as SPI/I2S1,2 and 3 kernel clock (default after reset)
001: **pll2_p_ck** selected as SPI/I2S1,2 and 3 kernel clock
010: **pll3_p_ck** selected as SPI/I2S1,2 and 3 kernel clock
011: I2S_CKIN selected as SPI/I2S1,2 and 3 kernel clock
100: **per_ck** selected as SPI/I2S1,2 and 3 kernel clock
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

Bits 11:9 **SAI2BSEL[2:0]**: SAI2 kernel clock B source selection

Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 379* for additional information.

000: **pll1_q_ck** selected as SAI2 kernel clock B (default after reset)
001: **pll2_p_ck** selected as SAI2 kernel clock B
010: **pll3_p_ck** selected as SAI2 kernel clock B
011: I2S_CKIN selected as SAI2 kernel clock B
100: **per_ck** selected as SAI2 kernel clock B
101: **spdifrx_symb_ck** selected as SAI2 kernel clock B
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin. ***spdifrx_symb_ck*** *is the symbol clock generated by the spdifrx (see Figure 55).*

Bits 8:6 **SAI2ASEL[2:0]**: SAI2 kernel clock source A selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 379* for additional information.

000: **pll1_q_ck** selected as SAI2 kernel clock A (default after reset)
001: **pll2_p_ck** selected as SAI2 kernel clock A
010: **pll3_p_ck** selected as SAI2 kernel clock A
011: I2S_CKIN selected as SAI2 kernel clock A
100: **per_ck** selected as SAI2 kernel clock A
101: **spdifrx_symb_ck** selected as SAI2 kernel clock A
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin. **spdifrx_symb_ck** *is the symbol clock generated by the SPDIFRX (see Figure 55).*

Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **SAI1SEL[2:0]**: SAI1 and DFSDM1 kernel **Aclk** clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it isnot be possible to switch to another clock. Refer to *Clock switches and gating on page 379* for additional information.

Note: DFSDM1 clock source selection is done by DFSDM1SEL.

000: **pll1_q_ck** selected as SAI1 and DFSDM1 **Aclk** kernel clock (default after reset)
001: **pll2_p_ck** selected as SAI1 and DFSDM1 **Aclk** kernel clock
010: **pll3_p_ck** selected as SAI1 and DFSDM1 **Aclk** kernel clock
011: I2S_CKIN selected as SAI1 and DFSDM1 **Aclk** kernel clock
100: **per_ck** selected as SAI1 and DFSDM1 **Aclk** kernel clock
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

8.7.19 RCC CPU domain kernel clock configuration register (RCC_CDCCIP2R)

Address offset: 0x054

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **LPTIM1SEL[2:0]**: LPTIM1 kernel clock source selection
Set and reset by software.
000: **rcc_pclk1** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:22 **CECSEL[1:0]**: HDMI-CEC kernel clock source selection
Set and reset by software.
00: **lse_ck** selected as kernel clock (default after reset)
01: **lsi_ck** selected as kernel clock
10: **csi_ker_ck** divided by 122 selected as kernel clock
11: reserved, the kernel clock is disabled

Bits 21:20 **USBSEL[1:0]**: USBOTG 1 and 2 kernel clock source selection
Set and reset by software.
00: Disable the kernel clock (default after reset)
01: **pll1_q_ck** selected as kernel clock
10: **pll3_q_ck** selected as kernel clock
11: **hsi48_ck** selected as kernel clock

Bits 19:14 Reserved, must be kept at reset value.

Bits 13:12 **I2C123SEL[1:0]**: I2C1,2,3 kernel clock source selection
Set and reset by software.
00: **rcc_pclk1** selected as kernel clock (default after reset)
01: **pll3_r_ck** selected as kernel clock
10: **hsi_ker_ck** selected as kernel clock
11: **csi_ker_ck** selected as kernel clock

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **RNGSEL[1:0]**: RNG kernel clock source selection
Set and reset by software.
00: **hsi48_ck** selected as kernel clock (default after reset)
01: **pll1_q_ck** selected as kernel clock
10: **lse_ck** selected as kernel clock
11: **lsi_ck** selected as kernel clock

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:3 **USART16910SEL[2:0]**: USART1, 6, 9 and 10 kernel clock source selection
Set and reset by software.
000: **rcc_pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

Bits 2:0 **USART234578SEL[2:0]**: USART2/3, UART4,5, 7 and 8 (APB1) kernel clock source selection
Set and reset by software.
000: **rcc_pclk1** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

8.7.20 RCC SmartRun domain kernel clock configuration register (RCC_SRDCCIPR)

Address offset: 0x058

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

101: **hse_ck** selected as kernel peripheral clock
110: I2S_CKIN selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bit 27 **DFSDM2SEL**: DFSDM2 kernel **Clk** clock source selection
Set and reset by software.
Note: The DFSDM2 Aclk clock source selection is done by SPI6SEL (see Figure 55 and Figure 56).
0: **rcc_pclk4** selected as DFSDM2 Clk kernel clock (default after reset)
1: **sys_ck** selected as DFSDM2 Clk kernel clock

Bits 26:18 Reserved, must be kept at reset value.

Bits 17:16 **ADCSEL[1:0]**: SAR ADC kernel clock source selection
Set and reset by software.
00: **pll2_p_ck** selected as kernel peripheral clock (default after reset)
01: **pll3_r_ck** selected as kernel peripheral clock
10: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 15:13 **LPTIM3SEL[2:0]**: LPTIM3 kernel clock source selection
Set and reset by software.
000: **rcc_pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 12:10 **LPTIM2SEL[2:0]**: LPTIM2 kernel clock source selection
Set and reset by software.
000: **rcc_pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 9:8 **I2C4SEL[1:0]**: I2C4 kernel clock source selection
Set and reset by software.
00: **rcc_pclk4** selected as kernel peripheral clock (default after reset)
01: **pll3_r_ck** selected as kernel peripheral clock
10: **hsi_ker_ck** selected as kernel peripheral clock
11: **csi_ker_ck** selected as kernel peripheral clock

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection
Set and reset by software.
000: **rcc_pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_q_ck** selected as kernel peripheral clock
010: **pll3_q_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **csi_ker_ck** selected as kernel peripheral clock
101: **lse_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

8.7.21 RCC clock source interrupt enable register (RCC_CIER)

Address offset: 0x060

Reset value: 0x0000 0000

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSIE**: LSE clock security system interrupt enable
Set and reset by software to enable/disable interrupt caused by the clock security system (CSS) on external 32 kHz oscillator.
0: LSE CSS interrupt disabled (default after reset)
1: LSE CSS interrupt enabled

Bit 8 **PLL3RDYIE**: PLL3 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL3 lock.
0: PLL3 lock interrupt disabled (default after reset)
1: PLL3 lock interrupt enabled

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL2 lock.
0: PLL2 lock interrupt disabled (default after reset)
1: PLL2 lock interrupt enabled

Bit 6 **PLL1RDYIE**: PLL1 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE**: HSI48 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.
0: HSI48 ready interrupt disabled (default after reset)
1: HSI48 ready interrupt enabled

Bit 4 **CSIRDYIE**: CSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 3 **HSERDYIE**: HSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 2 **HSIRDYIE**: HSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

8.7.22 RCC clock source interrupt flag register (RCC_CIFR)

Address offset: 0x64

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSF	LSECSSF	PLL3RDYF	PLL2RDYF	PLL1RDYF	HSI48RDYF	CSIRDYF	HSERDYF	HSIRDYF	LSERDYF	LSIRDYF
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Reset by software by writing HSECSSC bit.
Set by hardware in case of HSE clock failure.
0: no clock security interrupt caused by HSE clock failure (default after reset)
1: clock security interrupt caused by HSE clock failure

Bit 9 **LSECSSF**: LSE clock security system interrupt flag
Reset by software by writing LSECSSC bit.
Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.
0: no failure detected on the external 32 kHz oscillator (default after reset)
1: failure detected on the external 32 kHz oscillator

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
Reset by software by writing PLL3RDYC bit.
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
0: no clock ready interrupt caused by PLL3 lock (default after reset)
1: clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Reset by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: no clock ready interrupt caused by PLL2 lock (default after reset)
1: clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Reset by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: no clock ready interrupt caused by PLL1 lock (default after reset)
1: clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Reset by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: no clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: clock ready interrupt caused by the HSI48 oscillator

Bit 4 **CSIRDYF**: CSI ready interrupt flag
Reset by software by writing CSIRDYC bit.
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
0: no clock ready interrupt caused by the CSI (default after reset)
1: clock ready interrupt caused by the CSI

Bit 3 **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: no clock ready interrupt caused by the HSE (default after reset)
1: clock ready interrupt caused by the HSE

Bit 2 **HSIRDYF**: HSI ready interrupt flag
Reset by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: no clock ready interrupt caused by the HSI (default after reset)
1: clock ready interrupt caused by the HSI

Bit 1 **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: no clock ready interrupt caused by the LSE (default after reset)
1: clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: no clock ready interrupt caused by the LSI (default after reset)
1: clock ready interrupt caused by the LSI

8.7.23 RCC clock source interrupt clear register (RCC_CICR)

Address offset: 0x68

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF.
Reset by hardware when clear done.
0: HSECSSF no effect (default after reset)
1: HSECSSF cleared

Bit 9 **LSECSSC**: LSE clock security system interrupt clear
Set by software to clear LSECSSF.
Reset by hardware when clear done.
0: LSECSSF no effect (default after reset)
1: LSECSSF cleared

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Set by software to clear PLL3RDYF.
Reset by hardware when clear done.
0: PLL3RDYF no effect (default after reset)
1: PLL3RDYF cleared

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Set by software to clear PLL2RDYF.
Reset by hardware when clear done.
0: PLL2RDYF no effect (default after reset)
1: PLL2RDYF cleared

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Set by software to clear PLL1RDYF.
Reset by hardware when clear done.
0: PLL1RDYF no effect (default after reset)
1: PLL1RDYF cleared

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Set by software to clear HSI48RDYF.
Reset by hardware when clear done.
0: HSI48RDYF no effect (default after reset)
1: HSI48RDYF cleared

Bit 4 **CSIRDYC**: CSI ready interrupt clear
Set by software to clear CSIRDYF.
Reset by hardware when clear done.
0: CSIRDYF no effect (default after reset)
1: CSIRDYF cleared

Bit 3 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF.
Reset by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 2 **HSIRDYC**: HSI ready interrupt clear
Set by software to clear HSIRDYF.
Reset by hardware when clear done.
0: HSIRDYF no effect (default after reset)
1: HSIRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF.
Reset by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF.
Reset by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared

8.7.24 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x070

Reset value: 0x0000 0000

Reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC_BDCR register is write-protected. To modify this register, the DBP bit in the *PWR control register 1 (PWR_CR1)* must be set to 1. RCC_BDCR bits are only reset after a Backup domain reset (see *Section 8.4.6: Backup domain reset*). Any other internal or external reset does not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSWRST
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	Res.	Res.	Res.	RTCSEL[1:0]		LSEEXT	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw						rwo	rw	rw	r	rs	rw	rw	rw	r	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VSWRST:** VSwitch domain software reset
Set and reset by software.
0: reset not activated (default after Backup domain reset)
1: resets the entire VSW domain

Bit 15 **RTCEN**: RTC clock enable
Set and reset by software.
0: **rtc_ck** disabled (default after Backup domain reset)
1: **rtc_ck** enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection
Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The VSWRST bit can be used to reset them, then it can be written one time again.
If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).
00: no clock (default after Backup domain reset)
01: LSE selected as RTC clock
10: LSI selected as RTC clock
11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 **LSEEXT**: low-speed external clock type in Bypass mode

Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the LSEON bit, to be used by the device.
The LSEEXT bit can be written only if the LSE oscillator is disabled.
0: LSE in analog mode (default after Backup domain reset)
1: LSE in digital mode (do not use if RTC is active).

Bit 6 **LSECSSD**: LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator.
0: no failure detected on 32 kHz oscillator (default after Backup domain reset)
1: failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable

Set by software to enable the clock security system on 32 kHz oscillator.
LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.
Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case the software **must** disable LSECSSON.
0: CSS on 32 kHz oscillator OFF (default after Backup domain reset)
1: CSS on 32 kHz oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.
00: lowest drive (default after Backup domain reset)
01: medium-low drive
10: medium-high drive
11: highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and reset by software to bypass oscillator. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = 1)
0: LSE oscillator not bypassed (default after Backup domain reset)
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of **lse_ck** clock to fall down after LSEON has been set to 0.
0: LSE oscillator not ready (default after Backup domain reset)
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled

Set and reset by software.
0: LSE oscillator OFF (default after Backup domain reset)
1: LSE oscillator ON

8.7.25 RCC clock control and status register (RCC_CSR)

Address offset: 0x074

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LSIRDY	LSION
														r	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and reset by hardware to indicate when the low-speed internal RC oscillator is stable.
This bit needs 3 cycles of **lsi_ck** clock to fall down after LSION has been set to 0.
This bit can be set even when LSION is not enabled if there is a request for LSI clock by the clock security system on LSE or by the low-speed watchdog or by the RTC.
0: LSI clock is not ready (default after reset)
1: LSI clock is ready

Bit 0 **LSION**: LSI oscillator enable
Set and reset by software.
0: LSI is OFF (default after reset)
1: LSI is ON

8.7.26 RCC AHB3 reset register (RCC_AHB3RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	GFXMMURST	OTFD2RST	OTFD1RST	OCTOSPIMRST	Res.	OCTOSPI2RST	Res.	Res.	SDMMC1RST
							rw	rw	rw	rw		rw			rw

	rw		rw							rw	rw				rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **GFXMMURST**: GFXMMU reset
Set and reset by software
0: does not reset the GFXMMU (default after reset)
1: resets the GFXMMU

Bit 23 **OTFD2RST**: OTFD2 reset
Set and reset by software
Take care that resetting the OTFD means loosing the decryption key loaded during secure boot.
0: does not reset the OTFD2 (default after reset)
1: resets the OTFD2

Bit 22 **OTFD1RST**: OTFD1 reset
Set and reset by software
Take care that resetting the OTFD means loosing the decryption key loaded during secure boot.
0: does not reset the OTFD1 (default after reset)
1: resets the OTFD1

Bit 21 **OCTOSPIMRST**: OCTOSPIM reset
Set and reset by software
0: does not reset the OCTOSPIM (default after reset)
1: resets the OCTOSPIM

Bit 20 Reserved, must be kept at reset value.

Bit 19 **OCTOSPI2RST**: OCTOSPI2 and OCTOSPI2 delay block reset
Set and reset by software
0: does not reset the OCTOSPI2 and OCTOSPI2 delay block (default after reset)
1: resets the OCTOSPI2 and OCTOSPI2 delay block

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC1RST**: SDMMC1 and SDMMC1 delay blocks reset
Set and reset by software.
0: does not reset SDMMC1 and SDMMC1 delay blocks (default after reset)
1: resets SDMMC1 and SDMMC1 delay blocks

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OCTOSPI1RST**: OCTOSPI1 and OCTOSPI1 delay blocks reset
Set and reset by software.
0: does not reset OCTOSPI1 and OCTOSPI1 delay blocks (default after reset)
1: resets OCTOSPI1 and OCTOSPI1 delay blocks

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCRST**: FMC block reset
Set and reset by software.
0: does not reset FMC block (default after reset)
1: resets FMC block

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **JPGDECRST**: JPGDEC block reset
Set and reset by software.
0: does not reset JPGDEC block (default after reset)
1: resets JPGDEC block

Bit 4 **DMA2DRST**: DMA2D block reset
Set and reset by software.
0: does not reset DMA2D block (default after reset)
1: resets DMA2D block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMARST**: MDMA block reset
Set and reset by software.
0: does not reset MDMA block (default after reset)
1: resets MDMA block

8.7.27 RCC AHB1 peripheral reset register (RCC_AHB1RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw				rw				rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **USB1OTGRST**: USB1OTG block reset
Set and reset by software.
0: does not reset USB1OTG block (default after reset)
1: resets USB1OTG block

Bits 24:10 Reserved, must be kept at reset value.

Bit 9 **CRCRST**: CRC block reset
Set and reset by software.
0: does not reset CRC block (default after reset)
1: resets CRC block

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **ADC12RST**: ADC1 and 2 blocks reset
Set and reset by software.
0: does not reset ADC1 and 2 blocks (default after reset)
1: resets ADC1 and 2 blocks

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2RST**: DMA2 and DMAMUX2 blocks reset
Set and reset by software.
0: does not reset DMA2 and DMAMUX2 blocks (default after reset)
1: resets DMA2 and DMAMUX2 blocks

Bit 0 **DMA1RST**: DMA1 and DMAMUX1 blocks reset
Set and reset by software.
0: does not reset DMA1 and DMAMUX1 blocks (default after reset)
1: resets DMA1 and DMAMUX1 blocks

8.7.28 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw		rw			rw	rw	rw		rw		rw

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BDMA1RST**: BDMA1 reset (DFSDM dedicated DMA)
Set and reset by software.
0: does not reset DMA block (default after reset)
1: resets DMA block

Bit 10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2RST**: SDMMC2 and SDMMC2 delay blocks reset
Set and reset by software.
0: does not reset SDMMC2 and SDMMC2 delay blocks (default after reset)
1: resets SDMMC2 and SDMMC2 delay blocks

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **RNGRST**: random number generator block reset
Set and reset by software.
0: does not reset RNG block (default after reset)
1: resets RNG block

Bit 5 **HASHRST**: hash block reset
Set and reset by software.
0: does not reset hash block (default after reset)
1: resets hash block

Bit 4 **CRYPTRST**: cryptography block reset
Set and reset by software.
0: does not reset cryptography block (default after reset)
1: resets cryptography block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **HSEMRST**: HSEM block reset
Set and reset by software.
0: does not reset HSEM block (default after reset)
1: resets HSEM block

Bit 1 Reserved, must be kept at reset value.

Bit 0 **DCMI_PSSIRST**: digital camera interface block reset (DCMI or PSSI depending which IP is active)
Set and reset by software.
0: does not reset the DCMI/PSSI block (default after reset)
1: resets the DCMI/PSSI block

8.7.29 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x088

Reset value: 0x0000 0000

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **BDMA2RST**: SmartRun domain DMA and DMAMUX blocks reset
Set and reset by software.
0: does not reset the DMA and DMAMUX blocks (default after reset)
1: resets the DMA and DMAMUX blocks

Bits 20:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKRST**: GPIOK block reset
Set and reset by software.
0: does not reset the GPIOK block (default after reset)
1: resets the GPIOK block

Bit 9 **GPIOJRST**: GPIOJ block reset
Set and reset by software.
0: does not reset the GPIOJ block (default after reset)
1: resets the GPIOJ block

Bit 8 **GPIOIRST**: GPIOI block reset
Set and reset by software.
0: does not reset the GPIOI block (default after reset)
1: resets the GPIOI block

Bit 7 **GPIOHRST**: GPIOH block reset
Set and reset by software.
0: does not reset the GPIOH block (default after reset)
1: resets the GPIOH block

Bit 6 **GPIOGRST**: GPIOG block reset
Set and reset by software.
0: does not reset the GPIOG block (default after reset)
1: resets the GPIOG block

Bit 5 **GPIOFRST**: GPIOF block reset
Set and reset by software.
0: does not reset the GPIOF block (default after reset)
1: resets the GPIOF block

Bit 4 **GPIOERST**: GPIOE block reset
Set and reset by software.
0: does not reset the GPIOE block (default after reset)
1: resets the GPIOE block

Bit 3 **GPIODRST**: GPIOD block reset
Set and reset by software.
0: does not reset the GPIOD block (default after reset)
1: resets the GPIOD block

Bit 2 **GPIOCRST**: GPIOC block reset
Set and reset by software.
0: does not reset the GPIOC block (default after reset)
1: resets the GPIOC block

Bit 1 **GPIOBRST**: GPIOB block reset
Set and reset by software.
0: does not reset the GPIOB block (default after reset)
1: resets the GPIOB block

Bit 0 **GPIOARST**: GPIOA block reset
Set and reset by software.
0: does not reset the GPIOA block (default after reset)
1: resets the GPIOA block

8.7.30 RCC APB3 peripheral reset register (RCC_APB3RSTR)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UART8RST**: UART8 block reset
Set and reset by software.
0: does not reset the UART8 block (default after reset)
1: resets the UART8 block

Bit 30 **UART7RST**: UART7 block reset
Set and reset by software.
0: does not reset the UART7 block (default after reset)
1: resets the UART7 block

Bit 29 **DAC1RST**: DAC1 (containing two converters) reset
Set and reset by software.
0: does not reset the DAC1 (default after reset)
1: resets the DAC1

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECRST**: HDMI-CEC block reset
Set and reset by software.
0: does not reset the HDMI-CEC block (default after reset)
1: resets the HDMI-CEC block

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3RST**: I2C3 block reset
Set and reset by software.
0: does not reset the I2C3 block (default after reset)
1: resets the I2C3 block

Bit 22 **I2C2RST**: I2C2 block reset
Set and reset by software.
0: does not reset the I2C2 block (default after reset)
1: resets the I2C2 block

Bit 21 **I2C1RST**: I2C1 block reset
Set and reset by software.
0: does not reset the I2C1 block (default after reset)
1: resets the I2C1 block

Bit 20 **UART5RST**: UART5 block reset
Set and reset by software.
0: does not reset the UART5 block (default after reset)
1: resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and reset by software.
0: does not reset the UART4 block (default after reset)
1: resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and reset by software.
0: does not reset the USART3 block (default after reset)
1: resets the USART3 block

Bit 17 **USART2RST**: USART2 block reset
Set and reset by software.
0: does not reset the USART2 block (default after reset)
1: resets the USART2 block

Bit 16 **SPDIFRXRST**: SPDIFRX block reset
Set and reset by software.
0: does not reset the SPDIFRX block (default after reset)
1: resets the SPDIFRX block

Bit 15 **SPI3RST**: SPI3 block reset
Set and reset by software.
0: does not reset the SPI3 block (default after reset)
1: resets the SPI3 block

Bit 14 **SPI2RST**: SPI2 block reset
Set and reset by software.
0: does not reset the SPI2 block (default after reset)
1: resets the SPI2 block

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Set and reset by software.
0: does not reset the LPTIM1 block (default after reset)
1: resets the LPTIM1 block

Bit 8 **TIM14RST**: TIM14 block reset
Set and reset by software.
0: does not reset the TIM14 block (default after reset)
1: resets the TIM14 block

Bit 7 **TIM13RST**: TIM13 block reset
Set and reset by software.
0: does not reset the TIM13 block (default after reset)
1: resets the TIM13 block

Bit 6 **TIM12RST**: TIM12 block reset
Set and reset by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 5 **TIM7RST**: TIM7 block reset
Set and reset by software.
0: does not reset the TIM7 block (default after reset)
1: resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and reset by software.
0: does not reset the TIM6 block (default after reset)
1: resets the TIM6 block

Bit 3 **TIM5RST**: TIM5 block reset
Set and reset by software.
0: does not reset the TIM5 block (default after reset)
1: resets the TIM5 block

Bit 2 **TIM4RST**: TIM4 block reset
Set and reset by software.
0: does not reset the TIM4 block (default after reset)
1: resets the TIM4 block

Bit 1 **TIM3RST**: TIM3 block reset
Set and reset by software.
0: does not reset the TIM3 block (default after reset)
1: resets the TIM3 block

Bit 0 **TIM2RST**: TIM2 block reset
Set and reset by software.
0: does not reset the TIM2 block (default after reset)
1: resets the TIM2 block

8.7.32 RCC APB1 peripheral reset register (RCC_APB1HRSTR)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw			rw	rw		rw	rw	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN block reset
Set and reset by software.
0: does not reset the FDCAN block (default after reset)
1: resets the FDCAN block

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSRST**: MDIOS block reset
Set and reset by software.
0: does not reset the MDIOS block (default after reset)
1: resets the MDIOS block

Bit 4 **OPAMPRST**: OPAMP block reset
Set and reset by software.
0: does not reset the OPAMP block (default after reset)
1: resets the OPAMP block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPMIRST**: SWPMI block reset
Set and reset by software.
0: does not reset the SWPMI block (default after reset)
1: resets the SWPMI block

Bit 1 **CRSRST**: clock recovery system reset
Set and reset by software.
0: does not reset CRS (default after reset)
1: resets CRS

Bit 0 Reserved, must be kept at reset value.

8.7.33 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x098

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	DFSDM1RST	Res.	Res.	Res.	Res.	Res.	Res.	SAI2RST	SAI1RST	Res.	SPI5RST	Res.	TIM17RST	TIM16RST	TIM15RST

		rw	rw					rw	rw	rw	rw			rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DFSDM1RST**: DFSDM1 block reset
Set and reset by software.
0: does not reset DFSDM1 block (default after reset)
1: resets DFSDM1 block

Bits 29:24 Reserved, must be kept at reset value.

Bit 23 **SAI2RST**: SAI2 block reset
Set and reset by software.
0: does not reset the SAI2 block (default after reset)
1: resets the SAI2 block

Bit 22 **SAI1RST**: SAI1 block reset
Set and reset by software.
0: does not reset the SAI1 (default after reset)
1: resets the SAI1

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5RST**: SPI5 block reset
Set and reset by software.
0: does not reset the SPI5 block (default after reset)
1: resets the SPI5 block

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17RST**: TIM17 block reset
Set and reset by software.
0: does not reset the TIM17 block (default after reset)
1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
Set and reset by software.
0: does not reset the TIM16 block (default after reset)
1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
Set and reset by software.
0: does not reset the TIM15 block (default after reset)
1: resets the TIM15 block

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset
Set and reset by software.
0: does not reset the SPI4 block (default after reset)
1: resets the SPI4 block

Bit 12 **SPI1RST**: SPI1 block reset
Set and reset by software.
0: does not reset the SPI1 block (default after reset)
1: resets the SPI1 block

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10RST**: USART10 block reset
Set and reset by software.
0: does not reset the USART10 block (default after reset)
1: resets the USART10 block

Bit 6 **UART9RST**: UART9 block reset
Set and reset by software.
0: does not reset the UART9 block (default after reset)
1: resets the UART9 block

Bit 5 **USART6RST**: USART6 block reset
Set and reset by software.
0: does not reset the USART6 block (default after reset)
1: resets the USART6 block

Bit 4 **USART1RST**: USART1 block reset
Set and reset by software.
0: does not reset the USART1 block (default after reset)
1: resets the USART1 block

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 block reset
Set and reset by software.
0: does not reset the TIM8 block (default after reset)
1: resets the TIM8 block

Bit 0 **TIM1RST**: TIM1 block reset
Set and reset by software.
0: does not reset the TIM1 block (default after reset)
1: resets the TIM1 block

8.7.34 RCC APB4 peripheral reset register (RCC_APB4RSTR)

Address offset: 0x09C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw			rw	rw		rw		rw		rw		rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **DFSDM2RST**: DFSDM2 block reset
Set and reset by software.
0: does not reset the DFSDM2 block (default after reset)
1: resets the DFSDM2 block

Bit 26 **DTSRST**: Digital temperature sensor block reset
Set and reset by software.
0: does not reset the DTS block (default after reset)
1: resets the DTS block

Bits 25:16 Reserved, must be kept at reset value.

Bit 15 **VREFRST**: VREF block reset
Set and reset by software.
0: does not reset the VREF block (default after reset)
1: resets the VREF block

Bit 14 **COMP12RST**: COMP1 and 2 blocks reset
Set and reset by software.
0: does not reset the COMP1 and 2 blocks (default after reset)
1: resets the COMP1 and 2 blocks

Bit 13 **DAC2RST**: DAC2 (containing one converter) reset
Set and reset by software.
0: does not reset the DAC2 (default after reset)
1: resets the DAC2

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **LPTIM3RST**: LPTIM3 block reset
Set and reset by software.
0: does not reset the LPTIM3 block (default after reset)
1: resets the LPTIM3 block

Bit 9 **LPTIM2RST**: LPTIM2 block reset
Set and reset by software.
0: does not reset the LPTIM2 block (default after reset)
1: resets the LPTIM2 block

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4RST**: I2C4 block reset
Set and reset by software.
0: does not reset the I2C4 block (default after reset)
1: resets the I2C4 block

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6RST**: SPI6 block reset
Set and reset by software.
0: does not reset the SPI6 block (default after reset)
1: resets the SPI6 block

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1RST**: LPUART1 block reset
Set and reset by software.
0: does not reset the LPUART1 block (default after reset)
1: resets the LPUART1 block

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGRST**: SYSCFG block reset
Set and reset by software.
0: does not reset the SYSCFG block (default after reset)
1: resets the SYSCFG block

Bit 0 Reserved, must be kept at reset value.

8.7.35 RCC SmartRun domain Autonomous mode register (RCC_SRDAMR)

The Autonomous mode allows the peripheral clocks to be provided to peripherals located in the SmartRun domain, even if the CPU is in CStop mode.

When a peripheral is enabled and has its autonomous bit activated, it receives its peripheral clocks according to the SmartRun domain state, if the CPU is in CStop mode.

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SRDSRAMAMEN	BKPRAMAMEN	DFSDM2AMEN	DTSAMEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTCAMEN
		rw	rw	rw	rw										rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VREFAMEN	COMP12AMEN	DAC2AMEN	Res.	Res.	LPTIM3AMEN	LPTIM2AMEN	Res.	I2C4AMEN	Res.	SPI6AMEN	Res.	LPUART1AMEN	Res.	GPIOAMEN	BDMA2AMEN
rw	rw	rw			rw	rw		rw		rw		rw		rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **SRDSRAMAMEN**: SmartRun domain SRAM Autonomous mode enable
Set and reset by software.
0: SRDSRAM clock disabled when the CPU is in CStop (default after reset)
1: SRDSRAM bus clock enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 28 **BKPRAMAMEN**: Backup RAM Autonomous mode enable
Set and reset by software.
0: Backup RAM clock disabled when the CPU is in CStop (default after reset)
1: Backup RAM clock enabling is controlled by the SmartRun domain state.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 27 **DFSDM2AMEN**: DFSDM2 Autonomous mode enable
Set and reset by software.
0: DFSDM2 clock disabled when the CPU is in CStop (default after reset)
1: DFSDM2 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 26 **DTSAMEN**: Digital temperature sensor Autonomous mode enable
Set and reset by software.
0: DTS clocks disabled when the CPU is in CStop (default after reset)
1: DTS clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAMEN**: RTC Autonomous mode enable
Set and reset by software.
0: RTC bus clocks disabled when the CPU is in CStop (default after reset)
1: RTC bus clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 15 **VREFAMEN**: VREF Autonomous mode enable
Set and reset by software.
0: VREF clocks disabled when the CPU is in CStop (default after reset)
1: VREF clocks enabled when the SmartRun domain is in Run or Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 14 **COMP12AMEN**: COMP1 and 2 Autonomous mode enable
Set and reset by software.
0: COMP1 and 2 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: COMP1 and 2 peripheral clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 13 **DAC2AMEN**: DAC2 (containing one converter) Autonomous mode enable
Set and reset by software.
0: DAC2 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: DAC2 peripheral clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **LPTIM3AMEN**: LPTIM3 Autonomous mode enable
Set and reset by software.
0: LPTIM3 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: LPTIM3 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock is enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 9 **LPTIM2AMEN**: LPTIM2 Autonomous mode enable
Set and reset by software.
0: LPTIM2 peripheral clocks are disabled when the CPU is in CStop (default after reset)
1: LPTIM2 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock is enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4AMEN**: I2C4 Autonomous mode enable
Set and reset by software.
0: I2C4 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: I2C4 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock is enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6AMEN**: SPI6 Autonomous mode enable
Set and reset by software.
0: SPI6 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: SPI6 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock is enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1AMEN**: LPUART1 Autonomous mode enable
Set and reset by software.
0: LPUART1 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: LPUART1 peripheral clocks enabled when the SmartRun domain is in Run mode. Kernel clock is enabled when the SmartRun domain is in Stop mode.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **GPIOAMEN**: GPIO Autonomous mode enable
Set and reset by software.
0: GPIO peripheral clocks disabled when the CPU is in CStop (default after reset)
1: GPIO peripheral clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

Bit 0 **BDMA2AMEN**: SmartRun domain DMA and DMAMUX Autonomous mode enable
Set and reset by software.
0: BDMA2 and DMAMUX2 peripheral clocks disabled when the CPU is in CStop (default after reset)
1: BDMA2 and DMAMUX2 peripheral clocks enabled when the SmartRun domain is in Run.
Refer to *Section 8.5.11: Peripheral clock gating control* for additional information.

8.7.36 RCC AXI clocks gating enable register (RCC_CKGAENR)

Address offset: 0x0B0

Reset value: 0x0000 0000

The dynamic power consumption can be optimized by enabling the functional clock gating.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **JTAGCKG**: JTAG automatic clock gating

This bit is set and reset by software.

0: The clock gating is disabled. The clock is always enabled.

1: The clock gating is enabled. The clock is disabled except if a JTAG connection has been detected

Bit 30 **EXTICKG**: EXTI clock gating

This bit is set and reset by software.

0: The clock gating is disabled. The clock is always enabled.

1: The clock gating is enabled. The clock is enabled after an event detection and stopped again when the event flag is cleared.

Bit 29 **ECCRAMCKG**: RAM error code correction (ECC) clock gating

This bit is set and reset by software.

0: The clock gating is disabled. The clock is always enabled.

1: The clock gating is enabled. The ECC clock is enabled only during a RAM access.

Bits 28:18 Reserved, must be kept at reset value.

Bit 17 **GFXMMUSCKG**: AXI matrix slave GFXMMU clock gating

This bit is set and reset by software.

0: The clock gating is disabled. The clock is always enabled

1: The clock gating is enabled. The AXI matrix slave GFXMMU clock is enabled on bus transaction request.

Bit 16 **AXIRAM3CKG**: AXI matrix slave SRAM3 clock gating

This bit is set and reset by software.

0: The clock gating is disabled. The clock is always enabled.

1: The clock gating is enabled. The AXI matrix slave SRAM3 clock is enabled on bus transaction request.

Bit 15 **AXIRAM2CKG**: AXI matrix slave SRAM2 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave SRAM2 clock is enabled on bus transaction request.

Bit 14 **AXIRAM1CKG**: AXI slave SRAM1 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave SRAM1 clock is enabled on bus transaction request.

Bit 13 **OCTOSPI1CKG**: AXI slave OCTOSPI1 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave OCTOSPI1 clock is enabled on bus transaction request.

Bit 12 **FMCCKG**: AXI slave FMC clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave FMC clock is enabled on bus transaction request.

Bit 11 **OCTOSPI2CKG**: AXI slave OCTOSPI2 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave OCTOSPI2 clock is enabled on bus transaction request.

Bit 10 **FLIFTCKG**: AXI slave flash interface (FLIFT) clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix slave FLIFT clock is enabled on bus transaction request.

Bit 9 **AHB34CKG**: AXI slave AHB34 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI matrix slave AHB34 clock is enabled on bus transaction request.

Bit 8 **AHB12CKG**: AXI slave AHB12 clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI matrix slave AHB12 clock is enabled on bus transaction request.

Bit 7 **GFXMMUMCKG**: AXI master GFXMMU clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI matrix master GFXMMU clock is enabled on bus transaction request.

Bit 6 **LTDCCKG**: AXI master LTDC clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix master LTDC clock is enabled on bus transaction request.

Bit 5 **DMA2DCKG**: AXI master DMA2D clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI matrix master DMA2D clock is enabled on bus transaction request.

Bit 4 **MDMACKG**: AXI master MDMA clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI matrix master MDMA clock is enabled on bus transaction request.

Bit 3 **SDMMCCKG**: AXI master SDMMC clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix master SDMMC clock is enabled on bus transaction request.

Bit 2 **CPUCKG**: AXI master CPU clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix master CPU clock is enabled on bus transaction request.

Bit 1 **AHBCKG**: AXI master AHB clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled.
1: The clock gating is enabled. The AXI matrix master AHB clock is enabled on bus transaction request.

Bit 0 **AXICKG**: AXI interconnect matrix clock gating
This bit is set and reset by software.
0: The clock gating is disabled. The clock is always enabled
1: The clock gating is enabled. The AXI interconnect matrix clock is enabled on bus transaction request.

8.7.37 RCC reset status register (RCC_RSR)

Address offset: 0x0D0

Reset value: 0x00E8 0000

Reset by power-on reset only.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	LPWRRSTF	Res.	WWDGRSTF	Res.	IWDGRSTF	Res.	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	Res.	CDRSTF	Res.	Res.	RMVF

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: reset due to illegal CD DStop or CD DStop2 or CPU CStop flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the CPU domain goes erroneously in DStop or DStop2, or when the CPU goes erroneously in CStop.
0: no illegal reset occurred (default after power-on reset)
1: illegal CD DStop or CD DStop2 or CPU CStop reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDGRSTF**: window watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: no window watchdog reset occurred from WWDG (default after power-on reset)
1: window watchdog reset occurred from WWDG

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDGRSTF**: independent watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when an independent watchdog reset occurs.
0: no independent watchdog reset occurred (default after power-on reset)
1: independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

Bit 24 **SFTRSTF**: system reset from CPU reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the core M7.
0: no CPU software reset occurred (default after power-on reset)
1: a system reset has been generated by the CPU

Bit 23 **PORRSTF**: POR/PDR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a POR/PDR reset occurs.
0: no POR/PDR reset occurred
1: POR/PDR reset occurred (default after power-on reset)

Bit 22 **PINRSTF**: pin reset flag (NRST) (1)
Reset by software by writing the RMVF bit.
Set by hardware when a reset from pin occurs.
0: no reset from pin occurred
1: reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a BOR reset occurs (**pwr_bor_rst**).
0: no BOR reset occurred
1: BOR reset occurred (default after power-on reset)

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CDRSTF**: CPU domain power-switch reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a the CPU domain exits from DStop or after of power-on reset. Set also when the CPU domain exists DStop2 but only when a pad reset has occurred during DStop2 (PINRST bit also set by hardware)
0: no CPU domain power-switch reset occurred
1: CPU domain power-switch (ePOD2) reset occurred (default after power-on reset)

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **RMVF**: remove reset flag
Set and reset by software to reset the value of the reset flags.
0: reset of the reset flags not activated (default after power-on reset)
1: resets the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to *Table 54: Reset source identification (RCC_RSR)* for details on flag behavior.

8.7.38 RCC AHB3 clock register (RCC_AHB3ENR)

Address offset: 0x0D4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw		rw							rw	rw				rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **GFXMMUEN**: GFXMMU clock enable
Set and reset by software.
0: GFXMMU clock disabled (default after reset)
1: GFXMMU clock enabled

Bit 23 **OTFD2EN**: OTFD2 clock enable
Set and reset by software.
0: OTFD2 clock disabled (default after reset)
1: OTFD2 clock enabled

Bit 22 **OTFD1EN**: OTFD1 clock enable
Set and reset by software.
0: OTFD1 clock disabled (default after reset)
1: OTFD1 clock enabled

Bit 21 **OCTOSPIMEN**: OCTOSPIM clock enable
Set and reset by software.
0: OCTOSPIM clock disabled (default after reset)
1: OCTOSPIM clock enabled

Bit 20 Reserved, must be kept at reset value.

Bit 19 **OCTOSPI2EN**: OCTOSPI2 clock enable
Set and reset by software.
0: OCTOSPI2 and OCTOSPI2 delay clock disabled (default after reset)
1: OCTOSPI2 OCTOSPI2 delay clock enabled

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC1EN**: SDMMC1 and SDMMC1 delay clock enable
Set and reset by software.
0: SDMMC1 and SDMMC1 delay clock disabled (default after reset)
1: SDMMC1 and SDMMC1 delay clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OCTOSPI1EN**: OCTOSPI1 and OCTOSPI1 delay clock enable
Set and reset by software.
0: OCTOSPI1 and OCTOSPI1 delay clock disabled (default after reset)
1: OCTOSPI1 and OCTOSPI1 delay clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCEN**: FMC peripheral clocks enable
Set and reset by software.
0: FMC peripheral clocks disabled (default after reset)
1: FMC peripheral clocks enabled
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL and provided to fmc_ker_ck input, and the **rcc_hclk3** bus interface clock.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **JPGDECEN**: JPGDEC peripheral clock enable
Set and reset by software.
0: JPGDEC peripheral clock disabled (default after reset)
1: JPGDEC peripheral clock enabled

Bit 4 **DMA2DEN**: DMA2D peripheral clock enable
Set and reset by software.
0: DMA2D peripheral clock disabled (default after reset)
1: DMA2D peripheral clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMAEN**: MDMA peripheral clock enable
Set and reset by software.
0: MDMA peripheral clock disabled (default after reset)
1: MDMA peripheral clock enabled

8.7.39 RCC AHB1 clock register (RCC_AHB1ENR)

Address offset: 0x0D8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	USB1ULPIEN	USB1OTGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
					rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	CRCEN	Res.	Res.	Res.	ADC12EN	Res.	Res.	Res.	DMA2EN	DMA1EN
						rw				rw				rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **USB1ULPIEN**: USB_PHY1 clocks enable
Set and reset by software.
0: USB1ULPI PHY clocks disabled (default after reset)
1: USB1ULPI PHY clocks enabled

Bit 25 **USB1OTGEN**: USB1OTG peripheral clocks enable
Set and reset by software.
0: USB1OTG peripheral clocks disabled (default after reset)
1: USB1OTG peripheral clocks enabled
The peripheral clocks of the USB1OTG are the kernel clock selected by USBSEL and the **rcc_hclk1** bus interface clock.

Bits 24:10 Reserved, must be kept at reset value.

Bit 9 **CRCEN**: CRC peripheral clock enable
Set and reset by software.
0: CRC peripheral clock disabled (default after reset)
1: CRC peripheral clock enabled

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC1 and 2 peripheral clocks enable
Set and reset by software.
0: ADC1 and 2 peripheral clocks disabled (default after reset)
1: ADC1 and 2 peripheral clocks enabled
The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to adc_ker_ck input, and the **rcc_hclk1** bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2EN**: DMA2 clock enable
Set and reset by software.
0: DMA2 clock disabled (default after reset)
1: DMA2 clock enabled

Bit 0 **DMA1EN**: DMA1 clock enable
Set and reset by software.
0: DMA1 clock disabled (default after reset)
1: DMA1 clock enabled

8.7.40 RCC AHB2 clock register (RCC_AHB2ENR)

Address offset: 0x0DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AHBSRAM2EN	AHBSRAM1EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	BDMA1EN	Res.	SDMMC2EN	Res.	Res.	RNGEN	HASHEN	CRYPTEN	Res.	HSEMEN	Res.	DCMI_PSSIEN
				rw		rw			rw	rw	rw		rw		rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **AHBSRAM2EN**: AHBSRAM2 block enable

Set and reset by software.

When set, this bit indicates that the SRAM2 is allocated by the CPU. It causes the CPU domain to take into account also the CPU operation modes, keeping the CPU domain in DRun when the CPU is in CRun.

0: AHBSRAM2 interface clock is disabled. (default after reset)

1: AHBSRAM2 interface clock is enabled.

Bit 29 **AHBSRAM1EN**: AHBSRAM1 block enable

Set and reset by software.

When set, this bit indicates that the SRAM1 is allocated by the CPU. It causes the CPU domain to take into account also the CPU operation modes, keeping the CPU domain in DRun when the CPU is in CRun.

0: AHBSRAM1 interface clock is disabled. (default after reset)

1: AHBSRAM1 interface clock is enabled.

Bits 28:12 Reserved, must be kept at reset value.

Bit 11 **BDMA1EN**: DMA clock enable (DFSDM dedicated DMA)

Set and reset by software.

0: DMA clock disabled (default after reset)

1: DMA clock enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2EN**: SDMMC2 and SDMMC2 delay clock enable

Set and reset by software.

0: SDMMC2 and SDMMC2 delay clock disabled (default after reset)

1: SDMMC2 and SDMMC2 delay clock enabled

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **RNGEN**: RNG peripheral clocks enable
Set and reset by software.
0: RNG peripheral clocks disabled (default after reset)
1: RNG peripheral clocks enabled:
The peripheral clocks of the RNG are the kernel clock selected by RNGSEL and provided to **rng_clk** input, and the **rcc_hclk2** bus interface clock.

Bit 5 **HASHEN**: HASH peripheral clock enable
Set and reset by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled

Bit 4 **CRYPTEN**: CRYPT peripheral clock enable
Set and reset by software.
0: CRYPT peripheral clock disabled (default after reset)
1: CRYPT peripheral clock enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **HSEMEN**: HSEM peripheral clock enable
Set and reset by software.
0: HSEM peripheral clock disabled (default after reset)
1: HSEM peripheral clock enabled

Bit 1 Reserved, must be kept at reset value.

Bit 0 **DCMI_PSSIEN**: digital camera interface peripheral clock enable (DCMI or PSSI depending which IP is active)
Set and reset by software.
0: DCMI/PSSI peripheral clock disabled (default after reset)
1: DCMI/PSSI peripheral clock enabled

8.7.41 RCC AHB4 Clock Register (RCC_AHB4ENR)

Address offset: 0x0E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **SRDSRAMEN**: SmartRun domain SRAM clock enable
Set and reset by software.
0: SRDSRAM clock disabled (default after reset)
1: SRDSRAM clock enabled

Bit 28 **BKPRAMEN**: Backup RAM clock enable
Set and reset by software.
0: Backup RAM clock disabled (default after reset)
1: Backup RAM clock enabled

Bits 27:22 Reserved, must be kept at reset value.

Bit 21 **BDMA2EN**: SmartRun domain DMA and DMAMUX clock enable
Set and reset by software.
0: BDMA2 and DMAMUX2 clock disabled (default after reset)
1: BDMA2 and DMAMUX2 clock enabled

Bits 20:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKEN**: GPIOK peripheral clock enable
Set and reset by software.
0: GPIOK peripheral clock disabled (default after reset)
1: GPIOK peripheral clock enabled

Bit 9 **GPIOJEN**: GPIOJ peripheral clock enable
Set and reset by software.
0: GPIOJ peripheral clock disabled (default after reset)
1: GPIOJ peripheral clock enabled

Bit 8 **GPIOIEN**: GPIOI peripheral clock enable
Set and reset by software.
0: GPIOI peripheral clock disabled (default after reset)
1: GPIOI peripheral clock enabled

Bit 7 **GPIOHEN**: GPIOH peripheral clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG peripheral clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF peripheral clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE peripheral clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD peripheral clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 2 **GPIOCEN**: GPIOC peripheral clock enable
Set and reset by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 1 **GPIOBEN**: GPIOB peripheral clock enable
Set and reset by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 0 **GPIOAEN**: GPIOA peripheral clock enable
Set and reset by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

8.7.42 RCC APB3 clock register (RCC_APB3ENR)

Address offset: 0x0E4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WWDGEN	Res.	Res.	LTDCEN	Res.	Res.	Res.
									rs			rw			

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **WWDGEN**: WWDG clock enable
Set by software, and reset by hardware when a system reset occurs.
Note that in order to work properly, before enabling the WWDG, the bit WW1RSC must be set to 1.
0: WWDG peripheral clock disable (default after reset)
1: WWDG peripheral clock enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **LTDCEN**: LTDC clock enable
Provides the clock (ltdc_pclk, ltdc_aclk, ltdc_ker_ck) to the LTDC block.
Set and reset by software.
0: LTDC peripheral clock disabled (default after reset)
1: LTDC peripheral clock provided to the LTDC block

Bits 2:0 Reserved, must be kept at reset value.

8.7.43 RCC APB1 clock register (RCC_APB1LENR)

Address offset: 0x0E8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UART8EN	UART7EN	DAC1EN	Res.	CECEN	Res.	Res.	Res.	I2C3EN	I2C2EN	I2C1EN	UART5EN	UART4EN	USART3EN	USART2EN	SPDIFRXEN
rw	rw	rw		rw				rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPI3EN	SPI2EN	Res.	Res.	Res.	Res.	LPTIM1EN	TIM14EN	TIM13EN	TIM12EN	TIM7EN	TIM6EN	TIM5EN	TIM4EN	TIM3EN	TIM2EN
rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UART8EN**: UART8 peripheral clocks enable
Set and reset by software.
0: UART8 peripheral clocks disabled (default after reset)
1: UART8 peripheral clocks enabled
The peripheral clocks of the UART8 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 30 **UART7EN**: UART7 peripheral clocks enable
Set and reset by software.
0: UART7 peripheral clocks disabled (default after reset)
1: UART7 peripheral clocks enabled
The peripheral clocks of the UART7 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 29 **DAC1EN**: DAC1 (containing two converters) peripheral clock enable
Set and reset by software.
0: DAC1 peripheral clock disabled (default after reset)
1: DAC1 peripheral clock enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECEN**: HDMI-CEC peripheral clock enable
Set and reset by software.
0: HDMI-CEC peripheral clock disabled (default after reset)
1: HDMI-CEC peripheral clock enabled
The peripheral clocks of the HDMI-CEC are the kernel clock selected by CECSEL and provided to **cec_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3EN**: I2C3 peripheral clocks enable
Set and reset by software.
0: I2C3 peripheral clocks disabled (default after reset)
1: I2C3 peripheral clocks enabled
The peripheral clocks of the I2C3 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 22 **I2C2EN**: I2C2 peripheral clocks enable
Set and reset by software.
0: I2C2 peripheral clocks disabled (default after reset)
1: I2C2 peripheral clocks enabled
The peripheral clocks of the I2C2 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 21 **I2C1EN**: I2C1 peripheral clocks enable
Set and reset by software.
0: I2C1 peripheral clocks disabled (default after reset)
1: I2C1 peripheral clocks enabled
The peripheral clocks of the I2C1 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 20 **UART5EN**: UART5 peripheral clocks enable
Set and reset by software.
0: UART5 peripheral clocks disabled (default after reset)
1: UART5 peripheral clocks enabled
The peripheral clocks of the UART5 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 19 **UART4EN**: UART4 peripheral clocks enable
Set and reset by software.
0: UART4 peripheral clocks disabled (default after reset)
1: UART4 peripheral clocks enabled
The peripheral clocks of the UART4 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 18 **USART3EN**: USART3 peripheral clocks enable
Set and reset by software.
0: USART3 peripheral clocks disabled (default after reset)
1: USART3 peripheral clocks enabled
The peripheral clocks of the USART3 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 17 **USART2EN**: USART2peripheral clocks enable
Set and reset by software.
0: USART2 peripheral clocks disabled (default after reset)
1: USART2 peripheral clocks enabled
The peripheral clocks of the USART2 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 16 **SPDIFRXEN**: SPDIFRX peripheral clocks enable
Set and reset by software.
0: SPDIFRX peripheral clocks disabled (default after reset)
1: SPDIFRX peripheral clocks enabled
The peripheral clocks of the SPDIFRX are the kernel clock selected by SPDIFRXSEL and provided to spdifrx_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 15 **SPI3EN**: SPI3 peripheral clocks enable
Set and reset by software.
0: SPI3 peripheral clocks disabled (default after reset)
1: SPI3 peripheral clocks enabled
The peripheral clocks of the SPI3 are the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bit 14 **SPI2EN**: SPI2 peripheral clocks enable
Set and reset by software.
0: SPI2 peripheral clocks disabled (default after reset)
1: SPI2 peripheral clocks enabled
The peripheral clocks of the SPI2 are the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
Set and reset by software.
0: LPTIM1 peripheral clocks disabled (default after reset)
1: LPTIM1 peripheral clocks enabled
The peripheral clocks of the LPTIM1 are the kernel clock selected by LPTIM1SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bit 8 **TIM14EN**: TIM14 peripheral clock enable
Set and reset by software.
0: TIM14 peripheral clock disabled (default after reset)
1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 peripheral clock enable
Set and reset by software.
0: TIM13 peripheral clock disabled (default after reset)
1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 peripheral clock enable
Set and reset by software.
0: TIM12 peripheral clock disabled (default after reset)
1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 peripheral clock enable
Set and reset by software.
0: TIM7 peripheral clock disabled (default after reset)
1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 peripheral clock enable
Set and reset by software.
0: TIM6 peripheral clock disabled (default after reset)
1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 peripheral clock enable
Set and reset by software.
0: TIM5 peripheral clock disabled (default after reset)
1: TIM5 peripheral clock enabled

Bit 2 **TIM4EN**: TIM4 peripheral clock enable
Set and reset by software.
0: TIM4 peripheral clock disable (default after reset)
1: TIM4 peripheral clock enabled

Bit 1 **TIM3EN**: TIM3 peripheral clock enable
Set and reset by software.
0: TIM3 peripheral clock disabled (default after reset)
1: TIM3 peripheral clock enabled

Bit 0 **TIM2EN**: TIM2 peripheral clock enable
Set and reset by software.
0: TIM2 peripheral clock disabled (default after reset)
1: TIM2 peripheral clock enabled

8.7.44 RCC APB1 clock register (RCC_APB1HENR)

Address offset: 0x0EC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANEN**: FDCAN peripheral clocks enable
Set and reset by software.
0: FDCAN peripheral clocks disabled (default after reset)
1: FDCAN peripheral clocks enabled:
The peripheral clocks of the FDCAN are the kernel clock selected by FDCANSEL and provided to **fdcan_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSEN**: MDIOS peripheral clock enable
Set and reset by software.
0: MDIOS peripheral clock disabled (default after reset)
1: MDIOS peripheral clock enabled

Bit 4 **OPAMPEN**: OPAMP peripheral clock enable
Set and reset by software.
0: OPAMP peripheral clock disabled (default after reset)
1: OPAMP peripheral clock enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPMIEN**: SWPMI peripheral clocks enable
Set and reset by software.
0: SWPMI peripheral clocks disabled (default after reset)
1: SWPMI peripheral clocks enabled:

Bit 1 **CRSEN**: clock recovery system peripheral clock enable
Set and reset by software.
0: CRS peripheral clock disabled (default after reset)
1: CRS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

8.7.45 RCC APB2 clock register (RCC_APB2ENR)

Address offset: 0x0F0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw					rw	rw	rw	rw			rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DFSDM1EN**: DFSDM1 peripheral clocks enable
Set and reset by software.
0: DFSDM1 peripheral clocks disabled (default after reset)
1: DFSDM1 peripheral clocks enabled
DFSDM1 peripheral clocks are the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to **Aclk** and **clk** inputs respectively,

Bits 29:24 Reserved, must be kept at reset value.

Bit 23 **SAI2EN**: SAI2 peripheral clocks enable
Set and reset by software.
0: SAI2 peripheral clocks disabled (default after reset)
1: SAI2 peripheral clocks enabled
The peripheral clocks of the SAI2 are the kernel clock selected by SAI2SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the **rcc_pclk2** bus interface clock.

Bit 22 **SAI1EN**: SAI1 peripheral clocks enable
Set and reset by software.
0: SAI1 peripheral clocks disabled (default after reset)
1: SAI1 peripheral clocks enabled:
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the **rcc_pclk2** bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5EN**: SPI5 peripheral clocks enable
Set and reset by software.
0: SPI5 peripheral clocks disabled (default after reset)
1: SPI5 peripheral clocks enabled:
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17EN**: TIM17 peripheral clock enable
Set and reset by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 peripheral clock enable
Set and reset by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 peripheral clock enable
Set and reset by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4EN**: SPI4 Peripheral Clocks Enable
Set and reset by software.
0: SPI4 peripheral clocks disabled (default after reset)
1: SPI4 peripheral clocks enabled:
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bit 12 **SPI1EN**: SPI1 Peripheral Clocks Enable
Set and reset by software.
0: SPI1 peripheral clocks disabled (default after reset)
1: SPI1 peripheral clocks enabled:
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10EN**: USART10 peripheral clocks enable
Set and reset by software.
0: USART10 peripheral clocks disabled (default after reset)
1: USART10 peripheral clocks enabled:
The peripheral clocks of the USART10 are the kernel clock selected by USART16910SEL and provided to UCKL input, and the **rcc_pclk2** bus interface clock.

Bit 6 **UART9EN**: UART9 peripheral clocks enable
Set and reset by software.
0: UART9 peripheral clocks disabled (default after reset)
1: UART9 peripheral clocks enabled:
The peripheral clocks of the UART9 are the kernel clock selected by USART16910SEL and provided to UCKL input, and the **rcc_pclk2** bus interface clock.

Bit 5 **USART6EN**: USART6 peripheral clocks enable
Set and reset by software.
0: USART6 peripheral clocks disabled (default after reset)
1: USART6 peripheral clocks enabled:
The peripheral clocks of the USART6 are the kernel clock selected by USART16910SEL and provided to UCKL input, and the **rcc_pclk2** bus interface clock.

Bit 4 **USART1EN**: USART1 peripheral clocks enable
Set and reset by software.
0: USART1 peripheral clocks disabled (default after reset)
1: USART1 peripheral clocks enabled:
The peripheral clocks of the USART1 are the kernel clock selected by USART16910SEL and provided to UCKL input, and the **rcc_pclk2** bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8EN**: TIM8 peripheral clock enable
Set and reset by software.
0: TIM8 peripheral clock disabled (default after reset)
1: TIM8 peripheral clock enabled

Bit 0 **TIM1EN**: TIM1 peripheral clock enable
Set and reset by software.
0: TIM1 peripheral clock disabled (default after reset)
1: TIM1 peripheral clock enabled

8.7.46 RCC APB4 clock register (RCC_APB4ENR)

Address offset: 0x0F4

Reset value: 0x0001 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw			rw	rw		rw		rw		rw		rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **DFSDM2EN**: DFSDM2peripheral clock enable
Set and reset by software.
0: DFSDM2peripheral peripheral clock disabled (default after reset)
1: DFSDM2peripheral peripheral clock enabled

Bit 26 **DTSEN**: Digital temperature sensor peripheral clock enable
Set and reset by software.
0: DTS peripheral clock disabled (default after reset)
1: DTS peripheral clock enabled

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBEN**: RTC APB clock enable
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled
1: The register clock interface of the RTC (APB) is enabled (default after reset)

Bit 15 **VREFEN**: VREF peripheral clock enable
Set and reset by software.
0: VREF peripheral clock disabled (default after reset)
1: VREF peripheral clock enabled

Bit 14 **COMP12EN**: COMP1 and 2 peripheral clock enable
Set and reset by software.
0: COMP1 and 2 peripheral clock disabled (default after reset)
1: COMP1 and 2 peripheral clock enabled

Bit 13 **DAC2EN**: DAC2 (containing one converter) peripheral clock enable
Set and reset by software.
0: DAC2 peripheral clock disabled (default after reset)
1: DAC2 peripheral clock enabled

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **LPTIM3EN**: LPTIM3 peripheral clocks enable
Set and reset by software.
0: LPTIM3 peripheral clocks disabled (default after reset)
1: LPTIM3 peripheral clocks enabled
The peripheral clocks of the LPTIM3 are the kernel clock selected by LPTIM345SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 9 **LPTIM2EN**: LPTIM2 peripheral clocks enable
Set and reset by software.
0: LPTIM2 peripheral clocks disabled (default after reset)
1: LPTIM2 peripheral clocks enabled
The peripheral clocks of the LPTIM2 are the kernel clock selected by LPTIM2SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4EN**: I2C4 peripheral clocks enable
Set and reset by software.
0: I2C4 peripheral clocks disabled (default after reset)
1: I2C4 peripheral clocks enabled
The peripheral clocks of the I2C4 are the kernel clock selected by I2C4SEL and provided to i2C_ker_ck input, and the **rcc_pclk4** bus interface clock.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6EN**: SPI6 peripheral clocks enable
Set and reset by software.
0: SPI6 peripheral clocks disabled (default after reset)
1: SPI6 peripheral clocks enabled
The peripheral clocks of the SPI6 are the kernel clock selected by SPI6SEL and provided to **spi_ker_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1EN**: LPUART1 peripheral clocks enable
Set and reset by software.
0: LPUART1 peripheral clocks disabled (default after reset)
1: LPUART1 peripheral clocks enabled
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to lpuart_ker_ck input, and the **rcc_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGEN**: SYSCFG peripheral clock enable
Set and reset by software.
0: SYSCFG peripheral clock disabled (default after reset)
1: SYSCFG peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

8.7.47 RCC AHB3 sleep clock register (RCC_AHB3LPENR)

Address offset: 0x0FC

Reset value: 0xFDE9 5131

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **AXISRAM1LPEN**: AXISRAM1 block clock enable during CSleep mode
Set and reset by software.
0: AXISRAM1 interface clock disabled during CSleep mode
1: AXISRAM1 interface clock enabled during CSleep mode (default after reset)

Bit 30 **ITCMLPEN**: ITCM block clock enable during CSleep mode
Set and reset by software.
0: ITCM interface clock disabled during CSleep mode
1: ITCM interface clock enabled during CSleep mode (default after reset)

Bit 29 **DTCM2LPEN**: DTCM2 block clock enable during CSleep mode
Set and reset by software.
0: DTCM2 interface clock disabled during CSleep mode
1: DTCM2 interface clock enabled during CSleep mode (default after reset)

Bit 28 **DTCM1LPEN**: DTCM1 block clock enable during CSleep mode
Set and reset by software.
0: DTCM1 interface clock disabled during CSleep mode
1: DTCM1 interface clock enabled during CSleep mode (default after reset)

Bit 27 **AXISRAM3LPEN**: AXISRAM3 block clock enable during CSleep mode
Set and reset by software.
0: AXISRAM3 interface clock disabled during CSleep mode
1: AXISRAM3 interface clock enabled during CSleep mode (default after reset)

Bit 26 **AXISRAM2LPEN**: AXISRAM2 block clock enable during CSleep mode
Set and reset by software.
0: AXISRAM2 interface clock disabled during CSleep mode
1: AXISRAM2 interface clock enabled during CSleep mode (default after reset)

Bit 25 Reserved, must be kept at reset value.

Bit 24 **GFXMMULPEN**: GFXMMU block clock enable during CSleep mode
Set and reset by software.
0: GFXMMU interface clock disabled during CSleep mode
1: GFXMMU interface clock enabled during CSleep mode (default after reset)

Bit 23 **OTFD2LPEN**: OTFD2 block clock enable during CSleep mode
Set and reset by software.
0: OTFD2 interface clock disabled during CSleep mode
1: OTFD2 interface clock enabled during CSleep mode (default after reset)

Bit 22 **OTFD1LPEN**: OTFD1 block clock enable during CSleep mode
Set and reset by software.
0: OTFD1 interface clock disabled during CSleep mode
1: OTFD1 interface clock enabled during CSleep mode (default after reset)

Bit 21 **OCTOSPIMLPEN**: OCTOSPIM block clock enable during CSleep mode
Set and reset by software.
0: OCTOSPIM interface clock disabled during CSleep mode
1: OCTOSPIM interface clock enabled during CSleep mode (default after reset)

Bit 20 Reserved, must be kept at reset value.

Bit 19 **OCTOSPI2LPEN:** OCTOSPI2 and OCTOSPI2 delay clock enable during CSleep mode
Set and reset by software.
0: OCTOSPI2 and OCTOSPI2 delay clock disabled during CSleep mode
1: OCTOSPI2 and OCTOSPI2 delay clock enabled during CSleep mode (default after reset)

Bits 18:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay clock enable during CSleep mode
Set and reset by software.
0: SDMMC1 and SDMMC1 delay clock disabled during CSleep mode
1: SDMMC1 and SDMMC1 delay clock enabled during CSleep mode (default after reset)

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OCTOSPI1LPEN**: OCTOSPI1 and OCTOSPI1 delay clock enable during CSleep mode
Set and reset by software.
0: OCTOSPI1 and OCTOSPI1 delay clock disabled during CSleep mode
1: OCTOSPI1 and OCTOSPI1 delay clock enabled during CSleep mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCLPEN**: FMC peripheral clocks enable during CSleep mode
Set and reset by software.
0: FMC peripheral clocks disabled during CSleep mode
1: FMC peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL and provided to fmc_ker_ck input, and the **rcc_hclk3** bus interface clock.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLITFLPEN**: FLITF clock enable during CSleep mode
Set and reset by software.
0: FLITF clock disabled during CSleep mode
1: FLITF clock enabled during CSleep mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JPGDECLPEN**: JPGDEC clock enable during CSleep mode
Set and reset by software.
0: JPGDEC peripheral clock disabled during CSleep mode
1: JPGDEC peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **DMA2DLPEN**: DMA2D clock enable during CSleep mode
Set and reset by software.
0: DMA2D peripheral clock disabled during CSleep mode
1: DMA2D peripheral clock enabled during CSleep mode (default after reset)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMALPEN**: MDMA clock enable during CSleep mode
Set and reset by software.
0: MDMA peripheral clock disabled during CSleep mode
1: MDMA peripheral clock enabled during CSleep mode (default after reset)

8.7.48 RCC AHB1 sleep clock register (RCC_AHB1LPENR)

Address offset: 0x100

Reset value: 0x0600 0223

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw				rw				rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **USB1ULPILPEN**: USB_PHY1 clock enable during CSleep mode
Set and reset by software.
0: USB_PHY1 peripheral clock disabled during CSleep mode
1: USB_PHY1 peripheral clock enabled during CSleep mode (default after reset)

Bit 25 **USB1OTGLPEN**: USB1OTG peripheral clock enable during CSleep mode
Set and reset by software.
0: USB1OTG peripheral clock disabled during CSleep mode
1: USB1OTG peripheral clock enabled during CSleep mode (default after reset)
The peripheral clocks of the USB1OTG are the kernel clock selected by USBSEL and the **rcc_hclk1** bus interface clock.

Bits 24:10 Reserved, must be kept at reset value.

Bit 9 **CRCLPEN**: CRC peripheral clock enable during CSleep mode
Set and reset by software.
0: CRC peripheral clock disabled during CSleep mode
1: CRC peripheral clock enabled during CSleep mode (default after reset)

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **ADC12LPEN**: ADC1 and 2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: ADC1 and 2 peripheral clocks disabled during CSleep mode
1: ADC1 and 2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to adc_ker_ck input, and the **rcc_hclk1** bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2LPEN**: DMA2 clock enable during CSleep mode
Set and reset by software.
0: DMA2 clock disabled during CSleep mode
1: DMA2 clock enabled during CSleep mode (default after reset)

Bit 0 **DMA1LPEN**: DMA1 clock enable during CSleep mode
Set and reset by software.
0: DMA1 clock disabled during CSleep mode
1: DMA1 clock enabled during CSleep mode (default after reset)

8.7.49 RCC AHB2 sleep clock register (RCC_AHB2LPENR)

Address offset: 0x104

Reset value: 0x6000 0A71

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw		rw			rw	rw	rw				rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **AHBSRAM2LPEN**: AHBSRAM2 clock enable during CSleep mode
Set and reset by software.
0: AHBSRAM2 clock disabled during CSleep mode
1: AHBSRAM2 clock enabled during CSleep mode (default after reset)

Bit 29 **AHBSRAM1LPEN**: AHBSRAM1 clock enable during CSleep mode
Set and reset by software.
0: AHBSRAM1 clock disabled during CSleep mode
1: AHBSRAM1 clock enabled during CSleep mode (default after reset)

Bits 28:12 Reserved, must be kept at reset value.

Bit 11 **DFSDMDMALPEN**: DFSDMDMA clock enable during CSleep mode
Set and reset by software.
0: DFSDMDMA clock disabled during CSleep mode
1: DFSDMDMA clock enabled during CSleep mode (default after reset)

Bit 10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay clock enable during CSleep mode
Set and reset by software.
0: SDMMC2 and SDMMC2 delay clock disabled during CSleep mode
1: SDMMC2 and SDMMC2 delay clock enabled during CSleep mode (default after reset)

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **RNGLPEN**: RNG peripheral clock enable during CSleep mode
Set and reset by software.
0: RNG peripheral clocks disabled during CSleep mode
1: RNG peripheral clock enabled during CSleep mode (default after reset)
The peripheral clocks of the RNG are the kernel clock selected by RNGSEL and provided to **rng_clk** input, and the **rcc_hclk2** bus interface clock.

Bit 5 **HASHLPEN**: HASH peripheral clock enable during CSleep mode
Set and reset by software.
0: HASH peripheral clock disabled during CSleep mode
1: HASH peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **CRYPTLPEN**: CRYPT peripheral clock enable during CSleep mode
Set and reset by software.
0: CRYPT peripheral clock disabled during CSleep mode
1: CRYPT peripheral clock enabled during CSleep mode (default after reset)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMI_PSSILPEN**: digital camera interface peripheral clock enable during CSleep mode (DCMI or PSSI depending which IP is active)
Set and reset by software.
0: DCMI/PSSI peripheral clock disabled during CSleep mode
1: DCMI/PSSI peripheral clock enabled during CSleep mode (default after reset)

8.7.50 RCC AHB4 sleep clock register (RCC_AHB4LPENR)

Address offset: 0x108

Reset value: 0x3020 07FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **SRDSRAMLPEN**: SmartRun domain SRAM clock enable during CSleep mode
Set and reset by software.
0: SRDSRAM clock disabled during CSleep mode
1: SRDSRAM clock enabled during CSleep mode (default after reset)

Bit 28 **BKPRAMLPEN**: Backup RAM clock enable during CSleep mode
Set and reset by software.
0: Backup RAM clock disabled during CSleep mode
1: Backup RAM clock enabled during CSleep mode (default after reset)

Bits 27:22 Reserved, must be kept at reset value.

Bit 21 **BDMA2LPEN**: SmartRun domain DMA and DMAMUX clock enable during CSleep mode
Set and reset by software.
0: BDMA2 and DMAMUX2 clock disabled during CSleep mode
1: BDMA2 and DMAMUX2 clock enabled during CSleep mode (default after reset)

Bits 20:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKLPEN**: GPIOK peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOK peripheral clock disabled during CSleep mode
1: GPIOK peripheral clock enabled during CSleep mode (default after reset)

Bit 9 **GPIOJLPEN**: GPIOJ peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOJ peripheral clock disabled during CSleep mode
1: GPIOJ peripheral clock enabled during CSleep mode (default after reset)

Bit 8 **GPIOILPEN**: GPIOI peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOI peripheral clock disabled during CSleep mode
1: GPIOI peripheral clock enabled during CSleep mode (default after reset)

Bit 7 **GPIOHLPEN**: GPIOH peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOH peripheral clock disabled during CSleep mode
1: GPIOH peripheral clock enabled during CSleep mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOG peripheral clock disabled during CSleep mode
1: GPIOG peripheral clock enabled during CSleep mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOF peripheral clock disabled during CSleep mode
1: GPIOF peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOE peripheral clock disabled during CSleep mode
1: GPIOE peripheral clock enabled during CSleep mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOD peripheral clock disabled during CSleep mode
1: GPIOD peripheral clock enabled during CSleep mode (default after reset)

Bit 2 **GPIOCLPEN**: GPIOC peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOC peripheral clock disabled during CSleep mode
1: GPIOC peripheral clock enabled during CSleep mode (default after reset)

Bit 1 **GPIOBLPEN**: GPIOB peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOB peripheral clock disabled during CSleep mode
1: GPIOB peripheral clock enabled during CSleep mode (default after reset)

Bit 0 **GPIOALPEN**: GPIOA peripheral clock enable during CSleep mode
Set and reset by software.
0: GPIOA peripheral clock disabled during CSleep mode
1: GPIOA peripheral clock enabled during CSleep mode (default after reset)

8.7.51 RCC APB3 sleep clock register (RCC_APB3LPENR)

Address offset: 0x10C

Reset value: 0x0000 0048

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw			rw			

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **WWDGLPEN**: WWDG clock enable during CSleep mode
Set and reset by software.
0: WWDG clock disable during CSleep mode
1: WWDG clock enabled during CSleep mode (default after reset)

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **LTDCLPEN**: LTDC peripheral clock enable during CSleep mode
Set and reset by software.
0: LTDC clock disabled during CSleep mode
1: LTDC clock provided to the LTDC during CSleep mode (default after reset)
The LTDC peripheral clocks are the kernel clock provided to **ltdc_ker_ck** input and the **rcc_pclk3** bus interface clock.

Bits 2:0 Reserved, must be kept at reset value.

8.7.52 RCC APB1 low-sleep clock register (RCC_APB1LLPENR)

Address offset: 0x110

Reset value: 0xE8FF C3FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UART8LPEN**: UART8 peripheral clocks enable during CSleep mode
Set and reset by software.
0: UART8 peripheral clocks disabled during CSleep mode
1: UART8 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the UART8 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 30 **UART7LPEN**: UART7 peripheral clocks enable during CSleep mode
Set and reset by software.
0: UART7 peripheral clocks disabled during CSleep mode
1: UART7 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the UART7 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 29 **DAC1LPEN**: DAC1 (containing two converters) peripheral clock enable during CSleep mode
Set and reset by software.
0: DAC1 peripheral clock disabled during CSleep mode
1: DAC1 peripheral clock enabled during CSleep mode (default after reset)

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECLPEN**: HDMI-CEC peripheral clocks enable during CSleep mode
Set and reset by software.
0: HDMI-CEC peripheral clocks disabled during CSleep mode
1: HDMI-CEC peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the HDMI-CEC are the kernel clock selected by CECSEL and provided to **cec_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3LPEN**: I2C3 peripheral clocks enable during CSleep mode
Set and reset by software.
0: I2C3 peripheral clocks disabled during CSleep mode
1: I2C3 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the I2C3 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 22 **I2C2LPEN**: I2C2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: I2C2 peripheral clocks disabled during CSleep mode
1: I2C2 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the I2C2 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 21 **I2C1LPEN**: I2C1 peripheral clocks enable during CSleep mode
Set and reset by software.
0: I2C1 peripheral clocks disabled during CSleep mode
1: I2C1 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the I2C1 are the kernel clock selected by I2C123SEL and provided to i2C_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 20 **UART5LPEN**: UART5 peripheral clocks enable during CSleep mode
Set and reset by software.
0: UART5 peripheral clocks disabled during CSleep mode
1: UART5 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the UART5 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 19 **UART4LPEN**: UART4 peripheral clocks enable during CSleep mode
Set and reset by software.
0: UART4 peripheral clocks disabled during CSleep mode
1: UART4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the UART4 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 18 **USART3LPEN**: USART3 peripheral clocks enable during CSleep mode
Set and reset by software.
0: USART3 peripheral clocks disabled during CSleep mode
1: USART3 peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the USART3 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 17 **USART2LPEN**: USART2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: USART2 peripheral clocks disabled during CSleep mode
1: USART2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the USART2 are the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 16 **SPDIFRXLPEN**: SPDIFRX peripheral clocks enable during CSleep mode
Set and reset by software.
0: SPDIFRX peripheral clocks disabled during CSleep mode
1: SPDIFRX peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPDIFRX are: the kernel clock selected by SPDIFRXSEL and provided to spdifrx_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 15 **SPI3LPEN**: SPI3 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SPI3 peripheral clocks disabled during CSleep mode
1: SPI3 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI3 are the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bit 14 **SPI2LPEN**: SPI2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SPI2 peripheral clocks disabled during CSleep mode
1: SPI2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI2 are the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable during CSleep mode
Set and reset by software.
0: LPTIM1 peripheral clocks disabled during CSleep mode
1: LPTIM1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM1 are the kernel clock selected by LPTIM1SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk1** bus interface clock.

Bit 8 **TIM14LPEN**: TIM14 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM14 peripheral clock disabled during CSleep mode
1: TIM14 peripheral clock enabled during CSleep mode (default after reset)

Bit 7 **TIM13LPEN**: TIM13 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM13 peripheral clock disabled during CSleep mode
1: TIM13 peripheral clock enabled during CSleep mode (default after reset)

Bit 6 **TIM12LPEN**: TIM12 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM12 peripheral clock disabled during CSleep mode
1: TIM12 peripheral clock enabled during CSleep mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM7 peripheral clock disabled during CSleep mode
1: TIM7 peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM6 peripheral clock disabled during CSleep mode
1: TIM6 peripheral clock enabled during CSleep mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM5 peripheral clock disabled during CSleep mode
1: TIM5 peripheral clock enabled during CSleep mode (default after reset)

Bit 2 **TIM4LPEN**: TIM4 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM4 peripheral clock disabled during CSleep mode
1: TIM4 peripheral clock enabled during CSleep mode (default after reset)

Bit 1 **TIM3LPEN**: TIM3 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM3 peripheral clock disabled during CSleep mode
1: TIM3 peripheral clock enabled during CSleep mode (default after reset)

Bit 0 **TIM2LPEN**: TIM2 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM2 peripheral clock disabled during CSleep mode
1: TIM2 peripheral clock enabled during CSleep mode (default after reset)

8.7.53 RCC APB1 high-sleep clock register (RCC_APB1HLPENR)

Address offset: 0x114

Reset value: 0x0000 0136

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

							rw			rw	rw		rw	rw	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANLPEN**: FDCAN peripheral clocks enable during CSleep mode
Set and reset by software.
0: FDCAN peripheral clocks disabled during CSleep mode
1: FDCAN peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the FDCAN are: the kernel clock selected by FDCANSEL and provided to **fdcan_clk** input, and the **rcc_pclk1** bus interface clock.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSLPEN**: MDIOS peripheral clock enable during CSleep mode
Set and reset by software.
0: MDIOS peripheral clock disabled during CSleep mode
1: MDIOS peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **OPAMPLPEN**: OPAMP peripheral clock enable during CSleep mode
Set and reset by software.
0: OPAMP peripheral clock disabled during CSleep mode
1: OPAMP peripheral clock enabled during CSleep mode (default after reset)

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPMILPEN**: SWPMI peripheral clocks enable during CSleep mode
Set and reset by software.
0: SWPMI peripheral clocks disabled during CSleep mode
1: SWPMI peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SWPMI are the kernel clock selected by SWPMISEL and provided to swpmi_ker_ck input, and the **rcc_pclk1** bus interface clock.

Bit 1 **CRSLPEN**: clock recovery system peripheral clock enable during CSleep mode
Set and reset by software.
0: CRS peripheral clock disabled during CSleep mode
1: CRS peripheral clock enabled during CSleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

8.7.54 RCC APB2 sleep clock register (RCC_APB2LPENR)

Address offset: 0x118

Reset value: 0x40D7 30F3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw					rw	rw	rw	rw			rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DFSDM1LPEN**: DFSDM1 peripheral clocks enable during CSleep mode
Set and reset by software.
0: DFSDM1 peripheral clocks disabled during CSleep mode
1: DFSDM1 peripheral clocks enabled during CSleep mode (default after reset)
DFSDM1 peripheral clocks are the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to **AcIk** and **cIk** inputs respectively, and the **rcc_pclk2** bus interface clock.

Bits 29:24 Reserved, must be kept at reset value.

Bit 23 **SAI2LPEN**: SAI2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SAI2 peripheral clocks disabled during CSleep mode
1: SAI2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SAI2 are the kernel clock selected by SAI23EL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the **rcc_pclk2** bus interface clock.

Bit 22 **SAI1LPEN**: SAI1 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SAI1 peripheral clocks disabled during CSleep mode
1: SAI1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the **rcc_pclk2** bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5LPEN**: SPI5 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SPI5 peripheral clocks disabled during CSleep mode
1: SPI5 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17LPEN**: TIM17 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM17 peripheral clock disabled during CSleep mode
1: TIM17 peripheral clock enabled during CSleep mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM16 peripheral clock disabled during CSleep mode
1: TIM16 peripheral clock enabled during CSleep mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM15 peripheral clock disabled during CSleep mode
1: TIM15 peripheral clock enabled during CSleep mode (default after reset)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4LPEN**: SPI4 peripheral clock enable during CSleep mode
Set and reset by software.
0: SPI4 peripheral clocks disabled during CSleep mode
1: SPI4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bit 12 **SPI1LPEN**: SPI1 peripheral clock enable during CSleep mode
Set and reset by software.
0: SPI1 peripheral clocks disabled during CSleep mode
1: SPI1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to **spi_ker_ck** input, and the **rcc_pclk2** bus interface clock.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **USART10LPEN**: USART10 peripheral clock enable during CSleep mode
Set and reset by software.
0: USART10 peripheral clocks disabled during CSleep mode
1: USART10 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the USART10 are the kernel clock selected by USART16910SEL and provided to usart_ker_ck input, and the **rcc_pclk2** bus interface clock.

Bit 6 **UART9LPEN**: UART9 peripheral clock enable during CSleep mode
Set and reset by software.
0: UART9 peripheral clocks disabled during CSleep mode
1: UART9 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the UART9 are the kernel clock selected by USART16910SEL and provided to usart_ker_ck input, and the **rcc_pclk2** bus interface clock.

Bit 5 **USART6LPEN**: USART6 peripheral clock enable during CSleep mode
Set and reset by software.
0: USART6 peripheral clocks disabled during CSleep mode
1: USART6 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the USART6 are the kernel clock selected by USART16910SEL and provided to usart_ker_ck input, and the **rcc_pclk2** bus interface clock.

Bit 4 **USART1LPEN**: USART1 peripheral clock enable during CSleep mode
Set and reset by software.
0: USART1 peripheral clocks disabled during CSleep mode
1: USART1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the USART1 are the kernel clock selected by USART16910SEL and provided to usart_ker_ck inputs, and the **rcc_pclk2** bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM8 peripheral clock disabled during CSleep mode
1: TIM8 peripheral clock enabled during CSleep mode (default after reset)

Bit 0 **TIM1LPEN**: TIM1 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM1 peripheral clock disabled during CSleep mode
1: TIM1 peripheral clock enabled during CSleep mode (default after reset)

8.7.55 RCC APB4 sleep clock register (RCC_APB4LPENR)

Address offset: 0x11C

Reset value: 0x0C01 E6AA

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw			rw	rw		rw		rw		rw		rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **DFSDM2LPEN**: DFSDM2 peripheral clock enable during CSleep mode
Set and reset by software.
0: DFSDM2 peripheral clock disabled during CSleep mode
1: DFSDM2 peripheral clock enabled during CSleep mode (default after reset)

Bit 26 **DTSLPEN**: temperature sensor peripheral clock enable during CSleep mode
Set and reset by software.
0: DTS peripheral clock disabled during CSleep mode
1: DTS peripheral clock enabled during CSleep mode (default after reset)

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBLPEN**: RTC APB clock enable during CSleep mode
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled during CSleep mode
1: The register clock interface of the RTC (APB) is enabled during CSleep mode (default after reset)

Bit 15 **VREFLPEN**: VREF peripheral clock enable during CSleep mode
Set and reset by software.
0: VREF peripheral clock disabled during CSleep mode
1: VREF peripheral clock enabled during CSleep mode (default after reset)

Bit 14 **COMP12LPEN**: COMP1 and 2 peripheral clock enable during CSleep mode
Set and reset by software.
0: COMP1 and 2 peripheral clock disabled during CSleep mode
1: COMP1 and 2 peripheral clock enabled during CSleep mode (default after reset)

Bit 13 **DAC2LPEN**: DAC2 (containing one converter) peripheral clock enable during CSleep mode
Set and reset by software.
0: DAC2 peripheral clock disabled during CSleep mode
1: DAC2 peripheral clock enabled during CSleep mode (default after reset)

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **LPTIM3LPEN**: LPTIM3 peripheral clocks enable during CSleep mode
Set and reset by software.
0: LPTIM3 peripheral clocks disabled during CSleep mode
1: LPTIM3 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM3 are the kernel clock selected by LPTIM345SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 9 **LPTIM2LPEN**: LPTIM2 peripheral clocks enable during CSleep mode
Set and reset by software.
0: LPTIM2 peripheral clocks disabled during CSleep mode
1: LPTIM2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM2 are the kernel clock selected by LPTIM2SEL and provided to **lptim_ker_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4LPEN**: I2C4 peripheral clocks enable during CSleep mode
Set and reset by software.
0: I2C4 peripheral clocks disabled during CSleep mode
1: I2C4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the I2C4 are the kernel clock selected by I2C4SEL and provided to i2C_ker_ck input, and the **rcc_pclk4** bus interface clock.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPEN**: SPI6 peripheral clocks enable during CSleep mode
Set and reset by software.
0: SPI6 peripheral clocks disabled during CSleep mode
1: SPI6 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI6 are the kernel clock selected by SPI6SEL and provided to **com_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPEN**: LPUART1 peripheral clocks enable during CSleep mode
Set and reset by software.
0: LPUART1 peripheral clocks disabled during CSleep mode
1: LPUART1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to lpuart_ker_ck input, and the **rcc_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGLPEN**: SYSCFG peripheral clock enable during CSleep mode
Set and reset by software.
0: SYSCFG peripheral clock disabled during CSleep mode
1: SYSCFG peripheral clock enabled during CSleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

8.8 RCC register map

9 Clock recovery system (CRS)

9.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

9.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 9.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

9.3 CRS implementation

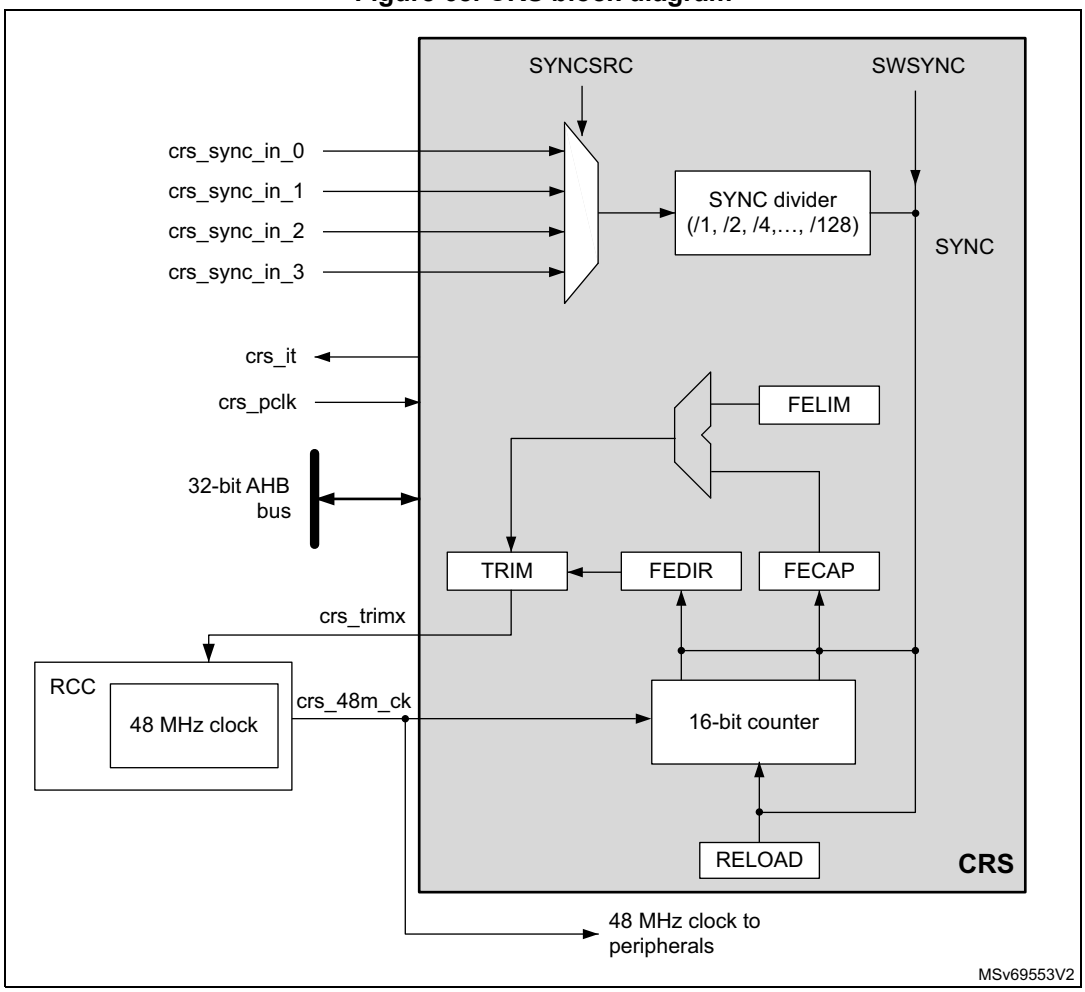

Table 64. CRS features

Feature	CRS
TRIM width	6 bits

9.4 CRS functional description

9.4.1 CRS block diagram

Figure 68. CRS block diagram

9.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 65. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSI48 48 MHz clock
crs_trim[0:5]	Digital output	HSI48 oscillator smooth trimming value

Table 65. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 66. CRS interconnection

Internal signal name	Source
crs_sync_in_0	CRS_SYNC pin selected as SYNC signal source
crs_sync_in_1	LSE selected as SYNC signal source
crs_sync_in_2	OTG HS SOF selected as SYNC signal source (default)
crs_sync_in_3	Reserved

9.4.3 Synchronization input

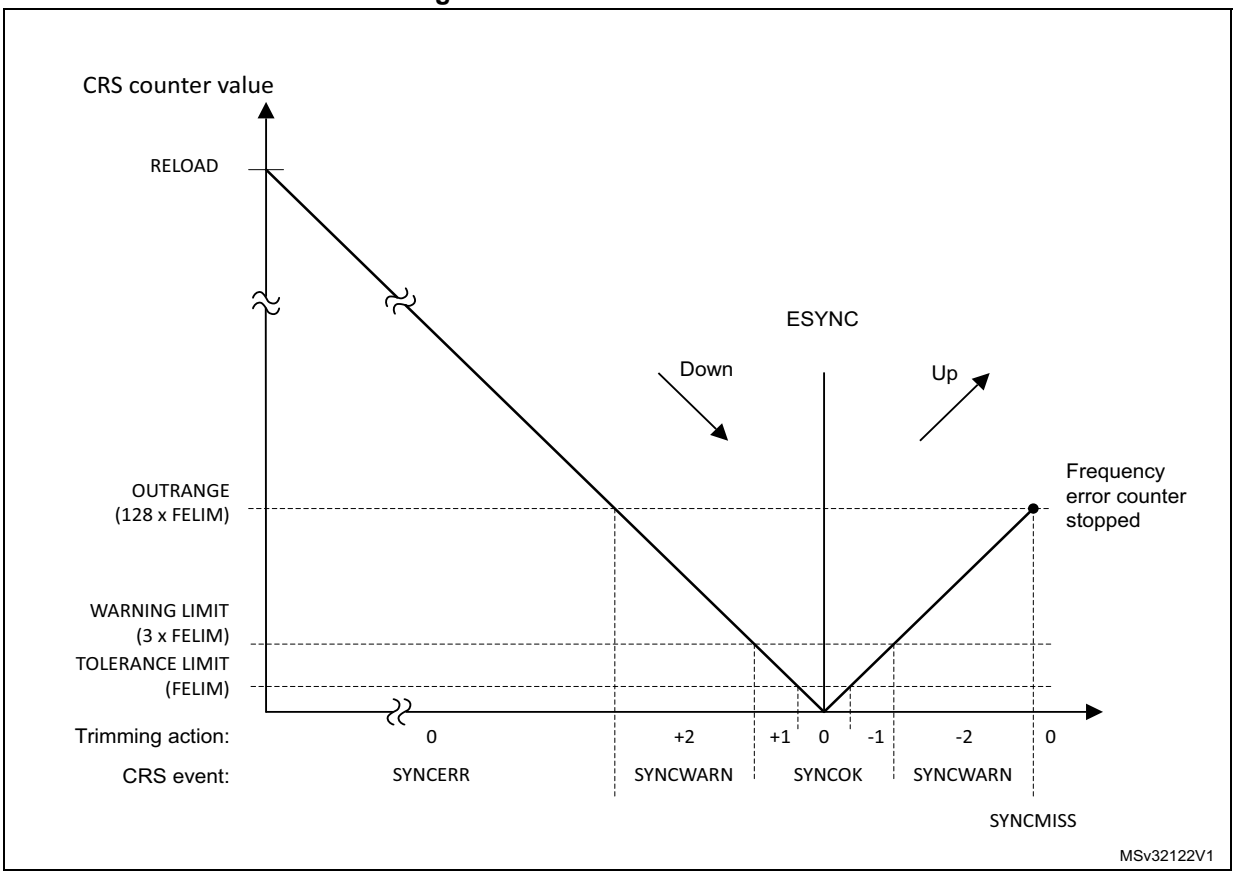
The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 9.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.



9.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual

frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 69. CRS counter behavior

9.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated

  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

9.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

9.5 CRS in low-power modes

Table 67. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.
Shutdown	The peripheral is powered down and must be reinitialized after exiting Shutdown mode.

9.6 CRS interrupts

Table 68. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

9.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

9.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 2000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
		rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value is 32, corresponding to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 9.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

9.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.

0: SYNC active on rising edge (default)

1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 9.4.2: CRS internal signals*).

00: crs_sync_in_0 selected as SYNC signal source

01: crs_sync_in_1 selected as SYNC signal source

10: crs_sync_in_2 selected as SYNC signal source

11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.

000: SYNC not divided (default)

001: SYNC divided by 2

010: SYNC divided by 4

011: SYNC divided by 8

100: SYNC divided by 16

101: SYNC divided by 32

110: SYNC divided by 64

111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 9.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 9.4.4* for more details about counter behavior.

9.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 9.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

9.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

9.7.5 CRS register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

10 Hardware semaphore (HSEM)

10.1 HSEM introduction

The hardware semaphore block provides 16 (32-bit) register based semaphores.

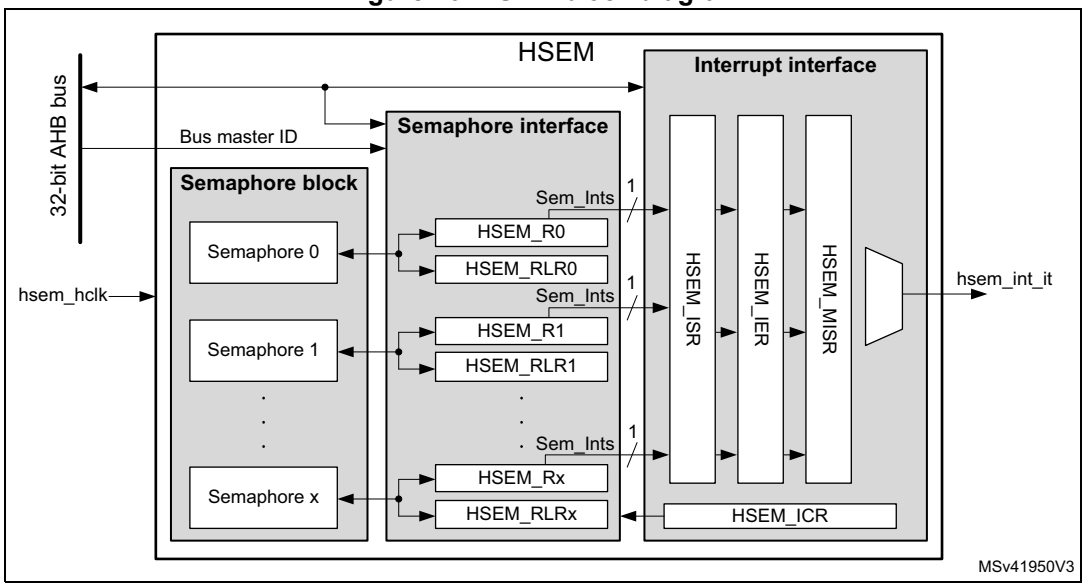
The semaphores can be used to ensure synchronization between different processes running on the core. The HSEM provides a non-blocking mechanism to lock semaphores in an atomic way. The following functions are provided:

- Semaphore lock, in two ways:
  - 2-step lock: by writing MASTERID and PROCID to the semaphore, followed by a read check
  - 1-step lock: by reading the MASTERID from the semaphore
- Interrupt generation when a semaphore is unlocked
  - Each semaphore may generate an interrupt
- Semaphore clear protection
  - A semaphore is only unlocked when MASTERID and PROCID match
- Global semaphore clear per MASTERID

10.2 HSEM main features

The HSEM includes the following features:

- 16 (32-bit) semaphores
- 8-bit PROCID
- 4-bit MASTERID
- One interrupt line
- Lock indication



10.3 Functional description

10.3.1 HSEM block diagram

As shown in *Figure 70*, the HSEM is based on three sub-blocks:

- the semaphore block containing the semaphore status and IDs
- the semaphore interface block providing AHB access to the semaphore via the HSEM_Rx and HSEM_RLRx registers
- the interrupt interface block providing control for the interrupts via HSEM_ISR, HSEM_IER, HSEM_MISR, and HSEM_ICR registers.

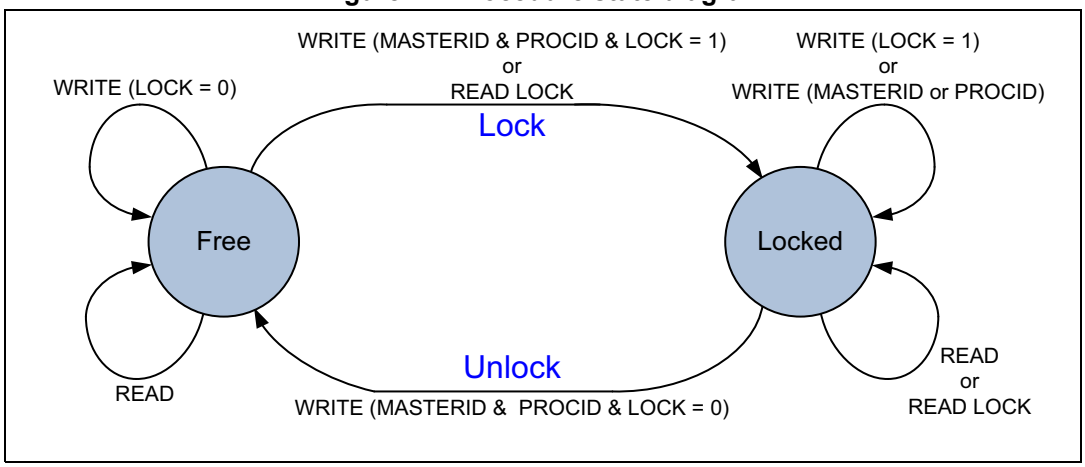
Figure 70. HSEM block diagram

10.3.2 HSEM internal signals

Table 70. HSEM internal input/output signals

Signal name	Signal type	Description
AHB bus	Digital input/output	AHB register access bus
BusMasterID	Digital input	AHB bus master ID
hsem_int_it	Digital output	interrupt line

10.3.3 HSEM lock procedures



There are two lock procedures, namely 2-step (write) and 1-step (read) lock. The two procedures can be used concurrently.

The semaphore is free when its LOCK bit is 0. In this case, the MASTERID and PROCID are also 0. When the LOCK bit is 1, the semaphore is locked and the MASTERID indicates which AHB bus master ID has locked it. The PROCID indicates which process of that AHB bus master ID has locked the semaphore.

When write locking a semaphore, the written MASTERID must match the AHB bus master ID , and the PROCID is written by the AHB bus master software process taking the lock.

When read locking the semaphore, the MASTERID is taken from the AHB bus master ID, and the PROCID is forced to 0 by hardware. There is no PROCID available with read lock.

Figure 71. Procedure state diagram

2-step (write) lock procedure

The 2-step lock procedure consists in a write to lock the semaphore, followed by a read to check if the lock has been successful, carried out from the HSEM_Rx register.

- Write semaphore with PROCID and MASTERID, and LOCK = 1. The MASTERID data written by software must match the AHB bus master information, that is, a AHB bus master ID = 1 writes data MASTERID = 1.

  Lock is put in place when the semaphore is free at write time.
- Read-back the semaphore

  The software checks the lock status, if PROCID and MASTERID match the written data, then the lock is confirmed.
- Else retry (the semaphore has been locked by another process).

A semaphore can only be locked when it is free.

A semaphore can be locked when the PROCID = 0.

Consecutive write attempts with LOCK = 1 to a locked semaphore are ignored.

1-step (read) lock procedure

The 1-step procedure consists in a read to lock and check the semaphore in a single step, carried out from the HSEM_RLRx register.

- Read lock semaphore with the AHB bus master MASTERID.
- If read MASTERID matches and PROCID = 0, then lock is put in place. If MASTERID matches and PROCID is not 0, this means that another process from the same MASTERID has locked the semaphore with a 2-step (write) procedure.
- Else retry (the semaphore has been locked by another process).

A semaphore can only be locked when it is free. When read locking a free semaphore, PROCID is 0. Read locking a locked semaphore returns the MASTERID and PROCID that locked it. All read locks, including the first one that locks the semaphore, return the MASTERID that locks or locked the semaphore.

Note: The 1-step procedure must not be used when running multiple processes of the same AHB bus master ID. All processes using the same semaphore read the same status. When only one process locks the semaphore, each process of that AHB bus master ID reads the semaphore as locked by itself with the MASTERID.

10.3.4 HSEM write/read/read lock register address

For each semaphore, two AHB register addresses are provided, separated in two banks of 32-bit semaphore registers, spaced by a 0x80 address offset.

In the first register address bank the semaphore can be written (locked/unlocked) and read through the HSEM_Rx registers.

In the second register address bank the semaphore can be read (locked) through the HSEM_RLRx registers.

10.3.5 HSEM unlock procedures

Unlocking a semaphore is a protected process, to prevent accidental clearing by a AHB bus master ID or by a process not having the semaphore lock right. The procedure consists in writing to the semaphore HSEM_Rx register with the corresponding MASTERID and PROCID and LOCK = 0. When unlocked, the MASTERID, and the PROCID are all 0.

When unlocked, an interrupt may be generated to signal the event. To this end, the semaphore interrupt must be enabled.

The unlock procedure consists in a write to the semaphore HSEM_Rx register with matching MASTERID regardless on how the semaphore has been locked (1- or 2-step).

- Write semaphore with PROCID, MASTERID, and LOCK = 0
- If the written data matches the semaphore PROCID and MASTERID and the AHB bus master ID , the semaphore is unlocked and an interrupt may be generated when enabled, else write is ignored, semaphore remains locked and no interrupt is generated (the semaphore is locked by another process or the written data does not match the AHB bus master signaling).

Note: Different processes of the AHB bus master ID can write any PROCID value. Preventing other processes of the AHB bus master ID from unlocking a semaphore must be ensured by software, handling the PROCID correctly.

10.3.6 HSEM MASTERID semaphore clear

All semaphores locked by a MASTERID can be unlocked at once by using the HSEM_CR register. Write MASTERID and correct KEY value in HSEM_CR. All locked semaphores with a matching MASTERID are unlocked, and may generate an interrupt when enabled.

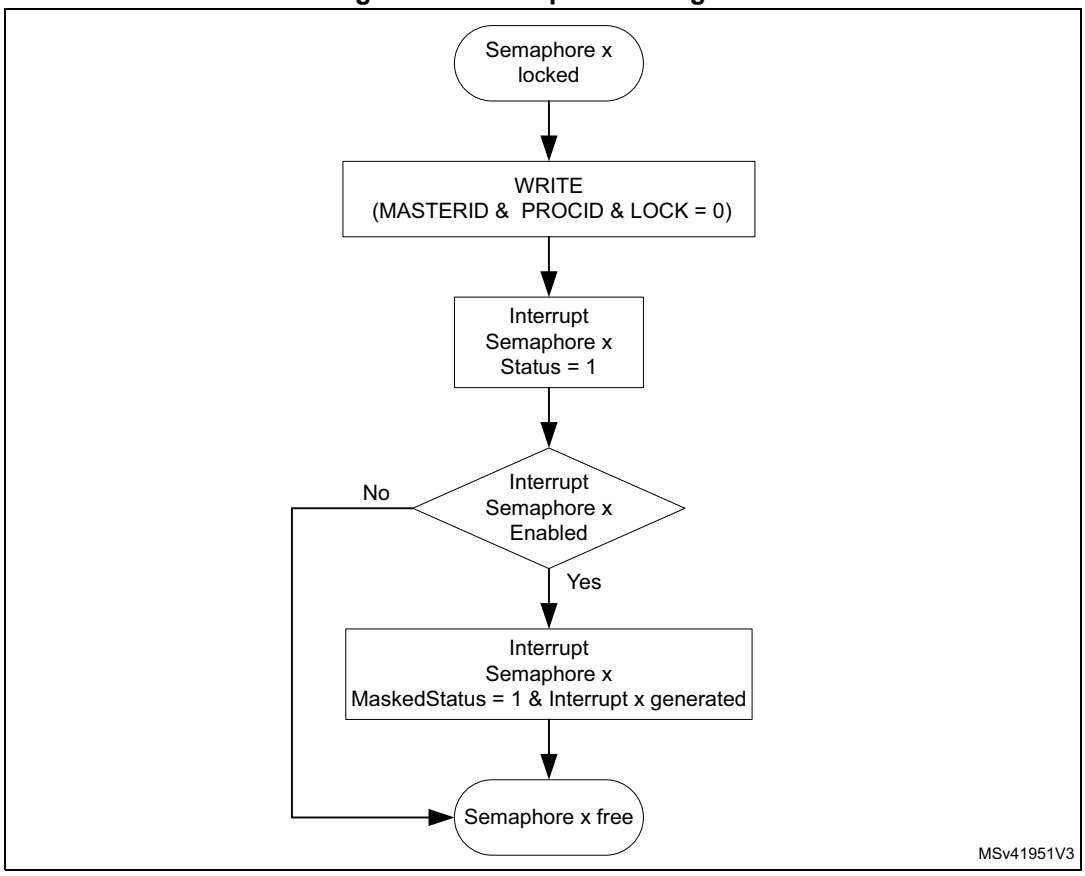
An interrupt may be generated for the unlocked semaphore(s). To this end, the semaphore interrupt must be enabled in the HSEM_IER register.

10.3.7 HSEM interrupts

An interrupt line hsem_int_it allows each semaphore to generate an interrupt.

An interrupt line provides the following features per semaphore:

- interrupt enable
- interrupt clear
- interrupt status
- masked interrupt status



With the interrupt enable (HSEM_IER) the semaphores affecting the interrupt line can be enabled. Disabled (masked) semaphore interrupts do not set the masked interrupt status MISF for that semaphore, and do not generate an interrupt on the interrupt line.

The interrupt clear (HSEM_ICR) clears the interrupt status ISF and masked interrupt status MISF of the associated semaphore for the interrupt line.

The interrupt status (HSEM_ISR) mirrors the semaphore interrupt status ISF before the enable.

The masked interrupt status (HSEM_MISR) only mirrors the semaphore enabled interrupt status MISF on the interrupt line. All masked interrupt status MISF of the enabled semaphores must be cleared to clear the interrupt line.

Figure 72. Interrupt state diagram

The procedure to get an interrupt when a semaphore becomes free is described hereafter.

Try to lock semaphore x

- If the semaphore lock is obtained, no interrupt is needed.
- If the semaphore lock fails:
- Clear pending semaphore x interrupt status for the interrupt line in HSEM_ICR.
  Re-try to lock the semaphore x again:
  - If the semaphore lock is obtained, no interrupt is needed (semaphore has been freed between first try to lock and clear semaphore interrupt status).
  - If the semaphore lock fails, enable the semaphore x interrupt in HSEM_IER.

On semaphore x free interrupt, try to lock semaphore x

- If the semaphore lock is obtained:
  Disable the semaphore x interrupt in HSEM_IER.
  Clear pending semaphore x interrupt status in HSEM_ICR.
- If the semaphore x lock fails:
  Clear pending semaphore x interrupt status in HSEM_ICR.
  Try again to lock the semaphore x:
  - If the semaphore lock is obtained (semaphore has been freed between first try to lock and semaphore interrupt status clear), disable the semaphore interrupt in HSEM_IER.

– If the semaphore lock fails, wait for semaphore free interrupt.

Note: An interrupt does not lock the semaphore. After an interrupt, either the AHB bus master or the process must still perform the lock procedure to lock the semaphore.

10.3.8 AHB bus master ID verification

The HSEM allows only authorized AHB bus master ID to lock and unlock semaphores.

- The AHB bus master 2-step lock write access to the semaphore HSEM_Rx register is checked against the valid bus master ID.
  – Accesses from unauthorized AHB bus master IDs are discarded and do not lock the semaphore.
- The AHB bus master 1-step lock read access from the semaphore HSEM_RLRx register is checked against the valid bus master ID.
  – An unauthorized AHB bus master ID read from HSEM_RLRx returns all 0.
- The semaphore unlock write access to the HSEM_CR register is checked against the valid bus master ID. Only the valid bus master ID can write to the HSEM_CR register and unlock any of the MASTERID semaphores.
  – Accesses from unauthorized AHB bus master IDs are discarded and do not clear the MASTERID semaphores.

The relation between bus master/processor and MASTERID is detailed in *Table 71*.

Table 71. Authorized AHB bus master ID

Bus master 0 (CPU)
MASTERID = 1

Note: Accesses from unauthorized AHB bus master IDs to other registers are granted.

10.4 HSEM registers

Registers must be accessed using word format. Byte and half-word accesses are ignored and have no effect on the semaphores, they generate a bus error.

10.4.1 HSEM register semaphore x (HSEM_Rx)

Address offset: 0x000 + 0x4 * x (x = 0 to 15)

Reset value: 0x0000 0000

The HSEM_Rx must be used to perform a 2-step write lock, read back, and for unlocking a semaphore. Only write accesses with authorized AHB bus master ID is granted. Write accesses with unauthorized AHB bus master IDs are discarded.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	MASTERID[3:0]				PROCID[7:0]							
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Lock indication
This bit can be written and read by software.
0: On write free semaphore (only when MASTERID and PROCID match), on read semaphore is free.
1: On write try to lock semaphore, on read semaphore is locked.

Bits 30:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **MASTERID[3:0]:** Semaphore MASTERID
Written by software
- When the semaphore is free and the LOCK bit is at the same time written to 1 and the MASTERID matches the AHB bus master ID.
- When the semaphore is unlocked (LOCK written to 0 and AHB bus master ID matched MASTERID, the MASTERID is cleared to 0.
- When the semaphore is unlocked (LOCK bit written to 0 or AHB bus master ID does not match MASTERID, the MASTERID is not affected.
- Write when LOCK bit is already 1 (semaphore locked), the MASTERID is not affected.
- An authorized read returns the stored MASTERID value.

Bits 7:0 **PROCID[7:0]:** Semaphore PROCID
Written by software
-When the semaphore is free and the LOCK is written to 1, and the MASTERID matches the AHB bus master ID, PROCID is set to the written data.
- When the semaphore is unlocked, LOCK written to 0 and AHB bus master ID matched MASTERID, the PROCID is cleared to 0.
- When the semaphore is unlocked, LOCK bit written to 0 and AHB bus master ID does not match MASTERID, the PROCID is not affected.
- Write when LOCK bit is already 1 (semaphore locked), the PROCID is not affected.
- An authorized read returns the stored PROCID value.

10.4.2 HSEM read lock register semaphore x (HSEM_RLRx)

Address offset: 0x080 + 0x4 * x (x = 0 to 15)

Reset value: 0x0000 0000

Accesses the same physical bits as HSEM_Rx. The HSEM_RLRx must be used to perform a 1-step read lock. Only read accesses with authorized AHB bus master ID is granted. Read accesses with unauthorized AHB bus master IDs are discarded and return 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	MASTERID[3:0]				PROCID[7:0]							
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **LOCK:** Lock indication

This bit is read only by software at this address.

- When the semaphore is free:

A read with a valid AHB bus master ID locks the semaphore and returns 1.

- When the semaphore is locked:

A read with a valid AHB bus master ID returns 1 (the MASTERID and PROCID reflect the already locked semaphore information).

Bits 30:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **MASTERID[3:0]:** Semaphore MASTERID

This field is read only by software at this address.

On a read, when the semaphore is free, the hardware sets the MASTERID to the AHB bus master ID reading the semaphore. The MASTERID of the AHB bus master locking the semaphore is read.

On a read when the semaphore is locked, this field returns the MASTERID of the AHB bus master that has locked the semaphore.

Bits 7:0 **PROCID[7:0]:** Semaphore processor ID

This field is read only by software at this address.

- On a read when the semaphore is free:

A read with a valid AHB bus master ID locks the semaphore and hardware sets the PROCID to 0.

- When the semaphore is locked:

A read with a valid AHB bus master ID returns the PROCID of the AHB bus master that has locked the semaphore.

10.4.3 HSEM interrupt enable register (HSEM_IER)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ISE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ISE[15:0]:** Interrupt semaphore x enable bit (x = 0 to 15)
This bit is read and written by software.
0: Interrupt generation for semaphore x disabled (masked)
1: Interrupt generation for semaphore x enabled (not masked)

10.4.4 HSEM interrupt clear register (HSEM_ICR)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ISC[15:0]:** Interrupt semaphore x clear bit (x = 0 to 15)
This bit is written by software, and is always read 0.
0: Interrupt semaphore x status ISFx and masked status MISFx not affected.
1: Interrupt semaphore x status ISFx and masked status MISFx cleared.

10.4.5 HSEM interrupt status register (HSEM_ISR)

Address offset: 0x108

Reset value: 0x0000 0000

ISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ISF[15:0]:** Interrupt semaphore x status bit before enable (mask) (x = 0 to 15)
This bit is set by hardware, and reset only by software. This bit is cleared by software writing the corresponding HSEM_ICR bit.
0: Interrupt semaphore x status, no interrupt pending
1: Interrupt semaphore x status, interrupt pending

10.4.6 HSEM interrupt status register (HSEM_MISR)

Address offset: 0x10C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISF[15:0]:** Masked interrupt semaphore x status bit after enable (mask) (x = 0 to 15)
This bit is set by hardware and read only by software. This bit is cleared by software writing the corresponding HSEM_ICR bit. This bit is read as 0 when semaphore x status is masked in HSEM_IER bit x.
0: interrupt semaphore x status after masking not pending
1: interrupt semaphore x status after masking pending

10.4.7 HSEM clear register (HSEM_CR)

Address offset: 0x140

Reset value: 0x0000 0000

Only write accesses with authorized AHB bus master ID are granted. Write accesses with unauthorized AHB bus master ID are discarded.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				w	w	w	w								

Bits 31:16 **KEY[15:0]:** Semaphore clear key
This field can be written by software and is always read 0.
If this key value does not match HSEM_KEYR.KEY, semaphores are not affected.
If this key value matches HSEM_KEYR.KEY, all semaphores matching the MASTERID are cleared to the free state.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **MASTERID[3:0]:** MASTERID of semaphores to be cleared
This field can be written by software and is always read 0.
This field indicates the MASTERID for which the semaphores are cleared when writing the HSEM_CR.

Bits 7:0 Reserved, must be kept at reset value.

10.4.8 HSEM clear semaphore key register (HSEM_KEYR)

Address offset: 0x144

Reset value: 0x0000 0000

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

11 General-purpose I/Os (GPIO)

11.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

11.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

11.3 GPIO functional description

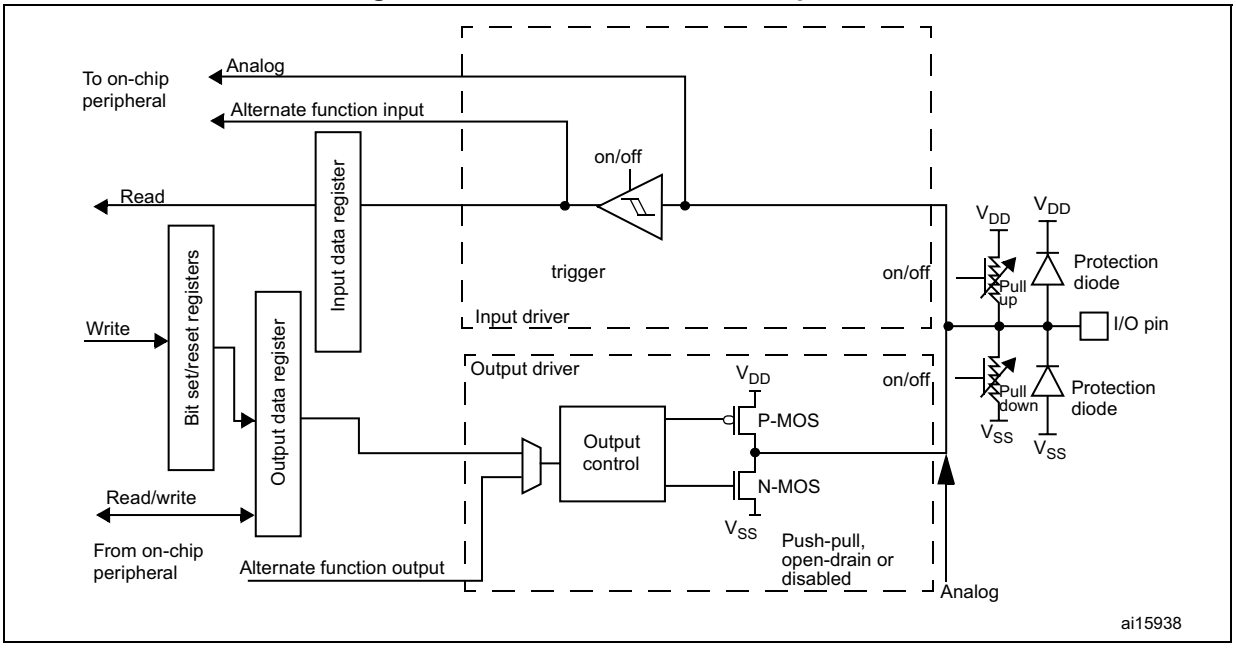
Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR register is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 73 and *Figure 74* show the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. *Table 73* gives the possible port bit configurations.

Figure 73. Basic structure of an I/O port bit



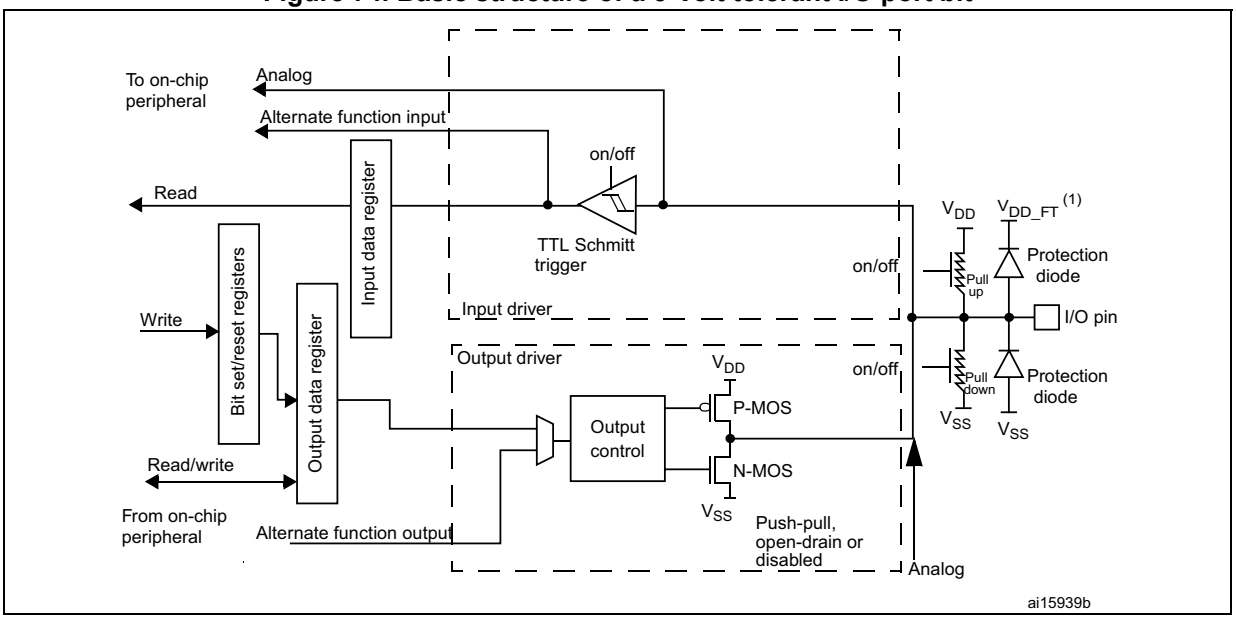


Figure 74. Basic structure of a 5-Volt tolerant I/O port bit

1. V_{DD_FT} is a potential specific to 5-Volt tolerant I/Os and different from V_{DD}.

Table 73. Port bit configuration table(1)

MODE(i) [1:0]	OTYPER(i)	OSPEED(i) [1:0]		PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]		0	0	GP output	PP
	0			0	1	GP output	PP + PU
	0			1	0	GP output	PP + PD
	0			1	1	Reserved	
	1			0	0	GP output	OD
	1			0	1	GP output	OD + PU
	1			1	0	GP output	OD + PD
	1			1	1	Reserved (GP output OD)	
10	0	SPEED [1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

11.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

11.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.
- Cortex-M7 with FPU EVENTOUT is mapped on AF15

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:

- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **System function:** MCOx pins have to be configured in alternate function mode.
- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function:**
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.

  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
  - The Cortex®-M7 output EVENTOUT signal can be output as alternate function on I/O pin. An event can be signaled through the configured pin after executing SEV instruction.
- **Additional functions:**
  - For the ADC, DAC and OPAMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC and OPAMP registers.
  - For the additional functions like RTC_OUT, RTC_TS, RTC_TAMPx, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers. For details about I/O control by the RTC, refer to *Section 50.3: RTC functional description on page 1810*.
- EVENTOUT
  - Configure the I/O pin used to output the core EVENTOUT signal by connecting it to AF15.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

11.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

11.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See *Section 11.4.5: GPIO port input data register (GPIOx_IDR) (x = A to K)* and *Section 11.4.6: GPIO port output data register (GPIOx_ODR) (x = A to K)* for the register descriptions.

11.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BR(i) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

11.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to *Section 11.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K)*) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in *Section 11.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K)*.

11.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

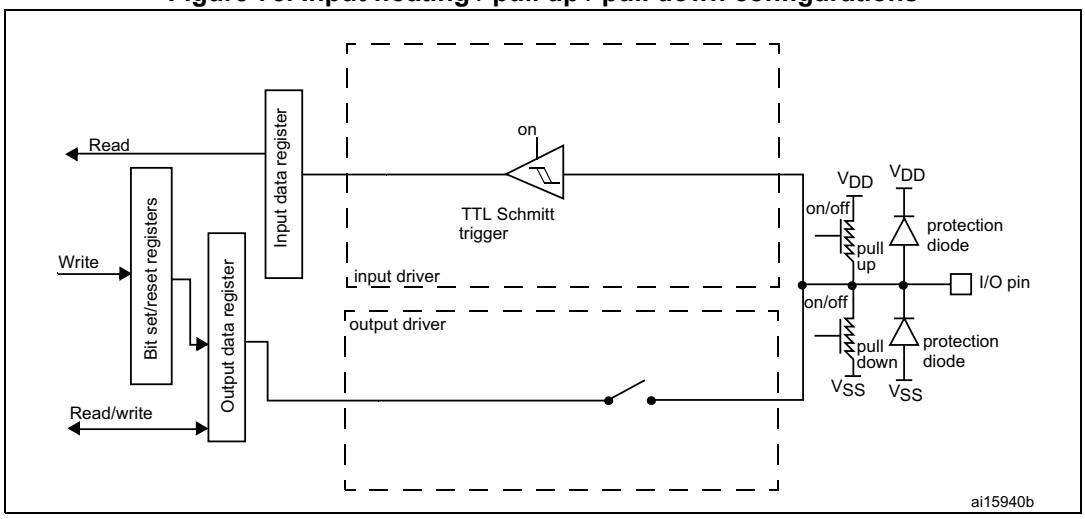
This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin refer to the device datasheet.

11.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode.

Refer to *Section 20: Extended interrupt and event controller (EXTI).*



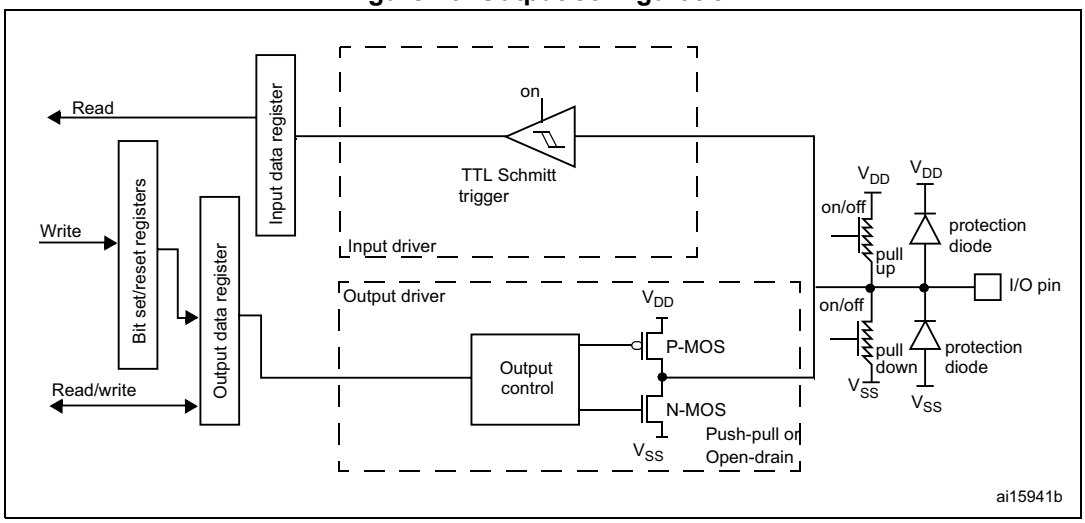
11.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

Figure 75 shows the input configuration of the I/O port bit.

Figure 75. Input floating / pull up / pull down configurations



11.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: a “0” in the output register activates the N-MOS whereas a “1” in the output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: a “0” in the output register activates the N-MOS whereas a “1” in the output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

Figure 76 shows the output configuration of the I/O port bit.

Figure 76. Output configuration

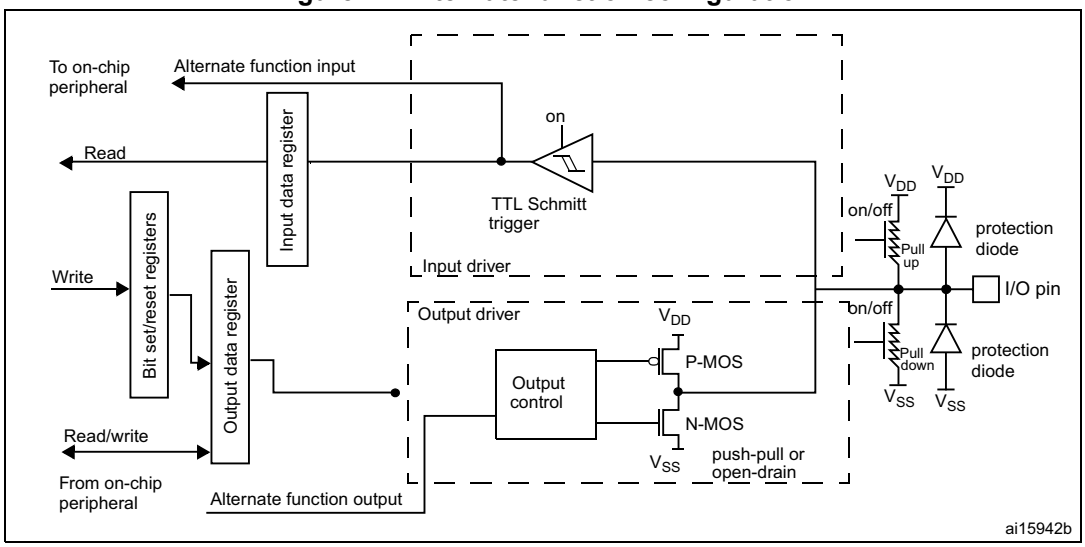
11.3.11 I/O compensation cell

This cell is used to control the I/O commutation slew rate (t_{fall} / t_{rise}) to reduce the I/O noise on power supply.

The cell is split into two blocks:

- The first block provides an optimal code for the current PVT. The code stored in this block can be read when the READY flag of the SYSCFG_CCSR is set.
- The second block controls the I/O slew rate.The user selects the code to be applied and programs it by software.

The I/O compensation cell features 2 voltage ranges: 1.62 to 2.0 V and 2.7 to 3.6 V.



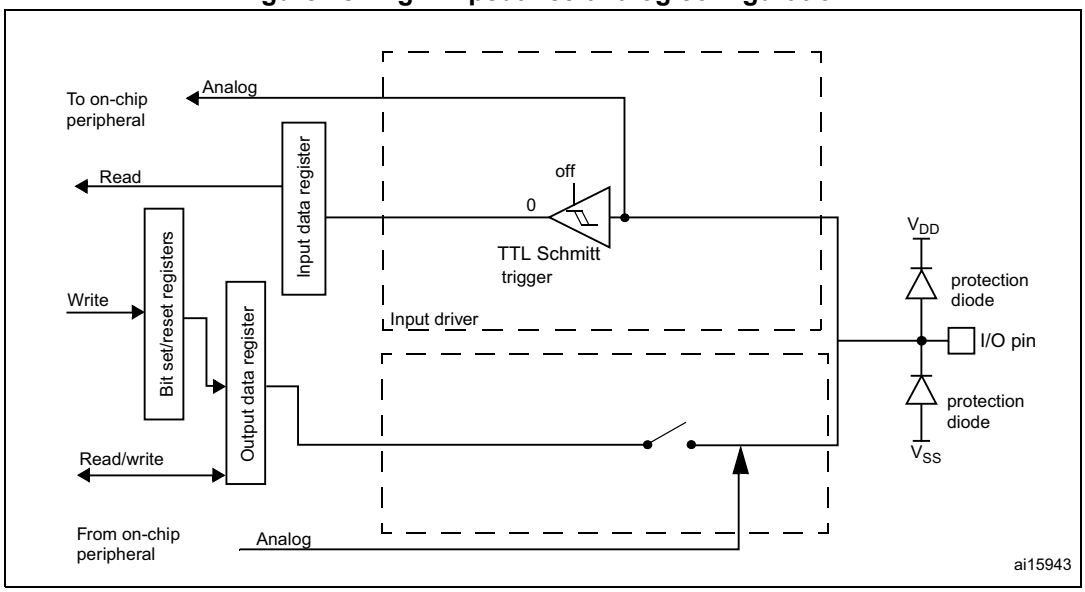
11.3.12 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

Figure 77 shows the alternate function configuration of the I/O port bit.

Figure 77. Alternate function configuration



11.3.13 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value “0”

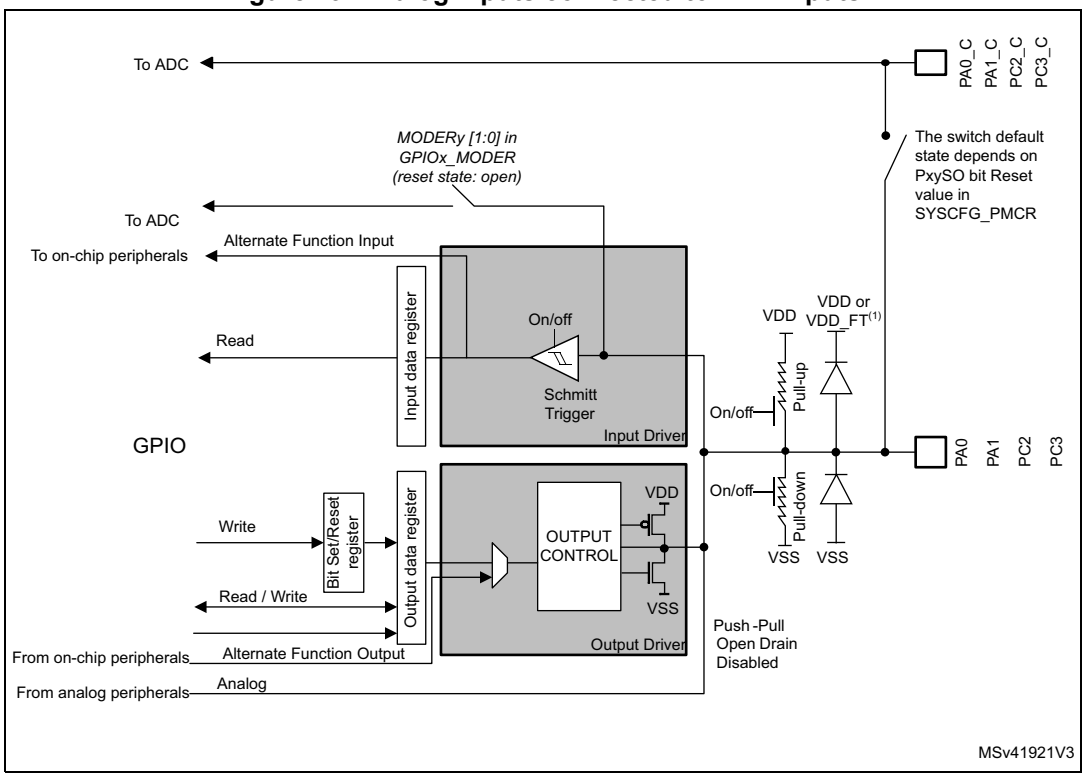


Figure 78 shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 78. High impedance-analog configuration

Some pins/balls are directly connected to PA0_C, PA1_C, PC2_C and PC3_C ADC analog inputs (see *Figure 79*): there is a direct path between Pxy_C and Pxy pins/balls, through an analog switch (refer to *Section 12.4.1: SYSCFG peripheral mode configuration register (SYSCFG_PMCR)* for details on how to configure analog switches).

Figure 79. Analog inputs connected to ADC inputs

1. VDD_FT is a potential specific to 5V tolerant I/Os. It is distinct from VDD.

11.3.14 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the OSC_IN or OSC32_IN pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

11.3.15 Using the GPIO pins in the backup supply domain

The PC13/PC14/PC15/PI8 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

11.4 GPIO registers

For a summary of register bits, register address offsets and reset values, refer to *Table 74*.

The peripheral registers can be written in word, half word or byte mode.

11.4.1 GPIO port mode register (GPIOx_MODER) (x = A to K)

Address offset:0x00

Reset value: 0xABFF FFFF for port A

Reset value: 0xFFFF FEBF for port B

Reset value: 0xFFFF FFFF for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODER15[1:0]		MODER14[1:0]		MODER13[1:0]		MODER12[1:0]		MODER11[1:0]		MODER10[1:0]		MODER9[1:0]		MODER8[1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODER[15:0][1:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O mode.
00: Input mode
01: General purpose output mode
10: Alternate function mode
11: Analog mode (reset state)

11.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to K)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OT[15:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O output type.
0: Output push-pull (reset state)
1: Output open-drain

11.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to K)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEEDR15 [1:0]		OSPEEDR14 [1:0]		OSPEEDR13 [1:0]		OSPEEDR12 [1:0]		OSPEEDR11 [1:0]		OSPEEDR10 [1:0]		OSPEEDR9 [1:0]		OSPEEDR8 [1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDR[15:0][1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very high speed

Note: Refer to the product datasheets for the values of OSPEEDRy bits versus V_{DD} range and external load.

11.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to K)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for other ports)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDR[15:0][1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

11.4.5 GPIO port input data register (GPIOx_IDR) (x = A to K)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDR[15:0]:** Port x input data I/O pin y (y = 15 to 0)
These bits are read-only. They contain the input value of the corresponding I/O port.

11.4.6 GPIO port output data register (GPIOx_ODR) (x = A to K)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

ODR15	ODR14	ODR13	ODR12	ODR11	ODR10	ODR9	ODR8	ODR7	ODR6	ODR5	ODR4	ODR3	ODR2	ODR1	ODR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODR[15:0]:** Port output data I/O pin y (y = 15 to 0)
These bits can be read and written by software.

Note: For atomic bit set/reset, the ODR bits can be individually set and/or reset by writing to the GPIOx_BSRR register (x = A..F).

11.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to K)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BR[15:0]:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Resets the corresponding ODRx bit

Note: If both BSx and BRx are set, BSx has priority.

Bits 15:0 **BS[15:0]:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Sets the corresponding ODRx bit

11.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to K)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

RD LCKR

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the lock.

After the first lock sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCK[15:0]:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0.

0: Port configuration not locked

1: Port configuration locked

11.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to K)

Address offset: 0x20

Reset value: 0x0000 0000

Refer to *Section 2.3 on page 130* for the register boundary addresses.

12 System configuration controller (SYSCFG)

12.1 Introduction

The devices feature a set of configuration registers. The objectives of this section is to describe in details the system configuration controller.

12.2 SYSCFG main features

The system configuration controller main functions are the following:

- Analog switch configuration management
- I2C Fm+ configuration
- Timer break input lockup management
- Management of the external interrupt line connection to the GPIOs
- Management of I/O speed in low-voltage mode
- Management of the I/O compensation cell for VDD and VDDMMC dual-power rail

12.3 SYSCFG functional description

12.3.1 Analog switch configuration management

To optimize the ADC performance, PA0_C, PA1_C, PC2_C and PC3_C pads are directly connected to the ADC (see *Figure 79: Analog inputs connected to ADC inputs*).

The switch connecting Pxx_C and Pxx pads is controlled through the SYSCFG_PMCR register (see *Section 12.4.1*).

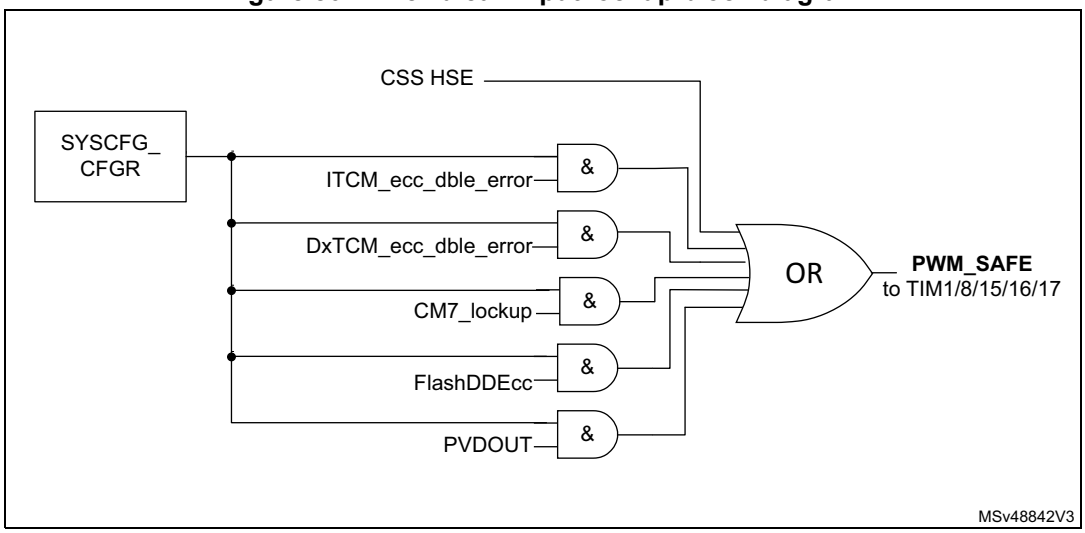
Some packages feature Pxx_C pads but not Pxx. All Pxx alternate functions are available on Pxx_C pads by closing the switch.

Other packages feature Pxx pads but not Pxx_C pads. ADC applications can benefit from closing the switch and using an ADC fast channel input (see *Figure 159: ADC1 connectivity* and *Figure 160: ADC2 connectivity*).

12.3.2 I2C Fm+ configuration

The I2C Fast-mode Plus (see *Section 52: Inter-integrated circuit interface (I2C)*) requires to set the corresponding GPIOs in high driving mode.

The I2CxFMP bits of SYSCFG_PMCR register activate the Fast-mode Plus driving capability for the I2Cx GPIOs.



In addition, the high drive mode can be activated on some GPIOs independently from the I2C (through PxxFMP bits in SYSCFG_PMCR register). This can be useful to drive LEDs directly.

12.3.3 Timer break input lockup management

In addition to HSE break detection, this feature allows the disabling of the timer output when an ECC double error or a core lockup is detected. This is particularly useful when using timers to drive motors. In addition to HSE break detection, the lockup can be selected through the dedicated SYSCFG_CFGR register (see *Section 12.4.6*).

Note: The SYSCFG_CFGR register bits can be cleared only by a system reset.

Figure 80. Timer break input lockup block diagram

12.3.4 Management of external interrupt line connections to GPIOs

Any GPIO can be configured as an external interrupt by programming the SYSCFG_EXTICRx registers (refer also to *Section 11.3.8: External interrupt/wake-up lines*).

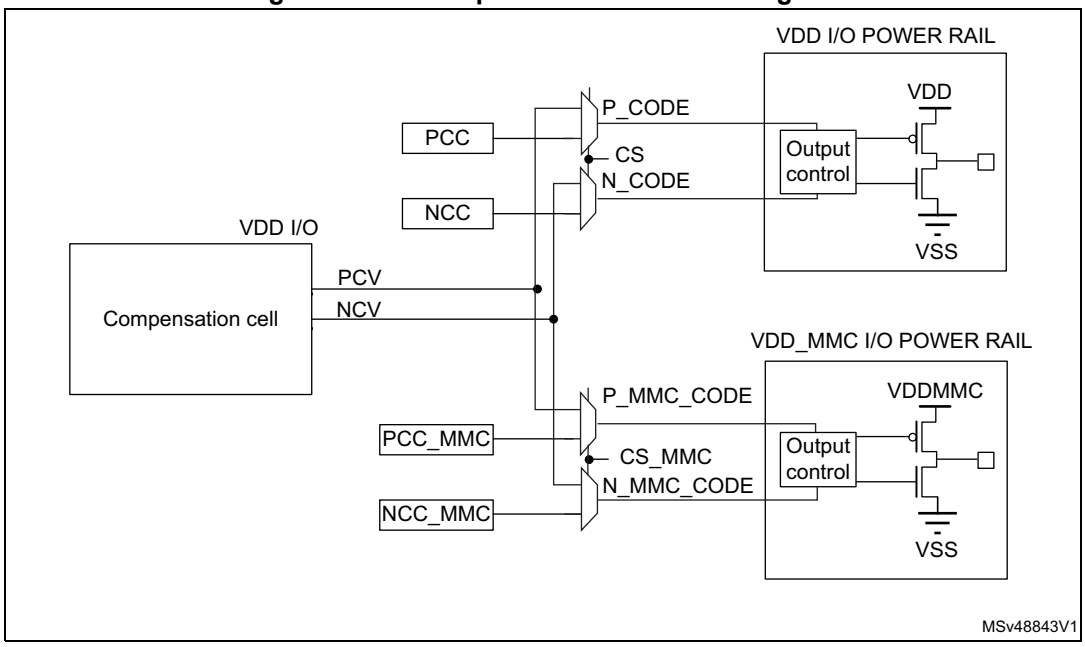
12.3.5 I/O speed in low-voltage mode

The speed of some I/Os can be increased at low voltage by programming the corresponding HSLVx bits in the SYSCFG_CCCSR register. This feature is intended mainly for SDMMC, FMC and OCTOSPI interfaces.

Caution: This feature must be used only when the I/O power supply is below 2.7 V.

12.3.6 I/O compensation cell management

The cell generates an 8-bit value for the I/O buffer (4-bit for N-MOS and 4-bit for P-MOS) that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the current slew-rate and output impedance in the I/O buffer.



By default, the compensation cell is disabled, and a fixed code is applied to all the I/Os.

When enabled, the compensation cell tracks the PVT, and the 8-bit code (PCV and NCV) is applied to all I/Os for both VDD and VDDMMC I/O supply domains.

To optimize trimming, the code can be adjusted through SYSCFG_CCCR register. Two sets of bitfields are available: PCC/NCC for the VDD power rail and PCC_MMC/NCC_MCC for the VDDMMC power rail. They can be selected independently through CS and CS_MMC bits of SYSCFG_CCCSR register (see *Figure 81*).

When the two power rails are not at the same voltage, it is recommended to adjust VDDMMC code through SYSCFG_CCCR compensation cell code register since the compensation cell tracks the PVT on VDD power supply.

Figure 81. I/O compensation cell block diagram

12.4 SYSCFG registers

12.4.1 SYSCFG peripheral mode configuration register (SYSCFG_PMCR)

Address offset: 0x04

Reset value: 0x0F00 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PB9FMP	PB8FMP	PB7FMP	PB6FMP	I2C4FMP	I2C3FMP	I2C2FMP	I2C1FMP
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PC3SO**: PC3 switch open
This bit controls the analog switch between PC3 and PC3_C (dual pad).
0: Analog switch closed (pads connected through the analog switch)
1: Analog switch open (two separated pads)

Bit 26 **PC2SO**: PC2 switch open
This bit controls the analog switch between PC2 and PC2_C (dual pad).
0: Analog switch closed (pads connected through the analog switch)
1: Analog switch open (two separated pads)

Bit 25 **PA1SO**: PA1 switch open
This bit controls the analog switch between PA1 and PA1_C (dual pad).
0: Analog switch closed (pads connected through the analog switch)
1: Analog switch open (two separated pads)

Bit 24 **PA0SO**: PA0 switch open
This bit controls the analog switch between PA0 and PA0_C (dual pad).
0: Analog switch closed (pads connected through the analog switch)
1: Analog switch open (two separated pads)

Bits 23:8 Reserved, must be kept at reset value.

Bit 7 **PB9FMP**: Fast-mode Plus driving capability activation on PB9
This bit enables the Fm+ driving mode on PB9.
0: PB9 pin operates in standard mode
1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed

Bit 6 **PB8FMP**: Fast-mode Plus driving capability activation on PB8
This bit enables the Fm+ driving mode on PB8.
0: PB8 pin operates in standard mode
1: Fm+ mode is enabled on PB8 pin and the speed control is bypassed

Bit 5 **PB7FMP**: Fast-mode Plus driving capability activation on PB7
This bit enables the Fm+ driving mode for PB7.
0: PB7 pin operates in standard mode
1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed

Bit 4 **PB6FMP**: Fast-mode Plus driving capability activation on PB6
This bit enables the Fm+ driving mode for PB6.
0: PB6 pin operates in standard mode
1: Fm+ mode is enabled on PB6 pin and the speed control is bypassed

Bit 3 **I2C4FMP**: I2C4 Fm+
This bit enables Fm+ on I2C4.
The corresponding GPIOs are configured in Fast-mode Plus driving capability.
0: Fm+ disabled
1: Fm+ enabled

Bit 2 **I2C3FMP**: I2C3 Fm+
This bit enables Fm+ on I2C3.
The corresponding GPIOs are configured in Fast-mode Plus driving capability
0: Fm+ disabled
1: Fm+ enabled

Bit 1 **I2C2FMP**: I2C2 Fm+
This bit enables Fm+ on I2C2.
The corresponding GPIOs are configured in Fast-mode Plus driving capability
0: Fm+ disabled
1: Fm+ enabled

Bit 0 **I2C1FMP**: I2C1 Fm+
This bit enables Fm+ on I2C1.
The corresponding GPIOs are configured in Fast-mode Plus driving capability
0: Fm+ disabled
1: Fm+ enabled

12.4.2 SYSCFG external interrupt configuration register 1 (SYSCFG_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0111: PH[x] pin
1001: PJ[x] pin
1010: PK[x] pin
Other configurations: reserved

Note: PK[15:12] are not used.

12.4.6 SYSCFG timer break lockup register (SYSCFG_CFGR)

Address offset: 0x18

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ITCML	DTCML	Res.	Res.	Res.	Res.	Res.	Res.	CM7L	Res.	Res.	FLASHL	PVDL	Res.	Res.
	rs	rs							rs			rs	rs		

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ITCML:** ITCM double ECC error signal lock
This bit is set by software and cleared only by a reset system.
It is used to enable and lock the ITCM double ECC error signal connection to TIM1/8/15/16 /17 Break inputs.
0: ITCM double ECC disconnected
1: ITCM double ECC connected

Bit 13 **DTCML:** D1TCM or D0TCM double ECC error signal lock
This bit is set by software and cleared only by reset system.
It is used to enable and lock the DxTCM double ECC error signal connection to TIM1/8/15/16 /17 Break inputs.
0: DxTCM double ECC disconnected
1: DxTCM double ECC connected

Bits 12:7 Reserved, must be kept at reset value.

Bit 6 **CM7L**: Cortex®-M7 LOCKUP (HardFault) output enable bit
This bit is set by software and cleared only by reset system.
It is used to enable and lock the Cortex®-M7 LOCKUP output connection to TIM1/8/15/16 /17 Break inputs.
0: Cortex®-M7 LOCKUP output disconnected
1: Cortex®-M7 LOCKUP output connected

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **FLASHL:** Flash double ECC error lock bit
This bit is set by software and cleared only by reset system.
It is used to enable and lock the Cortex®-M7 LOCKUP output connection to TIM1/8/15/16 /17 Break inputs.
0: Double ECC disconnected
1: Double ECC connected

Bit 2 **PVDL:** PVD lock enable bit.
This bit is set by software and cleared only by reset system.
It is used to enable and lock the PVD connection to TIM1/8/15/16 /17 Break inputs.
0: PVD signal disconnected
1: PVD signal connected

Bits 1:0 Reserved, must be kept at reset value.

12.4.7 SYSCFG compensation cell control/status register (SYSCFG_CCCSR)

Address offset: 0x20

Reset value: 0x0000 0000

Refer to *Section 11.3.11: I/O compensation cell* for a detailed description of I/O compensation mechanism.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSLV3	HSLV2	HSLV1	HSLV0

							r					rw		rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 19 **HSLV3:** High-speed at low-voltage for VDDMMC I/Os

This bit is written by software to optimize the I/O speed when the product voltage is low.

It is active only if VDDMMC_HSLV user option bit is set. It must be used only when the VDDMMC I/O power supply is below 2.7 V. Setting this bit when V_{DDMMC} is higher than 2.7 V might damage the I/Os.

It controls the speed of the following I/Os (mainly SDIO on VDDMMC power rail): PB[9:8], PD[7:6] and PG[14:9].

0: No I/O speed optimization

1: I/O speed optimization

Bit 18 **HSLV2:** High-speed at low-voltage for VDD I/Os

This bit is written by software to optimize the I/O speed when the product voltage is low.

It is active only if VDDIO_HSLV user option bit is set. It must be used only when the VDD I/O power supply is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V might damage the I/Os.

This bit controls the speed of the following I/Os (mainly for FMC): PD[15:8], PD[3], PD[1:0], PE[15:0], PF[15:12], PF[5:2], PG[8:0], PH[15:8], PH[3:2], PI[10:9] and PI[7:0].

0: No I/O speed optimization

1: I/O speed optimization

Bit 17 **HSLV1:** High-speed at low-voltage for VDD I/Os

This bit is written by software to optimize the I/O speed when the product voltage is low.

It is active only if VDDIO_HSLV user option bit is set. It must be used only when the VDD I/O power supply is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V might damage the I/Os.

It control the speed of the following I/Os (mainly for OCTOSPI): PA[7:6], PA[3], PA[1], PB[12], PB[2], PC[5], PD[5:4], PF[11:6], PG[15], PI[4:2], PJ[2:1] and PK[6:3].

0: No I/O speed optimization

1: I/O speed optimization

Bit 16 **HSLV0:** High-speed at low-voltage for VDD I/Os

This bit is written by software to optimize the I/O speed when the product voltage is low.

It is active only if VDDIO_HSLV user option bit is set. It must be used only when the VDD I/O power supply is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V might damage the I/Os.

This bit controls the speed of the following I/Os (mainly for SDMMC or others): PA[8], PA[5], PB[15:13], PB[5:3], PB[1:0], PC[12:6], PC[1] and PD[2].

0: No I/O speed optimization

1: I/O speed optimization

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **READY:** Compensation cell ready flag

This bit provides the status of the compensation cell.

0: I/O compensation cell not ready

1: I/O compensation cell ready

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CS_MMC:** Code selection for VDDMMC power rail

This bit selects the code to be applied to the VDDMMC I/O buffer.

0: Value from the compensation cell (available in the SYSCFG_CCVR)

1: Code register from the SYSCFG compensation cell code bits (available in SYSCFG_CCCR)

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CS:** Code selection for all VDD power rails

This bit selects the code to be applied to the VDD I/O buffer.

0: Value from the compensation cell (available in the SYSCFG_CCVR)

1: Code register from the SYSCFG compensation cell code (available in SYSCFG_CCCR)

Bit 0 **EN:** Enable bit

This bit enables the I/O compensation cell.

0: I/O compensation cell disabled

1: I/O compensation cell enabled

12.4.8 SYSCFG compensation cell value register (SYSCFG_CCVR)

Address offset: 0x24

Reset value: 0x0000 0088

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCV[3:0]				NCV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PCV[3:0]:** PMOS compensation cell value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is reset.

Bits 3:0 **NCV[3:0]:** NMOS compensation cell value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is reset.

12.4.9 SYSCFG compensation cell code register (SYSCFG_CCCR)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCC_MMC[3:0]				NCC_MMC[3:0]				PCC[3:0]				NCC[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCC_MMC[3:0]:** PMOS compensation code register

These bits are written by software to define an I/O compensation cell code for PMOS transistors corresponding to the VDDMMC power rail.
This code is applied to the I/O when the CS_MMC bit of SYSCFG_CCCSR is set.

Bits 11:8 **NCC_MMC[3:0]:** NMOS compensation code register

These bits are written by software to define an I/O compensation cell code for NMOS transistors corresponding to the VDDMMC power rail.
This code is applied to the I/O when the CS_MMC bit of SYSCFG_CCCSR is set.

Bits 7:4 **PCC[3:0]:** PMOS compensation code register

These bits are written by software to define an I/O compensation cell code for PMOS transistors corresponding to the VDD power rail.
This code is applied to the I/O when the CS bit of SYSCFG_CCCSR is set.

Bits 3:0 **NCC[3:0]:** NMOS compensation code register

These bits are written by software to define an I/O compensation cell code for NMOS transistors corresponding to the VDD power rail.
This code is applied to the I/O when the CS bit of SYSCFG_CCCSR is set.

12.4.10 SYSCFG register maps

The following table gives the SYSCFG register map and the reset values.

Table 75. SYSCFG register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 130* for the register boundary addresses.

13 Block interconnect

13.1 Peripheral interconnect

13.1.1 Introduction

Several peripherals have direct connections between them.

This enables autonomous communication and synchronization between peripherals, thus saving CPU resources and power consumption.

These hardware connections remove software latency, allow the design of a predictable system and result in a reduction of the number of pins and GPIOs.

13.1.2 Connection overview

There are several types of connections.

- Asynchronous connections (A)

  The source output signal is sampled by the destination clock, leading to introduction of a possible jitter in the latency between the source output event and the destination event detection
- Synchronous connections (S)

  Both source and destination are synchronous (they run on the same clock), and the latency from the source to the destination is deterministic. No jitter is introduced.
- Immediate connections (I)

  Either the source or the destination is an analog signal.
- Break/fault connection for TIM outputs (B)

  The source output signal disables the timer outputs through a pure combinational logic path, without any latency.

1. Letters in the table correspond to the type of connection described in *Section 13.1.2: Connection overview*.
2. comp1_out and comp2_out are connected to the inputs of an OR gate. The output of this OR gate is connected to the The lptim2_in1_mux3 input.

13.2 Wakeup from low-power modes

The Extended interrupt and event controller module (EXTI) allows to wake up the system from Stop mode and/or a CPU from CStop mode. Wakeup events are coming from peripherals.

These events are handled by the EXTI either as Configurable events (**C**), or as Direct events (**D**). See *Type* column in *Table 79*. Refer to *Section 20: Extended interrupt and event controller (EXTI)* for further details.

Three types of peripheral output signals are connected to the EXTI input events:

- The wakeup signals. These signals can be generated by the peripheral without any bus interface clock, they are referred to as xxx_wkup in *Table 79*. Some peripherals do not have this capability.
- The interrupt signals. These signals can be generated only if the peripheral bus interface clock is running. These interrupt signals are generally directly connected to the NVIC of CPU. They are referred to as xxx_it.
- The signals, i.e. the pulses generated by the peripheral. Once a peripheral has generated a signal, no action (flag clearing) is required at peripheral level.

Each EXTI input event has a different wakeup capability or possible target (see *Target* column in *Table 79*):

- CPU wakeup (**CPU**): the input event can be enabled to wake up the CPU
- CPU and SRD domain wakeup for autonomous Run mode (**ANY**): the input event can be enabled to wake up the CPU or the SRD domain only for an autonomous Run mode phase.

1. The source peripheral needs its bus clock in order to generate the event. The required clock is described in Section *Reset and clock controller.*
2. The source peripheral signal is not connected to the NVIC.

The Extended Interrupt and Event Controller (EXTI) module event inputs able to wake up the SRD domain for autonomous Run mode have a pending request logic that can be cleared by 4 different input sources (*Table 80*). Refer to *Section 20: Extended interrupt and event controller (EXTI)* for further details.

13.3 DMA

In CD domain, the MDMA allows the memory to transfer data. It can be triggered by software or by hardware, according to the connections described in *Section 13.3.1*.

DMA Multiplexer in CD domain (DMAMUX1) allows to map any peripheral DMA request to any stream of the DMA1 or the DMA2. In addition to this, The DMAMUX provides two other functionalities:

- It's possible to synchronize a peripheral DMA request with a timer, with an external pin or with a DMA transfer complete of another stream.
- DMA requests can be generated on a stream by the DMAMUX1 itself. This event can be triggered by a timer, by an external pin event, or by a DMA transfer complete of another stream. The number of DMA requests generated is configurable.

The connections on DMAMUX1 and DMA1/DMA2 are described in *Section 17: DMA request multiplexer (DMAMUX)*, *Section 15: Direct memory access controller (DMA)* and *Section 16: Basic direct memory access controller (BDMA)*.

The BDMA1 in the CD domain is dedicated to the DFSDM1. The connections on BDMA1 are described in *Section 13.3.2: DMAMUX1, DMA1, DMA2 and BDMA1 (CD domain)*.

DMA Multiplexer in SRD domain (DMAMUX2) has the same functionality as DMAMUX1, it is connected to the basic DMA (BDMA2).

The connections on DMAMUX2 and BDMA2 are described in *Section 13.3.3: DMAMUX2, BDMA2 (SRD domain)*. Refer to *Section 13.3.3: DMAMUX2, BDMA2 (SRD domain)* and *Section 16: Basic direct memory access controller (BDMA)* for more details.

14 MDMA controller (MDMA)

14.1 MDMA introduction

The master direct memory access (MDMA) is used in order to provide high-speed data transfer between memory and memory, or between peripherals and memory. Data can be quickly moved by the MDMA without any CPU action. This keeps the CPU resources free for other operations.

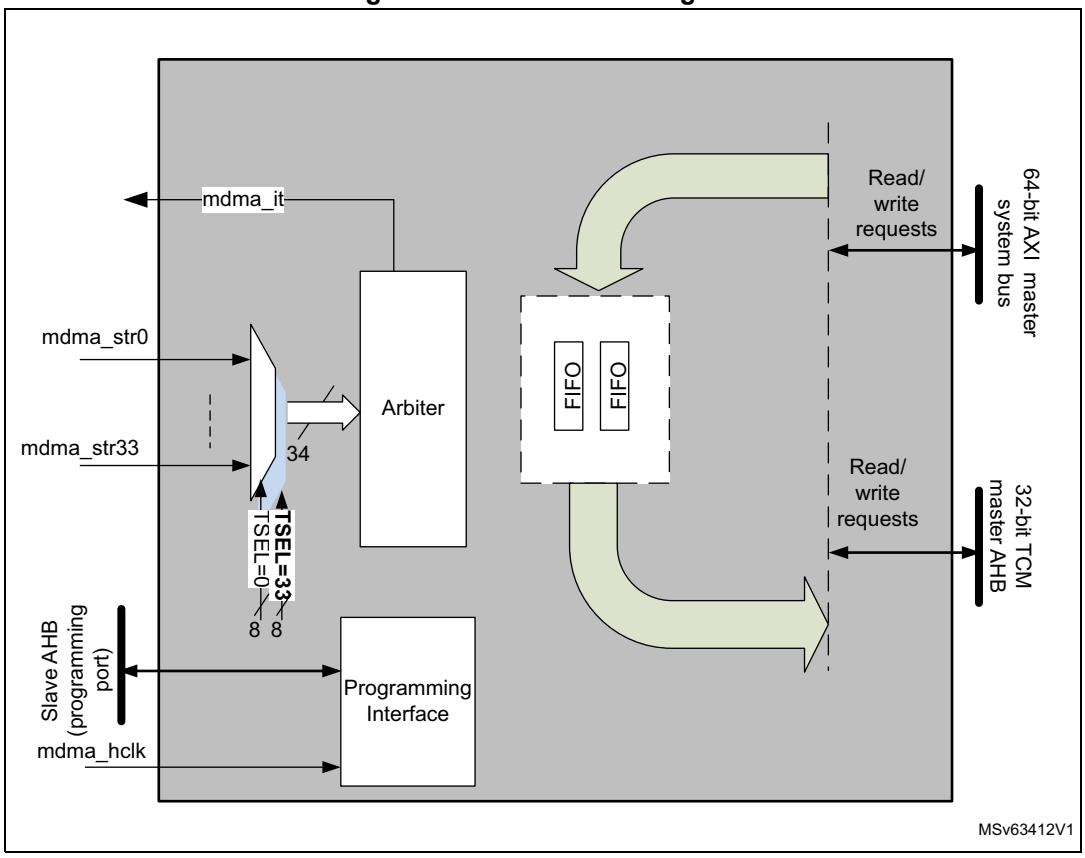
The MDMA controller provides a master AXI interface for main memory and peripheral register access (system access port) and a master AHB interface only for Cortex-M7 TCM memory access (TCM access port).

The MDMA works in conjunction with the standard DMA controllers (DMA1 or DMA2). It offers up to 16 channels, each dedicated to manage memory access requests from one of the DMA stream memory buffer or other peripherals (with integrated FIFO).

14.2 MDMA main features

- AXI/AHB master bus architecture, one dedicated to main memory/peripheral accesses and one dedicated to Cortex-M7 AHBS port (only for TCM accesses).
- 16 channels
- Up to 34 hardware trigger sources
- Each channel request can be selected among any of the request sources. This selection is software-configurable and allows several peripherals to initiate DMA requests. The trigger selection can be automatically changed at the end of one block transfer.
- All channels are identical and can be connected either to a standard DMA or a peripheral request (acknowledge by data read/write) system
- Each channel also supports software trigger.
- One 256-level memory buffer, split in two 128-level first-in, first-out (FIFO), that is used to store temporary the data to be transferred (in burst or single transfer mode), for one or two consecutive buffers. The FIFO stores the data that are transferred during the current channel block transfer (up to the block transfer size). The second FIFO can be used for the next buffer to be transferred, either for the same channel or for the next channel transfer.
- The priorities between DMA channels are software-programmable (four levels consisting of very-high, high, medium, low) or hardware in case of equality (for example, channel 0 has priority over channel 1)
- Independent source and destination transfer width (byte, half-word, word, double-word): when the data widths of the source and destination are not equal, the MDMA can pack/unpack the necessary data to optimize the bandwidth.
- The size and address increment for both source and destination can be independently selected.

Note: Based on this separation, some more advanced packing/unpacking operations are available at software level. As an example, 2 x 16-bit data blocks can be interleaved together using two MDMA channels, in the destination memory, by simply programming the two channels with an increment step of 4 bytes and a data size of 16 bits + a start address shifted by two between the two channels.



- Incrementing, decrementing or non incrementing/fixed addressing for source and destination
- Data packing/unpacking is always done respecting the little endian convention: lower address in a data entity (double-word, word, or half-word) contains always the lowest significant byte. This is independent of the address increment/decrement mode of both source and destination.
- Supports incremental burst transfers. The size of the burst is software-configurable, up to 128 bytes. For larger data sizes the burst length is limited, as to respect the maximum 128 bytes data burst size (such as 16 x 64 bits or 32 x 32 bits).
- For the TCM memory accesses, the burst access is only allowed when the increment and data size are identical and lower than or equal to 32 bits.
- Five event flags (MDMA channel transfer complete, MDMA block transfer complete, MDMA block repeat transfer Complete, MDMA buffer transfer Complete, MDMA transfer error) are available and can generate interrupts.

14.3 MDMA functional description

14.3.1 MDMA block diagram

The figure below shows the block diagram of the MDMA.

Figure 82. MDMA block diagram

14.3.2 MDMA internal signals

The table below shows the internal MDMA signals.

Table 84. MDMA internal input/output signals

Signal name	Signal type	Description
mdma_hclk	Digital input	MDMA AHB clock
mdma_it	Digital output	MDMA interrupt
mdma_str[0:31]	Digital input	MDMA stream request

14.3.3 MDMA overview

The MDMA performs a direct memory transfer: as an AXI/AHB master, the MDMA can take the control of the AXI/AHB bus matrix to initiate AXI/AHB transactions.

The MDMA can carry out the following transactions:

- memory-to-memory (software triggered)
- peripheral-to-memory
- memory-to-peripheral

For the last two transaction types, the memory can also be replaced by a memory-mapped peripheral, which has no control over the MDMA flow. When these types of transaction are used and the request comes from a standard DMA (DMA1 or DMA2), the peripheral register access is replaced by a memory access to the memory buffer used by this DMA.

Note: Non-incrementing/decrementing mode is not used for memory accesses.

The source and destination are simply defined by the address (peripherals being memory-mapped also).

The AHB slave port is used to program the MDMA (it supports 8-,16-, and 32-bit accesses).

The size of the data array to be transferred for a single request is one of the following:

- buffer transfer size
- block size
- repeated block
- complete channel data (until the linked-list pointer for the channel is null)

The choice of the size is done through the TRGM[1:0] (Trigger mode) selection field.

The user must choose one of them based on the data array size available (usually in the DMA1/2 memory buffer) and the “real time” requirements for other MDMA channels (knowing that a buffer transfer is the minimum data aggregate to be transferred by the MDMA without doing a new arbitration between MDMA channel requests).

For each channel, there are three key data array sizes:

- Burst size: this is the length of the data transfer which can be performed in burst mode. This burst length defines the maximum transfer length which cannot be interrupted at bus arbitration level and can block other masters from accessing the bus.
- Buffer transfer size: this is the length of the data array to be transferred, on a channel, before checking for MDMA requests on other channels. This is the data array transfer lengths which cannot be interrupted at MDMA level (from other channel requests).
- Block size: this value has two meanings which can be used together:
  - main: this is length of the data block which is described in a block structure of the MDMA linked list (corresponds to one entry in the linked list)
  - selectable: when TRGM[1:0] equals 01, this is the length of the data array which is transferred on a single MDMA request activation (for the respective channel)

14.3.4 MDMA channel

Each MDMA channel provides an unidirectional transfer link between a source and a destination.

Each channel can perform transfer of the following types:

- Single block transfer: one block is transferred. At the end of the block, the MDMA channel is disabled and an end-of-channel transfer interrupt is generated.
- Repeated block transfer: a number of blocks is transferred before disabling the channel.
- Linked-list transfer: when the transfer of the current data block (or last block in a repeat) is completed, a new block control structure is loaded from memory and a new block transfer is started.

The minimum amount of data to be transferred for each request (buffer size, up to 128 bytes) is programmable. The total amount of data in a block, is programmable up to 64 Kbytes. This value is decremented after each transfer. When this counter reaches zero, the end of the block is reached and an action is taken based on the repeat counter (for repeated block transfer) and/or linked-list structure value.

Note: If the block length is not a multiple of the buffer length, the last buffer transfer in the block is shorter, covering the remaining bytes to be transferred in the current block.

If the link structure address points to a valid memory address, the MDMA reloads the whole channel descriptor structure register contents from memory at this address. Then, a new block transfer is then executed (on the next MDMA channel request) based on this information.

If the link structure address is 0x0, at the end of the current/repeated block transfer, the MDMA channel is disabled and the end-of-channel transfer interrupt is generated.

14.3.5 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The source/destination addresses can be fixed (such as FIFO/single data register peripherals) or incremented/decremented. The transfer can be done in single access or in burst mode (programmable).

14.3.6 Pointer update

The source and destination memory pointers can optionally be automatically post-incremented/decremented, or kept constant after each transfer depending on the SINC[1:0] and DINC[1:0] bitfields in the MDMA_CxCR register.

Disabling the increment mode is useful when the peripheral source or destination data are accessed through a single register/FIFO mode.

If the increment/decrement mode is enabled, the address of the next data transfer is the address of the previous one incremented/decrement by 1, 2, 4 or 8 depending on the increment size programmed in SINCOS[1:0] or DINCOS[1:0] in MDMA_CxCR.

In order to optimize the packing operation, the increment offset size and the data size are programmable independently.

14.3.7 MDMA buffer transfer

This is the minimum logical amount of data (up to 128 bytes) which is transferred on an MDMA request event, on one channel.

An MDMA buffer transfer consists of a sequence of a given number of data transfers (done as single or burst data transfers). The number of data items to be transferred and their width (8, 16, 32, or 64 bits) are software programmable. The length of the burst used for data transfers is also programmable, independently.

After an event requiring a data array to be transferred, the DMA/peripheral sends a request signal to the MDMA, which serves the request depending on the channel priorities.

The request is acknowledged by writing the mask data value to the address given mask address, when these registers are set.

If the mask address register is not set (0x00 value), the request can be reset by simply reading/writing the data to the peripheral. In this case, if the request is done by a destination peripheral, the write must be set as non bufferable, in order to avoid a false new MDMA request.

The total amount of data to be transferred, on the current channel, following a MDMA request, is determined by the TRGM[1:0] field.

If TRGM[1:0] equals 00, a single buffer is transferred, then the MDMA waits for another request on the same channel.

Note: In this case, the hardware request for the currently active channel (data in the FIFO) is not considered again until the end of the write phase for this channel. Even if the channel is still active at the end of the read phase, another channel (even with lower priority) can start the read phase. Lower priority channels can be interleaved with current channel transfer.

If TRGM[1:0] is different from 00 (multiple buffers need to be transferred), the mdma_strx for the current channel remains active (internally memorized) until the whole transfer defined by TRGM (block, repeated block or whole channel/linked list data) is completed.
After transferring an individual buffer, the MDMA enters in a new arbitration phase (between new external requests and internally memorized ones). If no other higher priority, the channel request is active, and a new buffer transfer is started for the same channel.

Note: When TRGM[1:0] is different from 00, a larger array of data is transferred for a single request. But, as the channel arbitration is done after each buffer transfer, no higher level MDMA requests are blocked for the more than a buffer transfer period, on any lower priority channel.

14.3.8 Request arbitration

An arbiter manages the MDMA channel requests based on their priority. When the MDMA is idle and after the end of each buffer transfer, all MDMA requests (hardware or software) are checked for all enabled channels.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the MDMA_CxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: at hardware level, the channel priority is fixed. If two requests have the same software priority level, the channel with the lower number takes priority over the stream with the higher number. For example, Channel 2 takes priority over Channel 4 when they have the same software priority level.

14.3.9 FIFO

A FIFO structure is used to temporarily store data coming from the source before writing them to the destination. There is a central FIFO structure which is used for all channels.

In order to maximize data bandwidth and bus usage, the following mechanisms are used, allowing multiple read/write operation to be executed in parallel.

- During a buffer transfer, as soon as the FIFO contains enough data for a destination burst transfer, the write operation starts.
- When the complete data for a buffer transfer has been read into the FIFO, the arbitration procedure is started. Following that, the next buffer data to be transferred can be read to the FIFO.

When an active channel is disabled due to an error, during a buffer transfer, the remaining data in the internal FIFO is discarded.

14.3.10 Block transfer

A block is a “contiguous” array of data, up to 64 Kbytes, which is transferred by successive buffer transfers.

Each block of data is defined by the start address and the block length. When a block transfer is completed, one of the following three actions can be executed:

- The block is part of a repeated block transfer: the block length is reloaded and new block start address is computed (based on the information in MDMA_CxBRUR).
- It is a single block or the last block in a repeated block transfer: the next block information is loaded from the memory (using the linked list address information, from MDMA_CxLAR).
- It is the last block which needs to be transferred for the current MDMA channel (MDMA_CxLAR = 0): the channel is disabled and no further MDMA requests are accepted for this channel.

14.3.11 Block repeat mode

The block repeat mode is used to repeat a block transfer, with different start addresses for source and destination.

When the repeat block mode is active (repeat counter ≠ 0), at the end of the current block transfer, the block parameters are updated (BNDT value reloaded and SAR/DAR values updated according to BRSUM/BRDUM configuration), and the repeat counter decremented by one.

When the repeat block counter reaches 0, this last block is treated as a single block transfer.

14.3.12 Linked-list mode

The linked-list mode allows a new MDMA configuration to be loaded (MDMA_CxTCR, MDMA_CxBNDTR, MDMA_CxSAR, MDMA_CxDAR, MDMA_CxBRUR, MDMA_CxLAR, MDMA_CxTBR, MDMA_CxMAR and MDMA_CxMDR registers), from the address given in MDMA_CxLAR. This address must address a memory mapped on the AXI system bus.

Following this operation, the channel is ready to accept new requests, as defined in the block/repeated block modes above, or continue the transfer if TRGM[1:0] = 11.

The trigger source can be automatically changed, when loading the MDMA_CxTBR value.

The TRGM and SWRM values must not be changed when TRGM[1:0] = 11.

14.3.13 MDMA transfer completion

Different events can generate an end of transfer by setting the CTCIF bit in the status register (MDMA_CxISR):

- The MDMA_CxBNDTR counter has reached zero, the Block Repeat Counter is 0 and the Link list pointer address is 0
- The channel is disabled before the end of transfer (by clearing the EN bit in MDMA_CxCR) and all the remaining data have been transferred from the FIFO to the destination

14.3.14 MDMA transfer suspension

At any time, a MDMA transfer can be suspended in order to be to be restarted later on or to be definitively disabled before the end of the MDMA transfer.

There are two cases:

- The channel is disabled, with no later-on restart from the point where it was stopped. There is no particular action to do, besides clearing the EN bit in the MDMA_CxCR register to disable the channel. The stream can take time to be disabled (on going buffer transfer is completed first). The transfer complete interrupt flag is set in order to indicate the end of transfer. The value of the EN bit in MDMA_CxCR is now 0 to confirm the channel interruption. The MDMA_CxNDTR register contains the number of remaining data items when the channel was stopped. The software can then determine how many data items have been transferred before the channel was interrupted.
- The channel is suspended before the number of remaining bytes to be transferred in the MDMA_CxBNDTR register reaches zero. The aim is to restart the transfer later by re-enabling the channel. The channel transfer complete interrupt flag CTCIF is set in order to indicate the end of transfer. If the MDMA_CxBNDTR, MDMA_CxSAR and

MDMA_CxDAR registers are not modified by software, the transfer continues when the channel is re-enabled. CTCIF must also be reset before restarting the channel.

Note: If the completed buffer is the last of the block, the configuration registers are also updated before disabling the channel, in order to be correctly prepared for a soft restart.

Before reprogramming the channel, the software must wait the MDMA_CTCIF register is set, in order to guarantee that any ongoing operation has been completed.

14.3.15 Error management

The MDMA can detect the following errors and the transfer error interrupt flag (TEIF) is set:

- when a bus error occurs during a MDMA read/write access
- when an address alignment does not correspond to the data size
- when the block size is not a multiple of the data size (for source and/or destination): this error is activated on the last transfer and the error address points to the last transfer (which cannot be done)

14.4 MDMA interrupts

For each MDMA channel, an interrupt can be produced on the following events:

- Channel transfer completed
- Block-transfer completed
- Block-transfer repeat completed
- Buffer transfer completed
- Transfer error

Separate interrupt enable control bits are available for flexibility as shown in the table below.

Table 85. MDMA interrupt requests

Interrupt event	Event flag	Enable control bit
Channel transfer completed	CTCIF	CTCIE
Block-transfer repeat completed	BTRIF	BTRIE
Block-transfer completed	BTIF	BTIE
Buffer transfer completed	TCIF	TCIE
Transfer error	TEIF	TEIE

Note: Before setting an enable control bit to 1, the corresponding event flag must be cleared, otherwise an interrupt may be immediately generated, if the bit is already set.

When at least one interrupt flag and the respective enable control bit are set, the channel interrupt bit is set in the MDMA_GISR. The interrupt output is also activated. This generates an interrupt if the respective interrupt channel is enabled in the NVIC.

14.5 MDMA registers

The MDMA registers can be accessed in word, half-word, or byte format.

14.5.1 MDMA global interrupt status register (MDMA_GISR0)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GIF15	GIF14	GIF13	GIF12	GIF11	GIF10	GIF9	GIF8	GIF7	GIF6	GIF5	GIF4	GIF3	GIF2	GIF1	GIF0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **GIF[15:0]**: Channel x global interrupt flag (x = 15 to 0)

This bitfield is set and reset by hardware. It is a logical OR of all channel x interrupt flags (CTCIF, BTIF, BRTIF, TEIF) which are enabled in MDMA_CTCIEx, MDMA_BTIEx, MDMA_BRTIEx, and MDMA_TEIEx.

0: No interrupt generated by channel x

1: Interrupt generated by channel x

14.5.2 MDMA channel x interrupt status register (MDMA_CxISR)

Address offset: 0x40 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRQA
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TCIF	BTIF	BRTIF	CTCIF	TEIF
											r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CRQA**: Channel x request active flag

This bit is set by software writing 1 to SWRQx in MDMA_CxCR, in order to request an MDMA transfer, and the channel x is enabled.

This bit is also set by hardware when the channel request becomes active, and the channel is enabled. The hardware request memorized until it is served.

This bit is cleared by hardware when the channel x request is completed (after the source write phase of the last buffer transfer due for the current request).

0: The MDMA transfer mdma_strx is inactive for channel x.

1: The MDMA transfer mdma_strx is active for channel x

Note: This bit is also reset by hardware when the channel is disabled (in case of transfer error, or when reaching the end of the channel data transfer - repeat block = 0 and linked list pointer null-, or by software programming the channel enable bit to 0 before that).

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **TCIF**: Channel x buffer transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No buffer transfer complete event on channel x

1: A buffer transfer complete event occurred on channel x

TC is set when a single buffer is transferred. It is activated on each channel transfer request.

This can be used as a debug feature (without interrupt), indicating that (at least) an MDMA buffer transfer has been generated since the last flag reset.

Bit 3 **BTIF**: Channel x block transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No block transfer complete event on channel x

1: A block transfer complete event occurred on channel x.

Bit 2 **BRTIF**: Channel x block repeat transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No block repeat transfer complete event on channel x

1: A block repeat transfer complete event occurred on channel x

Bit 1 **CTCIF**: Channel x channel transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No channel transfer complete event on channel x

1: A channel transfer complete event occurred on channel x

CTC is set when the last block was transferred and the channel has been automatically disabled.

CTC is also set when the channel is suspended, as a result of writing EN bit to 0.

Bit 0 **TEIF**: Channel x transfer error interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No transfer error on stream x

1: A transfer error occurred on stream x

14.5.3 MDMA channel x interrupt flag clear register (MDMA_CxIFCR)

Address offset: 0x44 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLTCIF	CBTIF	CBRTIF	CCTCIF	CTEIF
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CLTCIF**: Clear buffer transfer complete Interrupt flag for channel x
Writing 1 into this bit clears TCIF in MDMA_ISRy.

Bit 3 **CBTIF**: Channel x clear block transfer complete interrupt flag
Writing 1 into this bit clears BTIF in MDMA_ISRy.

Bit 2 **CBRTIF**: Channel x clear block repeat transfer complete interrupt flag
Writing 1 into this bit clears BRTIF in MDMA_ISRy.

Bit 1 **CCTCIF**: Clear channel transfer complete interrupt flag for channel x
Writing 1 into this bit clears CTCIF in MDMA_ISRy.

Bit 0 **CTEIF**: Channel x clear transfer error interrupt flag
Writing 1 into this bit clears TEIF in MDMA_ISRy.

14.5.4 MDMA channel x error status register (MDMA_CxESR)

Address offset: 0x48 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	BSE	ASE	TEMD	TELD	TED	TEA[6:0]						
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BSE**: Block size error
This bit is set by hardware, when the block size is not an integer multiple of the data size either for source or destination. TED indicates whether the problem is on the source or destination. This bit is cleared by software writing 1 to CTEIF in MDMA_IFCRy.
0: No block size error
1: Programmed block size is not an integer multiple of the data size.

Bit 10 **ASE**: Address size error

This bit is set by hardware, when the programmed address is not aligned with the data size. TED indicates whether the problem is on the source or destination. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No address size error

1: Programmed address is not coherent with the data size.

Bit 9 **TEMD**: Transfer error mask data

This bit is set by hardware, in case of a transfer error while writing the mask data. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No mask write access error

1: The last transfer error on the channel was a related to a write of the mask data.

Bit 8 **TELD**: Transfer error link data

This bit is set by hardware, in case of a transfer error while reading the block link data structure. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No link data read access error

1: The last transfer error on the channel was a related to a read of the link data structure.

Bit 7 **TED**: Transfer error direction

This bit is set and cleared by hardware, in case of an MDMA data transfer error.

0: The last transfer error on the channel was a related to a read access.

1: The last transfer error on the channel was a related to a write access.

Bits 6:0 **TEA[6:0]**: Transfer error address

These bits are set and cleared by hardware in case of an MDMA data transfer error. They are used in conjunction with TED. This field indicates the 7 LSB bits of the address which generated a transfer/access error.

This field can be used by software to retrieve the failing address, by adding this value (truncated to the buffer transfer length size) to the current SAR/DAR value.

Note: The SAR/DAR current value does not reflect this last address due to the FIFO management system. The SAR/DAR are only updated at the end of a (buffer) transfer (of TLEN+1 bytes).

This field is not set in case of a link data error.

14.5.5 MDMA channel x control register (MDMA_CxCR)

This register is used to control the concerned channel.

Address offset: 0x4C + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWRQ
															w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	WEX	HEX	BEX	Res.	Res.	Res.	Res.	PL[1:0]		TCIE	BTIE	BRTIE	CTCIE	TEIE	EN
	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SWRQ**: Software request

Writing 1 into this bit sets the CRQA in MDMA_ISRy, activating the request on channel x.

Note: Either the whole MDMA_CxCR register or the 8-/16-bit register at the address offset: 0x4E + 0x40 × channel number, can be used for SWRQ activation.

In case of software request, acknowledge is not generated (neither hardware signal, nor MDMA_CxMAR write access).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WEX**: Word endianness exchange

This bit is set and cleared by software.

0: Little endianness preserved for words

1: Word order exchanged in double word

When this bit is set, the word order in the destination double word is reversed: higher address word contains the data read from the lower address of the source.

If the destination is not a double word, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bit 13 **HEX**: Half-word endianness exchange

This bit is set and cleared by software.

0: Little endianness preserved for half words

1: half-word order exchanged in each word

When this bit is set, the half-word order in each destination word is reversed: higher address half-word contains the data read from the lower address of the source.

If destination length is shorter than word, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bit 12 **BEX**: Byte endianness exchange

This bit is set and cleared by software.

0: Little endianness preserved for bytes

1: byte order exchanged in each half-word

When this bit is set, the byte order in each destination half-word is reversed: higher address word contains the data read from the lower address of the source.

If destination is byte, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **PL[1:0]**: Priority level

These bits are set and cleared by software.

00: Low

01: Medium

10: High

11: Very high

Note: These bits are protected and can be written only if EN is 0.

Bit 5 **TCIE**: Buffer transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

Bit 4 **BTIE**: Block transfer interrupt enable
This bit is set and cleared by software.
0: BT complete interrupt disabled
1: BT complete interrupt enabled

Bit 3 **BRTIE**: Block repeat transfer interrupt enable
This bit is set and cleared by software.
0: BT interrupt disabled
1: BT interrupt enabled

Bit 2 **CTCIE**: Channel transfer complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 1 **TEIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 0 **EN**: Channel enable/flag channel ready when read low
This bit is set and cleared by software.
0: Channel disabled
1: Channel enabled
This bit can be cleared by hardware:
– on a MDMA end of transfer (stream ready to be configured)
– if a transfer error occurs on the AHB/AXI master buses (bus error/HardFault)
– if another error condition is encountered (data alignment, block/data size incompatibility)
When this bit is reset by software, the ongoing buffer transfer (if any) is completed.
All status/configuration registers keep their current values. If the channel is re-enabled without writing these registers, the channel continues from the point where it was interrupted.
When this bit is read as 0, the software is allowed to program the configuration registers.
It is forbidden to write these registers when the EN bit is read as 1 (writes are ignored).

Note: When this bit is reset by software, it is recommended to wait for the CTCIF = 1, in order to ensure that any ongoing buffer transfer has been completed, before reprogramming the channel.

14.5.6 MDMA channel x transfer configuration register (MDMA_CxTCR)

Address offset: 0x50 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register is used to configure the concerned channel. In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from the memory (from address given by current LAR[31:0] + 0x00).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWM	SWRM	TRGM[1:0]		PAM[1:0]		PKE	TLEN[6:0]							DBURST[2:1]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBURST[0]	SBURST[2:0]			DINCOS[1:0]		SINCOS[1:0]		DSIZE[1:0]		SSIZE[1:0]		DINC[1:0]		SINC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BWM**: Bufferable write mode

This bit is set and cleared by software.

0: The destination write operation is non-bufferable.

1: The destination write operation is bufferable.

Note: This bit is protected and can be written only if EN is 0.

All MDMA destination accesses are non-cacheable.

Bit 30 **SWRM**: Software request mode

This bit is set and cleared by software. If an hardware or software request is currently active, the bit change is delayed until the current transfer is completed.

0: Hardware request are taken into account: the transfer is initiated as defined by TRGM value and acknowledged by the MDMA ACKx signal. If the MDMA_CxMAR contains a valid address, the MDMA_CxMDR value is also written at MDMA_CxMAR address.

1: Hardware request are ignored. Transfer is triggered by software writing 1 to the SWRQ bit.

Note: This bit is protected and can be written only if EN is 0.

Bits 29:28 **TRGM[1:0]**: Trigger mode

These bits are set and cleared by software.

00: Each MDMA request (software or hardware) triggers a buffer transfer.

01: Each MDMA request (software or hardware) triggers a block transfer.

10: Each MDMA request (software or hardware) triggers a repeated block transfer (if the block repeat is 0, a single block is transferred).

11: Each MDMA request (software or hardware) triggers the transfer of the whole data for the respective channel (for example linked list) until the channel reach the end and it is disabled.

Note: If TRGM is 11 for the current block, all values loaded at the end of the current block through the linked-list mechanism must keep the same value (TRGM = 11), and the same SWRM value, otherwise the result is undefined.

These bits are protected and can be written only if EN is 0.

Bits 27:26 **PAM[1:0]**: Padding/alignment mode

These bits are set and cleared by software.

00: Right aligned, padded with 0s (default). If source data is larger than destination size, only LSB part of the source is written to the destination address. The reminder part is discarded.

01: Right aligned, sign extended

10: Left aligned (padded with 0s). if source data is larger than destination size, only MSB part of the source is written to the destination address. The reminder part is discarded.

11: Reserved

Note: When PKE = 1 or DSIZE=SSIZE, these bits are ignored.

These bits are protected and can be written only if EN is 0.

Bit 25 **PKE**: Pack enable

This bit is set and cleared by software.

0: The source data is written to the destination as is. If source size is smaller than destination, it is padded according to the PAM value. If source data size is larger than destination one, it is truncated. The alignment is done according to the PAM[1:0] value.

1: The source data is packed/unpacked into the destination data size. All data are right aligned, in little-endian mode.

Note: This bit is protected and can be written only if EN is 0.

Bits 24:18 **TLEN[6:0]**: Buffer transfer length (number of bytes - 1)

These bits are set and cleared by software. TLEN + 1 value represents the number of bytes to be transferred in a single transfer.

The transfer length must be a multiple of the data size (for both source and destination)

When the source/destination sizes are different and padding/truncation is used, TLEN + 1 refers to the source data array size.

Note: These bits are protected and can be written only if EN is 0.

DBURST value must be programmed in order to ensure that the burst size is lower than the transfer size.

Bits 17:15 **DBURST[2:0]**: Destination burst transfer configuration

These bits are set and cleared by software.

000: Single transfer

N: burst of 2^N beats

DBURST value must be programmed as to ensure that the burst size is lower than the transfer length. If this is not ensured, the result is unpredictable.

Note: These bits are protected and can be written only if EN is 0.

When the destination bus is TCM/AHB (DBUS = 1) and DINCOS = 11 or DINC = 00 or DINCOS ≠ DSIZE, DBURST must be programmed to 000 (single transfer), else the result is unpredictable.

When the destination bus is system/AXI bus (DBUS = 0) and DINC = 00, DBURST must be maximum 100 (burst of 16), else the result is unpredictable.

Bits 14:12 **SBURST[2:0]**: Source burst transfer configuration

These bits are set and cleared by software.

000: single transfer

N: burst of 2^N beats

SBURST value must be programmed as to ensure that the burst size is lower than the transfer length. If this is not ensured, the result is unpredictable.

Note: These bits are protected and can be written only if EN is 0.

When the source bus is TCM (SBUS = 1) and SINCOS = 11 or SINC = 00 or SINCOS ≠SSIZE, SBURST must be programmed to 000 (single transfer), else the result is unpredictable.

When the source bus is system/AXI bus (SBUS = 0) and SINC = 00, SBURST must be maximum 100 (burst of 16), else the result is unpredictable.

Bits 11:10 **DINCOS[1:0]**: Destination increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit DINC[1:0] = 00.

Note: If DINCOS < DSIZE and DINC ≠ 00, the result is unpredictable.

If destination is AHB and DBURST ≠ 000, destination address must be aligned with DINCOS size, else the result is unpredictable.

These bits are protected and can be written only if EN = 0.

Bits 9:8 **SINCOS[1:0]**: Source increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit SINC[1:0] = 00.

Note: If SINCOS < SSIZE and SINC ≠ 00, the result is unpredictable.

If source is TCM/AHB and SBURST ≠ 000, source address must be aligned with SINCOS size, else the result is unpredictable.

These bits are protected and can be written only if EN = 0.

Bits 7:6 **DSIZE[1:0]**: Destination data size

These bits are set and cleared by software.

00: Byte (8 bits)

01: Half-word (16 bits)

10: Word (32 bits)

11: Double-word (64 bits)

Note: If DINCOS < DSIZE and DINC ≠ 00, the result is unpredictable.

If a value of 11 is programmed for the TCM access/AHB port, a transfer error occurs (TEIF bit set). DSIZE = 11 (double-word) is forbidden when destination is TCM/AHB bus (DBUS = 1).

These bits are protected and can be written only if EN = 0.

Bits 5:4 **SSIZE[1:0]**: Source data size

These bits are set and cleared by software.

00: Byte (8 bits)

01: Half-word (16 bits)

10: Word (32 bits)

11: Double-word (64 bits)

Note: If SINCOS < SSIZE and SINC ≠ 00, the result is unpredictable.

If a value of 11 is programmed for the TCM access/AHB port, a transfer error occurs (TEIF bit set). SSIZE = 11 (double-word) is forbidden when source is TCM/AHB bus (SBUS = 1).

These bits are protected and can be written only if EN is 0.

Bits 3:2 **DINC[1:0]**: Destination increment mode

These bits are set and cleared by software.

00: Destination address pointer is fixed.

10: Destination address pointer is incremented after each data transfer (increment is done according to DINCOS).

11: Destination address pointer is decremented after each data transfer (increment is done according to DINCOS).

Note: These bits are protected and can be written only if EN = 0.

When destination is AHB (DBUS = 1), DINC = 00 is forbidden.

Bits 1:0 **SINC[1:0]**: Source increment mode

These bits are set and cleared by software.

00: Source address pointer is fixed.

10: Source address pointer is incremented after each data transfer (increment is done according to SINCOS).

11: Source address pointer is decremented after each data transfer (decrement is done according to SINCOS).

Note: These bits are protected and can be written only if EN = 0.

When source is AHB (SBUS = 1), SINC = 00 is forbidden.

14.5.7 MDMA channel x block number of data register (MDMA_CxBNDTR)

Address offset: 0x54 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from the memory (from address given by current LAR[31:0] + 0x04).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRC[11:0]												BRDUM	BRSUM	Res.	BNDT[16]
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 **BRC[11:0]**: Block repeat count

This field contains the number of repetitions of the current block (0 to 4095). When the channel is enabled, this register is read-only, indicating the remaining number of blocks, excluding the current one. This register decrements after each complete block transfer.

Once the last block transfer has completed, this register can either stay at zero or be reloaded automatically from memory (in linked-list mode, meaning link address valid).

Note: These bits are protected and can be written only if EN = 0.

Bit 19 **BRDUM**: Block repeat destination address update mode

0: At the end of a block transfer, the MDMA_DAR register is updated by adding the DUV to the current DAR value (current destination address).

1: At the end of a block transfer, the MDMA_DAR register is updated by subtracting the DUV from the current DAR value (current destination address).

Note: These bits are protected and can be written only if EN = 0.

Bit 18 **BRSUM**: Block repeat source address update mode

0: At the end of a block transfer, the MDMA_SAR register is updated by adding the SUV to the current SAR value (current source address).

1: At the end of a block transfer, the MDMA_SAR register is updated by subtracting the SUV from the current SAR value (current source address).

Note: These bits are protected and can be written only if EN = 0.

Bit 17 Reserved, must be kept at reset value.

Bits 16:0 **BNDT[16:0]**: Block number of data bytes to transfer

Number of bytes to be transferred (0 up to 65536) in the current block. When the channel is enabled, this register is read-only, indicating the remaining data items to be transmitted. During the channel activity, this register decrements, indicating the number of data items remaining in the current block.

Once the block transfer has completed, this register can either stay at zero or be reloaded automatically with the previously programmed value if the channel is configured in block repeat mode.

If the value of this register is zero, no transaction can be served even if the stream is enabled.

Note: If the BNDT value is not an integer multiple of the TLEN + 1 value, the last transfer is shorter and contains only the remaining data in the block.

The block size must be a multiple of the source and destination data size. If this is not true, an error is set and the no data are written

These bits are protected and can be written only if EN = 0.

14.5.8 MDMA channel x source address register (MDMA_CxSAR)

Address offset: 0x58 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x08).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SAR[31:0]**: Source address

These bits represent the base address of the peripheral data register from/to which the data is read. They must be aligned with the SSIZE (SAR[1:0] = 00 when SSIZE = 10), but may be unaligned with the SINCOS.

When source is TCM/AHB, if address is not aligned with SINCOS, the access must be programmed as single (SBURST = 000).

During the channel activity, this register is updated, reflecting the current address from which the data is read next.

When the block repeat mode is active, when a block transfer is completed, the source address is updated by adding/subtracting the SAU value to the current value (already updated after the last transfer in the block).

When the linked-list mode is active, at the end of a block (repeated or not) transfer, the SAR value is loaded from memory (from address LSA + m).

Note: These bits are write-protected and can be written only when bit EN = 0.

14.5.9 MDMA channel x destination address register (MDMA_CxDAR)

Address offset: 0x5C + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x0C).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DAR[31:0]**: Destination address

Base address of the destination address to which the data is written. Must be aligned with the DSIZE (for example DAR[0] = 0 when DSIZE=01), but may be unaligned with the DINCOS.

When destination is AHB, if address is not aligned with DINCOS, access must be programmed as single (DBURST = 000).

During the channel activity, this register is updated, reflecting the current address to which the data is written next.

When the block repeat mode is active, when a block transfer is completed, the Destination address is updated by adding/subtracting the DAU value to the current value (after the last transfer in the block).

When the linked-list mode is active, at the end of a block (repeated or not) transfer, the DAR value is loaded from memory (from address LSA + m).

Note: These bits are write-protected and can be written only when bit EN = 0.

14.5.10 MDMA channel x block repeat address update register (MDMA_CxBRUR)

Address offset: 0x60 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x10).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **DUV[15:0]**: Destination address update value

This value is used to update (by addition or subtraction) the current destination address at the end of a block transfer. It must be an integer multiple of DSIZE, in order to keep DAR aligned to DSIZE (DAR[1:0] = 00 when DSIZ E =10).

If this value is 0, the next repetition of the block transfer continues to the next address.

When the block repeat mode is not active (BRC = 0), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

This field must be programmed to 0 when DINC[1:0] = 00.

Bits 15:0 **SUV[15:0]**: Source address update value

This value is used to update (by addition or subtraction) the current source address at the end of a block transfer. It must be an integer multiple of SSIZE, in order to keep SAR aligned to SSIZE (SAR[1:0] = 00 when SSIZE = 10).

If this value is 0, the next repetition of the block transfer continues from the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

This field must be programmed to 0 when SINC[1:0] = 00.

14.5.11 MDMA channel x link address register (MDMA_CxLAR)

Address offset: 0x64 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x14).

Note: The new value is only taken into account after all registers are updated, for the next end of block.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

LAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r

Bits 31:0 **LAR[31:0]**: Link address register

At the end of a (repeated) block transfer, the current channel configuration registers (MDMA_CxTCR, MDMA_CxBNDTR, MDMA_CxSAR, MDMA_CxDAR, MDMA_CxBRUR, MDMA_CxMAR, MDMA_CxMDR and MDMA_CxLAR itself) are loaded with the data structure found at this address.

If the value of this register is 0, no register update takes place, the channel is disabled and CTCIF is set, indicating the end of the transfer for this channel.

The channel configuration (LAR address) must be in the AXI address space.

LAR value must be aligned at a double-word address (LAR[2:0] = 0x0).

Note: These bits are write-protected and can be written only when bit EN = 0.

14.5.12 MDMA channel x trigger and bus selection register (MDMA_CxTBR)

Address offset: 0x68 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x18).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBUS	SBUS
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TSEL[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DBUS**: Destination bus select

0: The system/AXI bus is used as destination (write operation) on channel x.

1: The AHB bus/TCM is used as destination (write operation) on channel x.

Note: This bit is protected and can be written only if EN is 0.

Bit 16 **SBUS**: Source bus select

0: The system/AXI bus is used as source (read operation) on channel x.

1: The AHB bus/TCM is used as source (read operation) on channel x.

Note: This bit is protected and can be written only if EN is 0.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **TSEL[5:0]**: Trigger selection

This field selects the hardware trigger (RQ) input for channel x. The ACK is sent on the ACK output having the same index value.

When SWRM bit is set (software request selected), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

If multiple channels are triggered by the same event (have the same TSEL value), all of them are triggered in parallel. Only the channel with the lowest index acknowledges the request.

14.5.13 MDMA channel x mask address register (MDMA_CxMAR)

Address offset: 0x70 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x20).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MAR[31:0]**: Mask address

A write of the MDR value is also done to this address. This is used to clear the RQ signal generated by the DMA2 by writing to its interrupt clear register.

If the value of this register is 0, this function is disabled.

Note: These bits are write-protected and can be written only when bit EN = 0.

14.5.14 MDMA channel x mask data register (MDMA_CxMDR)

Address offset: 0x74 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x24).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MDR[31:0]**: Mask data

A write of the MDR value is also done to the address defined by the MDMA_MAR register. This is used to clear the RQ signal generated by the DMA2 by writing to its interrupt clear register.

Note: These bits are write-protected and can be written only when bit EN = 0.

14.5.15 MDMA register map

Table 86. MDMA register map and reset values

Refer to *Section 2.3* for the register boundary addresses.

15 Direct memory access controller (DMA)

15.1 DMA introduction

Direct memory access (DMA) is used to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers (DMA1, DMA2) have 8 streams each, dedicated to managing memory access requests from one or more peripherals.

Each DMA stream is driven by one DMAMUX1 output channel (request). Any DMAMUX1 output request can be individually programmed in order to select the DMA request source signal, from any of the 115 available request input signals.

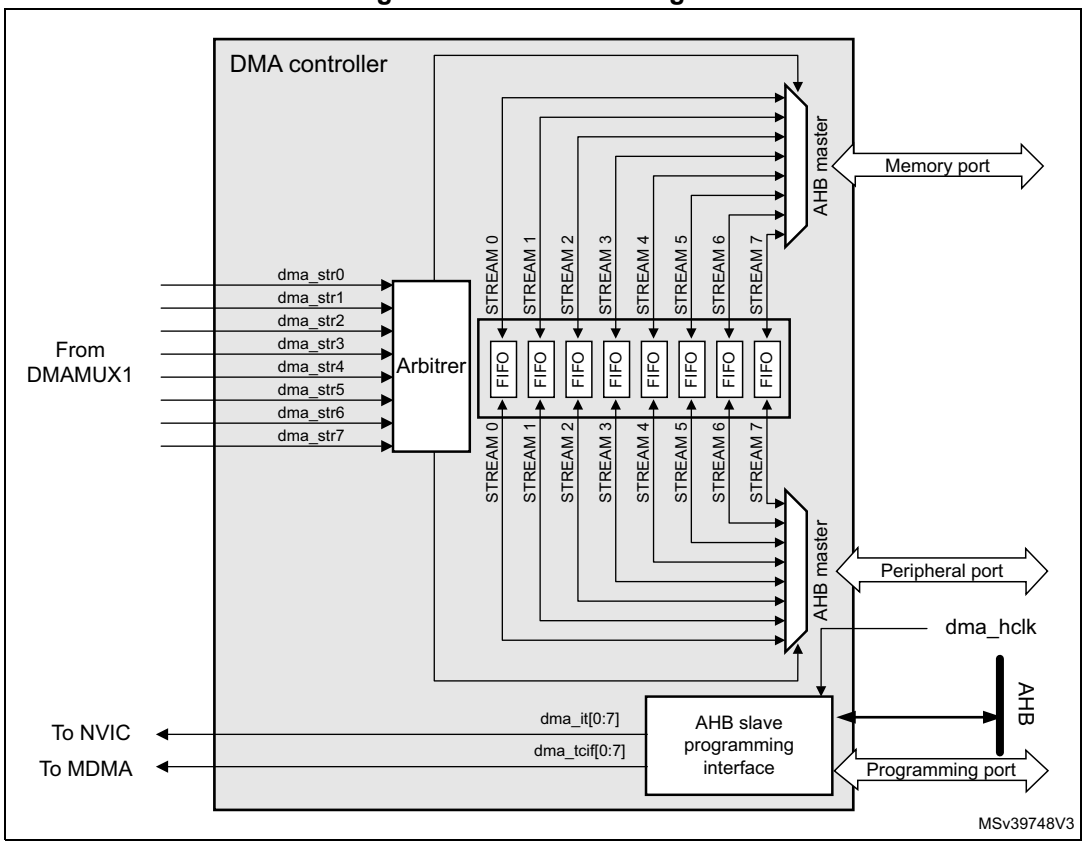
Refer to the *Section 17.3: DMAMUX implementation* for more information about the DMA requests and streams mapping.

Each DMA controller has an arbiter for handling the priority between DMA requests.

15.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
- AHB slave programming interface supporting only 32-bit accesses
- 8 streams for each DMA controller, up to 115 channels (requests) per stream
- Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
  - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
  - Direct mode: each DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.
- Each stream can be configured to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Priorities between DMA stream requests are software-programmable (four levels consisting of very high, high, medium, low) or hardware in case of equality (for example, request 0 has priority over request 1)
- Each stream also supports software trigger for memory-to-memory transfers



- Each stream request can be selected among up to 115 possible channel requests. This selection is software-configurable by the DMAMUX1 and allows 107 peripherals to initiate DMA requests
- The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:
  - DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
  - Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware
- Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode
- Incrementing or non-incrementing addressing for source and destination
- Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral
- Each stream supports circular buffer management
- 5 event flags (DMA half transfer, DMA transfer complete, DMA transfer error, DMA FIFO error, direct mode error) logically ORed together in a single interrupt request for each stream

15.3 DMA functional description

15.3.1 DMA block diagram

The figure below shows the block diagram of a DMA.

Figure 83. DMA block diagram

15.3.2 DMA internal signals

The table below shows the internal DMA signals.

Table 87. DMA internal input/output signals

Signal name	Signal type	Description
dma_hclk	Digital input	DMA AHB clock
dma_it[0:7]	Digital outputs	DMA stream [0:7] global interrupts
dma_tcif[0:7]	Digital outputs	MDMA triggers
dma_str[0:7]	Digital input	DMA stream [0:7] requests

15.3.3 DMA overview

The DMA controller performs direct memory transfer: as an AHB master, the DMA controller can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA controller carries out the following transactions:

- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the AHB memory port, intended to be connected to memories and the AHB peripheral port, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the AHB peripheral port must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

15.3.4 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:

- a loading from the peripheral data register or a location in memory, addressed through the DMA_SxPAR or DMA_SxM0AR register
- a storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA_SxPAR or DMA_SxM0AR register
- a post-decrement of the DMA_SxNDTR register, containing the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

15.3.5 DMA request mapping

The DMA request mapping from peripherals to DMA streams is described in *Section 17.3: DMAMUX implementation*.

15.3.6 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the DMA_SxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, stream 2 takes priority over stream 4.

15.3.7 DMA streams

Each of the eight DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:

- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

15.3.8 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers.

The table below describes the corresponding source and destination addresses.

Table 88. Source and destination address

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR
01	Memory-to-peripheral	DMA_SxM0AR	DMA_SxPAR

Table 88. Source and destination address (continued)

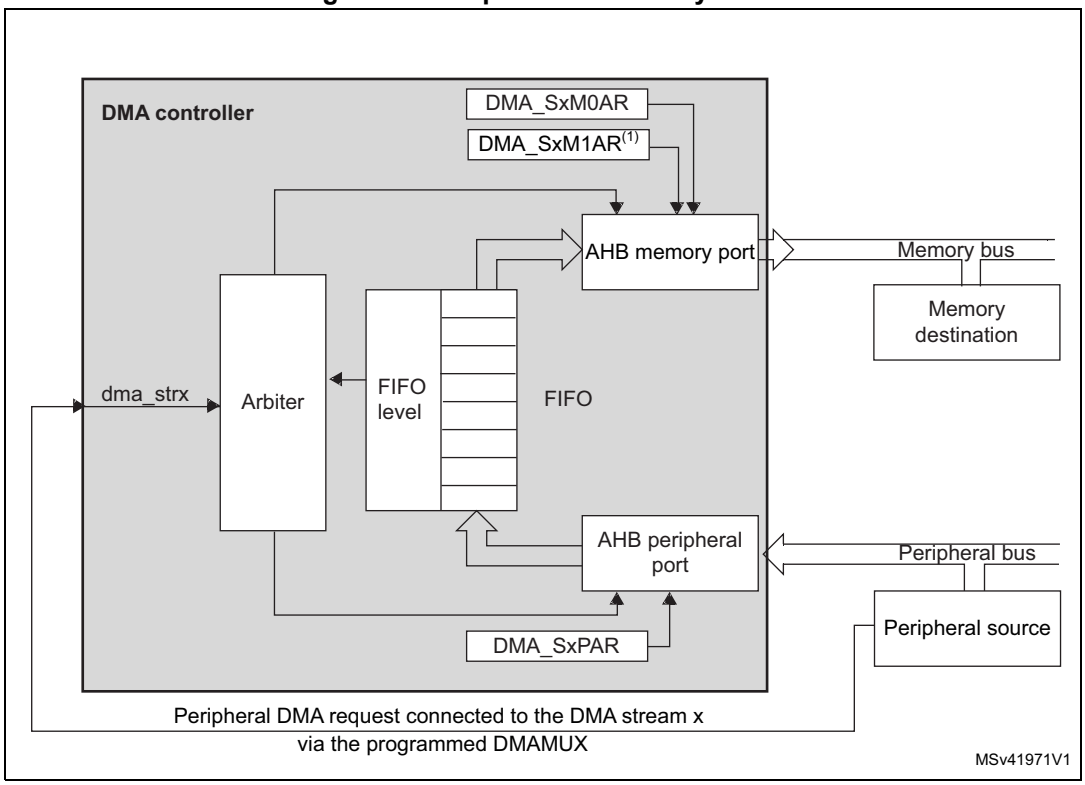
Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
10	Memory-to-memory	DMA_SxPAR	DMA_SxM0AR
11	Reserved	-	-

When the data width (programmed in the PSIZE or MSIZE bits in the DMA_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA_SxPAR or DMA_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

Peripheral-to-memory mode

Figure 84 describes this mode.

When this mode is enabled (by setting the bit EN in the DMA_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.



When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is 0), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

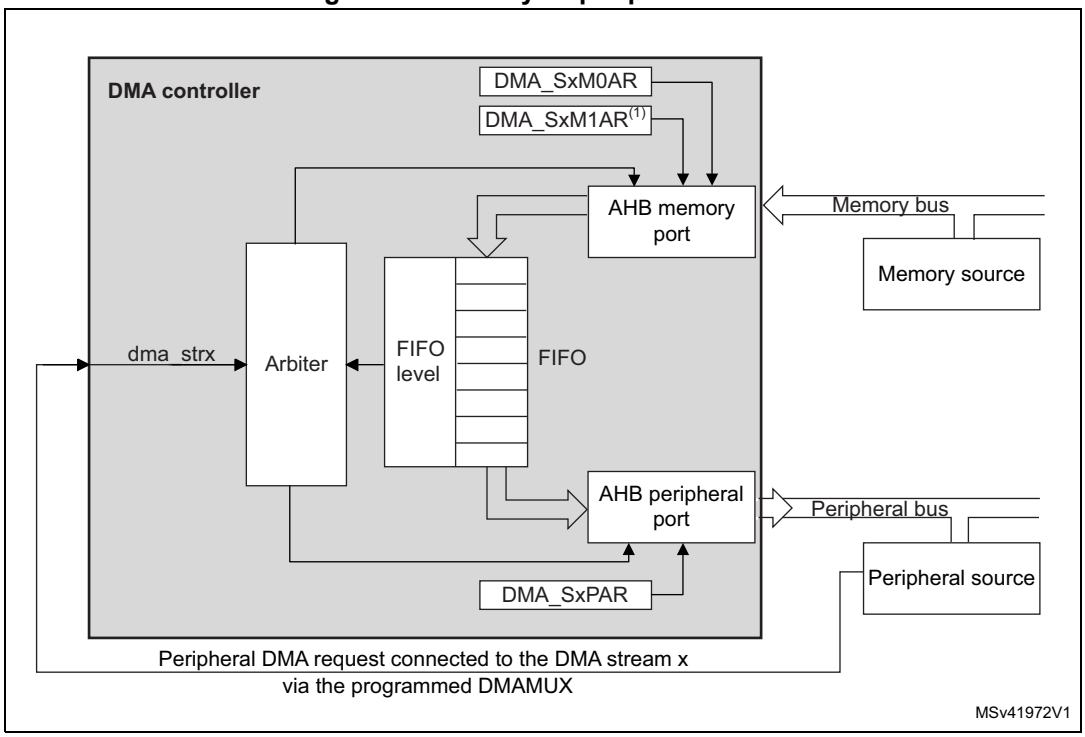
Figure 84. Peripheral-to-memory mode

1. For double-buffer mode.

Memory-to-peripheral mode

Figure 85 describes this mode.

When this mode is enabled (by setting the EN bit in the DMA_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.



Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is 0), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA_SxCR register.

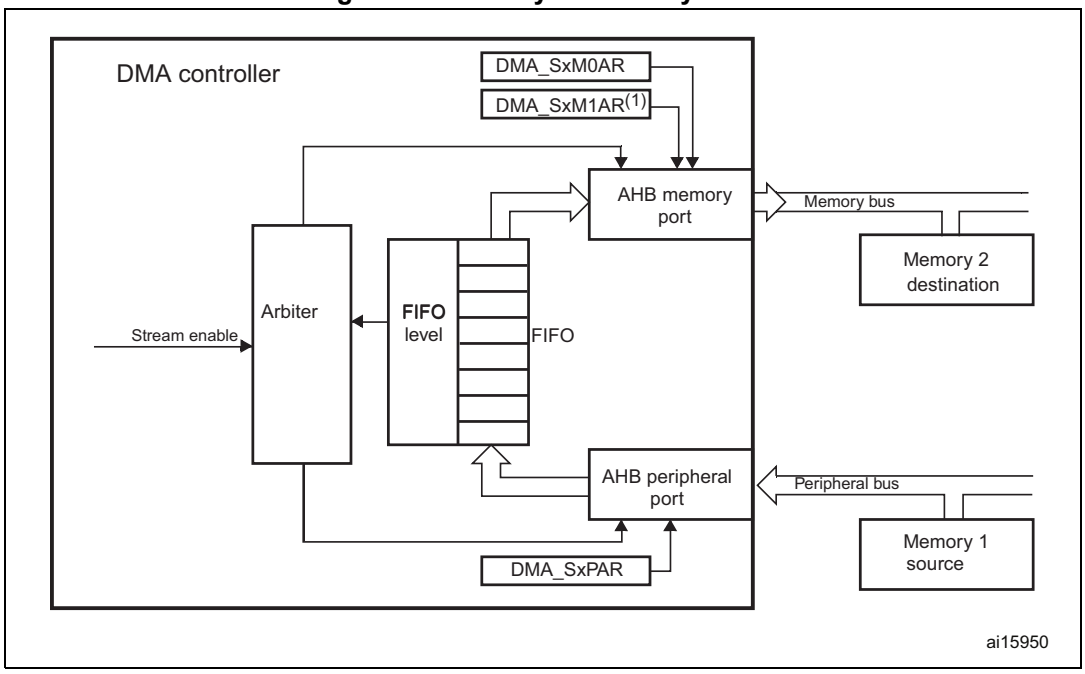
The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Figure 85. Memory-to-peripheral mode

1. For double-buffer mode.

Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in *Figure 86*.



When the stream is enabled by setting the Enable bit (EN) in the DMA_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero or when the EN bit in the DMA_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Note: When memory-to-memory mode is used, the circular and direct modes are not allowed.

Figure 86. Memory-to-memory mode

1. For double-buffer mode.

15.3.9 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA_SxCR register.

Disabling the increment mode is useful when the peripheral source or destination data is accessed through a single register.

If the increment mode is enabled, the address of the next transfer is the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA_SxCR register.

In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If the PINCOS bit is set, the address of the following transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address), whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

15.3.10 Circular mode

The circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

Note: In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:

DMA_SxNDTR = Multiple of ((Mburst beat) × (Msize)/(Psize)), where:

- *(Mburst beat) = 4, 8 or 16 (depending on the MBURST bits in the DMA_SxCR register)*
- *((Msize)/(Psize)) = 1, 2, 4, 1/2 or 1/4 (Msize and Psize represent the MSIZE and PSIZE bits in the DMA_SxCR register. They are byte dependent)*
- *DMA_SxNDTR = Number of data items to transfer on the AHB peripheral port*

For example: Mburst beat = 8 (INCR8), MSIZE = 00 (byte) and PSIZE = 01 (half-word), in this case: DMA_SxNDTR must be a multiple of (8 × 1/2 = 4).

If this formula is not respected, the DMA behavior and data integrity are not guaranteed.

NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.

15.3.11 Double-buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The double-buffer mode is enabled by setting the DBM bit in the DMA_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the double-buffer mode is enabled, the circular mode is automatically enabled (CIRC bit in DMA_SxCR is not relevant) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in *Table 89*.

*Note: In double-buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (*DMA_SxM0AR or DMA_SxM1AR*) when the stream is enabled, by respecting the following conditions:*

- *When the CT bit is 0 in the DMA_SxCR register, the DMA_SxM1AR register can be written. Attempting to write to this register while CT = 1 sets an error flag (TEIF) and the stream is automatically disabled.*
- *When the CT bit is 1 in the DMA_SxCR register, the DMA_SxM0AR register can be written. Attempting to write to this register while CT = 0, sets an error flag (TEIF) and the stream is automatically disabled.*

To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from

memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA_SxCR register in accordance with one of the two above conditions.

For all the other modes (except the double-buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

Table 89. Source and destination address registers in double-buffer mode (DBM = 1)

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR / DMA_SxM1AR
01	Memory-to-peripheral	DMA_SxM0AR / DMA_SxM1AR	DMA_SxPAR
10	Not allowed(1)		
11	Reserved	-	-

1. When the double-buffer mode is enabled, the circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the circular mode, when the double-buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

15.3.12 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to 2 × NDT.
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in *Table 90*.

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each group of transfers belonging to a burst are indivisible (refer to *Section 15.3.13*).

In direct mode (DMDIS = 0 in the DMA_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA_SxCR register. MSIZE bits are not relevant.

Table 90. Packing/unpacking and endian behavior (bit PINC = MINC = 1)

AHB memory port width	AHB peripheral port width	Number of data items to transfer (NDT)	Memory transfer number	Memory port address / byte lane	Peripheral transfer number	Peripheral port address / byte lane	
						PINCOS = 1	PINCOS = 0
8	8	4	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
8	16	2	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
8	32	1	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1	0x0 / B3|B2|B1|B0[31:0]	0x0 / B3|B2|B1|B0[31:0]
16	8	4	1 2	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
16	16	2	1 2	0x0 / B1|B0[15:0] 0x2 / B1|B0[15:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
16	32	1	1 2	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]	1	0x0 / B3|B2|B1|B0[31:0]	0x0 / B3|B2|B1|B0[31:0]
32	8	4	1	0x0 / B3|B2|B1|B0[31:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
32	16	2	1	0x0 /B3|B2|B1|B0[31:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
32	32	1	1	0x0 /B3|B2|B1|B0 [31:0]	1	0x0 / B3|B2|B1|B0 [31:0]	0x0 / B3|B2|B1|B0[31:0]

Note: Peripheral port may be the source or the destination (it can also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] must be configured so as to ensure that the last transfer is not incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in the table below.

Table 91. Restriction on NDT versus PSIZE and MSIZE

PSIZE[1:0] of DMA_SxCR	MSIZE[1:0] of DMA_SxCR	NDT[15:0] of DMA_SxNDTR
00 (8-bit)	01 (16-bit)	Must be a multiple of 2
00 (8-bit)	10 (32-bit)	Must be a multiple of 4
01 (16-bit)	10 (32-bit)	Must be a multiple of 2

15.3.13 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8, or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4,8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

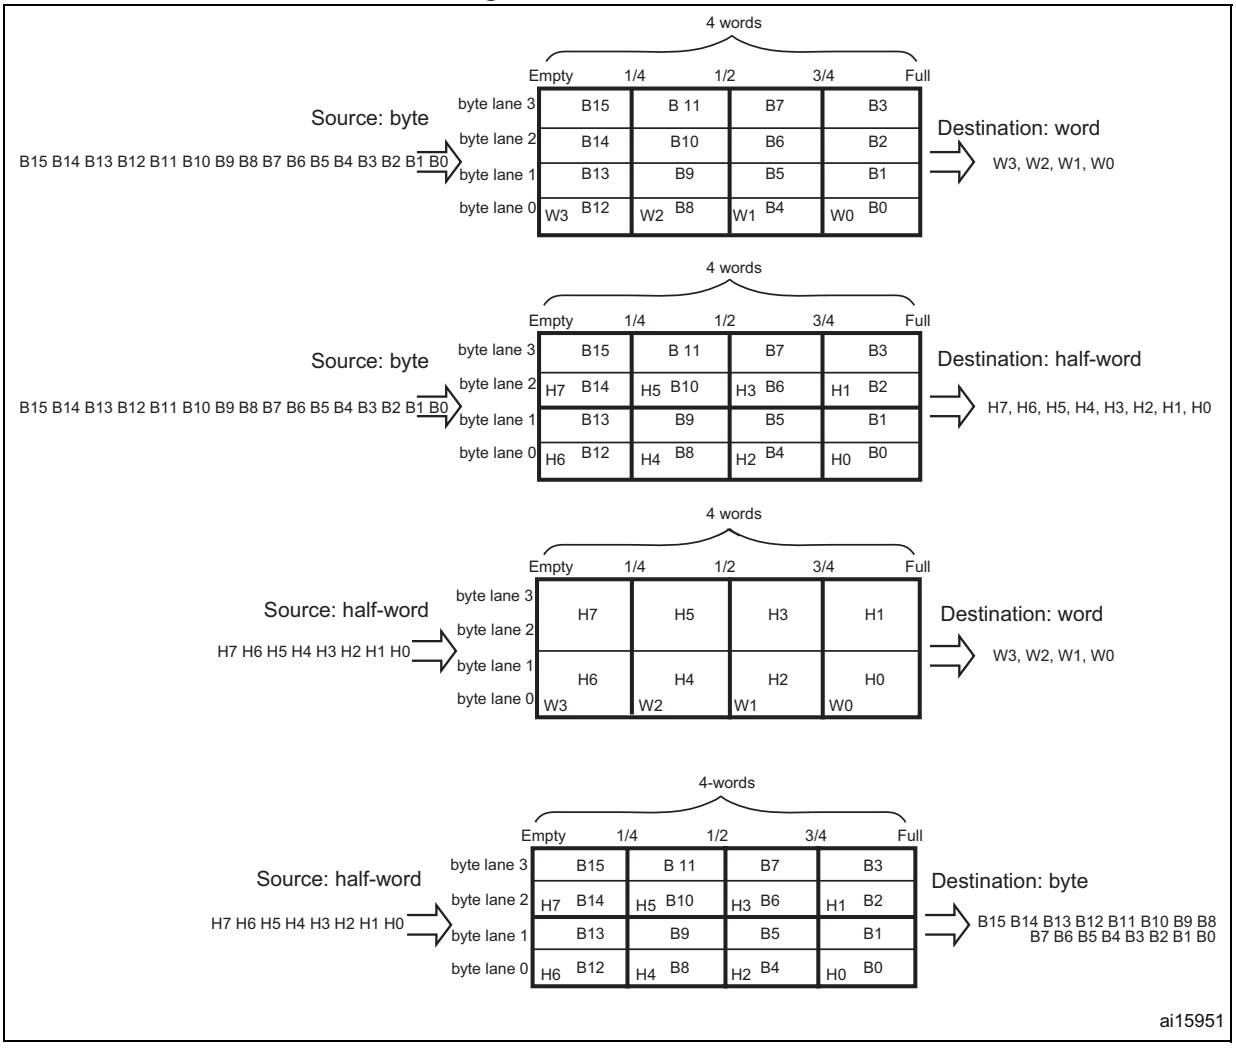
In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA_SxPAR or DMA_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts **must not** cross the 1 Kbyte address boundary because the minimum address space that can be allocated to a single slave is 1 Kbyte. This means that the 1-Kbyte address boundary **must not** be crossed by a burst block transfer, otherwise an AHB error is generated, that is not reported by the DMA registers.

15.3.14 FIFO

FIFO structure



The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in the figure below.

Figure 87. FIFO structure

FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA_SxCR register). The content pointed by the FIFO threshold must exactly match an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA_HISR or DMA_LISR register) is generated when the stream is enabled, then the stream is automatically disabled. The allowed and forbidden configurations are described in the table below. The forbidden configurations are highlighted in gray in the table.

Table 92. FIFO threshold configurations

MSIZE	FIFO level	MBURST = INCR4	MBURST = INCR8	MBURST = INCR16
Byte	1/4	1 burst of 4 beats	Forbidden	Forbidden
	1/2	2 bursts of 4 beats	1 burst of 8 beats	
	3/4	3 bursts of 4 beats	Forbidden	
	Full	4 bursts of 4 beats	2 bursts of 8 beats	1 burst of 16 beats
Half-word	1/4	Forbidden	Forbidden	Forbidden
	1/2	1 burst of 4 beats		
	3/4	Forbidden		
	Full	2 bursts of 4 beats	1 burst of 8 beats	
Word	1/4	Forbidden	Forbidden	
	1/2			
	3/4			
	Full	1 burst of 4 beats		

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA_SxNDTR register) is not a multiple of the burst size multiplied by the data size.
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size.

In such cases, the remaining data to be transferred is managed in single mode by the DMA, even if a burst transaction is requested during the DMA stream configuration.

Note: When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:

If (PBURST × PSIZE) = FIFO_SIZE (4 words), FIFO_Threshold = 3/4 is forbidden with PSIZE = 1, 2 or 4 and PBURST = 4, 8 or 16.

This rule ensures that enough FIFO space at a time is free to serve the request from the peripheral.

FIFO flush

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers. If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA_LISR or DMA_HISR register is set.

The remaining data counter DMA_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data is sent with the data width set in the MSIZE bit in the DMA_SxCR register. This means that memory is written with an undesired value. The software may read the DMA_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions are generated to complete the FIFO flush.

Direct mode

By default, the FIFO operates in direct mode (DMDIS bit in the DMA_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- the source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA_SxCR (MSIZE[1:0] bits are not relevant)
- burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA_SxCR are don’t care)

Direct mode must not be used when implementing memory-to-memory transfers.

15.3.15 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA_LISR or DMA_HISR status register:

- In DMA flow controller mode:
  - The DMA_SxNDTR counter has reached zero in the memory-to-peripheral mode.
  - The stream is disabled before the end of transfer (by clearing the EN bit in the DMA_SxCR register) and (when transfers are peripheral-to-memory or memory-

to-memory) all the remaining data have been flushed from the FIFO into the memory.

- In Peripheral flow controller mode:
  - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory
  - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory

Note: The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.

If the stream is configured in non-circular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA_SxCR register).

15.3.16 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA_LISR or DMA_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA_SxCR is now 0 to confirm the stream interruption. The DMA_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.
- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA_SxNDTR register after disabling the stream by writing the EN bit in DMA_SxCR register (and then checking that it is at 0) to know the number of data items already collected. Then:
  - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers
  - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled)
  - The stream may then be re-enabled to restart the transfer from the point it was stopped

Note: A transfer complete interrupt flag (TCIF in DMA_LISR or DMA_HISR) is set to indicate the end of transfer due to the stream interruption.

15.3.17 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals that are able to signal the end of the transfer.

When the peripheral flow controller is used for a given stream, the value written into the DMA_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it is forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA_SxNDTR register and apply the following formula:
  – Number_of_data_transferred = 0xFFFF – DMA_SxNDTR
- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA_SxNDTR register and apply the same formula as above.
- The DMA_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data is not lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

Note: When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

The circular mode is forbidden in the peripheral flow controller mode.

15.3.18 Summary of the possible DMA configurations

The table below summarizes the different possible DMA configurations. The forbidden configurations are highlighted in gray in the table.

Table 93. Possible DMA configurations

DMA transfer mode	Source	Destination	Flow controller	Circular mode	Transfer type	Direct mode	Double-buffer mode
Peripheral-to-memory	AHB peripheral port	AHB memory port	DMA	Possible	single	Possible	Possible
					burst	Forbidden	
			Peripheral	Forbidden	single	Possible	Forbidden
					burst	Forbidden	
Memory-to-peripheral	AHB memory port	AHB peripheral port	DMA	Possible	single	Possible	Possible
					burst	Forbidden	
			Peripheral	Forbidden	single	Possible	Forbidden
					burst	Forbidden	
Memory-to-memory	AHB peripheral port	AHB memory port	DMA only	Forbidden	single	Forbidden	Forbidden
					burst		

15.3.19 Stream configuration procedure

The following sequence must be followed to configure a DMA stream x (where x is the stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA_SxCR register, then read this bit in order to confirm that there is no ongoing stream operation. Writing this bit to 0 is not immediately effective since it is actually written to 0 once all the current transfers are finished. When the EN bit is read as 0, this means that the stream is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared before starting any stream configuration. All the stream dedicated bits set in the status register (DMA_LISR and DMA_HISR) from the previous data block DMA transfer must be cleared before the stream can be re-enabled.
2. Set the peripheral port register address in the DMA_SxPAR register. The data is moved from/ to this address to/ from the peripheral port after the peripheral event.
3. Set the memory address in the DMA_SxMA0R register (and in the DMA_SxMA1R register in the case of a double-buffer mode). The data is written to or read from this memory after the peripheral event.
4. Configure the total number of data items to be transferred in the DMA_SxNDTR register. After each peripheral event or each beat of the burst, this value is decremented.
5. Use DMAMUX1 to route a DMA request line to the DMA channel.
6. If the peripheral is intended to be the flow controller and if it supports this feature, set the PFCTRL bit in the DMA_SxCR register.
7. Configure the stream priority using the PL[1:0] bits in the DMA_SxCR register.
8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)

9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, circular mode, double-buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA_SxCR register.
10. Activate the stream by setting the EN bit in the DMA_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

Warning: **To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.**

15.3.20 Error management

The DMA controller can detect the following errors:

- **Transfer error**: the transfer error interrupt flag (TEIFx) is set when:
  - a bus error occurs during a DMA read or a write access
  - a write access is requested by software on a memory address register in double-buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to *Section 15.3.11: Double-buffer mode*)
- **FIFO error**: the FIFO error interrupt flag (FEIFx) is set if:
  - a FIFO underrun condition is detected
  - a FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - the stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to *Table 92: FIFO threshold configurations*)
- **Direct mode error**: the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that two data items were be transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation

In direct mode, the FIFO error flag can also be set under the following conditions:

- In the peripheral-to-memory mode, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests.
- In the memory-to-peripheral mode, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs.

If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA_LISR or DMA_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMEIE) in the DMA_SxCR or DMA_SxFCR register is set.

Note: When a FIFO overrun or underrun condition occurs, the data is not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.

15.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- FIFO error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in the table below.

Table 94. DMA interrupt requests

Interrupt event	Event flag	Enable control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE
FIFO overrun/underrun	FEIF	FEIE
Direct mode error	DMEIF	DMEIE

Note: Before setting an enable control bit EN = 1, the corresponding event flag must be cleared, otherwise an interrupt is immediately generated.

15.5 DMA registers

The DMA registers have to be accessed by words (32 bits).

15.5.1 DMA low interrupt status register (DMA_LISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				r	r	r	r		r	r	r	r	r		r

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[3:0]**: Stream x transfer complete interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No transfer complete event on stream x
1: A transfer complete event occurred on stream x.

Bits 26, 20, 10, 4 **HTIF[3:0]**: Stream x half transfer interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No half transfer event on stream x
1: An half transfer event occurred on stream x.

Bits 25, 19, 9, 3 **TEIF[3:0]**: Stream x transfer error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No transfer error on stream x
1: A transfer error occurred on stream x.

Bits 24, 18, 8, 2 **DMEIF[3:0]**: Stream x direct mode error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No direct mode error on stream x
1: A direct mode error occurred on stream x.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[3:0]**: Stream x FIFO error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No FIFO error event on stream x
1: A FIFO error event occurred on stream x.

15.5.2 DMA high interrupt status register (DMA_HISR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TCIF7	HTIF7	TEIF7	DMEIF 7	Res.	FEIF7	TCIF6	HTIF6	TEIF6	DMEIF 6	Res.	FEIF6

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[7:4]**: Stream x transfer complete interrupt flag (x = 7 to 4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.

0: No transfer complete event on stream x

1: A transfer complete event occurred on stream x.

Bits 26, 20, 10, 4 **HTIF[7:4]**: Stream x half transfer interrupt flag (x = 7 to 4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.

0: No half transfer event on stream x

1: An half transfer event occurred on stream x.

Bits 25, 19, 9, 3 **TEIF[7:4]**: Stream x transfer error interrupt flag (x = 7 to 4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.

0: No transfer error on stream x

1: A transfer error occurred on stream x.

Bits 24, 18, 8, 2 **DMEIF[7:4]**: Stream x direct mode error interrupt flag (x = 7 to 4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.

0: No direct mode error on stream x

1: A direct mode error occurred on stream x.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[7:4]**: Stream x FIFO error interrupt flag (x = 7 to 4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.

0: No FIFO error event on stream x

1: A FIFO error event occurred on stream x.

15.5.3 DMA low interrupt flag clear register (DMA_LIFCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[3:0]**: Stream x clear transfer complete interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA_LISR register.

Bits 26, 20, 10, 4 **CHTIF[3:0]**: Stream x clear half transfer interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA_LISR register

Bits 25, 19, 9, 3 **CTEIF[3:0]**: Stream x clear transfer error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA_LISR register.

Bits 24, 18, 8, 2 **CDMEIF[3:0]**: Stream x clear direct mode error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA_LISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[3:0]**: Stream x clear FIFO error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA_LISR register.

15.5.4 DMA high interrupt flag clear register (DMA_HIFCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				w	w	w	w		w	w	w	w	w		w

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[7:4]**: Stream x clear transfer complete interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA_HISR register.

Bits 26, 20, 10, 4 **CHTIF[7:4]**: Stream x clear half transfer interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA_HISR register.

Bits 25, 19, 9, 3 **CTEIF[7:4]**: Stream x clear transfer error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA_HISR register.

Bits 24, 18, 8, 2 **CDMEIF[7:4]**: Stream x clear direct mode error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA_HISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[7:4]**: Stream x clear FIFO error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA_HISR register.

15.5.5 DMA stream x configuration register (DMA_SxCR)

This register is used to configure the concerned stream.

Address offset: 0x010 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	MBURST[1:0]		PBURST[1:0]		TRBUFF	CT	DBM	PL[1:0]	
							rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:23 **MBURST[1:0]**: Memory burst transfer configuration
These bits are set and cleared by software.
00: Single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN = 0.
In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN = 1.

Bits 22:21 **PBURST[1:0]**: Peripheral burst transfer configuration
These bits are set and cleared by software.
00: Single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN = 0.
In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 **TRBUFF**: Enable the DMA to handle bufferable transfers
0: Bufferable transfers not enabled
1: Bufferable transfers enabled
Note: This bit must be set to 1 if the DMA stream manages UART/USART/LPUART transfers.

Bit 19 **CT**: Current target (only in double-buffer mode)
This bit is set and cleared by hardware. It can also be written by software.
0: Current target memory is memory 0 (addressed by the DMA_SxM0AR pointer).
1: Current target memory is memory 1 (addressed by the DMA_SxM1AR pointer).
This bit can be written only if EN = 0 to indicate the target memory area of the first transfer.
Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.

Bit 18 **DBM**: Double-buffer mode
This bit is set and cleared by software.
0: No buffer switching at the end of transfer
1: Memory target switched at the end of the DMA transfer
This bit is protected and can be written only if EN = 0.

Bits 17:16 **PL[1:0]**: priority level
These bits are set and cleared by software.
00: Low
01: Medium
10: High
11: Very high
These bits are protected and can be written only if EN = 0.

Bit 15 **PINCOS**: Peripheral increment offset size
This bit is set and cleared by software
0: The offset size for the peripheral address calculation is linked to the PSIZE.
1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).
This bit has no meaning if bit PINC = 0.
This bit is protected and can be written only if EN = 0.
This bit is forced low by hardware when the stream is enabled (EN = 1) if the direct mode is selected or if PBURST are different from 00.

Bits 14:13 **MSIZE[1:0]**: Memory data size
These bits are set and cleared by software.
00: Byte (8-bit)
01: Half-word (16-bit)
10: Word (32-bit)
11: Reserved
These bits are protected and can be written only if EN = 0.
In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as EN = 1.

Bits 12:11 **PSIZE[1:0]**: Peripheral data size
These bits are set and cleared by software.
00: Byte (8-bit)
01: Half-word (16-bit)
10: Word (32-bit)
11: Reserved
These bits are protected and can be written only if EN = 0.

Bit 10 **MINC**: Memory increment mode
This bit is set and cleared by software.
0: Memory address pointer fixed
1: Memory address pointer incremented after each data transfer (increment is done according to MSIZE)
This bit is protected and can be written only if EN = 0.

Bit 9 **PINC**: Peripheral increment mode
This bit is set and cleared by software.
0: Peripheral address pointer fixed
1: Peripheral address pointer incremented after each data transfer (increment done according to PSIZE)
This bit is protected and can be written only if EN = 0.

Bit 8 **CIRC**: Circular mode

This bit is set and cleared by software and can be cleared by hardware.
0: Circular mode disabled
1: Circular mode enabled
When the peripheral is the flow controller (bit PFCTRL = 1), and the stream is enabled (EN = 1), then this bit is automatically forced by hardware to 0.
It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (EN = 1).

Bits 7:6 **DIR[1:0]**: Data transfer direction

These bits are set and cleared by software.
00: Peripheral-to-memory
01: Memory-to-peripheral
10: Memory-to-memory
11: Reserved
These bits are protected and can be written only if EN = 0.

Bit 5 **PFCTRL**: Peripheral flow controller

This bit is set and cleared by software.
0: DMA is the flow controller.
1: The peripheral is the flow controller.
This bit is protected and can be written only if EN = 0.
When the memory-to-memory mode is selected (bits DIR[1:0] = 10), then this bit is automatically forced to 0 by hardware.

Bit 4 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 3 **HTIE**: Half transfer interrupt enable

This bit is set and cleared by software.
0: HT interrupt disabled
1: HT interrupt enabled

Bit 2 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 1 **DMEIE**: Direct mode error interrupt enable

This bit is set and cleared by software.
0: DME interrupt disabled
1: DME interrupt enabled

Bit 0 **EN**: Stream enable/flag stream ready when read low

This bit is set and cleared by software.

0: Stream disabled

1: Stream enabled

This bit is cleared by hardware:

- on a DMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AHB master buses
- when the FIFO threshold on memory AHB port is not compatible with the burst size

When this bit is read as 0, the software is allowed to program the configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.

Note: Before setting EN bit to 1 to start a new transfer, the event flags corresponding to the stream in DMA_LISR or DMA_HISR register must be cleared.

15.5.6 DMA stream x number of data register (DMA_SxNDTR)

Address offset: 0x014 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: Number of data items to transfer (0 up to 65535)

This bitfield can be written only when the stream is disabled. When the stream is enabled, this bitfield is read-only, indicating the remaining data items to be transmitted. This bitfield decrements after each DMA transfer.

Once the transfer is completed, this bitfield can either stay at zero (when the stream is in normal mode), or be reloaded automatically with the previously programmed value in the following cases:

- when the stream is configured in circular mode
- when the stream is enabled again by setting EN bit to 1

If the value of this bitfield is zero, no transaction can be served even if the stream is enabled.

15.5.7 DMA stream x peripheral address register (DMA_SxPAR)

Address offset: 0x018 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

PAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PAR[31:0]**: Peripheral address

Base address of the peripheral data register from/to which the data is read/written.
These bits are write-protected and can be written only when bit EN = 0 in DMA_SxCR.

15.5.8 DMA stream x memory 0 address register (DMA_SxM0AR)

Address offset: 0x01C + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **M0A[31:0]**: Memory 0 address

Base address of memory area 0 from/to which the data is read/written.
These bits are write-protected. They can be written only if:

- the stream is disabled (EN = 0 in DMA_SxCR) or
- the stream is enabled (EN = 1 in DMA_SxCR) and CT = 1 in DMA_SxCR (in double-buffer mode).

15.5.9 DMA stream x memory 1 address register (DMA_SxM1AR)

Address offset: 0x020 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M1A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **M1A[31:0]**: Memory 1 address (used in case of double-buffer mode)

Base address of memory area 1 from/to which the data is read/written.
This bitfield is used only for the double-buffer mode.
These bits are write-protected. They can be written only if:

- the stream is disabled (EN = 0 in DMA_SxCR) or
- the stream is enabled (EN = 1 in DMA_SxCR) and bit CT = 0 in DMA_SxCR .

15.5.10 DMA stream x FIFO control register (DMA_SxFCR)

Address offset: 0x024 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0021

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw		r	r	r	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable
This bit is set and cleared by software.
0: FE interrupt disabled
1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status
These bits are read-only.
000: 0 < fifo_level < 1/4
001: 1/4 ≤ fifo_level < 1/2
010: 1/2 ≤ fifo_level < 3/4
011: 3/4 ≤ fifo_level < full
100: FIFO is empty.
101: FIFO is full.
Others: Reserved (no meaning)
These bits are not relevant in the direct mode (DMDIS = 0).

Bit 2 **DMDIS**: Direct mode disable
This bit is set and cleared by software. It can be set by hardware.
0: Direct mode enabled
1: Direct mode disabled
This bit is protected and can be written only if EN = 0.
This bit is set by hardware if the memory-to-memory mode is selected (DIR = 10 in DMA_SxCR), and EN = 1 in DMA_SxCR because the direct mode is not allowed in the memory-to-memory configuration.

Bits 1:0 **FTH[1:0]**: FIFO threshold selection
These bits are set and cleared by software.
00: 1/4 full FIFO
01: 1/2 full FIFO
10: 3/4 full FIFO
11: Full FIFO
These bits are not used in the direct mode when the DMIS = 0.
These bits are protected and can be written only if EN = 0.

15.5.11 DMA register map

Refer to *Section 2.3* for the register boundary addresses.

16 Basic direct memory access controller (BDMA)

16.1 Introduction

The basic direct memory access (BDMA) controller is a bus master and system peripheral.

The BDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories, upon the control of an off-loaded CPU.

The BDMA controller features a single AHB master architecture.

There are two instances of BDMA, BDMA1 (dedicated to the 8-filter DFSDM) and BDMA2, with 8 channels each.

Each channel is dedicated to managing memory access requests from one or more peripherals. Each BDMA includes an arbiter for handling the priority between DMA requests.

16.2 BDMA main features

- Single AHB master
- Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Access to AHB SRAM1/SRAM2 and DFSDM peripheral (BDMA1)
- Access to SmartRun domain SRAM and AHB/APB peripherals (BDMA2)
- All BDMA channels independently configurable:
  - Each channel is associated either with a DMA request signal coming from a peripheral, or with a software trigger in memory-to-memory transfers. This configuration is done by software.
  - Priority between the requests is programmable by software (4 levels per channel: very high, high, medium, low) and by hardware in case of equality (such as request to channel 1 has priority over request to channel 2).
  - Transfer size of source and destination are independent (byte, half-word, word), emulating packing and unpacking. Source and destination addresses must be aligned on the data size.
  - Support of transfers from/to peripherals to/from memory with circular buffer management
  - Programmable number of data to be transferred: 0 to 2^{16} - 1
- Generation of an interrupt request per channel. Each interrupt request is caused from any of the three DMA events: transfer complete, half transfer, or transfer error.

16.3 BDMA implementation

16.3.1 BDMA1 and BDMA2

BDMA1 and BDMA2 are implemented with the hardware configuration parameters shown in the table below.

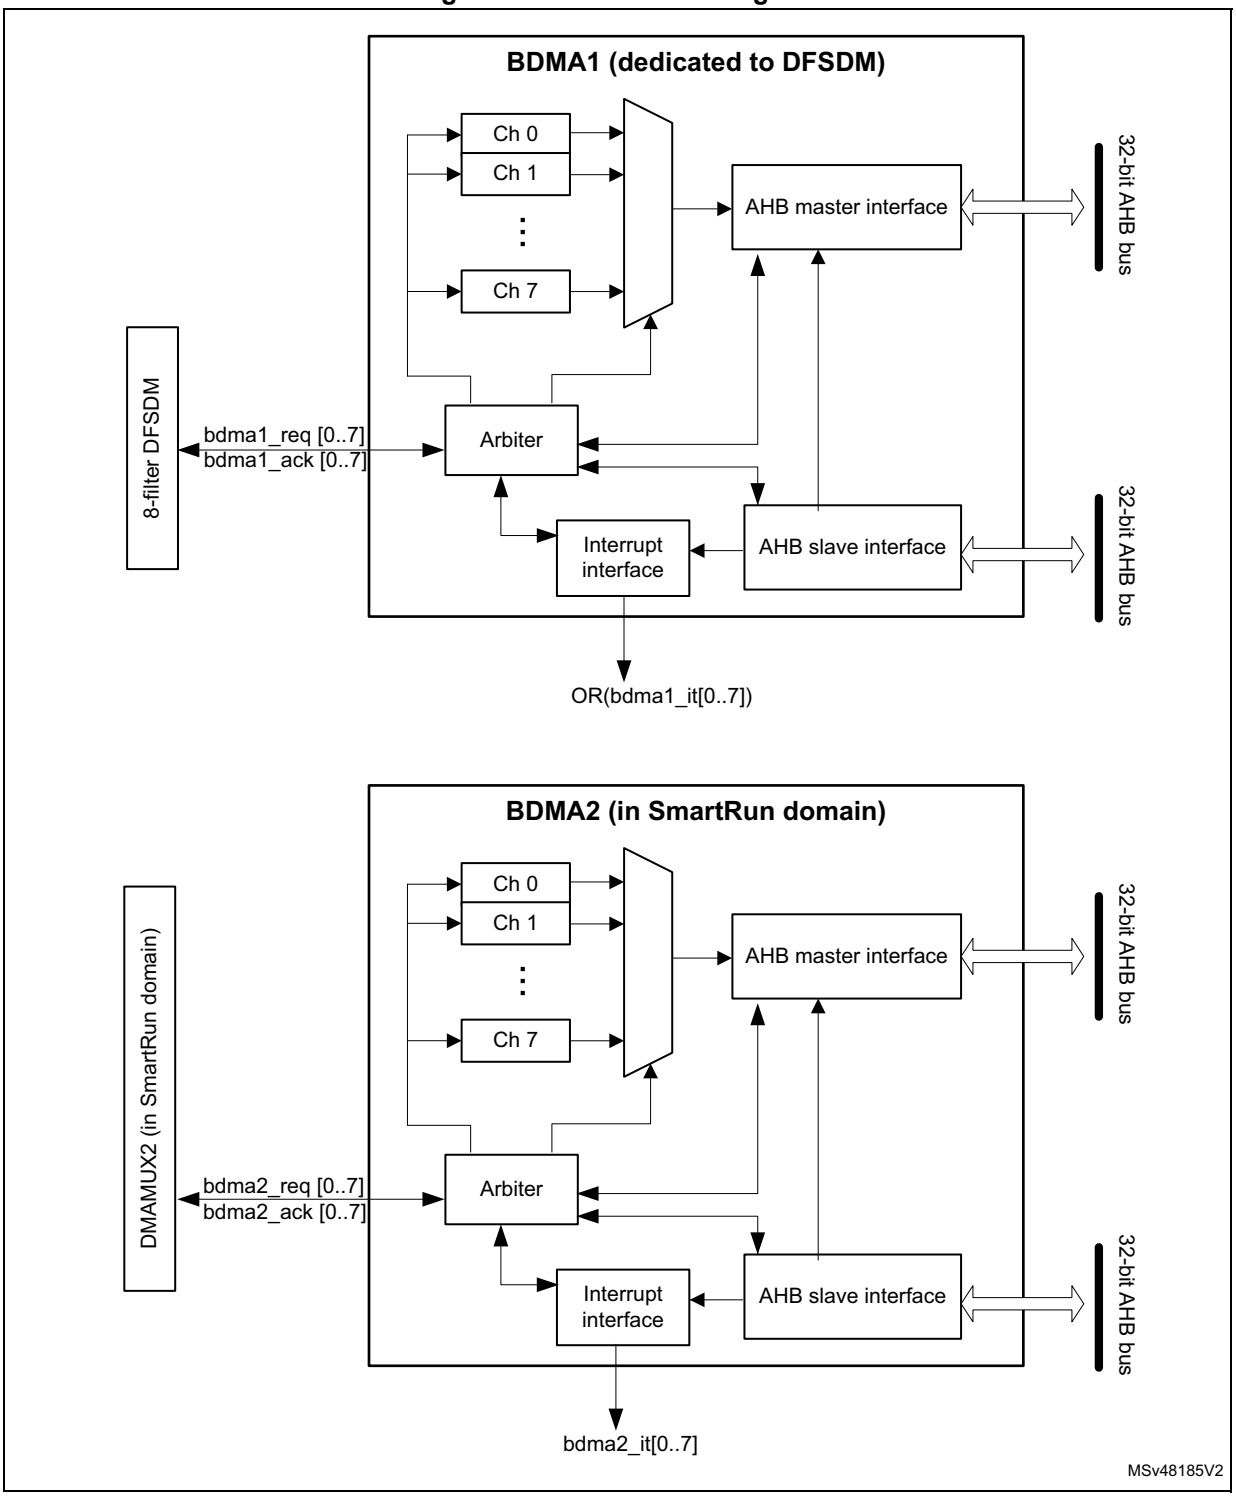
Table 96. BDMA1 and BDMA2 implementation

Feature	BDMA1	BDMA2
Number of channels (double-buffer)	8	8

16.3.2 BDMA request mapping

The BDMA2 controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX2 peripheral.

For the mapping of the different requests, refer to the *Section 17.3: DMAMUX implementation*.



A channel request x of the BDMA1 is connected to the DFSDM request of the same index x.

16.4 BDMA functional description

16.4.1 BDMA block diagram

The BDMA block diagram is shown in the figure below.

Figure 88. BDMA block diagram

The BDMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and BDMA target the same destination (memory or peripheral).

The BDMA2 controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX2 peripheral.

A channel request x of the BDMA1 is connected to the DFSDM request of the same index x.

According to its configuration through the AHB slave interface, the BDMA controller arbitrates between the DMA channels and their associated received requests. The BDMA controller also schedules the DMA data transfers over the single AHB port master.

The BDMA2 controller generates an interrupt per channel to the interrupt controller and the BDMA1 dedicated to DFSDM generates a single ORed interrupt.

16.4.2 BDMA pins and internal signals

Table 97. BDMA internal input/output signals

Signal name	Signal type	Description
bdma_req[x]	Input	BDMA channel x request
bdma_ack[x]	Output	BDMA channel x acknowledge
bdma_it[x]	Output	BDMA channel x interrupt

16.4.3 BDMA transfers

The software configures the BDMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB bus transfers.

A BDMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.

After an event, the following steps of a single BDMA transfer occur:

1. The peripheral sends a single DMA request signal to the BDMA controller.
2. The BDMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the BDMA controller grants the peripheral, an acknowledge is sent to the peripheral by the BDMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the BDMA controller.
5. Once the request is deasserted by the peripheral, the BDMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single BDMA transfer.

The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the BDMA controller. The BDMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel x, a BDMA block transfer consists of a repeated sequence of:

- a single BDMA transfer, encapsulating two AHB transfers of a single data, over the BDMA AHB bus master:
  - a single data read (byte, half-word or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory

address register.
The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the BDMA_CPARx or BDMA_CM0/1ARx register.

– a single data write (byte, half-word or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register.
The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the BDMA_CPARx or BDMA_CM0/1ARx register.

- post-decrementing of the programmed BDMA_CNDTRx register
This register contains the remaining number of data items to transfer (number of AHB ‘read followed by write’ transfers).

This sequence is repeated until BDMA_CNDTRx is null.

Note: The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.

16.4.4 BDMA arbitration

The BDMA arbiter manages the priority between the different channels.

When an active channel x is granted by the arbiter (hardware requested or software triggered), a single BDMA transfer is issued (such as a AHB ‘read followed by write’ transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.

The priorities are managed in two stages:

- software: priority of each channel is configured in the BDMA_CCRx register, to one of the four different levels:
  – very high
  – high
  – medium
  – low
- hardware: if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel x is programmed for a block transfer in memory-to-memory mode, re arbitration is considered between each single BDMA transfer of this channel x. Whenever there is another concurrent active requested channel, the BDMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.

16.4.5 BDMA channels

Each channel may handle a BDMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

A DMA channel is programmed at block transfer level.

Programmable data sizes

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the BDMA_CCRx register.

Pointer incrementation

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the BDMA_CCRx register.

If the **incremented mode** is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the BDMA_CPARx or BDMA_CM0/1ARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in **non-circular mode**, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the BDMA_CNDTRx register.

Note: If the channel x is disabled, the BDMA registers are not reset. The DMA channel registers (BDMA_CCRx, BDMA_CPARx and BDMA_CM0ARx) retain the initial values programmed during the channel configuration phase.

In **circular mode**, after the last data transfer, the BDMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the BDMA_CPARx and BDMA_CM0/1ARx registers.

Channel configuration procedure

The following sequence is needed to configure a DMA channel x:

1. Set the peripheral register address in the BDMA_CPARx register.
   The data is moved from/to this address to/from the memory after the peripheral event, or after the channel is enabled in memory-to-memory mode.
2. Set the memory address in the BDMA_CM0ARx register.
   The data is written to/read from the memory after the peripheral event or after the channel is enabled in memory-to-memory mode.
3. Configure the total number of data to transfer in the BDMA_CNDTRx register.
   After each data transfer, this value is decremented.
4. Configure the parameters listed below in the BDMA_CCRx register:
   - the channel priority
   - the data transfer direction
   - the circular mode
   - the double-buffer mode
   - the peripheral and memory incremented mode
   - the peripheral and memory data size
   - the interrupt enable at half and/or full transfer and/or transfer error
5. Activate the channel by setting the EN bit in the BDMA_CCRx register.

A channel, as soon as enabled, may serve any BDMA request from the peripheral connected to this channel, or may start a memory-to-memory block transfer.

Note: The two last steps of the channel configuration procedure may be merged into a single access to the BDMA_CCRx register, to configure and enable the channel.

Channel state and disabling a channel

A channel x in active state is an enabled channel (read BDMA_CCRx.EN = 1). An active channel x is a channel that must have been enabled by the software (BDMA_CCRx.EN set to 1) and afterwards with no occurred transfer error (BDMA_ISR.TEIFx = 0). In case there is a transfer error, the channel is automatically disabled by hardware (BDMA_CCRx.EN = 0).

The three following use cases may happen:

- Suspend and resume a channel

  This corresponds to the two following actions:

  – An active channel is disabled by software (writing BDMA_CCRx.EN = 0 whereas BDMA_CCRx.EN = 1).

  – The software enables the channel again (BDMA_CCRx.EN set to 1) without reconfiguring the other channel registers (such as BDMA_CNDTRx, BDMA_CPARx and BDMA_CM0/1ARx).

  This case is not supported by the BDMA hardware, that does not guarantee that the remaining data transfers are performed correctly.

- Stop and abort a channel

  If the application does not need any more the channel, this active channel can be disabled by software. The channel is stopped and aborted but the BDMA_CNDTRx register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/register.

- Abort and restart a channel

  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.

  This is supported by the hardware if the following conditions are met:

  – The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.

  – The software must operate separated write accesses to the same BDMA_CCRx register: First disable the channel. Second reconfigure the channel for a next block transfer including the BDMA_CCRx if a configuration change is needed. There are read-only BDMA_CCRx register fields when BDMA_CCRx.EN=1. Finally enable again the channel.

When a channel transfer error occurs, the EN bit of the BDMA_CCRx register is cleared by hardware. This EN bit can not be set again by software to re-activate the channel x, until the TEIFx bit of the BDMA_CxISR register is set.

Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the CIRC bit in the BDMA_CCRx register.

Note: The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (CIRC = 1), the software must clear the MEM2MEM bit of the BDMA_CCRx register. When the circular mode is activated, the amount of data to transfer is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel. The software must explicitly program the BDMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.

Memory-to-memory mode

The BDMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the BDMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the BDMA_CNDTRx register reaches zero.

Note: The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the BDMA_CCRx register.

Double-buffer mode (in memory-to-peripheral and peripheral-to memory transfers)

The BDMA channels can operate in double-buffer mode.

The difference compared to a regular operation is that the BDMA controller toggles between two memory address pointers at the end of each BDMA transfer, thus accessing two memory areas in an alternate way. This allows the software to access one of the two memory areas while the BDMA controller accesses the other one. The double-buffer mode transfer operates in both directions, so the target memory can be either the source or the destination.

The double-buffer mode is configured by setting both the DBM and CIRC bits of the BDMA_CCRx register.

Note: The double-buffer mode must not be used in memory-to-memory mode. Before enabling a channel in double-buffer mode (DBM = 1), the software has to configure appropriately the MEM2MEM bit (MEM2MEM = 0).

The steps described below allow the configuration of a BDMA channel x in double-buffer mode:

- Set the DBM and CIRC bits and clear the MEM2MEM bit of the BDMA_CCRx register. The circular mode is then activated for the swap mechanism to occur.
- Configure the second memory address register BDMA_CM1ARx.
- Continue with the regular channel configuration procedure, and lastly, activate the channel by setting the EN bit of the BDMA_CCRx register. The first BDMA transfer target memory of the corresponding BDMA channel x, is given by the CT bit of the BDMA_CCRx register.

Note: Independently from the value of DBM bit of the BDMA_CCRx register, if CT = 1, the memory address pointer for the BDMA transfer is defined by BDMA_CM1ARx, and not by BDMA_CM0ARx.

Peripheral-to-peripheral mode

Any BDMA channel can operate in peripheral-to-peripheral mode:

- when the hardware request from a peripheral is selected to trigger the BDMA channel

  This peripheral is the BDMA initiator and paces the data transfer from/to this peripheral to/from a register belonging to another memory-mapped peripheral (this one being not configured in DMA mode).
- when no peripheral request is selected and connected to the BDMA channel

  The software configures a register-to-register transfer by setting the MEM2MEM bit of the BDMA_CCRx register.

Programming transfer direction, assigning source/destination

The value of the DIR bit of the BDMA_CCRx register sets the direction of the transfer, and consequently, it identifies the source and the destination, regardless the source/destination type (peripheral or memory):

- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The **source** attributes are defined by the BDMA_MARx register, the MSIZE[1:0] field and MINC bit of the BDMA_CCRx register.
    Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the source peripheral in peripheral-to-peripheral mode.
  - The **destination** attributes are defined by the BDMA_PARx register, the PSIZE[1:0] field and PINC bit of the BDMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the destination memory in memory-to-memory mode.
- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The **source** attributes are defined by the BDMA_PARx register, the PSIZE[1:0] field and PINC bit of the BDMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the source memory in memory-to-memory mode
  - The **destination** attributes are defined by the BDMA_MARx register, the MSIZE[1:0] field and MINC bit of the BDMA_CCRx register.
    Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the destination peripheral in peripheral-to-peripheral mode.

16.4.6 BDMA data width, alignment and endianness

When PSIZE[1:0] and MSIZE[1:0] are not equal, the BDMA controller performs some data alignments as described in the table below.

Table 98. Programmable data width and endian behavior (when PINC = MINC = 1)

Source port width (MSIZE if DIR = 1, else PSIZE)	Destination port width (PSIZE if DIR = 1, else MSIZE)	Number of data items to transfer (NDT)	Source content: address / data (BDMA_CM0/1ARx if DIR = 1, else BDMA_CPARx)	DMA transfers	Destination content: address / data (BDMA_CPARx if DIR = 1, else BDMA_CM0/1ARx)

Addressing AHB peripherals not supporting byte/half-word write transfers

When the BDMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word write transfers and does not generate any error, the BDMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the BDMA controller sets the HWDATA bus to 0xABCDABCD with a half-word data size (HSIZE = HalfWord in AHB master bus).
- To write the byte 0xAB, the BDMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).

Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2 or 0x3 addresses, is converted to an APB word write transfer of 0xB0B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses, is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

16.4.7 BDMA error management

A BDMA transfer error is generated when reading from or writing to a reserved address space. When a BDMA transfer error occurs during a BDMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding BDMA_CCRx register.

The TEIFx bit of the BDMA_ISR register is set. An interrupt is then generated if the TEIE bit of the BDMA_CCRx register is set.

The EN bit of the BDMA_CCRx register can not be set again by software (channel x re-activated) until the TEIFx bit of the BDMA_ISR register is cleared (by setting the CTEIFx bit of the BDMA_IFCR register).

When the software is notified with a transfer error over a channel which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both BDMA and the peripheral in DMA mode for a new transfer.

16.5 BDMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x. Separate interrupt enable bits are available for flexibility.

Table 99. BDMA interrupt requests

Interrupt request	Interrupt event	Event flag	Interrupt enable bit
Channel x interrupt	Half transfer on channel x	HTIFx	HTIEx
	Transfer complete on channel x	TCIFx	TCIEx
	Transfer error on channel x	TEIFx	TEIEx
	Half transfer or transfer complete or transfer error on channel x	GIFx	-

16.6 BDMA registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The BDMA registers have to be accessed by words (32-bit).

16.6.1 BDMA interrupt status register (BDMA_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIFx, in the BDMA_IFCR register.

1: a TE, HT or TC event occurred

Bit 7 **TEIF1**: transfer error (TE) flag for channel 1
0: no TE event
1: a TE event occurred

Bit 6 **HTIF1**: half transfer (HT) flag for channel 1
0: no HT event
1: a HT event occurred

Bit 5 **TCIF1**: transfer complete (TC) flag for channel 1
0: no TC event
1: a TC event occurred

Bit 4 **GIF1**: global interrupt flag for channel 1
0: no TE, HT or TC event
1: a TE, HT or TC event occurred

Bit 3 **TEIF0**: transfer error (TE) flag for channel 0
0: no TE event
1: a TE event occurred

Bit 2 **HTIF0**: half transfer (HT) flag for channel 0
0: no HT event
1: a HT event occurred

Bit 1 **TCIF0**: transfer complete (TC) flag for channel 0
0: no TC event
1: a TC event occurred

Bit 0 **GIF0**: global interrupt flag for channel 0
0: no TE, HT or TC event
1: a TE, HT or TC event occurred

16.6.2 BDMA interrupt flag clear register (BDMA_IFCR)

Address offset: 0x04

Reset value: 0x0000 0000

Setting the global clear bit CGIFx of the channel x in this BDMA_IFCR register, causes the BDMA hardware to clear the corresponding GIFx bit and any individual flag among TEIFx, HTIFx, TCIFx, in the BDMA_ISR register.

Setting any individual clear bit among CTEIFx, CHTIFx, CTCIFx in this BDMA_IFCR register, causes the BDMA hardware to clear the corresponding individual flag and the global flag GIFx in the BDMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

Bit 31 **CTEIF7**: transfer error flag clear for channel 7

Bit 30 **CHTIF7**: half transfer flag clear for channel 7

Bit 29 **CTCIF7**: transfer complete flag clear for channel 7

Bit 28 **CGIF7**: global interrupt flag clear for channel 7

Bit 27 **CTEIF6**: transfer error flag clear for channel 6

Bit 26 **CHTIF6**: half transfer flag clear for channel 6

Bit 25 **CTCIF6**: transfer complete flag clear for channel 6

Bit 24 **CGIF6**: global interrupt flag clear for channel 6

Bit 23 **CTEIF5**: transfer error flag clear for channel 5

Bit 22 **CHTIF5**: half transfer flag clear for channel 5

Bit 21 **CTCIF5**: transfer complete flag clear for channel 5

Bit 20 **CGIF5**: global interrupt flag clear for channel 5

Bit 19 **CTEIF4**: transfer error flag clear for channel 4

Bit 18 **CHTIF4**: half transfer flag clear for channel 4

Bit 17 **CTCIF4**: transfer complete flag clear for channel 4

Bit 16 **CGIF4**: global interrupt flag clear for channel 4

Bit 15 **CTEIF3**: transfer error flag clear for channel 3

Bit 14 **CHTIF3**: half transfer flag clear for channel 3

Bit 13 **CTCIF3**: transfer complete flag clear for channel 3

Bit 12 **CGIF3**: global interrupt flag clear for channel 3

Bit 11 **CTEIF2**: transfer error flag clear for channel 2

Bit 10 **CHTIF2**: half transfer flag clear for channe2

Bit 9 **CTCIF2**: transfer complete flag clear for channel 2

Bit 8 **CGIF2**: global interrupt flag clear for channel 2

Bit 7 **CTEIF1**: transfer error flag clear for channel 1

Bit 6 **CHTIF1**: half transfer flag clear for channel 1

Bit 5 **CTCIF1**: transfer complete flag clear for channel 1

Bit 4 **CGIF1**: global interrupt flag clear for channel 0

Bit 3 **CTEIF0**: transfer error flag clear for channel 0

Bit 2 **CHTIF0**: half transfer flag clear for channel 0

Bit 1 **CTCIF0**: transfer complete flag clear for channel 0

Bit 0 **CGIF0**: global interrupt flag clear for channel 0

16.6.3 BDMA channel x configuration register (BDMA_CCRx)

Address offset: 0x08 + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

The register fields/bits CT, DBM, MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.

The states of MEM2MEM and CIRC bits must not be both high at the same time.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CT
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBM	MEM2MEM	PL[1:0]		MSIZE[1:0]		PSIZE[1:0]		MINC	PINC	CIRC	DIR	TEIE	HTIE	TCIE	EN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CT**: current target memory of DMA transfer in double-buffer mode

This bit is toggled by hardware at the end of each channel transfer in double-buffer mode.

0: memory 0 (addressed by the BDMA_CM0AR pointer)

1: memory 1 (addressed by the BDMA_CM1AR pointer)

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 15 **DBM**: double-buffer mode

This bit must be set only in memory-to-peripheral and peripheral-to-memory transfers (MEM2MEM=0). The CIRC bit must also be set in double buffer mode.

0: disabled (no memory address switch at the end of the BDMA transfer)

1: enabled (memory address switched at the end of the BDMA transfer)

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 14 **MEM2MEM**: memory-to-memory mode

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bits 13:12 **PL[1:0]**: priority level

00: low

01: medium

10: high

11: very high

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bits 11:10 **MSIZE[1:0]**: memory size

Defines the data size of each DMA transfer to the identified memory.

In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bits 9:8 **PSIZE[1:0]**: peripheral size

Defines the data size of each DMA transfer to the identified peripheral.

In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 7 **MINC**: memory increment mode

Defines the increment mode for each DMA transfer to the identified memory.

In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 6 **PINC**: peripheral increment mode

Defines the increment mode for each DMA transfer to the identified peripheral.

n memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 5 **CIRC**: circular mode

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 4 **DIR**: data transfer direction

This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.

0: read from peripheral

- Source attributes are defined by PSIZE and PINC, plus the BDMA_CPARx register. This is still valid in a memory-to-memory mode.
- Destination attributes are defined by MSIZE and MINC, plus the BDMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.

1: read from memory

- Destination attributes are defined by PSIZE and PINC, plus the BDMA_CPARx register. This is still valid in a memory-to-memory mode.
- Source attributes are defined by MSIZE and MINC, plus the BDMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 3 **TEIE**: transfer error interrupt enable

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 2 **HTIE**: half transfer interrupt enable

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 1 **TCIE**: transfer complete interrupt enable

0: disabled

1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 0 **EN**: channel enable

When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the BDMA_ISR register is cleared (by setting the CTEIFx bit of the BDMA_IFCR register).

0: disabled

1: enabled

Note: this bit is set and cleared by software.

16.6.4 BDMA channel x number of data to transfer register (BDMA_CNDTRx)

Address offset: 0x0C + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: number of data to transfer (0 to 2^{16} - 1)

This field is updated by hardware when the channel is enabled:

- It is decremented after each single BDMA 'read followed by write' transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the BDMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this field is zero, no transfer can be served whatever the channel status (enabled or not).

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

16.6.5 BDMA channel x peripheral address register (BDMA_CPARx)

Address offset: 0x10 + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PA[31:0]**: peripheral address

It contains the base address of the peripheral data register from/to which the data is read/written.

When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address.

When PSIZE = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this register identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0.

In peripheral-to-peripheral mode, this register identifies the peripheral destination address DIR = 1 and the peripheral source address if DIR = 0.

Note: this register is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

16.6.6 BDMA channel x memory 0 address register (BDMA_CM0ARx)

Address offset: 0x14 + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: peripheral address

It contains the base address of the memory from/to which the data is read/written.

When MSIZE[1:0] = 01 (16 bits), bit 0 of MA[31:0] is ignored. Access is automatically aligned to a half-word address.

When MSIZE = 10 (32 bits), bits 1 and 0 of MA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this register identifies the memory source address if DIR = 1 and the memory destination address if DIR = 0.

In peripheral-to-peripheral mode, this register identifies the peripheral source address DIR = 1 and the peripheral destination address if DIR = 0.

Note: this register is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

16.6.7 BDMA channel x memory 1 address register (BDMA_CM1ARx)

Address offset: 0x18 + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: peripheral address

It contains the base address of the memory from/to which the data is read/written.

When MSIZE[1:0] = 01 (16 bits), bit 0 of MA[31:0] is ignored. Access is automatically aligned to a half-word address.

When MSIZE = 10 (32 bits), bits 1 and 0 of MA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this register identifies the memory source address if DIR = 1 and the memory destination address if DIR = 0.

In peripheral-to-peripheral mode, this register identifies the peripheral source address DIR = 1 and the peripheral destination address if DIR = 0.

Note: this register is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

16.6.8 BDMA register map

The table below gives the BDMA register map and reset values.

Table 100. BDMA register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 130* for the register boundary addresses.

17 DMA request multiplexer (DMAMUX)

17.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is deasserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controller of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in *Section 17.3.1*.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend upon product implementation. They are detailed in *Section 17.3.2*.

17.2 DMAMUX main features

- Up to 16-channel programmable DMA request line multiplexer output
- Up to 8-channel DMA request generator
- Up to 32 trigger inputs to DMA request generator
- Up to 16 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - Up to 107 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining

17.3 DMAMUX implementation

17.3.1 DMAMUX1 and DMAMUX2 instantiation

The product integrates two instances of DMA request multiplexer:

- DMAMUX1 for DMA1 and DMA2 (CD domain)
- DMAMUX2 for BDMA (SRD domain)

DMAMUX1 and DMAMUX2are instantiated with the hardware configuration parameters listed in the following table.

Table 101. DMAMUX1 and DMAMUX2 instantiation

Feature	DMAMUX1	DMAMUX2
Number of DMAMUX output request channels	16	8
Number of DMAMUX request generator channels	8	8
Number of DMAMUX request trigger inputs	8	32
Number of DMAMUX synchronization inputs	8	16
Number of DMAMUX peripheral request inputs	101	8

17.3.2 DMAMUX1 mapping

The mapping of resources to DMAMUX is hardwired.

DMAMUX1 is used with DMA1 and DMA2 in CD domain

- DMAMUX1 channels 0 to 7 are connected to DMA1 channels 0 to 7
- DMAMUX1 channels 8 to 15 are connected to DMA2 channels 0 to 7

17.4 DMAMUX functional description

17.4.1 DMAMUX block diagram

Figure 89 shows the DMAMUX block diagram.

Figure 89. DMAMUX block diagram

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)

17.4.2 DMAMUX signals

Table 108 lists the DMAMUX signals.

Table 108. DMAMUX signals

Signal name	Description
dmamux_hclk	DMAMUX AHB clock
dmamux_req_inx	DMAMUX DMA request line inputs from peripherals
dmamux_trgx	DMAMUX DMA request triggers inputs (to request generator sub-block)
dmamux_req_genx	DMAMUX request generator sub-block channels outputs
dmamux_reqx	DMAMUX request multiplexer sub-block inputs (from peripheral requests and request generator channels)
dmamux_syncx	DMAMUX synchronization inputs (to request multiplexer sub-block)
dmamux_req_outx	DMAMUX requests outputs (to DMA controller)
dmamux_evtx	DMAMUX events outputs
dmamux_ovr_it	DMAMUX overrun interrupts

17.4.3 DMAMUX channels

A DMAMUX channel is a request multiplexer channel that can include, depending upon the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to a single channel of DMA controller.

Channel configuration procedure

Follow the sequence below to configure a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

17.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals, or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAREQ_ID field in the DMAMUX_CxCR register.

Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected.

Caution: A same non-null DMAREQ_ID cannot be programmed to different x and y DMAMUX request multiplexer channels (via DMAMUX_CxCR and DMAMUX_CyCR), except when the application guarantees that the two connected DMA channels are not simultaneously active.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

Synchronization mode and channel event generation

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once a programmable rising/falling edge is detected on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, internally to the DMAMUX request multiplexer, there is a programmable DMA request counter, which can be used for the channel request output generation, and for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in *Figure 91*, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output.

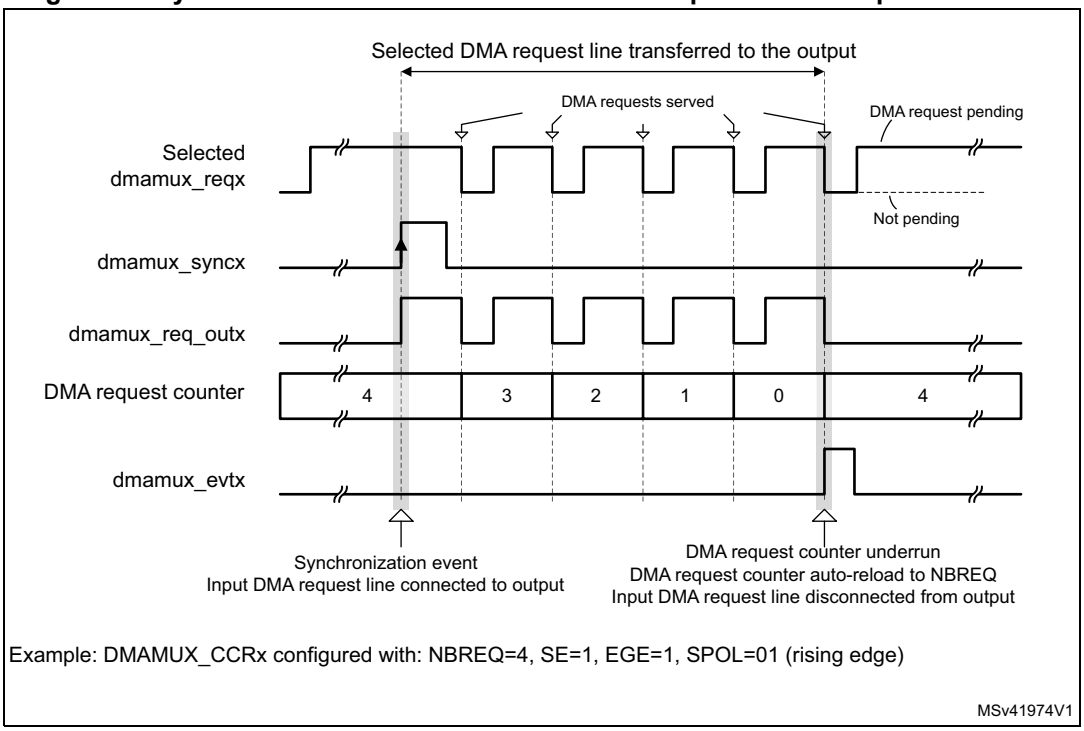
Note: If a synchronization event occurs while there is no pending selected input DMA request line, it is discarded. The following asserted input request lines is not connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is deasserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in the NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in the NBREQ field, plus one.

Note: The NBREQ field value can be written by software only when both synchronization enable bit (SE) and event generation enable bit (EGE) of the corresponding multiplexer channel x are disabled.

Figure 90. Synchronization mode of the DMAMUX request line multiplexer channel



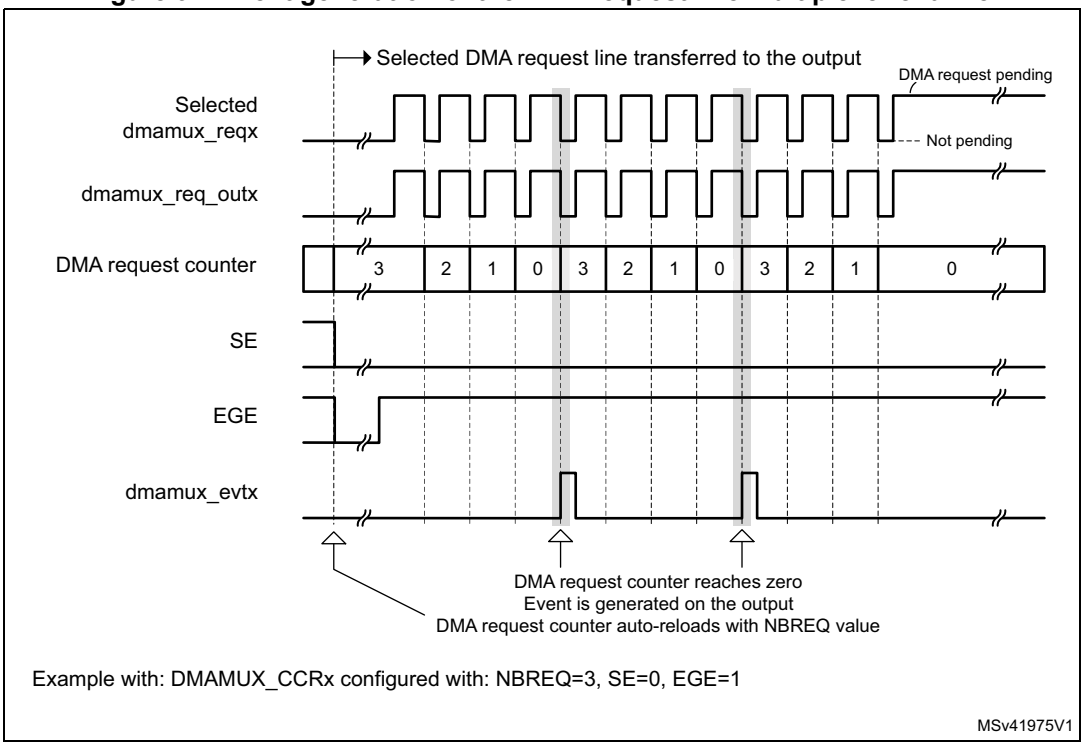


Figure 91. Event generation of the DMA request line multiplexer channel

If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in *Figure 90* and *Figure 91*.

Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

Synchronization overrun and interrupt

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR register.

Note: The request multiplexer channel x synchronization must be disabled (DMAMUX_CxCR.SE = 0) when the use of the related channel of the DMA controller is completed. Else, upon a new detected synchronization event, there is a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

17.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is deasserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter is automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.

Note: The GNBREQ field value can be written by software only when the enable GE bit of the corresponding generator channel x is disabled.

There is no hardware write protection.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

Trigger overrun and interrupt

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the DMAMUX_RGSR register.

Note: The request generator channel x must be disabled (DMAMUX_RGxCR.GE = 0) when the usage of the related channel of the DMA controller is completed. Else, upon a new detected trigger event, there is a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

17.5 DMAMUX interrupts

An interrupt can be generated upon:

- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel in.dividual interrupt enable, status, and clear flag register bits are available.

Table 109. DMAMUX interrupts

Interrupt signal	Interrupt event	Event flag	Clear bit	Enable bit
dmamuxovr_it	Synchronization event overrun on channel x of the DMAMUX request line multiplexer	SOFx	CSOFx	SOIE
	Trigger event overrun on channel x of the DMAMUX request generator	OFx	COFx	OIE

17.6 DMAMUX registers

Refer to the table containing register boundary addresses for the DMAMUX1 and DMAMUX2 base address.

DMAMUX registers may be accessed per byte (8-bit), half-word (16-bit), or word (32-bit). The address must be aligned with the data size.

17.6.1 DMAMUX1 request line multiplexer channel x configuration register (DMAMUX1_CxCR)

						rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **SYNC_ID[2:0]**: Synchronization identification

Selects the synchronization input (see *Table 102: DMAMUX1: assignment of multiplexer inputs to resources* and *Table 107: DMAMUX2: assignment of synchronization inputs to resources*).

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward

Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.
This field must only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity

Defines the edge polarity of the selected synchronization input:
00: No event (no synchronization, no detection).
01: Rising edge
10: Falling edge
11: Rising and falling edges

Bit 16 **SE**: Synchronization enable

0: Synchronization disabled
1: Synchronization enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EGE**: Event generation enable

0: Event generation disabled
1: Event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable

0: Interrupt disabled
1: Interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **DMAREQ_ID[6:0]**: DMA request identification
Selects the input DMA request. See the DMAMUX table about assignments of multiplexer inputs to resources.

17.6.2 DMAMUX2 request line multiplexer channel x configuration register (DMAMUX2_CxCR)

Address offset: 0x000 + 0x04 * x, where x = 0 to 7

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw				rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **SYNC_ID[3:0]**: Synchronization identification
Selects the synchronization input (see)

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward
Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.
This field shall only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity
Defines the edge polarity of the selected synchronization input:
00: no event (no synchronization, no detection).
01: rising edge
10: falling edge
11: rising and falling edges

Bit 16 **SE**: Synchronization enable
0: synchronization disabled
1: synchronization enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EGE**: Event generation enable
0: event generation disabled
1: event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DMAREQ_ID[4:0]**: DMA request identification
Selects the input DMA request. (see the DMAMUX table about assignments of multiplexer inputs to resources).

17.6.3 DMAMUX1 request line multiplexer interrupt channel status register (DMAMUX1_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SOF[15:0]**: Synchronization overrun event flag

The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX_CFR register.

For DMAMUX2 bits 15:8 are reserved, keep them at reset value.

17.6.4 DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

This register shall be accessed at bit level by a non-secure or secure read, according to the secure mode of the considered DMAMUX2 request line multiplexer channel x, depending on the secure control bit of the connected DMA controller channel y, and considering that the DMAMUX2 x channel output is connected to the y channel of the DMA (refer to the DMAMUX2 mapping implementation section).

This register shall be accessed at bit level by an unprivileged or privileged read, according to the privileged mode of the considered DMAMUX2 request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y, and considering that the DMAMUX2 x channel output is connected to the y channel of the DMA (refer to the DMAMXUX2 mapping implementation section).

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SOF[7:0]**: Synchronization overrun event flag

The flag is set when a new synchronization event occurs on a DMA request line multiplexer channel x before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register).

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX2_CFR register.

17.6.5 DMAMUX1 request line multiplexer interrupt clear flag register (DMAMUX1_CFR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CSOF[15:0]**: Clear synchronization overrun event flag

Writing 1 in each bit clears the corresponding overrun flag SOFx in the DMAMUX_CSR register.

17.6.6 DMAMUX2 request line multiplexer interrupt clear flag register (DMAMUX2_CFR)

Address offset: 0x084

Reset value: 0x0000 0000

This register shall be written at bit level by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMXUX mapping implementation section).

This register shall be written at bit level by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMXUX mapping implementation section).

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **CSOF[7:0]**: Clear synchronization overrun event flag

Writing 1 in each bit clears the corresponding overrun flag SOFx in the DMAMUX2_CSR register.

17.6.7 DMAMUX1 request generator channel x configuration register (DMAMUX1_RGxCR)

Address offset: 0x100 + 0x04 * x (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GNBREQ[4:0]					GPOL[1:0]		GE
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	OIE	Res.	Res.	Res.	Res.	Res.	SIG_ID[2:0]		
							rw						rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:19 **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)

Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ +1.

Note: This field must be written only when GE bit is disabled.

Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity

Defines the edge polarity of the selected trigger input
00: No event, i.e. no trigger detection nor generation.
01: Rising edge
10: Falling edge
11: Rising and falling edges

Bit 16 **GE**: DMA request generator channel x enable

0: DMA request generator channel x disabled
1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **OIE**: Trigger overrun interrupt enable

0: Interrupt on a trigger overrun event occurrence is disabled
1: Interrupt on a trigger overrun event occurrence is enabled

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **SIG_ID[2:0]**: Signal identification

Selects the DMA request trigger input used for the channel x of the DMA request generator

17.6.8 DMAMUX2 request generator channel x configuration register (DMAMUX2_RGxCR)

Address offset: 0x100 + 0x04 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register shall be written by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (see the DMAREQ_ID field of the DMAMUX2_CyCR register and the DMAMUX mapping implementation section).

This register shall be written by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (seethe DMAREQ_ID field of the DMAMUX2_CyCR register and the DMAMXUX mapping implementation section).

Note: With the request generator channel x disabled (GE=0) and thus ready to be configured again, the software shall operate (at least) two separated write accesses to this register. First, set/update the number of DMA requests to be generated (bits GNBREQ[4:0]), enable the request generator (i.e. set bit 16 GE), and disable the detection of the generator trigger input (i.e. set GPOL[1:0] to 00). Next, enable the detection of the generator trigger input by selecting as rising/falling the edge to be detected (i.e. set GPOL[1:0] to 01, 10 or 11).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GNBREQ[4:0]					GPOL[1:0]		GE

							rw				rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:19 **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)

Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ+1.

Note: This field shall only be written when GE bit is disabled.

Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity

Defines the edge polarity of the selected trigger input
00: no event. I.e. none trigger detection nor generation.
01: rising edge
10: falling edge
11: rising and falling edge

Bit 16 **GE**: DMA request generator channel x enable

0: DMA request generator channel x disabled
1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **OIE**: Trigger overrun interrupt enable

0: interrupt on a trigger overrun event occurrence is disabled
1: interrupt on a trigger overrun event occurrence is enabled

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **SIG_ID[4:0]**: Signal identification

Selects the DMA request trigger input used for the channel x of the DMA request generator

17.6.9 DMAMUX1 request generator interrupt status register (DMAMUX1_RGSR)

Address offset: 0x140

Reset value: 0x0000 0000

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **OF[7:0]**: Trigger overrun event flag

The flag is set when a new trigger event occurs on DMA request generator channel x, before the request counter underrun (the internal request counter programmed via the GNBREQ field of the DMAMUX_RGxCR register).

The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX_RGCFR register.

17.6.10 DMAMUX2 request generator interrupt status register (DMAMUX2_RGSR)

Address offset: 0x140

Reset value: 0x0000 0000

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **OF[7:0]**: Trigger overrun event flag

The flag is set when a new trigger event occurs on DMA request generator channel x.

The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX2_RGCFR register.

17.6.11 DMAMUX1 request generator interrupt clear flag register (DMAMUX1_RGCFR)

Address offset: 0x144

Reset value: 0x0000 0000

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **COF[7:0]**: Clear trigger overrun event flag

Writing 1 in each bit clears the corresponding overrun flag OFx in the DMAMUX_RGSR register.

17.6.12 DMAMUX2 request generator interrupt clear flag register (DMAMUX2_RGCFR)

Address offset: 0x144

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3 on page 130* for the register boundary addresses.

18 Chrom-ART Accelerator controller (DMA2D)

18.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

18.2 DMA2D main features

The main DMA2D features are:

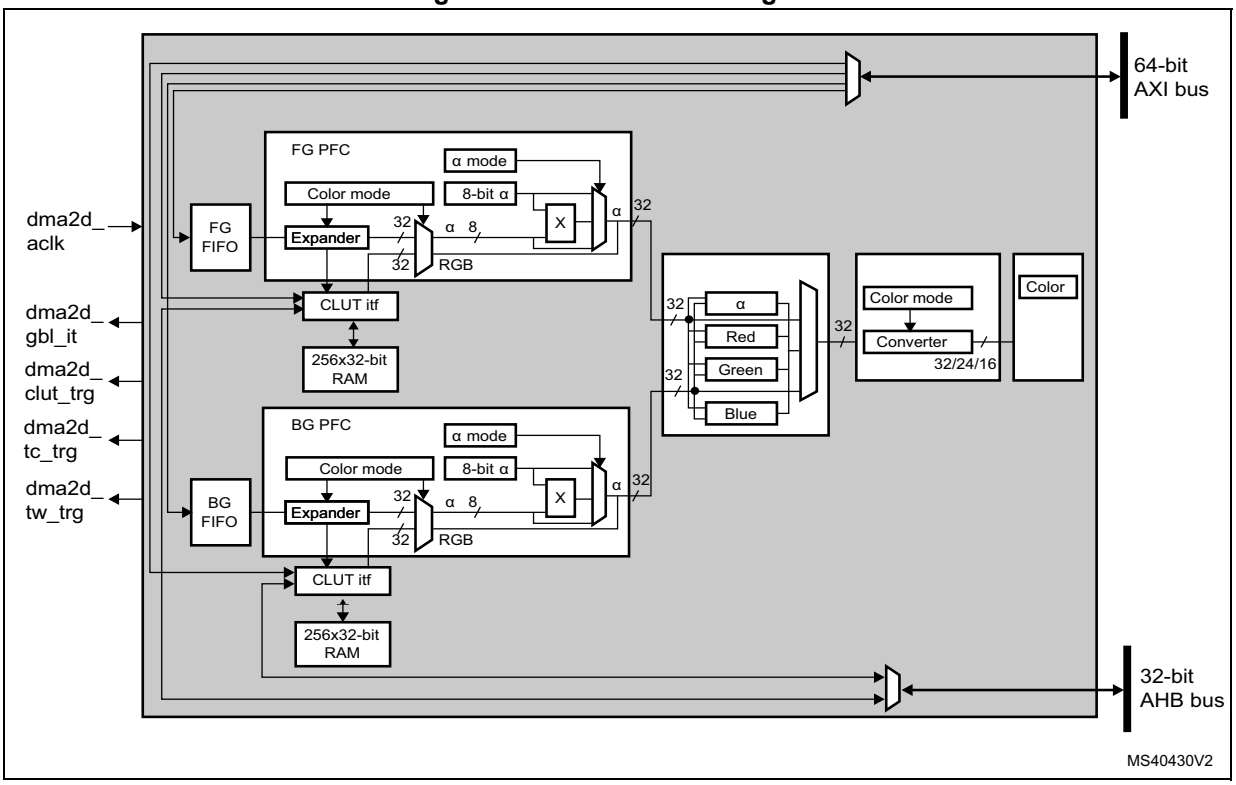
- Single AXI master bus architecture
- AHB slave programming interface supporting 8-,16-,32-bit accesses (except for CLUT accesses which are 32-bit)
- User-programmable working area size
- User-programmable offset for sources and destination areas expressed in pixels or bytes
- User-programmable sources and destination addresses on the whole memory space
- Up to two sources with blending operation
- Alpha value that can be modified (source value, fixed value, or modulated value)
- User programmable source and destination color format
- Up to 12 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to memory with pixel format conversion, blending and fixed color foreground, and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color

- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

18.3 DMA2D functional description

18.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.



The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with pixel format conversion
- Memory-to-memory with pixel format conversion and blending
- Memory-to-memory with pixel format conversion, blending and fixed color foreground
- Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in *Figure 92*.

Figure 92. DMA2D block diagram

18.3.2 DMA2D internal signals

The table below lists the DMA2D internal signals.

Table 112. DMA2D internal input/output signals

Signal name	Signal type	Description
dma2d_aclk	Input	64-bit AXI bus clock
dma2d_gbl_it	Output	DMA2D global interrupt
dma2d_clut_trg	Output	CLUT transfer complete (to MDMA)
dma2d_tc_trg	Output	Transfer complete (to MDMA)
dma2d_tw_trg	Output	Transfer watermark (to MDMA)

18.3.3 DMA2D control

The DMA2D controller is configured through DMA2D_CR. The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

18.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through the following control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated, and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

18.3.5 DMA2D foreground and background PFC

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first PFC stage converts the color format. The original color format of the foreground and background pixels are configured through CM[3:0] in DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

Table 113. Supported color mode in input

CM[3:0]	Color mode
0000	ARGB8888
0001	RGB888
0010	RGB565
0011	ARGB1555
0100	ARGB4444
0101	L8
0110	AL44
0111	AL88
1000	L4
1001	A8
1010	A4
1011	YCbCr (only for foreground)

The color format are coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

Table 114. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]
L8	L_3[7:0]	L_2[7:0]	L_1[7:0]	L_0[7:0]
AL44	A_3[3:0]L_3[3:0]	A_2[3:0]L_2[3:0]	A_1[3:0]L_1[3:0]	A_0[3:0]L_0[3:0]
AL88	A_1[7:0]	L_1[7:0]	A_0[7:0]	L_0[7:0]
L4	L_7[3:0]L_6[3:0]	L_5[3:0]L_4[3:0]	L_3[3:0]L_2[3:0]	L_1[3:0]L_0[3:0]
A8	A_3[7:0]	A_2[7:0]	A_1[7:0]	A_0[7:0]
A4	A_7[3:0]A_6[3:0]	A_5[3:0]A_4[3:0]	A_3[3:0]A_2[3:0]	A_1[3:0]A_0[3:0]

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR or DMA2D_BGPFCCR, as shown in *Table 115*.

One of the following happens for the alpha channel:

- It is kept as it is (no modification).
- It is replaced by ALPHA[7:0] value i nDMA2D_FGPFCCR/DMA2D_BGPFCCR.
- It is replaced by the original alpha value multiplied by ALPHA[7:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 115. Alpha mode configuration

AM[1:0]	Alpha mode
00	No modification
01	Replaced by value in DMA2D_xxPFCCR
10	Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255
11	Reserved

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the Alpha value stored in the DMA2D_FGPFCCR or DMA2D_BGPFCCR, and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the RGB order used in the CLUT, and in DMA2D_FGCOLR or DMA2D_BGCOLR.

18.3.6 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading

  The following sequence must be followed to load the CLUT:

  a) Program the CLUT address into DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

  b) Program the CLUT size with CS[7:0] field in DMA2D_FGPFCCR (foreground CLUT), or DMA2D_BGPFCCR (background CLUT).

  c) Set START in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading

  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped.The foreground CLUT (FGCLUT)

is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through CCM in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in table below.

Table 116. Supported CLUT color mode

CCM	CLUT color mode
0	32-bit ARGB8888
1	24-bit RGB888

The way the CLUT data are organized in the system memory is specified in the table below.

Table 117. CLUT data order in memory

CLUT Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]

18.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

18.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0] in DMA2D_OPFCCR.

Supported output formats are given in the table below

Table 118. Supported color mode in output

CM[2:0]	Color mode
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444

Note: To support the alternate format, the calculated alpha value can be inverted setting AI bit in DMA2D_OPFCCR. This applies also to the Alpha value used in DMA2D_OCOLR.

The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

18.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through the following registers:

- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR**)**
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR**)**

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

Table 119. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

18.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:

- RBS bit to swap red and blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, and the output memory address (MA field in DMA2D_OMAR) must be even. The output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must also be even. If not a configuration error is detected.

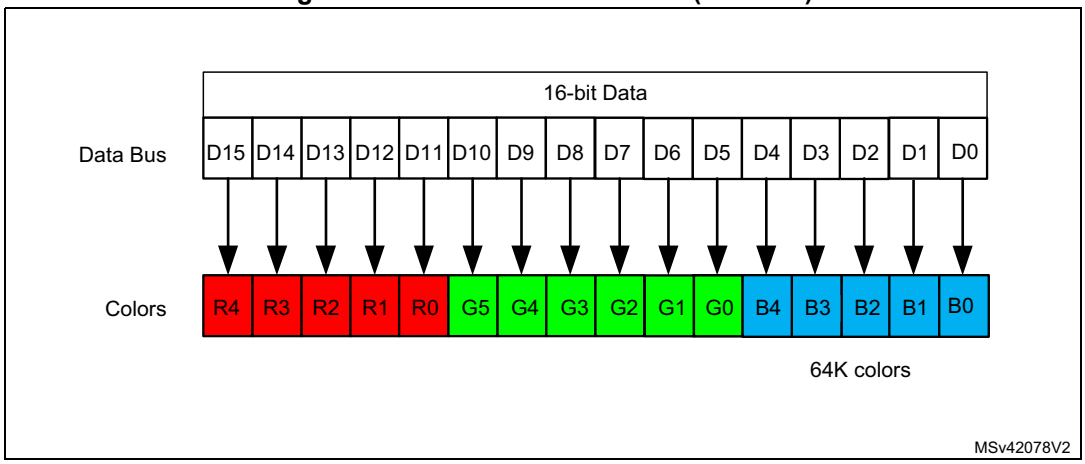


Table 120. Standard data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]

16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.

Figure 93. Intel 8080 16-bit mode (RGB565)

18/24-bit mode (RGB888)

This mode needs data reordering:

1. The red and the blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of an half-word must be swapped (setting SB bit).

Figure 94. Intel 8080 18/24-bit mode (RGB888)

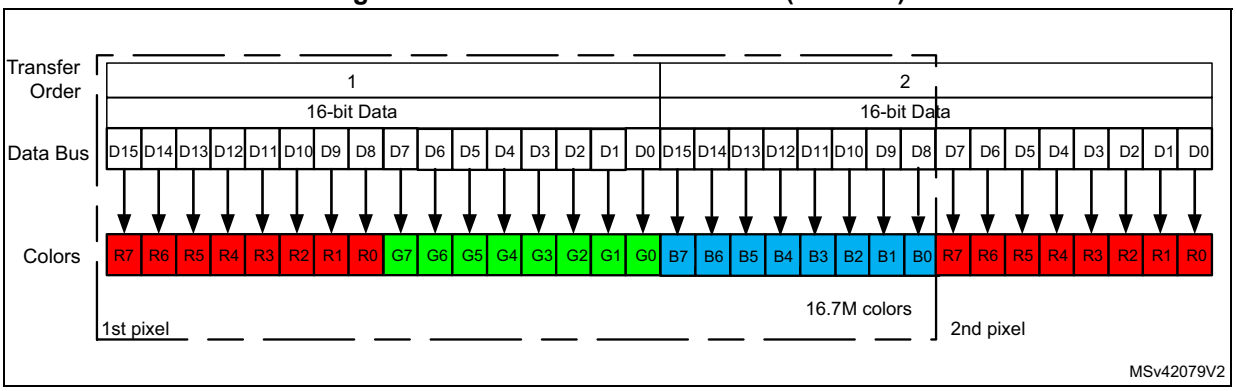

Table 121. Output FIFO byte reordering steps

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Original data ordering	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
Setting the RBS bit				
Data ordering after Red and Blue swap (RBS set)	R_1[7:0]	B_0[7:0]	G_0[7:0]	R_0[7:0]
	G_2[7:0]	R_2[7:0]	B_1[7:0]	G_1[7:0]
	B_3[7:0]	G_3[7:0]	R_3[7:0]	B_2[7:0]
Setting the SB bit				
Data ordering after byte swapping (SB set)	B_0[7:0]	R_1[7:0]	R_0[7:0]	G_0[7:0]
	R_2[7:0]	G_2[7:0]	G_1[7:0]	B_1[7:0]
	G_3[7:0]	B_3[7:0]	B_2[7:0]	R_3[7:0]

18.3.11 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar. This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and dead time value are configured through DMA2D_AMPTCR.

18.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. Number of data and width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:

1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR

3. Blending of all retrieved pixels according to the alpha channels resulting of PFC operation on alpha values
4. Pixel format conversion of resulting pixels according to DMA2D_OPFCCR and programming of data to the memory location addressed through DMA2D_OMAR

18.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR and defined in DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer, and data are transferred from the source memory location defined in DMA2D_FGMAR, to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data, and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR, and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.

If the original pixel format is direct-color mode, the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCCR.

Once the CLUT loading is complete, CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing, and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel.

The alpha value is modified as follows according to AM[1:0] in DMA2D_FGPFCCR:

- It is unchanged.
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR.
- It is replaced by the original value multiplied by ALPHA[7:0] value in DMA2D_FGPFCCR divided by 255.

The resulting 32-bit data are encoded by the output PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

Processed data are written into destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR respectively.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color FG

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color BG

In this mode, only open source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by DMA2D_BGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by their respective PFCs, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM is DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode, except in memory-to-memory with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with the CM in DMA2D_BGPFCCR
- Memory transfer (only in blending and blending with fixed color FG): CM bits in DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending and blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM inDMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending and blending with fixed color FG): LO bits in DMA2D_BGOR are odd while CM inDMA2D_BGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory): MA bits in DMA2D_OMAR are not aligned with CM in DMA2D_OPFCCR.
- Memory transfer (except in memory-to-memory): CM bits in DMA2D_OPFCCR are invalid.
- Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd, or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.
- Memory transfer: NL bits in DMA2D_NLR are all zeros.
- Memory transfer: PL bits in DMA2D_NLR are all zeros.
- Memory transfer: MODE bits in DMA2D_CR are invalid.
- YCbCr format: when a CLUT loading starts setting START in DMA2D_FGPFCCR
- YCbCr format: when memory-to-memory mode is selected
- YCbCr format: when YCbCR4:4:4 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 8 pixels
- YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 16 pixels

18.3.14 YCbCr support

The DMA2D foreground plane can support 8x8 block-based YCbCr as output by the JPEG decoder with different chroma subsampling factors.

The memory organization follows the standard JFIF rules:

- Each of the three color components must be coded on 8-bit.
- Each component must be arranged by blocks of 8x8 (64 bytes) called MCU.

Depending of the chroma subsampling factor, the MCU must be arranged in the memory as described in the table below.

Table 122. MCU order in memory

Sub-sampling	@	@ + 64	@ + 128	@+192	@+256	@ + 320
4:4:4	Y_1	Cb_1	Cr_1	Y_2	Cb_2	Cr_2
4:2:2	Y_1	Y_2	Cb_{12}	Cr_{12}	Y_3	Y_4
4:2:0	Y_1	Y_2	Y_3	Y_4	Cb_{1234}	Cr_{1234}

The chroma subsampling factor is configured through CSS in DMA2D_FGPFCCR.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first two chroma MCUs are loaded in the foreground CLUT. Once the chroma MCUs are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

18.3.15 DMA2D transfer control (start, suspend, abort, and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset, and TCIF flag is raised in DMA2D_ISR. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can be aborted by setting ABORT i nDMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using their own START bits in DMA2D_FGPFCCR and DMA2D_BGPFCCR.

18.3.16 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, TWIF flag is raised in DMA2D_ISR, and an interrupt is generated if TWIE is set in DMA2D_CR.

18.3.17 Error management

Two kind of errors can be triggered:

- AXI master port errors signaled by TEIF flag in DMA2D_ISR

- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF flag in DMA2D_ISR

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

18.3.18 AXI dead time

To limit the AXI bandwidth use, a dead time between two consecutive AXI accesses can be programmed. This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead-time value is stored in DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on AXI bus.

The update of the dead-time value while the DMA2D is running is taken into account for the next AXI transfer.

18.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Table 123. DMA2D interrupt requests

Interrupt event	Event flag	Enable control bit
Configuration error	CEIF	CEIE
CLUT transfer complete	CTCIF	CTCIE
CLUT access error	CAEIF	CAEIE
Transfer watermark	TWF	TWIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

18.5 DMA2D registers

18.5.1 DMA2D control register (DMA2D_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CEIE	CTCIE	CAEIE	TWIE	TCIE	TEIE	Res.	LOM	Res.	Res.	Res.	ABORT	SUSP	START
		rw	rw	rw	rw	rw	rw		rw				rs	rw	rs

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]**: DMA2D mode
This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.
000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with blending and fixed color BG (FG fetch only with FG and BG PFC active)
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error (CE) interrupt enable
This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete (CTC) interrupt enable
This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled

Bit 11 **CAEIE**: CLUT access error (CAE) interrupt enable
This bit is set and cleared by software.
0: CAE interrupt disabled
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark (TW) interrupt enable
This bit is set and cleared by software.
0: TW interrupt disabled
1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete (TC) interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error (TE) interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
This bit configures how the line offset is expressed (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is ongoing.
0: Line offsets expressed in pixels
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
This bit can be used to abort the current transfer. This bit is set by software, and is automatically reset by hardware when START = 0.
0: No transfer abort requested
1: Transfer abort requested

Bit 1 **SUSP**: Suspend
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when START = 0.
0: Transfer not suspended
1: Transfer suspended

Bit 0 **START**: Start
This bit can be used to launch the DMA2D according to parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
- at the end of the transfer
- when the data transfer is aborted by the user by setting ABORT in this register
- when a data transfer error occurs
- when the data transfer has not started due to a configuration error, or another transfer operation already ongoing (automatic CLUT loading)

18.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEIF	CTCIF	CAEIF	TWIF	TCIF	TEIF
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CEIF**: Configuration error interrupt flag
This bit is set when START is set in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCCR, and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

18.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCEIF	CCTCIF	CAECIF	CTWIF	CTCIF	CTEIF
										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears the CEIF flag in DMA2D_ISR.

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag
Programming this bit to 1 clears the CTCIF flag in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears the CAEIF flag in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears the TWIF flag in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears the TCIF flag in DMA2D_ISR.

Bit 0 **CTEIF**: Clear transfer error interrupt flag
Programming this bit to 1 clears the TEIF flag in DMA2D_ISR.

18.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the foreground image

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned, and a 4-bit per pixel format must be 8-bit aligned.

18.5.5 DMA2D foreground offset register (DMA2D_FGOR)

Address offset: 0x010

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the foreground image, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

18.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x014

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the background image

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

18.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x018

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the background image, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

18.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x01C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	CSS[1:0]		AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied by the original alpha value, according to the alpha mode selected through AM[1:0] in this register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap

This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha inverted

This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:18 **CSS[1:0]**: Chroma subsampling

These bits define the chroma subsampling mode for YCbCr color mode.
00: 4:4:4 (no chroma subsampling)
01: 4:2:2
10: 4:2:0
Others: Reserved

Bits 17:16 **AM[1:0]**: Alpha mode

These bits select the alpha channel value to be used for the foreground image.
00: No modification of the foreground image alpha channel value
01: Replace original foreground image alpha channel value by ALPHA[7: 0]
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size

These bits define the size of the CLUT used for the foreground image.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode

This bit defines the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode

These bits defines the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
1011: YCbCr
Others: Reserved

18.5.9 DMA2D foreground color register (DMA2D_FGCOLR)

Address offset: 0x020

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the foreground image

Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the foreground image

Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

18.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x024

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	Res.	Res.	AM[1:0]

CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0].

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode
These bits define which alpha channel value to be used for the background image.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7: 0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the BG.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode

These bits define the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode

These bits define the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
Others: Reserved

18.5.11 DMA2D background color register (DMA2D_BGCOLR)

Address offset: 0x028

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the background

Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the background

Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

18.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x02C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the foreground image.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

18.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)

Address offset: 0x030

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the background image.
If the background CLUT format is 32-bit, the address must be 32-bit aligned.

18.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)

Address offset: 0x034

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RBS	AI	Res.	Res.	Res.	Res.
										rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SB	Res.	Res.	Res.	Res.	Res.	CM[2:0]		
							rw						rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:9 Reserved, must be kept at reset value.

Bit 8 **SB**: Swap bytes
When this bit is set, the bytes in the output FIFO are swapped two by two. The number of pixels per line (PL) must be even, and the output memory address (OMAR) must be even.
0: Bytes in regular order in the output FIFO
1: Bytes swapped two by two in the output FIFO

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **CM[2:0]**: Color mode
These bits define the color format of the output image.
000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
Others: Reserved

18.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB8888 or RGB888 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								RED[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha channel value of the output color in ARGB8888 mode (otherwise reserved)

Bits 23:16 **RED[7:0]**: Red value of the output image in ARGB8888 or RGB888 mode

Bits 15:8 **GREEN[7:0]**: Green value of the output image in ARGB8888 or RGB888

Bits 7:0 **BLUE[7:0]**: Blue value of the output image in ARGB8888 or RGB888

18.5.16 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

RGB565 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RED[4:0]					GREEN[5:0]						BLUE[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:11 **RED[4:0]**: Red value of the output image in RGB565 mode

Bits 10:5 **GREEN[5:0]**: Green value of the output image in RGB565 mode

Bits 4:0 **BLUE[4:0]**: Blue value of the output image in RGB565 mode

18.5.17 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB1555 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A	RED[4:0]					GREEN[4:0]					BLUE[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **A**: Alpha channel value of the output color in ARGB1555 mode

Bits 14:10 **RED[4:0]**: Red value of the output image in ARGB1555 mode

Bits 9:5 **GREEN[4:0]**: Green value of the output image in ARGB1555 mode

Bits 4:0 **BLUE[4:0]**: Blue value of the output image in ARGB1555 mode

18.5.18 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB4444 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALPHA[3:0]				RED[3:0]				GREEN[3:0]				BLUE[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **ALPHA[3:0]**: Alpha channel of the output color value in ARGB4444

Bits 11:8 **RED[3:0]**: Red value of the output image in ARGB4444 mode

Bits 7:4 **GREEN[3:0]**: Green value of the output image in ARGB4444 mode

Bits 3:0 **BLUE[3:0]**: Blue value of the output image in ARGB4444 mode

18.5.19 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the output FIFO.

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

18.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the output, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

18.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **PL[13:0]**: Pixel per lines per lines of the area to be transferred
If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines of the area to be transferred.

18.5.22 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LW[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LW[15:0]**: Line watermark for interrupt generation
An interrupt is raised when the last pixel of the watermarked line has been transferred.

18.5.23 DMA2D AXI master timer configuration register (DMA2D_AMTCR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DT[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN
rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DT[7:0]**: Dead time

Dead time value in the AXI clock cycle inserted between two consecutive accesses on the AXI master port. These bits represent the minimum guaranteed number of cycles between two consecutive AXI accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Dead-time functionality enable

18.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx)

Address offset: 0x400 + 0x4 * x, (x = 0 to 255)

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								RED[7:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha

Alpha value for index {x} for the foreground

Bits 23:16 **RED[7:0]**: Red

Red value for index {x} for the foreground

Bits 15:8 **GREEN[7:0]**: Green

Green value for index {x} for the foreground

Bits 7:0 **BLUE[7:0]**: Blue

Blue value for index {x} for the foreground

18.5.25 DMA2D background CLUT (DMA2D_BGCLUTx)

Address offset: 0x800 + 0x4 * x, (x = 0 to 255)

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								RED[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**:Alpha
Alpha value for index {x} for the background

Bits 23:16 **RED[7:0]**: Red
Red value for index {x} for the background

Bits 15:8 **GREEN[7:0]**: Green
Green value for index {x} for the background

Bits 7:0 **BLUE[7:0]**: Blue
Blue value for index {x} for the background

18.5.26 DMA2D register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

19 Nested vectored interrupt controller (NVIC)

19.1 NVIC features

The NVIC includes the following features:

- up to 154 maskable interrupt channels for STM32H7A3/7B3 and STM32H7B0 (not including the 16 interrupt lines of Cortex®-M7 with FPU)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex®-M7.

19.1.1 SysTick calibration value register

The SysTick calibration value (SYST_CALIB) is fixed to 0x3E8. It provides a reference timebase of 1 ms based when the SysTick clock frequency is 1 MHz. To match the 1 ms timebase whatever the application frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- The SysTick clock source is the 100 MHz CPU clock (HCLK):

$$\text{reload value} = (F_{HCLK} \times \text{SYST_CALIB}) - 1$$

- or the SysTick clock source is an external clock:

$$\text{reload value} = ((F_{HCLK} / 8) \times \text{SYST_CALIB}) - 1$$

  where F_{HCLK} refers to the AHB frequency expressed in MHz.

For example, to achieve a timebase of 1 ms when the SysTick clock source is the 100 MHz HCLK:

$$\text{reload value} = (100 \times \text{SYST_CALIB}) - 1 = 0\text{x}1869\text{F}$$

19.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, Bus Fault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

Table 125. NVIC(1)

Signal	Priority	NVIC position	Acronym	Description	Address offset
-	-	-	-	Reserved	0x0000 0000

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.

20 Extended interrupt and event controller (EXTI)

The Extended Interrupt and event controller (EXTI) manages wakeup through configurable and direct event inputs. It provides wakeup requests to the power controller (PWR), and generates interrupt requests to the CPU NVIC and to the SRD domain DMAMUX2, and events to the CPU event input.

The EXTI wakeup requests allow the system to be woken up from Stop mode, and the CPU to be woken up from CStop mode.

In addition, both the interrupt request and event request generation can be used in Run mode.

20.1 EXTI main features

The EXTI main features are the following:

- All event inputs allow the CPU to wake up and to generate a CPU interrupt and/or a CPU event
- Some event inputs allow the user to wake up the SRD domain for Autonomous run mode and generate an interrupt to the SRD domain, i.e. the DMAMUX2

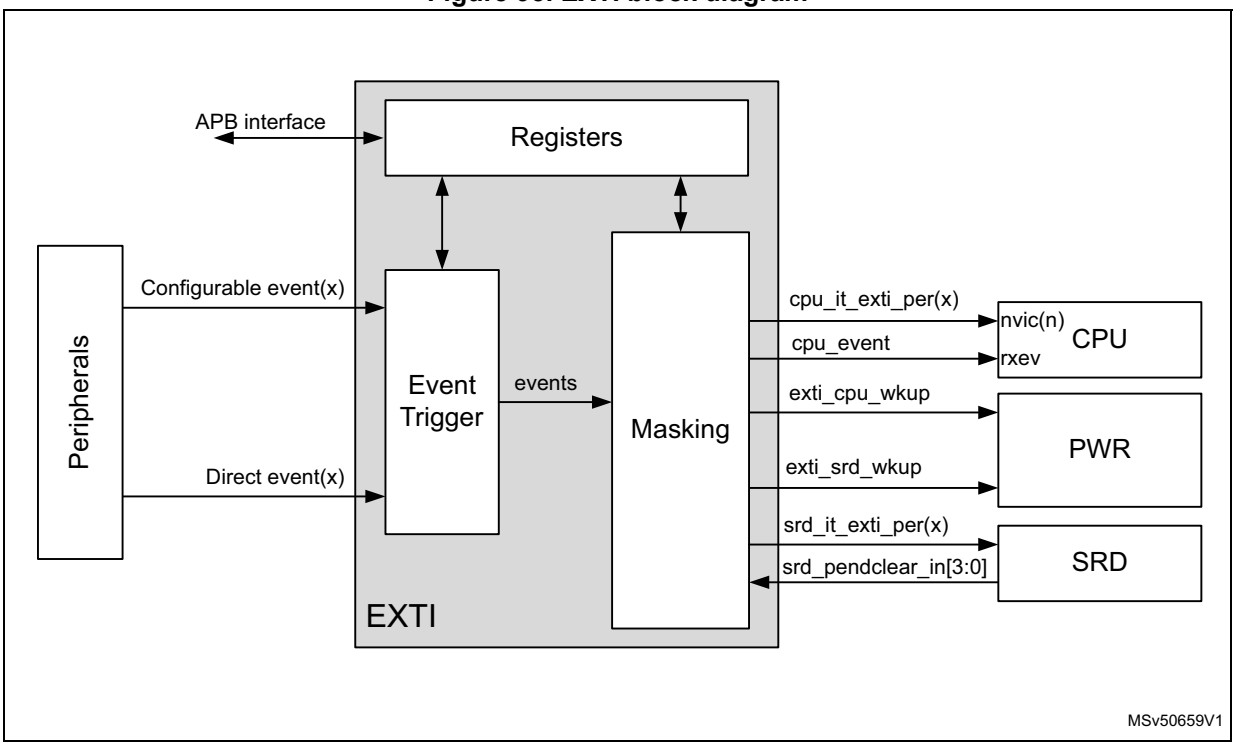
The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), that have the following features:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual Interrupt and event generation mask
  - Software trigger capability
  - Configurable system SRD domain wakeup events.

    They have an SRD pending mask and a status register, and may have an SRD interrupt signal.
- Direct events (interrupt and wakeup sources from other peripherals, requiring to be cleared in the peripheral)

  Direct events feature:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask
  - No software trigger capability
  - Direct system SRD domain wakeup events have an SRD pending mask and status register, and may have an SRD interrupt signal

20.2 EXTI block diagram



As shown in *Figure 95*, the EXTI consists of a register block accessed via an APB interface, an event input trigger block, and a masking block.

The register block contains all EXTI registers.

The event input trigger block provides event input edge triggering logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, as well as their masking.

Figure 95. EXTI block diagram

20.2.1 EXTI connections between peripherals, CPU and SRD domain

The peripherals able to generate wakeup events when the system is in Stop mode or the CPU is in CStop mode are connected to an EXTI configurable event input or direct event input:

- Peripheral signals that generate a pulse are connected to an EXTI configurable event input. For these events, the EXTI provides a CPU status pending bit that has to be cleared.
- Peripheral interrupt and wakeup sources that have to be cleared in the peripheral are connected to an EXTI direct event input. There is no CPU status pending bit within the EXTI. The Interrupt or Wakeup is cleared by the CPU in the peripheral.

The event inputs able to wakeup SRD for Autonomous run mode are provided with an SRD domain pending request function, that has to be cleared. This clearing request is taken care of by the signal selected by the pending clear selection.

The CPU interrupts are connected to their respective CPU NVIC. Similarly, the CPU event is connected to the CPU rxev input.

The EXTI wakeup signals are connected to the PWR block. They are used to wake up the SRD domain and/or the CPU.

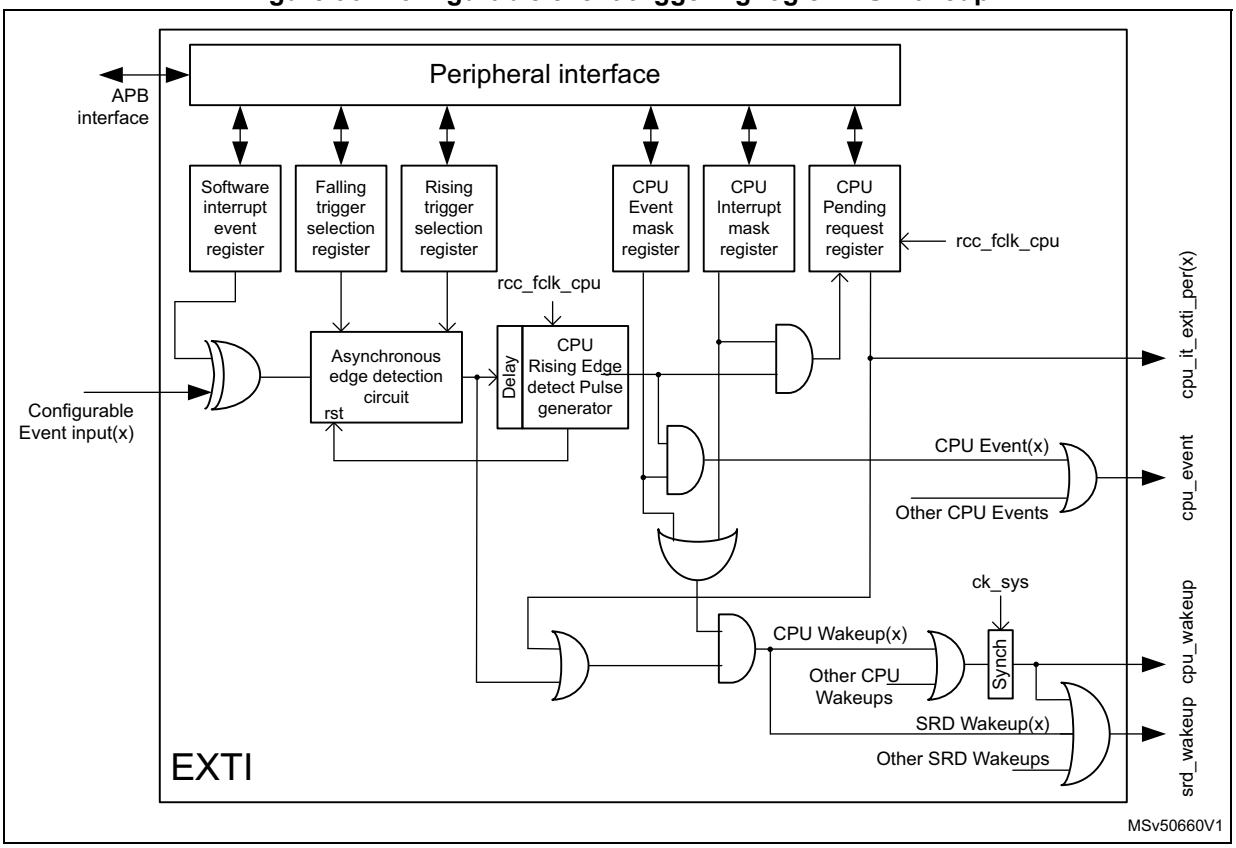
The SRD domain interrupts allow the system to trigger events for SRD domain Autonomous run operations.

20.3 EXTI functional description

Different logic implementations can be used, depending on the EXTI event input type and wakeup target(s). The applicable features are controlled from register bits:

- Active trigger edge enable, by *EXTI rising trigger selection register (EXTI_RTSR1)*, *EXTI rising trigger selection register (EXTI_RTSR2)*, *EXTI rising trigger selection register (EXTI_RTSR3)*, and *EXTI falling trigger selection register (EXTI_FTSR1)*, *EXTI falling trigger selection register (EXTI_FTSR2)*, *EXTI falling trigger selection register (EXTI_FTSR3)*
- Software trigger, by *EXTI software interrupt event register (EXTI_SWIER1)*, *EXTI software interrupt event register (EXTI_SWIER2)*, *EXTI software interrupt event register (EXTI_SWIER3)*
- CPU Interrupt enable, by *EXTI interrupt mask register (EXTI_CPUIMR1)*, *EXTI interrupt mask register (EXTI_CPUIMR2)*, *EXTI interrupt mask register (EXTI_CPUIMR3)*
- CPU Event enable, by *EXTI event mask register (EXTI_CPUEMR1)*, *EXTI event mask register (EXTI_CPUEMR2)*, *EXTI event mask register (EXTI_CPUEMR3)*
- SRD domain wakeup pending, by *EXTI SRD pending mask register (EXTI_SRDPMR1)*, *EXTI SRD pending mask register (EXTI_SRDPMR2)*, *EXTI SRD pending mask register (EXTI_SRDPMR3)*

Table 126. EXTI event input configurations and register control(1)



Event input type	Wakeup target(s)	Logic implementation	EXTI_RTSR	EXTI_FTSR	EXTI_SWIER	EXTI_CPUIMR	EXTI_CPUEMR	EXTI_SRDPMR
Configurable	CPU	Configurable event input, CPU wakeup logic	X	X	X	X	X	-
	Any(2)	Configurable event input, Any wakeup logic						X
Direct	CPU	Direct event input, CPU wakeup logic	-	-	-	X	X	-
	Any(2)	Direct event input, Any wakeup logic						X

1. X indicates that the functionality is available.
2. Waking up SRD domain for Autonomous run mode and/or CPU.

20.3.1 EXTI configurable event input CPU wakeup

Figure 97 provides a detailed representation of the logic associated to the configurable event inputs that always wake up the CPU.

Figure 96. Configurable event triggering logic CPU wakeup

The software interrupt event register allows the system to trigger configurable events by software, writing the *EXTI software interrupt event register (EXTI_SWIER1)*, the *EXTI software interrupt event register (EXTI_SWIER2)*, or the *EXTI software interrupt event register (EXTI_SWIER3)* register bit.

The rising edge *EXTI rising trigger selection register (EXTI_RTSR1)*, *EXTI rising trigger selection register (EXTI_RTSR2)*, *EXTI rising trigger selection register (EXTI_RTSR3)*, and falling edge *EXTI falling trigger selection register (EXTI_FTSR1)*, *EXTI falling trigger selection register (EXTI_FTSR2)*, *EXTI falling trigger selection register (EXTI_FTSR3)* selection registers allow the system to enable and select the configurable event active trigger edge or both edges.

The devices feature dedicated interrupt mask registers, namely *EXTI interrupt mask register (EXTI_CPUIMR1)* and *EXTI interrupt mask register (EXTI_CPUIMR2)*, *EXTI interrupt mask register (EXTI_CPUIMR3)*, and *EXTI pending register (EXTI_CPUPR1)*, *EXTI pending register (EXTI_CPUPR2)*, *EXTI pending register (EXTI_CPUPR3)* for configurable events pending request registers. The CPU pending register is only set for an unmasked CPU interrupt. Each event provides a individual CPU interrupt to the CPU NVIC. The configurable event interrupts need to be acknowledged by software in the EXTI_CPUPR register.

The devices feature dedicated event mask registers, i.e. *EXTI event mask register (EXTI_CPUEMR1)*, *EXTI event mask register (EXTI_CPUEMR2)*, and *EXTI event mask register (EXTI_CPUEMR3)*. The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU pending register (EXTI_CPUPR) is not set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the asynchronous edge detection circuit is reset.

Note: A detected configurable event, enabled by the CPU, is only cleared when the CPU wakes up.

20.3.2 EXTI configurable event input Any wakeup

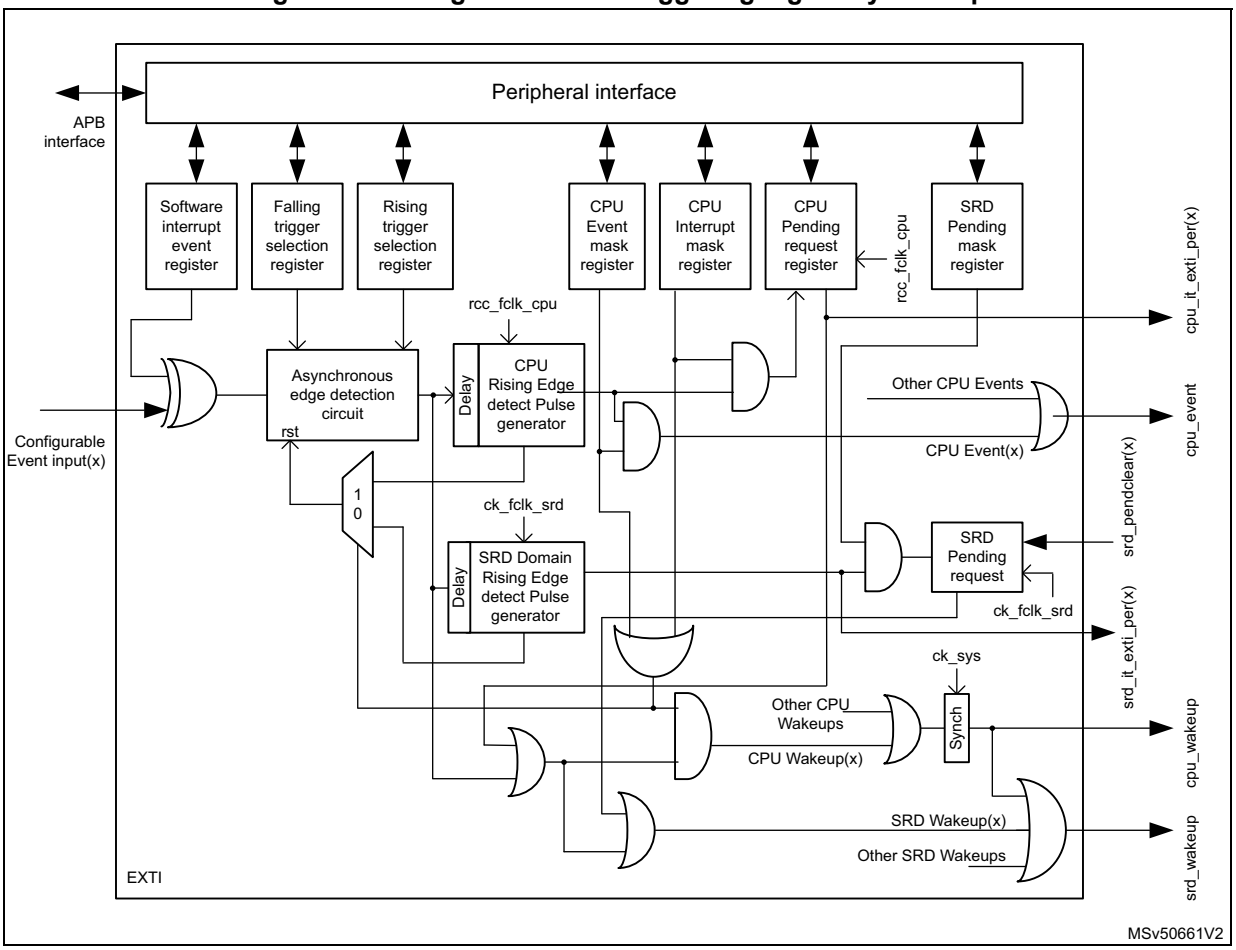


Figure 97 provides a detailed description of the logic associated to the configurable event inputs that can wake up SRD domain for Autonomous run mode and/or CPU (“Any” target). It provides the same functionality as the configurable event input CPU wakeup, with additional functionality to wake up the SRD domain independently.

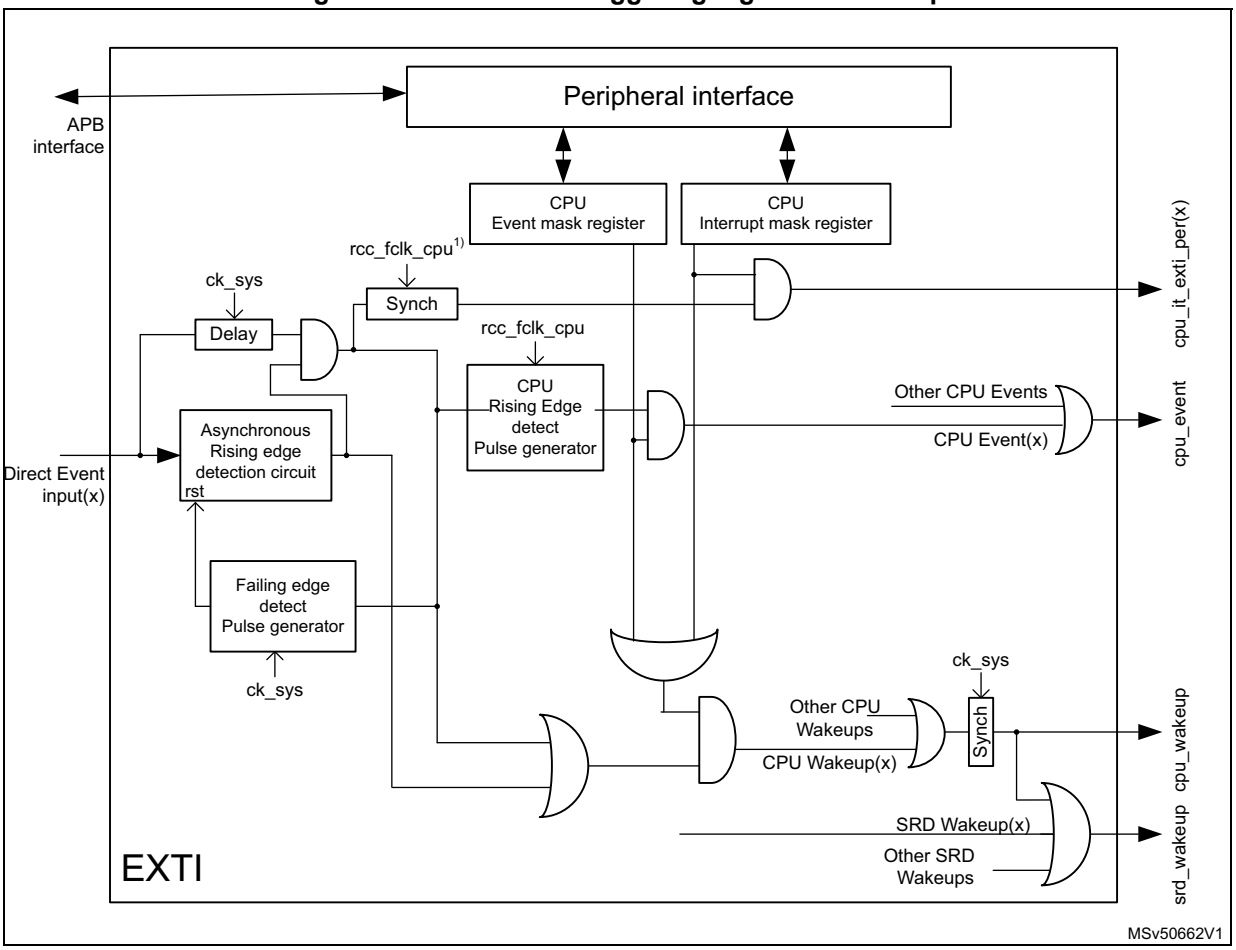
When all CPU interrupts and CPU events are disabled, the asynchronous edge detection circuit is reset by the SRD domain clocked delay and rising edge detect pulse generator. This guarantees that the SRD domain clock is woken up before the asynchronous edge detection circuit is reset.

Table 127. Configurable event input asynchronous edge detector reset

EXTI_C1IMR	EXTI_C1EMR	Asynchronous Edge detector reset by
Both = 0		SRD domain clock rising edge detect pulse generator
At least one = 1		CPU clock rising edge detect pulse generator

Figure 97. Configurable event triggering logic Any wakeup



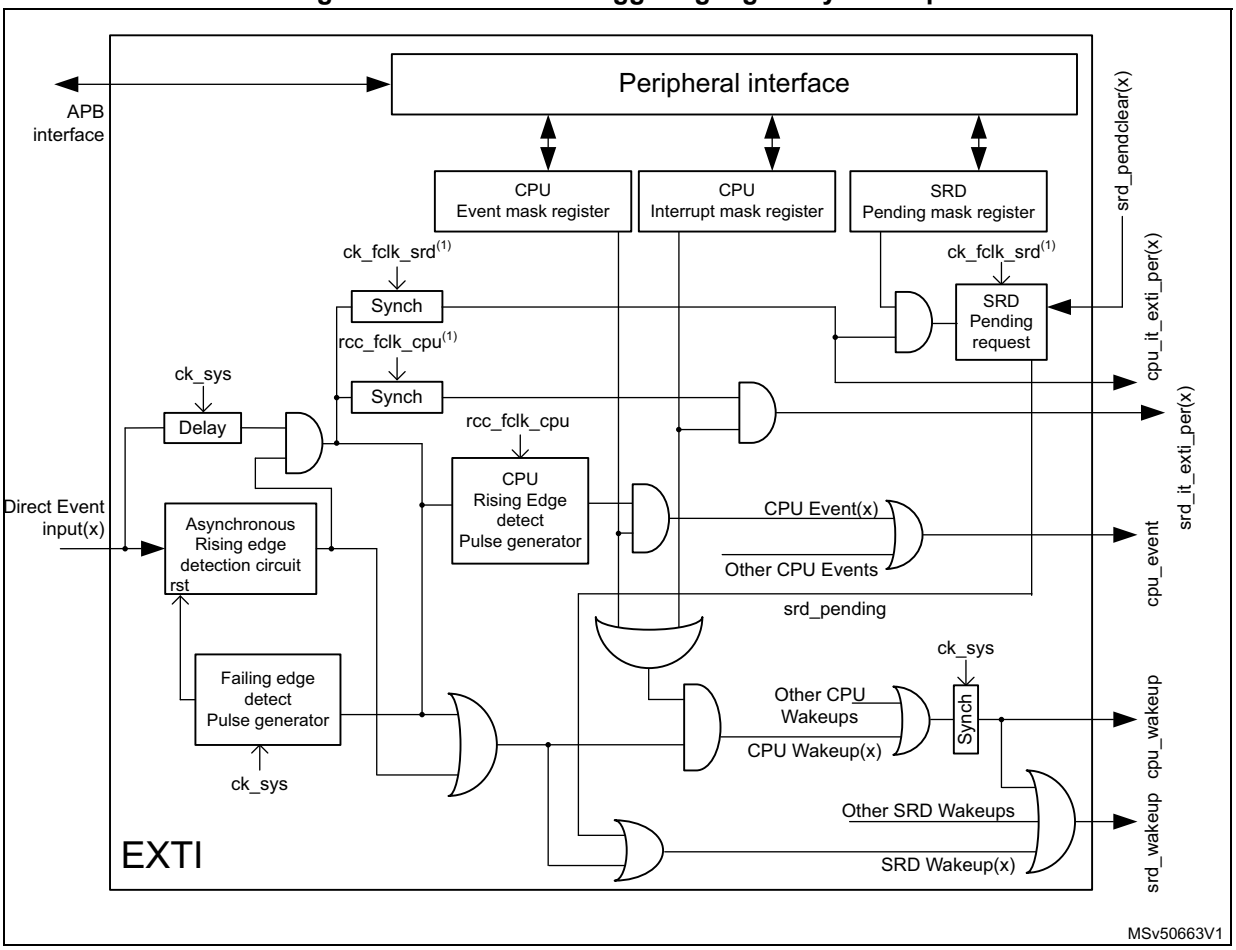
The event triggering logic for “Any” target has additional SRD pending mask register *EXTI SRD pending mask register (EXTI_SRDPMR1)*, *EXTI SRD pending mask register (EXTI_SRDPMR2)*, *EXTI SRD pending mask register (EXTI_SRDPMR3)* and SRD pending request logic. The SRD pending request logic is only set for unmasked SRD pending events. The SRD pending request logic keeps the SRD domain in Run mode until the SRD pending request logic is cleared by the selected SRD domain pendclear source.

20.3.3 EXTI direct event input CPU wakeup

Figure 98 provides a detailed description of the logic associated with the direct event inputs that wake up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

Figure 98. Direct event triggering logic CPU wakeup



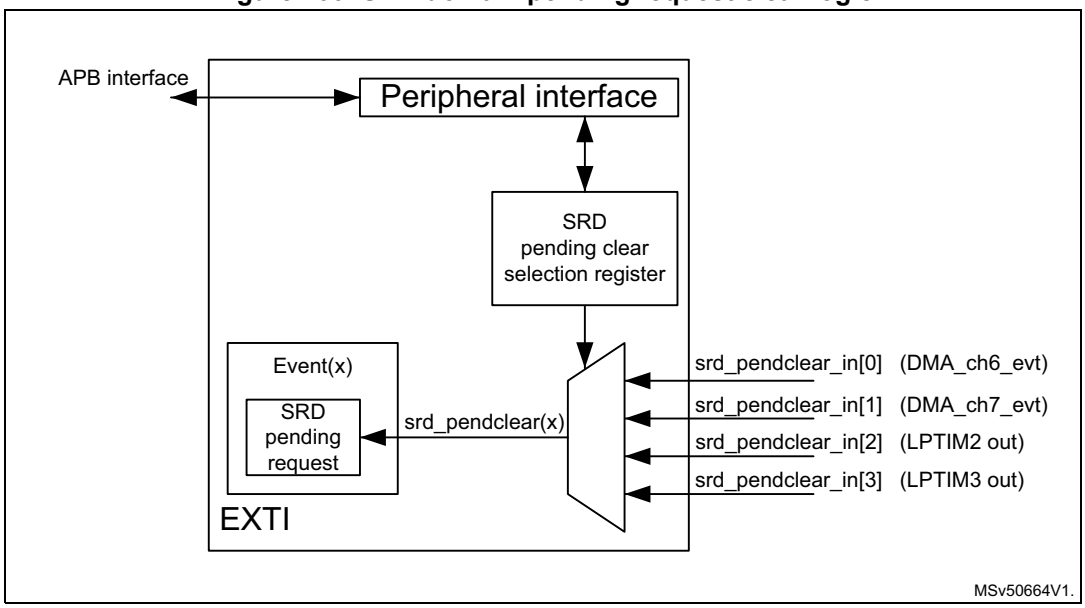
1. The CPU interrupt for asynchronous direct event inputs (peripheral wakeup signals) is synchronized with the CPU clock. The synchronous direct event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.

20.3.4 EXTI direct event input Any wakeup

Figure 99 provides a detailed description of the logic associated to the direct event inputs that wake up SRD domain for Autonomous run mode and/or CPU, (“Any” target). It provides the same functionality as the direct event input CPU wakeup, plus additional functionality to wakeup the SRD domain independently.

Figure 99. Direct event triggering logic Any wakeup

1. The CPU interrupt and SRD domain interrupt for asynchronous direct event inputs (peripheral wakeup signals) are synchronized with the CPU clock and the SRD domain clock, respectively. The synchronous direct event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt and the SRD domain interrupt without resynchronization in the EXTI.



20.3.5 EXTI SRD pending request clear selection

The SRD pending request logic of the event inputs that are able to wake up SRD domain for Autonomous run mode can be cleared by the selected SRD pendclear source.

For each SRD pending request, an SRD domain pendclear source can be selected from four different inputs.

Figure 100 provides a detailed description of the SRD pendclear source selection logic.

Figure 100. SRD domain pending request clear logic

The SRD pending request clear selection registers *EXTI SRD pending clear selection register low (EXTI_SRDPCR1L)*, *EXTI SRD pending clear selection register high (EXTI_SRDPCR1H)*, *EXTI SRD pending clear selection register low (EXTI_SRDPCR2L)*, *EXTI SRD pending clear selection register high (EXTI_SRDPCR2H)* and *EXTI SRD pending clear selection register high (EXTI_SRDPCR3H)* allow the system to select the source to reset the SRD pending request.

20.4 EXTI event input mapping

For the sixteen GPIO event inputs, the associated GPIO pin has to be selected in the SYSCFG_EXTICRn register. The same pin from each GPIO maps to the corresponding EXTI event input.

The wakeup capabilities of each event input are detailed in *Table 128*. An event input can wake up the CPU, and in the case of “Any” can also wake up SRD domain for Autonomous run mode.

The EXTI event inputs that are connected to the CPU NVIC are indicated in the *Connection to NVIC* column. For the EXTI events that do not have a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI event inputs are OR-ed together and connected to the CPU event input (rxev).

Table 128. EXTI Event input mapping

Event input	Source	Event input type	Wakeup target(s)	Connection to NVIC
0 - 15	EXTI[15:0]	Configurable	Any	Yes
16	PVD and AVD(1)	Configurable	CPU only	Yes
17	RTC alarms	Configurable	CPU only	Yes

Table 128. EXTI Event input mapping (continued)

Event input	Source	Event input type	Wakeup target(s)	Connection to NVIC
84	Reserved	-	-	-
85	HDMI-CEC wakeup	Configurable	CPU only	Yes
86	Reserved	-	-	-
87	HSECSS interrupt	Direct	CPU only	No(5)
88	TEMP wakeup	Direct	Any	Yes

1. PVD and AVD signals are OR-ed together on the same EXTI event input.
2. RTC Tamper, RTC timestamp and RCC LSECSS signals are OR-ed together on the same EXTI event input.
3. Not available on CPU NVIC, to be used for system wakeup only or CPU event input (rxev).
4. Signals of WKUP1 to WKUP6 correspond to WKUPn pin+1.
5. Available on CPU NVIC directly from the peripheral.

20.5 EXTI functional behavior

The direct event inputs are enabled in the respective peripheral that generating the event. The configurable events are enabled by enabling at least one of the trigger edges.

In Stop mode, an event always wakes up the SRD domain.

In system Run and Stop modes, an event always generates an associated SRD domain interrupt. An event only wakes up the CPU when the event associated CPU interrupt is unmasked and/or the CPU event is unmasked.

Table 129. Masking functionality

CPU		Configurable event inputs PRx bits of EXTI_CPUPR	CPU			SRD domain wakeup
Interrupt enable MRx bits of EXTI_CPUIMR	Event enable MRx bits of EXTI_CPUEMR		Interrupt	Event	Wakeup	
0	0	No	Masked	Masked	Masked	Yes(1) / Masked(2)
0	1	No	Masked	Yes	Yes	Yes
1	0	Status latched	Yes	Masked	Yes	Yes
1	1	Status latched	Yes	Yes	Yes	Yes

1. Only for event inputs that allow the system to wake up SRD domain for Autonomous run mode (Any target).
2. For event inputs that always wake up the CPU.

For configurable event inputs, an event request is generated when the enabled edge(s) is/are detected on the event input. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_CPUPR is set and the CPU interrupt signal is activated. EXTI_CPUPR PRx pending bit must be cleared by software by programming it to 1. This clears the CPU interrupt.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked, the corresponding CPU interrupt signal is activated.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) is/are detected on the event input, a CPU event pulse is generated. There is no CPU event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same event input. They both trigger the same event input condition(s).

For configurable event inputs, an event input request can be generated by software by writing 1 in the software interrupt/event register EXTI_SWIER.

Whenever an event input is enabled and a CPU interrupt and/or CPU event is unmasked, the event input also generates an SRD domain wakeup next to the CPU wakeup.

Some event inputs can wake up the SRD domain Autonomous run mode. In this case the CPU interrupt and CPU event are masked, preventing the CPU to be woken up. Two SRD domain Autonomous run mode wakeup mechanisms are supported:

- SRD domain wakeup without pending (EXTI_SRDPMR = 0)
  - On a configurable event input, this mechanism wakes up SRD domain and automatically clears the SRD domain wakeup signal after the delay + rising edge detect pulse generator.
  - On a direct event input, this mechanism wakes up SRD domain and clears the SRD domain wakeup signal after the direct event input signal is cleared.
- SRD domain wakeup with pending (EXTI_SRDPMR = 1)
  - On a configurable event input, this mechanism wakes up SRD domain and clears the SRD domain wakeup signal after the delay + rising edge detect pulse generator and when the SRD pending request is cleared.
  - On a direct event input, this mechanism wakes up SRD domain and clears the SRD domain wakeup signal after the direct event input signal is cleared and when the SRD pending request is cleared.

20.5.1 EXTI CPU interrupt procedure

1. Unmask the event input interrupt by setting the corresponding mask bits in the EXTI_CPUIMR register.
2. For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
3. Enable the associated interrupt source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal can be detected by the CPU after a WFI/WFE instruction.

   For configurable event inputs, the associated EXTI pending bit needs to be cleared.

20.5.2 EXTI CPU event procedure

1. Unmask the event input by setting the corresponding mask bits of the EXTI_CPUEMR register.
2. For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
3. The CPU event signal is detected by the CPU after a WFE instruction.

   For configurable event inputs, there is no EXTI pending bit to clear.

20.5.3 EXTI CPU wakeup procedure

1. Unmask the event input by setting at least one of the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers. The CPU wakeup is generated at the same time as the unmasked CPU interrupt and/or CPU event.
2. For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
3. Direct events automatically generate a CPU wakeup.

20.5.4 EXTI SRD domain wakeup for Autonomous run mode procedure

1. Mask the event input for waking up the CPU by clearing both the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers.
2. For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
3. Direct events automatically generate an SRD domain wakeup.
4. Select the SRD domain wakeup mechanism in EXTI_SRDPMR.
   - When SRD domain wakeup without pending (EXTI_PMR = 0) is selected, the Wakeup is automatically cleared following the clearing of the event input.
   - When SRD domain wakeup with pending (EXTI_PMR = 1) is selected, the Wakeup needs to be cleared by a selected SRD domain pendclear source.

     A pending SRD domain wakeup signal can also be cleared by firmware by clearing the associated EXTI_SRDPMR register bit.
5. An SRD domain interrupt is generated after the SRD domain wakeup:
   - Configurable event inputs generate a pulse on SRD domain interrupt.
   - Direct event inputs activate the SRD domain interrupt until the event input is cleared in the peripheral.

20.5.5 EXTI software interrupt/event trigger procedure

Any of the configurable event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event shall be enabled by their respective procedure). Follow the steps below:

1. Enable the event input by setting at least one of the corresponding edge trigger bits in the EXTI_RTSR and/or EXTI_FTSR registers.
2. Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers.
3. Trigger the software interrupt/event by writing 1 to the corresponding bit in the EXTI_SWIER register.
4. The event input can be disabled by clearing the EXTI_RTSR and EXTI_FTSR register bits.

Note: An edge on the configurable event input also triggers an interrupt/event.

A software trigger can be used to set the SRD pending request logic, keeping the SRD domain in Run until the SRD pending request logic is cleared.

20.6 EXTI registers

EXTI registers can only be accessed in 32-bit (word) mode. Byte or half-word formats are not allowed.

20.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR21	TR20	TR19	TR18	TR17	TR16
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TR15	TR14	TR13	TR12	TR11	TR10	TR9	TR8	TR7	TR6	TR5	TR4	TR3	TR2	TR1	TR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **TR[21:0]:** Rising trigger event configuration bit of configurable event input x (x= 21 to 0)

0: Rising trigger disabled (for event and Interrupt) for input line

1: Rising trigger enabled (for event and Interrupt) for input line

Note: The configurable event inputs are edge triggered, no glitch must be generated on these inputs.

If a rising edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

20.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR21	TR20	TR19	TR18	TR17	TR16
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TR15	TR14	TR13	TR12	TR11	TR10	TR9	TR8	TR7	TR6	TR5	TR4	TR3	TR2	TR1	TR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **TR[21:0]:** Falling trigger event configuration bit of configurable event input x (x= 21 to 0)

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

Note: The configurable event inputs are edge triggered, no glitch must be generated on these inputs.

If a falling edge on the configurable event input occurs while writing to the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same Configurable event input. In this case, both edges generate a trigger.

20.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWIER 21	SWIER 20	SWIER 19	SWIER 18	SWIER 17	SWIER 16
										rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWIER 15	SWIER 14	SWIER 13	SWIER 12	SWIER 11	SWIER 10	SWIER 9	SWIER 8	SWIER 7	SWIER 6	SWIER 5	SWIER 4	SWIER 3	SWIER 2	SWIER 1	SWIER 0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **SWIER[21:0]:** Software interrupt on line x (x = 21 to 0)

This bitfield always returns 0 when read.

0: Writing 0 has no effect.

1: Writing a 1 to this bit will trigger an event on line x.

This bit is automatically cleared by hardware.

20.6.4 EXTI SRD pending mask register (EXTI_SRDPMR1)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	MR25	Res.	Res.	Res.	MR21	MR20	MR19	Res.	Res.	Res.
						rw				rw	rw	rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR15	MR14	MR13	MR12	MR11	MR10	MR9	MR8	MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **MR25:** SRD pending mask on event input x (x =25)

0: SRD pending request from line x is masked. Writing this bit to 0 also clears the SRD Pending request.

1: SRD pending request from line x is unmasked. When triggered, the SRD domain pending signal keeps SRD domain wakeup active until cleared.

Bits 24:22 Reserved, must be kept at reset value.

Bits 21:19 **MR[21:19]:** SRD pending mask on event input x (x = 21 to 19)

0: SRD pending request from line x is masked. Writing this bit to 0 also clears the SRD pending request.

1: SRD pending request from line x is unmasked. When triggered, the SRD domain pending signal keeps SRD domain wakeup active until cleared.

Bits 18:16 Reserved, must be kept at reset value.

Bits 15:0 **MR[15:0]:** SRD pending mask on event input x (x = 15 to 0)

0: SRD pending request from line x is masked. Writing this bit to 0 also clears the SRD pending request.

1: SRD pending request from line x is unmasked. When triggered, the SRD domain pending signal keeps SRD domain wakeup active until cleared.

20.6.5 EXTI SRD pending clear selection register low (EXTI_SRDPCR1L)

Address offset: 0x10

Reset value: 0x0000 0000

Bits 31:20 **MR[63:52]:** CPU interrupt mask on direct event input x+32 (x = 63 to 52)

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Note: The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.

Bit 19 **MR51:** CPU interrupt mask on configurable event input x+32 (x = 51)

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Note: The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

Bit 18 **MR50:** CPU Interrupt mask on direct Event input x+32 (x = 50)

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Note: The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.

Bit 17 **MR49:** CPU interrupt mask on configurable event input x+32 (x = 49)
0: Interrupt request from Line x is masked
1: Interrupt request from Line x is unmasked
Note: The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

Bits 16:15 **MR[48:47]:** CPU interrupt mask on direct event input x+32 (x = 47 to 46)
0: Interrupt request from Line x is masked
1: Interrupt request from Line x is unmasked
Note: The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.

Bits 14:12 Reserved, must be kept at reset value.
Note: The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.

Bits 11:0 **MR[43:32]:** CPU Interrupt mask on direct event input x+32 (x = 43 to 32)
0: Interrupt request from Line x is masked
1: Interrupt request from Line x is unmasked
Note: The reset value for direct event inputs is set to 1 in order to enable the interrupt by default.

20.6.22 EXTI event mask register (EXTI_CPUEMR2)

Address offset: 0x94

Reset value: 0x0000 0000

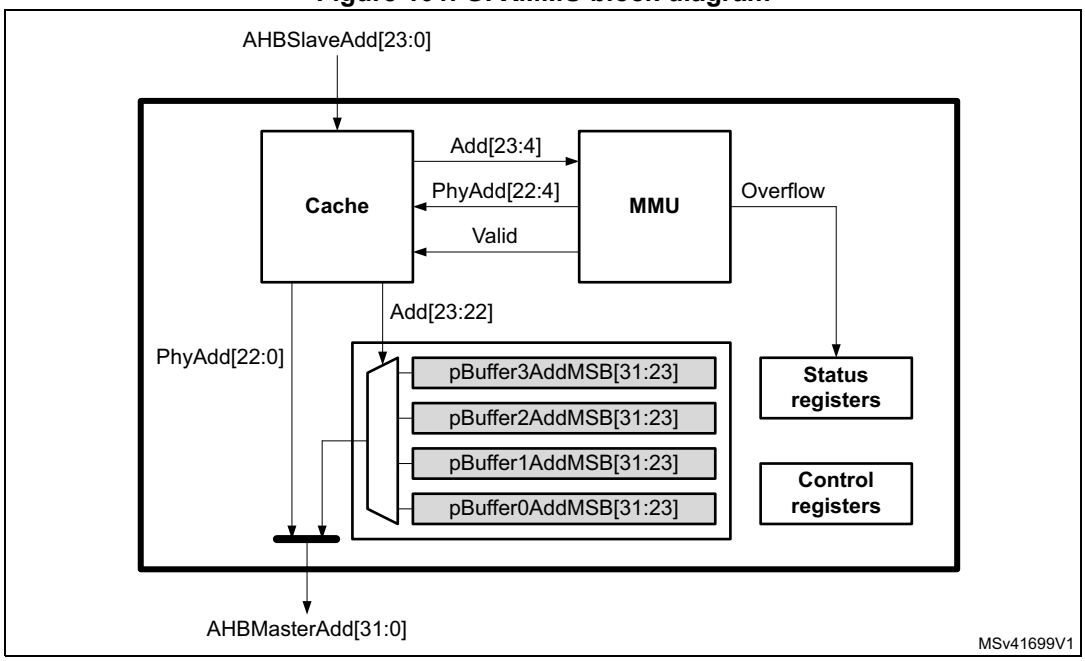
21 Chrom-GRC (GFXMMU)

21.1 Introduction

The graphic MMU is a graphical oriented memory management unit aimed to:

- Optimize memory usage according to the display shape
- Cache linear accesses to the frame buffer
- Prefetch data

21.2 GFXMMU main features



- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Optional cache for linear accesses
- Cache can be locked to a virtual buffer
- Cache prefetch mechanism for linear accesses anticipation
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error

21.3 GFXMMU functional and architectural description

The GFXMMU is composed of two main blocks:

- The MMU, responsible of address resolution
- The cache, responsible of data/address caching, prefetching and packing/unpacking

Figure 101. GFXMMU block diagram

21.3.1 Virtual memory

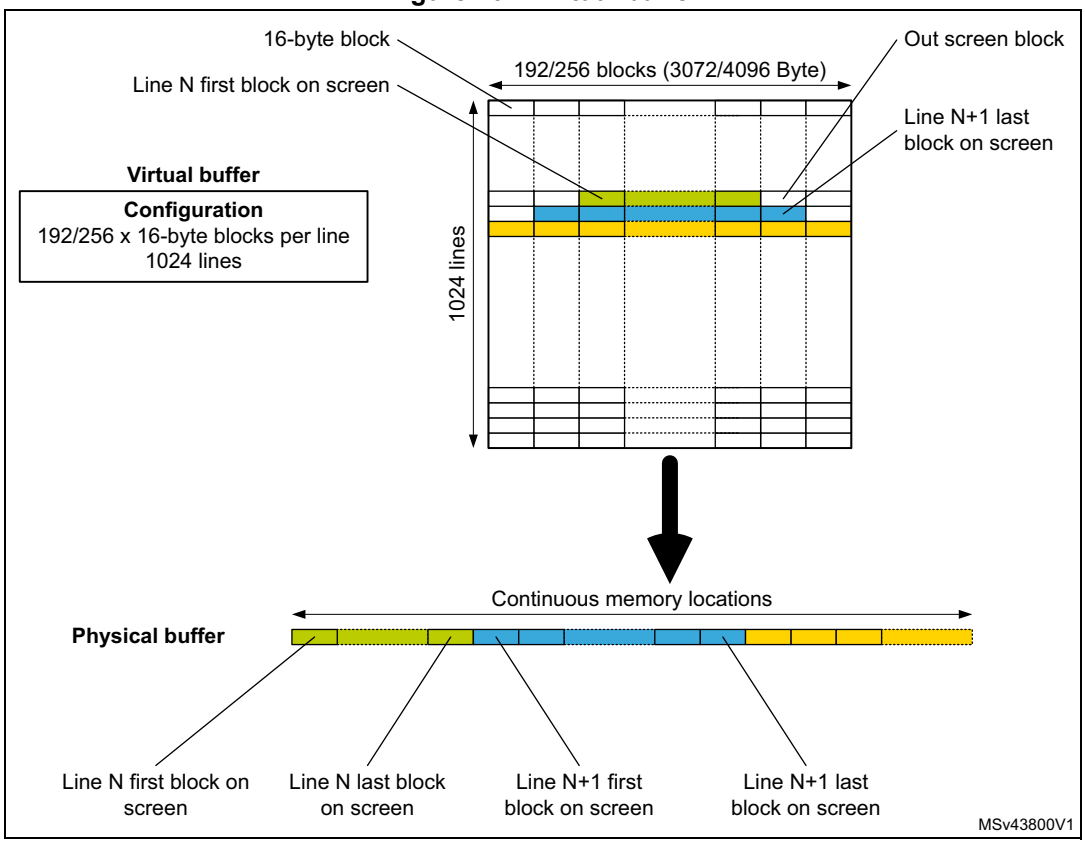
The GFXMMU provides a virtual memory space seen by the system masters[(a)]. This virtual memory space is divided into four virtual buffers.

Virtual buffer

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 192 or 256 16-byte blocks depending on the 192BM bit of the GFXMMU configuration register (GFXMMU_CR).

Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:



- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

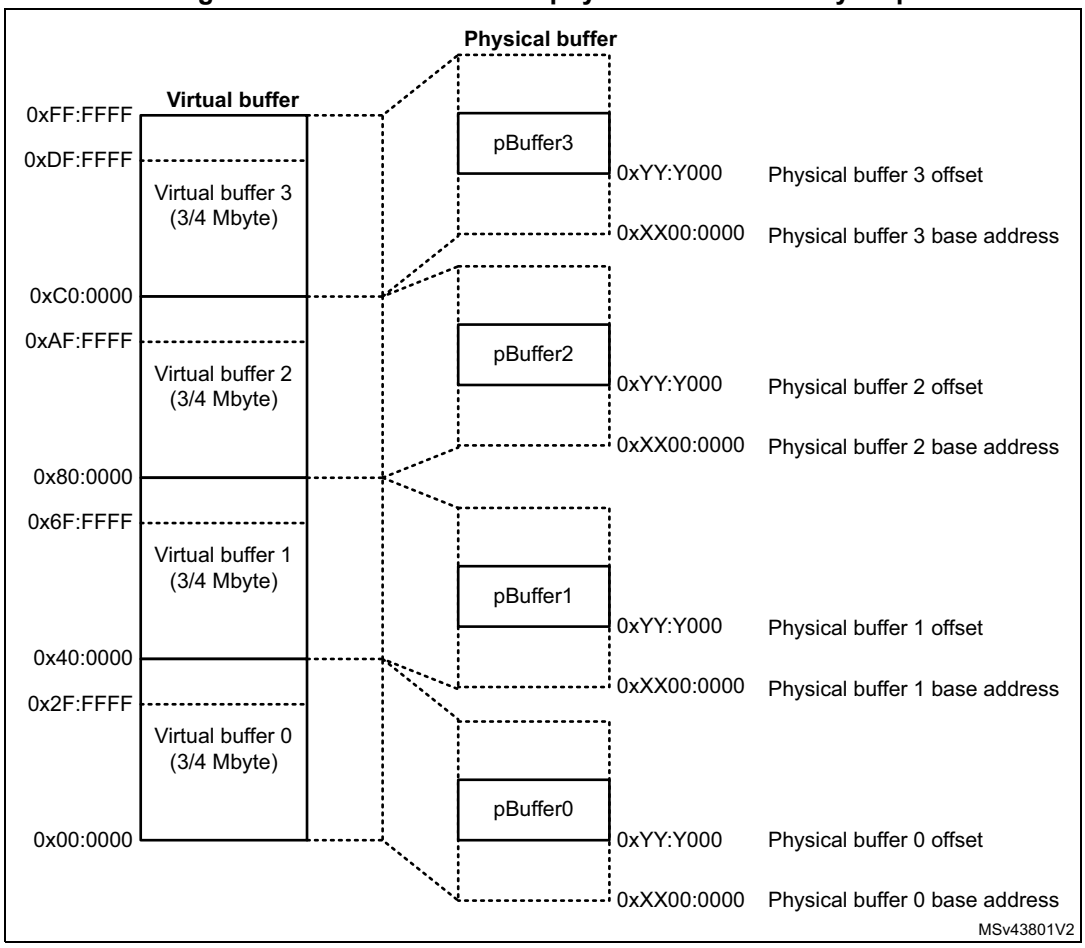
The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

a. Refer to section “System architecture” for system masters accessing GFXMMU.

The LUT is common to all the buffers i.e. all the buffers have the same “shape”.

Figure 102. Virtual buffer

Virtual buffer overview



For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 192 or 256 blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 192 blocks to have an integer number of pixel per lines. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).

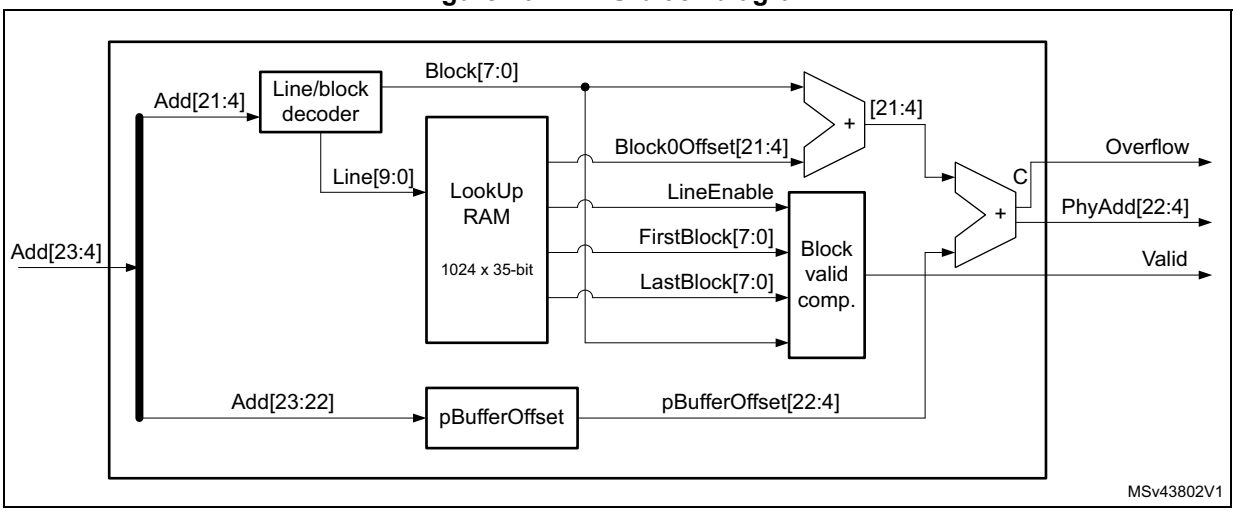
Figure 103. Virtual buffer and physical buffer memory map

The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

Virtual buffer application use case

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Chrom ART for frame buffer calculation while an other one must be used by the LTDC.



The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

21.3.2 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signals to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.

The MMU LUT is implemented as a 1024 x 35-bit RAM

Figure 104. MMU block diagram

Line block decoder

The line block decoder is generating the block number and the line number according the address.

Look up RAM

The look up RAM is a 1024 x 35-bit RAM with the following fields:

- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:

1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

Block validation/comparator

This block is checking if the block is valid.

A block is considered as valid (physically mapped) when:

- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

Block offset address calculation within the buffer

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

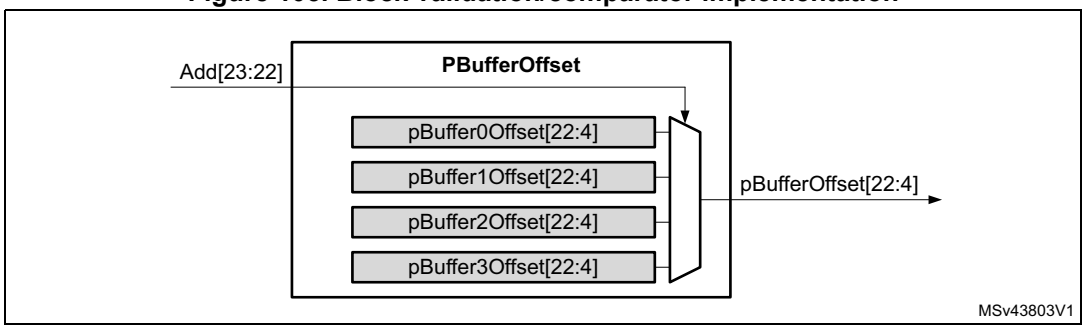
Line offset = [(Number of visible blocks already used) - (1^{st} visible block)] x block size

with:

- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum:
  1023 x 256 x 16 = 0x3F:F00x
- The minimum value for the line offset is when the last block of the first line is the first valid block: -255*16 = - 0xFFx i.e 0x3F:F01x

As the consequence the full range of the line offset entry of the LUT is used.

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3F:F01x to 0x3F:FFFx)



As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

Block offset address calculation

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in *Figure 105*:

Figure 105. Block validation/comparator implementation

The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_SR) to set the buffer x overflow flag (BxOF).

Example of calculation

Consider the following configuration for virtual buffer 0:

- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:

- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) x 0x10 = -0x70 = 0x3F:FF90
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) x 0x10 = (0xA - 0x6) x 0x10 = 0x40

As a consequence:

- the physical address of block 7 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x70 without carry) = 0xC020:0000

- the physical address of block 16 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x100 without carry) = 0xC020:0090

- the physical address of block 6 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x40 + 0x60 without carry) = 0xC020:00A0

- the physical address of block 17 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x40 + 0x110 without carry) = 0xC020:0150

21.3.3 Cache and prefetch mechanism

The GFXMMU integrated cache targets internal or external RAM devices storing the graphical frame buffer.

Master accessing the GFXMMU

Several masters are supposed to access memories through the GFXMMU:

- When the CPU is accessing the framebuffer, it is because it is performing a read/modify/write of a single pixel in the frame buffer. As a consequence the granularity of the R/M/W is less or equal to a word and a data cache is necessary. As the frame buffer is scanned linearly, it is realistic to says that the next data that is requested by the CPU within a buffer, is the next pixel. A prefetch mechanism can anticipate this efficiently.
- When Chrom ART or the LTDC are accessing the framebuffer, they are generating long accesses up to 128 bytes. A cache may not be necessary in this case as successive operation is done only once.

As a consequence the cache is aimed for CPU and must not be used together with DMA2D or LTDC. It is recommended to use the cache only with the CPU and manage coherency by software, flushing the cache when the CPU operations are finished.

Cache enabling

The cache is enabled setting the CE (cache enable) bit of the GFXMMU control register (GFXMMU_CR).

Cache lock mechanism

It is possible to lock the cache by setting the cache lock bit (CL) and configuring the cache lock buffer (CLB) field of the GFXMMU configuration register (GFXMMU_CR).

When the cache is locked on a given buffer, all the other buffer can not be cached.

An operation on the locked buffered can be cachable according to attribute of the master request, or can be always cachable setting the force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR). The force caching mechanism is only available when the cache is locked to a buffer. The force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR) is automatically reset when the cache lock (CL) bit of the GFXMMU configuration register (GFXMMU_CR) is reset.

Cache line size

A cache line size is 32 bytes.

Number of cache lines

The number of line is reduced as much as possible taking into account that CPU is performing linear accesses.

As a consequence three lines are needed:

- one line for the current access
- one line for the previous access (as pixels can be split into two 16-byte blocks)
- one line for the prefetched access

Prefetch mechanism

Because the CPU performs most of the time, linear accesses to the frame buffer, a prefetch mechanism is provided in order to automatically retrieve the next cache line from the memory.

The prefetch mechanism can be disabled setting the prefetch disable (PD) bit of the GFXMMU configuration register (GFXMMU_CR).

When the prefetch mechanism is disabled, only the TAG of the line dedicated for prefetching is updated but the data are retrieved from the memory.

Cache maintenance operation

When the cache is working in non force caching mode, this is the case when the force caching (FC) bit of the GFXMMU configuration register (GFXMMU_CR) is reset, then line eviction is done:

- Each time a non cachable access is performed on the buffer having data cached
- Each time a miss occurs

As a consequence the cache maintenance operation can be naturally automatic.

Nevertheless, it is possible to force a flush if the cache setting the force flush (FF) bit of the GFXMMU cache control register (GFXMMU_CCR). When flushing the cache, all the dirty entries are sent to the write buffer, and all the dirty bit of the TAGs are reset. But the entries are not invalidate.

It is also possible to invalidate the cache entries setting the force invalidate (FI) bit of the GFXMMU cache control register (GFXMMU_CCR). This does not send the dirty entries to the write buffer (modification done in the cache are lost). This just resets the ID field of the TAGs (unused state)

Setting the two force flush (FF) bits and forcing invalidate (FI) of the GFXMMU cache control register (GFXMMU_CCR) trigs the following operations:

- flush the cache, all the dirty entries are sent to the write buffer
- reset the dirty bit of the TAGs
- reset the ID field of the TAGs

When any of these two operations is done while the flash is having transaction already in the write buffer, the write buffer continues its operations.

The force flush (FF) and force invalidate (FI) are reset automatically when all the operations are finished (write buffer empty) creating a synchronization barrier.

21.4 GFXMMU interrupts

An interrupt can be produced on the following events:

- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AHB master error

Separate interrupt enable bits are available for flexibility.

Table 131. GFXMMU interrupt requests

Interrupt event	Event flag	Enable control bit
Buffer 0 overflow	B0OF	B0OIE
Buffer 1 overflow	B1OF	B1OIE
Buffer 2 overflow	B2OF	B2OIE
Buffer 3 overflow	B3OF	B3OIE
AHB master error	AMEF	AMEIE

21.5 GFXMMU registers

21.5.1 GFXMMU configuration register (GFXMMU_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **OB**: Outter bufferability
This bit configure the bufferability of an access generated by the GFXMMU cache.
0: No bufferable
1: Bufferable

Bit 16 **OC**: Outter cachability
This bit configure the cachability of an access generated by the GFXMMU cache.
0: No cachable
1: Cachable

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **PD**: Prefetch disable
This bit disables the prefetch of the cache.
0: Prefetch enable
1: Prefetch disable

Bit 11 **FC**: Force caching
This bit force the caching into the cache regardless of the MPU attributes.
The cache must be enable (CE bit set).
0: Caching not forced
1: Caching forced

Bits 10:9 **CLB[1:0]**: Cache lock buffer
This field select the buffer on which the cache is locked.
00: Cache locked on buffer 0
01: Cache locked on buffer 1
10: Cache locked on buffer 2
11: Cache locked on buffer 3

Bit 8 **CL**: Cache lock
This bit lock the cache onto the buffer defined in the CLB field.
0: Cache not locked
1: Cache locked to a buffer

Bit 7 **CE**: Cache enable
This bit enables the cache unit.
0: Cache disable
1: Cache enable

Bit 6 **192BM**: 192 Block mode
This bit defines the number of blocks per line
0: 256 blocks per line
1: 192 blocks per line

Bit 5 Reserved, must be kept at reset value.

Bit 4 **AMEIE**: AHB master error interrupt enable
This bit enables the AHB master error interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 3 **B3OIE**: Buffer 3 overflow interrupt enable
This bit enables the buffer 3 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 2 **B2OIE**: Buffer 2 overflow interrupt enable
This bit enables the buffer 2 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 1 **B1OIE**: Buffer 1 overflow interrupt enable
This bit enables the buffer 1 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 0 **B0OIE**: Buffer 0 overflow interrupt enable
This bit enables the buffer 0 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

21.5.2 GFXMMU status register (GFXMMU_SR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AMEF	B3OF	B2OF	B1OF	B0OF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **AMEF**: AHB master error flag

This bit is set when an AHB error happens during a transaction. It is cleared by writing 1 to CAMEF.

Bit 3 **B3OF**: Buffer 3 overflow flag

This bit is set when an overflow occurs during the offset calculation of the buffer 3. It is cleared by writing 1 to CB3OF.

Bit 2 **B2OF**: Buffer 2 overflow flag

This bit is set when an overflow occurs during the offset calculation of the buffer 2. It is cleared by writing 1 to CB2OF.

Bit 1 **B1OF**: Buffer 1 overflow flag

This bit is set when an overflow occurs during the offset calculation of the buffer 1. It is cleared by writing 1 to CB1OF.

Bit 0 **B0OF**: Buffer 0 overflow flag

This bit is set when an overflow occurs during the offset calculation of the buffer 0. It is cleared by writing 1 to CB0OF.

21.5.3 GFXMMU flag clear register (GFXMMU_FCR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CAMEF**: Clear AHB master error flag

Writing 1 clears the AHB master error flag in the GFXMMU_SR register.

Bit 3 **CB3OF**: Clear buffer 3 overflow flag

Writing 1 clears the buffer 3 overflow flag in the GFXMMU_SR register.

Bit 2 **CB2OF**: Clear buffer 2 overflow flag

Writing 1 clears the buffer 2 overflow flag in the GFXMMU_SR register.

Bit 1 **CB1OF**: Clear buffer 1 overflow flag

Writing 1 clears the buffer 1 overflow flag in the GFXMMU_SR register.

Bit 0 **CB0OF**: Clear buffer 0 overflow flag

Writing 1 clears the buffer 0 overflow flag in the GFXMMU_SR register.

21.5.4 GFXMMU cache control register (GFXMMU_CCR)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **FI**: Force invalidate

When set, the cache entries are invalidated. This bit is reset by hardware when the invalidation is complete. Write 0 has no effect.

0: Invalidation process complete

1: Force invalidation/invalidation process on going

Bit 0 **FF**: Force flush

When set, the cache entries are flushed. This bit is reset by hardware when the flushing is complete. Write 0 has no effect.

0: Flushing process complete

1: Force flush/flushing process on going

21.5.5 GFXMMU default value register (GFXMMU_DVR)

Address offset: 0x0010

Reset value: 0x0000 0000

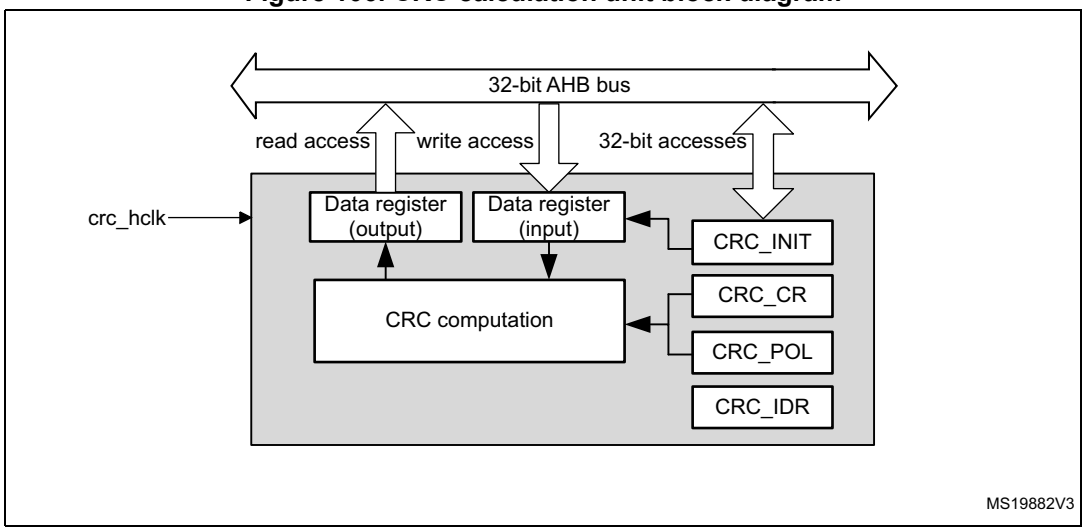
22 Cyclic redundancy check calculation unit (CRC)

22.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.



22.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

22.3 CRC functional description

22.3.1 CRC block diagram

Figure 106. CRC calculation unit block diagram

22.3.2 CRC internal signals

Table 133. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

22.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

22.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

22.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

22.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

22.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REV_OUT	REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
								rw	rw	rw	rw	rw			rs

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.

0: Bit order not affected

1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data

This bitfield controls the reversal of the bit order of the input data

00: Bit order not affected

01: Bit reversal done by byte

10: Bit reversal done by half-word

11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

22.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

22.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

22.4.6 CRC register map

Table 134. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

23 Flexible memory controller (FMC)

The flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

23.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

  The Write FIFO is common to all memory controllers and consists of:
  - a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in Burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only a few bits can be changed on-the-fly:

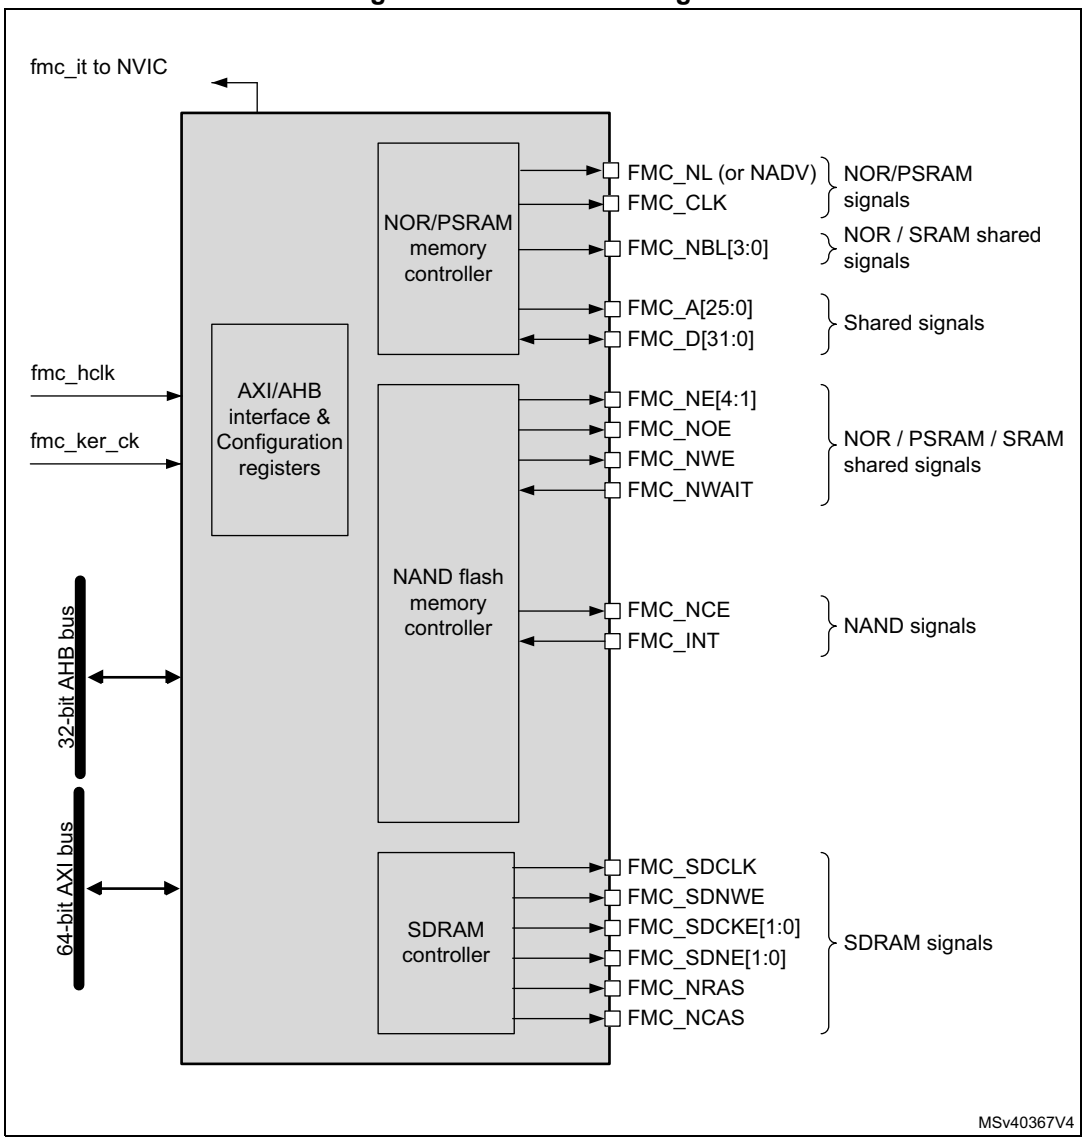
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in the FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.

1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC by resetting the FMCEN bit in the FMC_BCR1 register.
3. Update the required parameters.
4. Enable the FMC once all parameters have been updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.



23.2 FMC block diagram

The FMC consists of the following main blocks:

- The NOR flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.

Figure 107. FMC block diagram

23.3 FMC internal signals

Table 135 gives the list of FMC internal signals. FMC pins (or external signals) are described in *Section 23.7.1: External memory interface signals*.

Table 135. FMC pins

Names	Signal type	Description
fmc_it	Digital output	FMC interrupt
fmc_ker_ck	Digital input	FMC kernel clock
fmc_hclk	Digital input	FMC interface clock

23.4 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (fmc_hclk) is the reference clock for the FMC register accesses.

23.5 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC_NEx) does not toggle between consecutive accesses except in case of accesses in mode D when the Extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.
- Writing to a write protected SDRAM bank (WP bit set in the FMC_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC is the asynchronous fmc_ker_ck clock (refer to *Section 8: Reset and clock control (RCC)* for fmc_ker_ck clock source selection).

23.5.1 Supported memories and transactions

General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. The best performance is always achieved with aligned AXI transactions whose size matches the external device data width.

When AXI transaction data size is different from the device data width, the result depends on the following factors:

- AXI transaction data size is greater than the device data width:
  - Read/Write transactions: the FMC splits the AXI transaction into smaller consecutive accesses matching the external device data width.
- AXI transaction data size is smaller than the external device data width and the device supports byte selection (SRAM, PSRAM, SDRAM):
  - Write transactions, the FMC manages the transaction using the byte lane signals.
  - Read transactions, the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.
- AXI transaction data size is smaller than the external device data width and the device does not support byte selection (NOR and NAND flash memories):
  - Write transactions: the FMC writes some irrelevant bytes which may corrupt the external device
  - Read transactions: the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.

Caution: Address alignment

- Read transactions with unaligned addresses (such as half-word starting at an odd address) are not supported by the FMC.
- Write transactions with unaligned addresses

  Their support depends on byte selection availability on the external device:
  - If the device does not support byte selection (NOR and NAND flash memories), narrow write transactions and/or unaligned write transaction are not supported since the FMC would write irrelevant bytes and corrupt the external device.

Wrap support for NOR flash/PSRAM and SDRAM

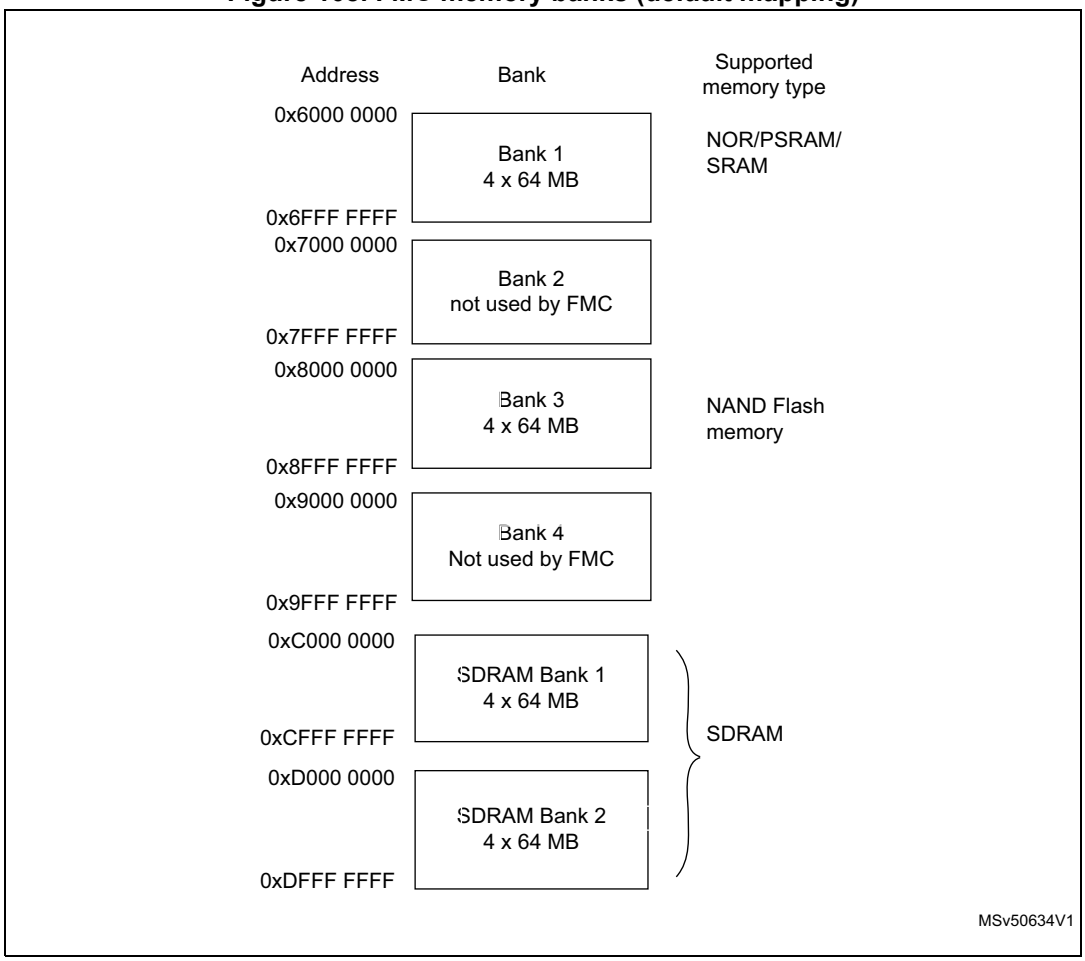
The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 23.7.6*, for a detailed description of the NOR flash/PSRAM controller registers. Refer to *Section 23.8.7*, for a detailed description of the NAND flash registers and to *Section 23.9.5* for a detailed description of the SDRAM controller registers.



23.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see *Figure 108*):

- Bank 1 is used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 and Bank 4 are not used by the FMC.
- Bank 3 is used to address NAND flash memory devices.The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 5 and 6 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 108. FMC memory banks (default mapping)

The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC_BCR1 register. *Table 136* shows the configuration to swap the NOR/PSRAM bank with SDRAM banks.

Table 136. FMC bank mapping options

Start -End address	BMAP[1:0]=00 (Default mapping)	BMAP[1:0]=01 NOR/PSRAM and SDRAM banks swapped
0x6000 0000 - 0x6FFF FFFF	NOR/PSRAM bank	SDRAM bank1
0x7000 0000 - 0x7FFF FFFF	Not used by FMC	
0x8000 0000 - 0x8FFF FFFF	NAND bank	NAND bank
0x9000 0000 - 0x9FFF FFFF	Not used by FMC	
0xC000 0000 - 0xCFFF FFFF	SDRAM bank1	NOR/PSRAM bank
0xD000 0000 - 0xDFFF FFFF	SDRAM bank2	SDRAM bank2

23.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 137*.

Table 137. NOR/PSRAM bank selection

ADDR[27:26](1)	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 138. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	ADDR[25:0]	64 Mbytes x 8 = 512 Mbit
16-bit	ADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbit
32-bit	ADDR[25:2] >> 2	64 Mbytes/4 x 32 = 512 Mbit

1. In case of a 16-bit external memory width, the FMC internally uses ADDR[25:1] to generate the address for external memory FMC_A[24:0]. In case of a 32-bit memory width, the FMC internally uses ADDR[25:2] to generate the external address.
Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

23.6.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 139*.

Table 139. NAND memory mapping and timing registers

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in *Table 140* below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 140. NAND bank selection

Section name	ADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFF

The application software uses the 3 sections to access the NAND flash memory:

- **To send a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

23.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in *Table 141*.

Table 141. SDRAM bank selection

Selected bank	Control register	Timing register
SDRAM Bank1	FMC_SDCR1	FMC_SDTR1
SDRAM Bank2	FMC_SDCR2	FMC_SDTR2

Table 142 shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.

Table 142. SDRAM address mapping

Memory width(1)	Internal bank	Row address	Column address(2)	Maximum memory capacity (Mbytes)
8-bit	ADDR[25:24]	ADDR[23:11]	ADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	ADDR[26:25]	ADDR[24:12]	ADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2
32-bit	ADDR[27:26]	ADDR[25:13]	ADDR[12:2]	256 Mbytes: 4 x 8K x 2K x 4

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it is always driven low.

The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size:8, 16 or 32 bits
- Row size:11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

Table 143. SDRAM address mapping with 8-bit data bus width(1)(2)

Row size configuration	ADDR(Internal Address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.							Bank [1:0]	Row[10:0]												Column[7:0]							
	Res.								Bank [1:0]	Row[10:0]											Column[8:0]							
	Res.									Bank [1:0]	Row[10:0]										Column[9:0]							
	Res.										Bank [1:0]	Row[10:0]									Column[10:0]							

Table 143. SDRAM address mapping with 8-bit data bus width(1)(2) (continued)

Row size configuration	ADDR(Internal Address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
12-bit row size configuration	Res.						Bank [1:0]		Row[11:0]										Column[7:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[8:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[9:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[10:0]									
13-bit row size configuration	Res.						Bank [1:0]		Row[12:0]										Column[7:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[8:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[9:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[10:0]									

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to ‘0’.
2. Access to Reserved (Res.) address range generates an AXI slave error.

Table 144. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	ADDR(address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.						Bank [1:0]		Row[10:0]										Column[7:0]									BM0 (3)
	Res.						Bank [1:0]		Row[10:0]										Column[8:0]									BM0
	Res.						Bank [1:0]		Row[10:0]										Column[9:0]									BM0
	Res.						Bank [1:0]		Row[10:0]										Column[10:0]									BM0
12-bit row size configuration	Res.						Bank [1:0]		Row[11:0]										Column[7:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[8:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[9:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[10:0]									BM0

Table 144. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	ADDR(address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
13-bit row size configuration	Res.				Bank [1:0]		Row[12:0]													Column[7:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[8:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[9:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[10:0]								BM0

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM0: is the byte mask for 16-bit access.

Table 145. SDRAM address mapping with 32-bit data bus width(1)(2)

Row size configuration	ADDR(address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.					Bank [1:0]		Row[10:0]											Column[7:0]								BM[1:0](3)	
	Res.					Bank [1:0]		Row[10:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[10:0]											Column[9:0]								BM[1:0	
	Res.					Bank [1:0]		Row[10:0]											Column[10:0]								BM[1:0	
12-bit row size configuration	Res.					Bank [1:0]		Row[11:0]											Column[7:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[9:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[10:0]								BM[1:0	
13-bit row size configuration	Res.					Bank [1:0]		Row[12:0]											Column[7:0]								BM[1:0	
	Res.					Bank [1:0]		Row[12:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[12:0]											Column[9:0]								BM[1:0	
	Bank [1:0]					Row[12:0]													Column[10:0]								BM[1:0	

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI slave error.
3. BM[1:0]: is the byte mask for 32-bit access.

23.7 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a sub-multiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see *Section 23.7.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AXI data transaction (refer to *Section 23.7.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see *Section 23.7.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 146*) and support for wait management (for PSRAM and NOR flash memory accessed in Burst mode).

Table 146. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	FMC clock cycle (fmc_ker_ck)	1	15
Data setup	Duration of the data setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	1	256
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read	FMC clock cycle (fmc_ker_ck)	0	15
Clock divide ratio	Number of FMC clock cycles (fmc_ker_ck) to build one memory clock cycle (CLK)	Synchronous	FMC clock cycle (fmc_ker_ck)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (fmc_ker_ck)	2	17

23.7.1 External memory interface signals

Table 147, *Table 148* and *Table 149* list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals which are active low.

NOR flash memory, non-multiplexed I/Os

Table 147. Non-multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Bidirectional data bus
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR flash memory, 16-bit multiplexed I/Os

Table 148. 16-bit multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/SRAM, non-multiplexed I/Os

Table 149. Non-multiplexed I/Os PSRAM/SRAM

FMC pin name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Data bidirectional bus
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[3:0]	O	Byte lane output. Byte 0 to Byte 3 control (Upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 150. 16-Bit multiplexed I/O PSRAM

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)

Table 150. 16-Bit multiplexed I/O PSRAM (continued)

FMC pin name	I/O	Function
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

23.7.2 Supported memories and transactions

Table 151 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 151. NOR flash/PSRAM: Example of supported memories and transactions(1)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NOR flash (muxed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	N	
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	

Table 151. NOR flash/PSRAM: Example of supported memories and transactions(1) (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32/64	16	Y	
SRAM and ROM	Asynchronous	R	8/16	16	Y	
	Asynchronous	W	8/16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses Use of byte lanes NBL[1:0]

1. NBL[1:0] are also driven by AXI write strobes.

23.7.3 General timing rules

Signal synchronization is performed as follows:

- All controller output signals change on the rising edge of the fmc_ker_ck clock.
- In Synchronous read and write modes, all output signals change on the rising edge of fmc_ker_ck clock. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

23.7.4 NOR flash/PSRAM controller asynchronous transactions

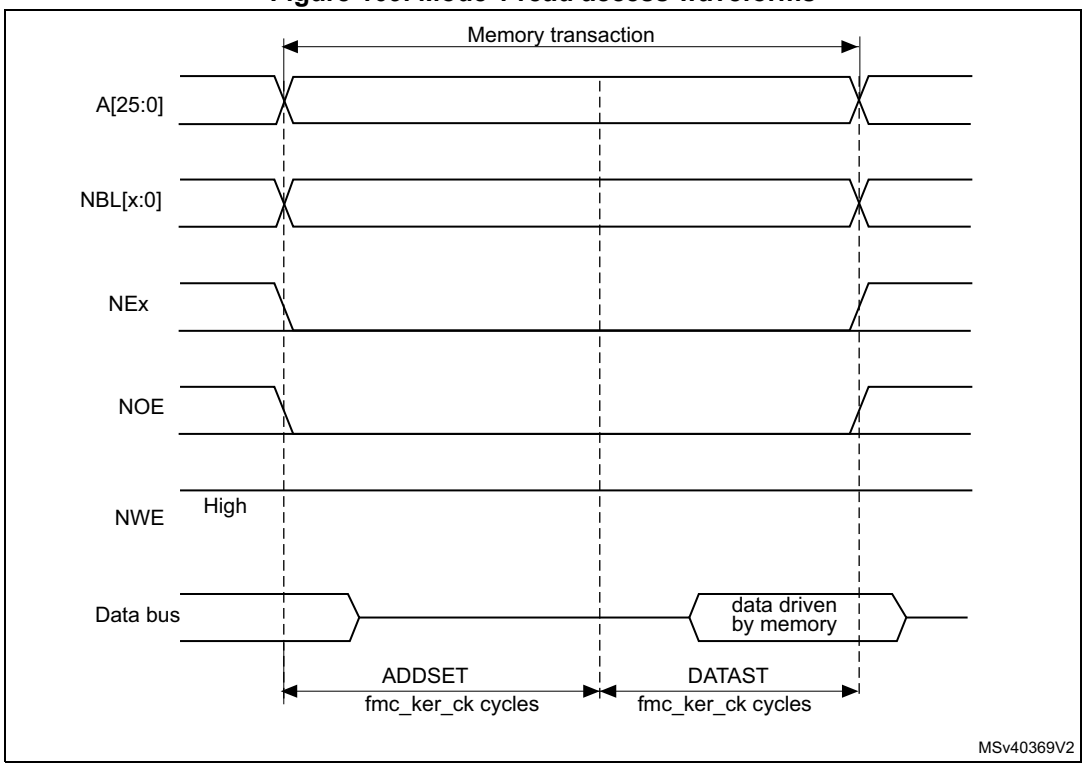
Asynchronous transactions on static memories (NOR flash memory, PSRAM, SRAM) are performed as follows:

- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before deasserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 109. Mode 1 read access waveforms



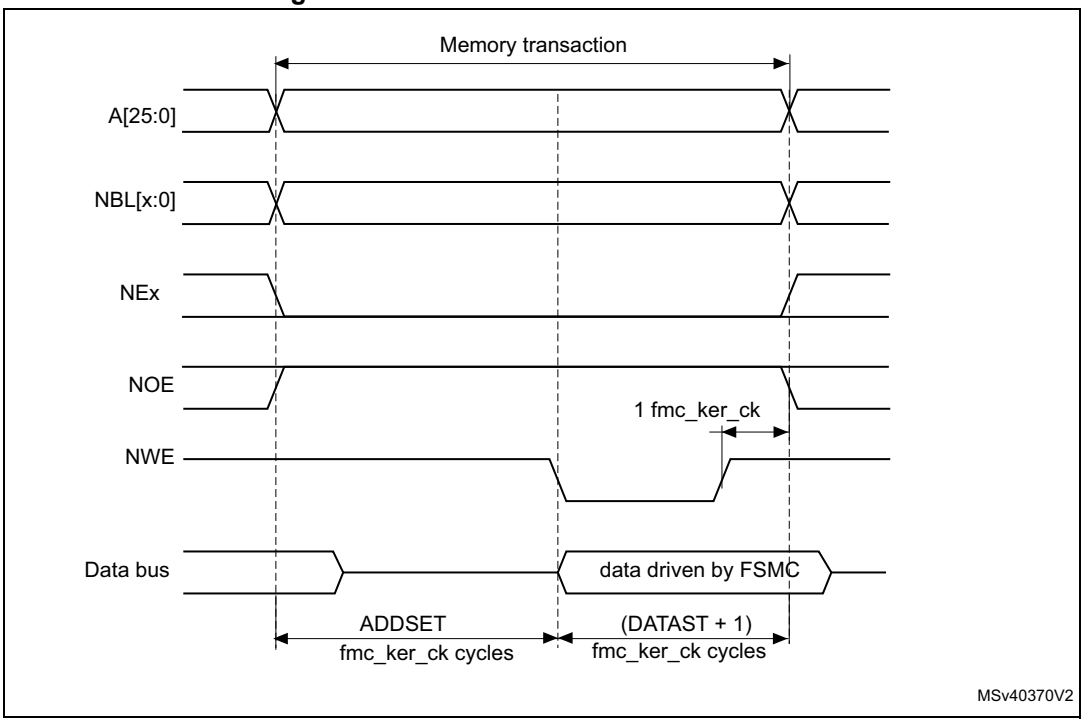


Figure 110. Mode 1 write access waveforms

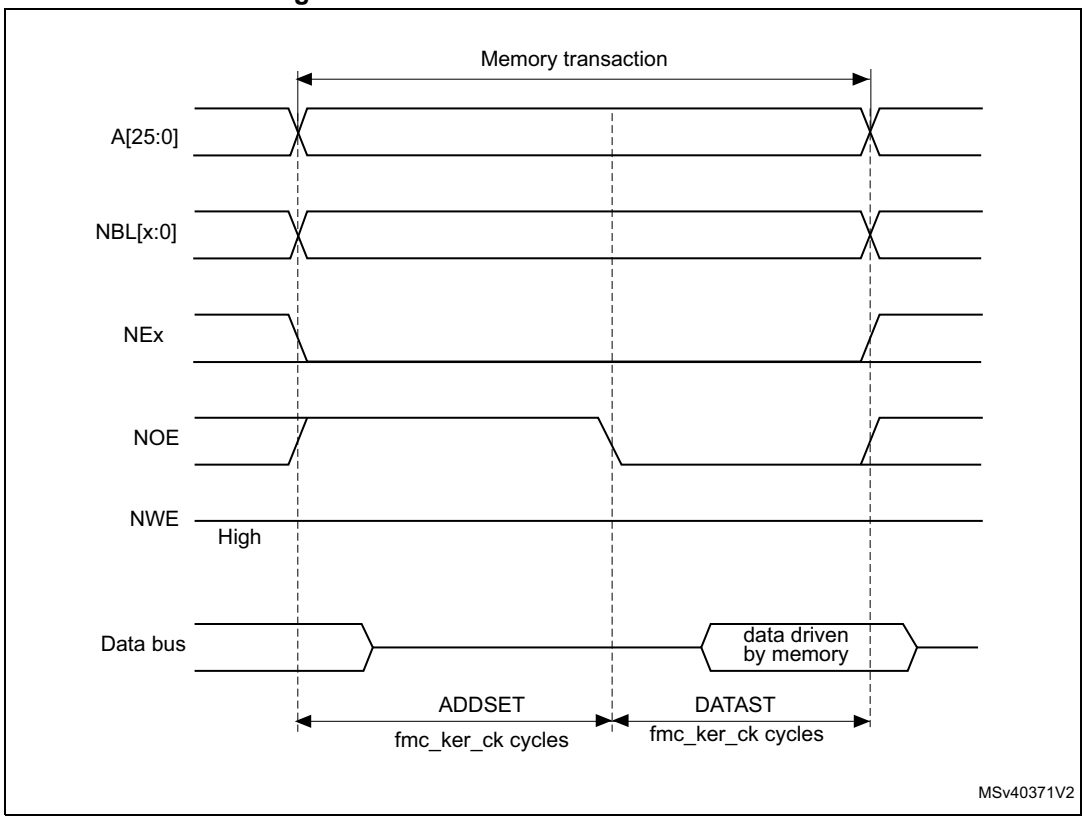
The fmc_ker_ck cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this fmc_ker_ck cycle, the DATAST value must be greater than zero (DATAST > 0).

Table 152. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:26	Reserved	0x000
25:24	BMAP	As needed
23:22	Reserved	0x000
21	WFDIS	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed
11	WAITCFG	Don’t care
10	Reserved	0x0

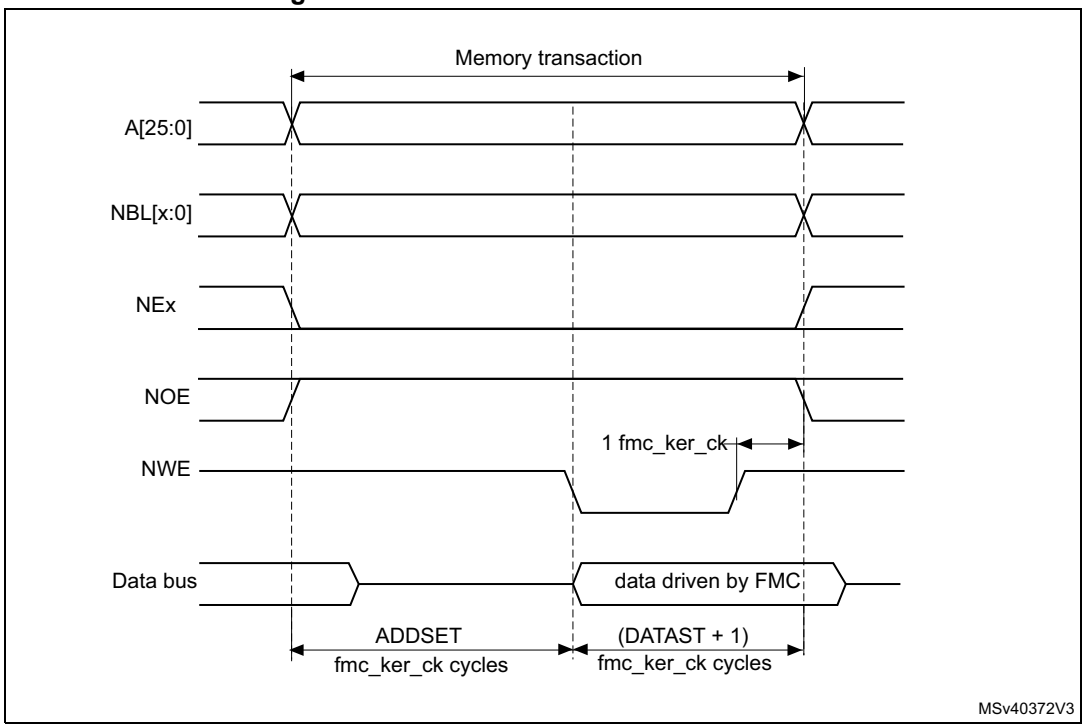
Table 152. FMC_BCRx bitfields (mode 1) (continued)



Bit number	Bit name	Value to set
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	FACCEN	Don’t care
5:4	MWID	As needed
3:2	MTYP	As needed, exclude 0x2 (NOR flash memory)
1	MUXE	0x0
0	MBKEN	0x1

Table 153. FMC_BTRx bitfields (mode 1)

Bit number	Bit name	Value to set
31:30	Reserved	0x0
29:28	ACCMOD	Don’t care
27:24	DATLAT	Don’t care
23:20	CLKDIV	Don’t care
19:16	BUSTURN	Time between NEx high to NEx low (BUSTURN fmc_ker_ck)
15:8	DATAST	Duration of the second access phase (DATAST+1 fmc_ker_ck cycles for write accesses, DATAST fmc_ker_ck cycles for read accesses).
7:4	ADDHLD	Don’t care
3:0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles). Minimum value for ADDSET is 0.



Mode A - SRAM/PSRAM (CRAM) OE toggling

Figure 111. Mode A read access waveforms

1. NBL[3:0] are driven low during the read access

Figure 112. Mode A write access waveforms

The differences compared with Mode1 are the toggling of NOE and the independent read and write timings.

Table 154. FMC_BCRx bitfields (mode A)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:26	Reserved	0x000
25:24	BMAP	As needed
23:22	Reserved	0x000

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + \text{max_wait_assertion_time}$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if

$$\text{max_wait_assertion_time} > \text{address_phase} + \text{hold_phase}$$

   then:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + (\text{max_wait_assertion_time} - \text{address_phase} - \text{hold_phase})$$

   otherwise

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck})$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

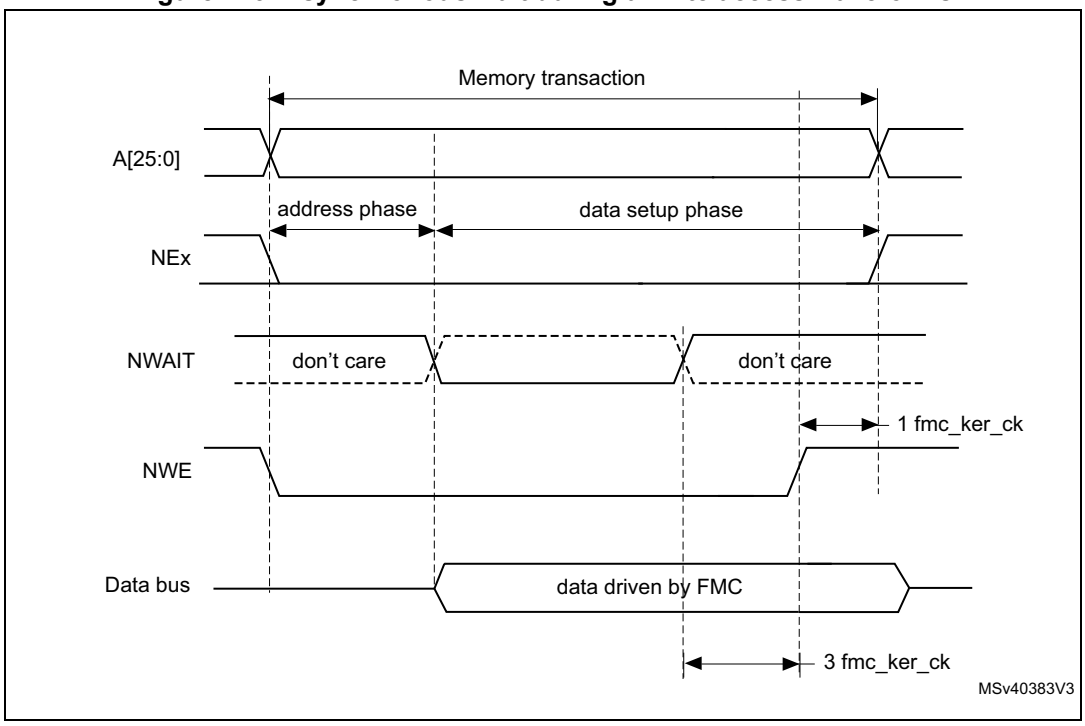

Figure 122 and *Figure 123* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 122. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 123. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

23.7.5 Synchronous transactions

The memory clock, FMC_CLK, is a sub-multiple of fmc_ker_ck. It depends on the value of CLKDIV and the MWID/ AXI data size, following the formula given below:

$$\text{FMC_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AXI data size}))$$

If MWID is 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC_CLK divider ratio depends also on AXI data size.

Example:

- If CLKDIV=1, MWID = 32 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/4.
- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/2.

NOR flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to Synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) FMC_CLK clock cycles
- or NOR flash latency = (DATLAT + 3) FMC_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and deassert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

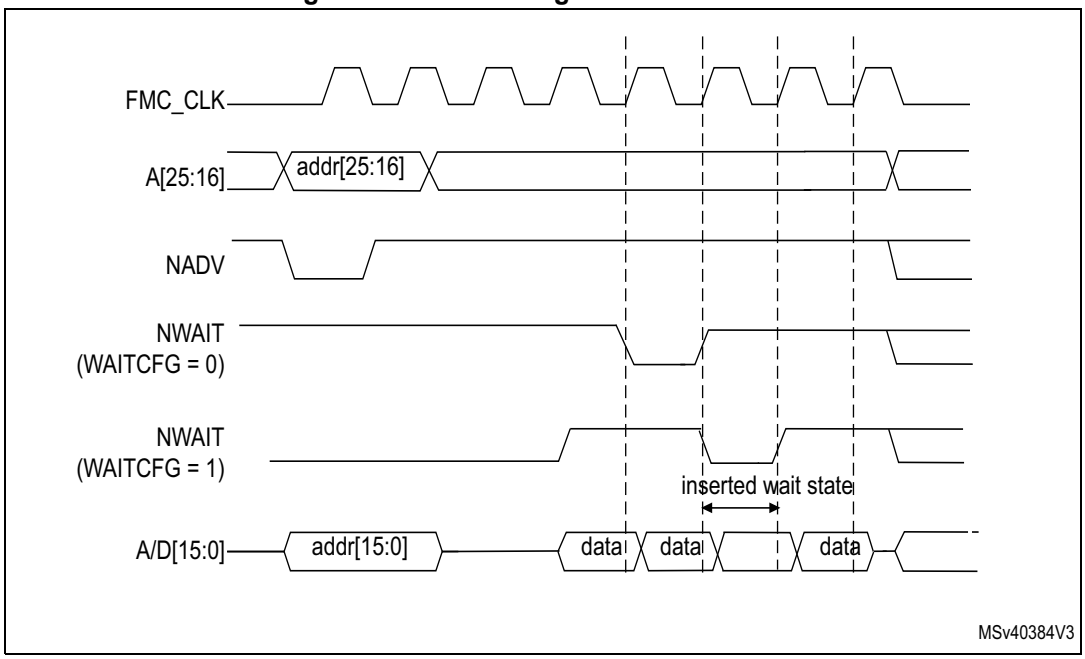
During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

Figure 124. Wait configuration waveforms



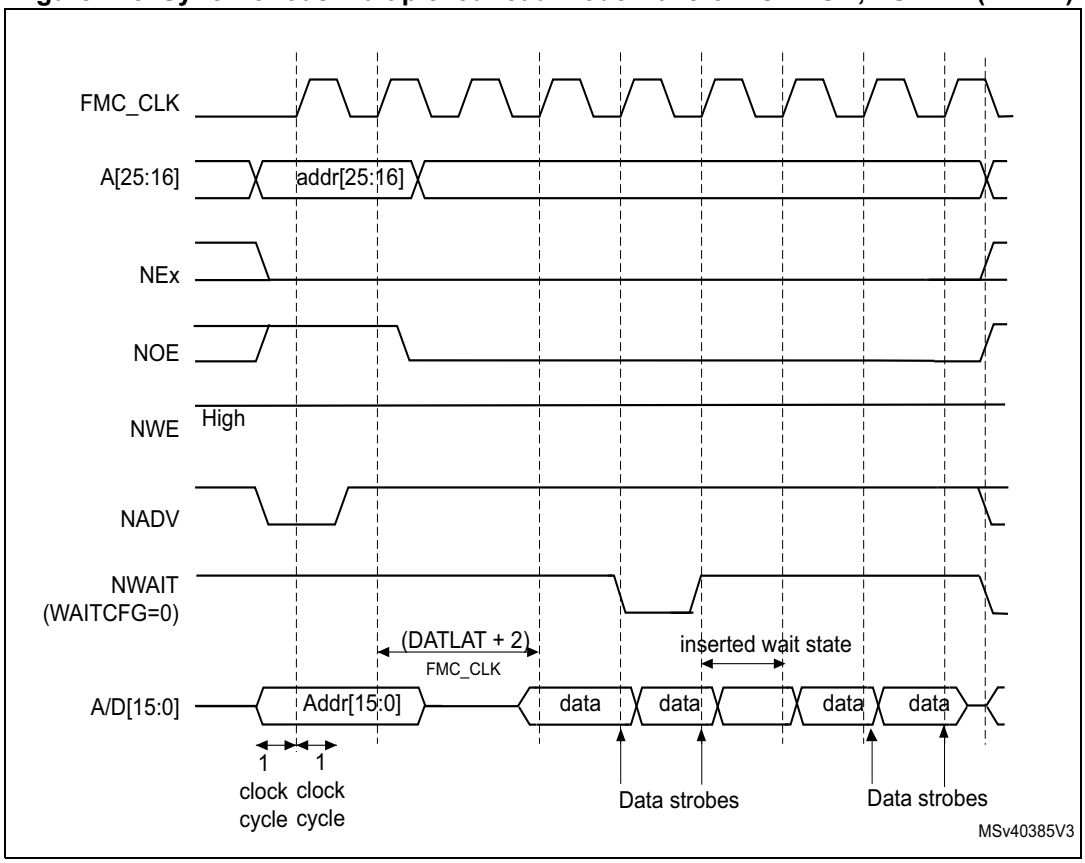


Figure 125. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

Table 168. FMC_BCRx bitfields (Synchronous multiplexed read mode)

23.7.6 NOR/PSRAM controller registers

SRAM/NOR-flash chip-select control registers for bank x (FMC_BCRx)

Address offset: 0x00 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 30DB, 0x0000 30D2, Block 3: 0x0000 30D2, 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.

Bit 31 **FMCEN:** FMC Enable

This bit enables/disables the FMC.

0: Disable the FMC

1: Enable the FMC

Note: The FMCEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **BMAP[1:0]:** FMC bank mapping

These bits allow different remap or swap of the FMC NOR/PSRAM and SDRAM banks (refer to *Table 136*).

00: Default mapping (refer to *Figure 108* and *Table 136*).

01: NOR/PSRAM bank and SDRAM bank 1 are swapped.

10: Reserved

11: Reserved.

Note: The BMAP bits of the FMC_BCR2..4 registers are don't care. It is only enabled through the FMC_BCR1 register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **WFDIS:** Write FIFO Disable

This bit disables the Write FIFO used by the FMC.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous Clock Enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM Page Size

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset).

001: 128 bytes

010: 256 bytes

100: 1024 bytes

Other configuration: reserved.

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP =0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period)

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC:

0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset)

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit

This bit defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:

0: NWAIT active low (default after reset)

1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode

1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

This bit enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled

1: Corresponding NOR flash memory access is enabled (default after reset)

Bits 5:4 **MWID[1:0]:** Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: 32 bits

11: reserved

Bits 3:2 **MTYP[1:0]:** Memory type

These bits define the type of external memory attached to the corresponding memory bank:
00: SRAM (default after reset for Bank 2...4)
01: PSRAM (CRAM)
10: NOR flash/OneNAND flash (default after reset for Bank 1)
11: reserved

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
0: Address/Data non-multiplexed
1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory bank enable bit

This bit enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AXI bus.
0: Corresponding memory bank is disabled
1: Corresponding memory bank is enabled

SRAM/NOR-flash chip-select timing registers for bank x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode

These bits specify the Asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 FMC_CLK clock cycles for first burst access

1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

These bits define the period of FMC_CLK clock output signal, expressed in number of fmc_ker_ck cycles:

0000: FMC_CLK period = 1 x fmc_ker_ck period

0001: FMC_CLK period = 2 × fmc_ker_ck periods

0010: FMC_CLK period = 3 × fmc_ker_ck periods

1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don’t care.

Note: Refer to Section 23.7.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t_{EHQZ}). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed

as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - –Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - –An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - –An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read.
  - –Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 x fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to *Figure 109* to *Figure 121*), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 109* to *Figure 121*).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc_ker_ck clock cycles.

Note: In synchronous accesses, this value is don't care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 109* to *Figure 121*), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × fmc_ker_ck clock cycle
0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
...
1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (*Figure 109* to *Figure 121*).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 109* to *Figure 121*), used in SRAMs, ROMs and asynchronous NOR flash:
0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
...
1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (refer to *Figure 109* to *Figure 121*).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.
On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers for bank x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN[3:0]			
		rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions (t_{EHEL} from ENx high to ENx low):

(BUSTRUN + 1) fmc_ker_ck period ≥ $t_{EHELmin}$.

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different expect for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to *Figure 109* to *Figure 121*), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 109* to *Figure 121*), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle

0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle

...

1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in fmc_ker_ck cycles (refer to *Figure 109* to *Figure 121*), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle

...

1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

23.8 NAND flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND flash memories.

The NAND bank is configured through dedicated registers (*Section 23.8.7*). The programmable memory parameters include access timings (shown in *Table 172*) and ECC configuration.

Table 172. Programmable NAND flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (fmc_ker_ck) required to set up the address before the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	255
Memory wait	Minimum duration (in fmc_ker_ck clock cycles) of the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	2	255
Memory hold	Number of clock cycles (fmc_ker_ck) during which the address must be held (as well as the data if a write access is performed) after the command deassertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	254
Memory databus high-Z	Number of clock cycles (fmc_ker_ck) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (fmc_ker_ck)	0	254

23.8.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND flash memories.

Note: The prefix “N” identifies the signals which are active low.

8-bit NAND flash memory

Table 173. 8-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND flash memory

Table 174. 16-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Note: Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

23.8.2 NAND flash supported memories and transactions

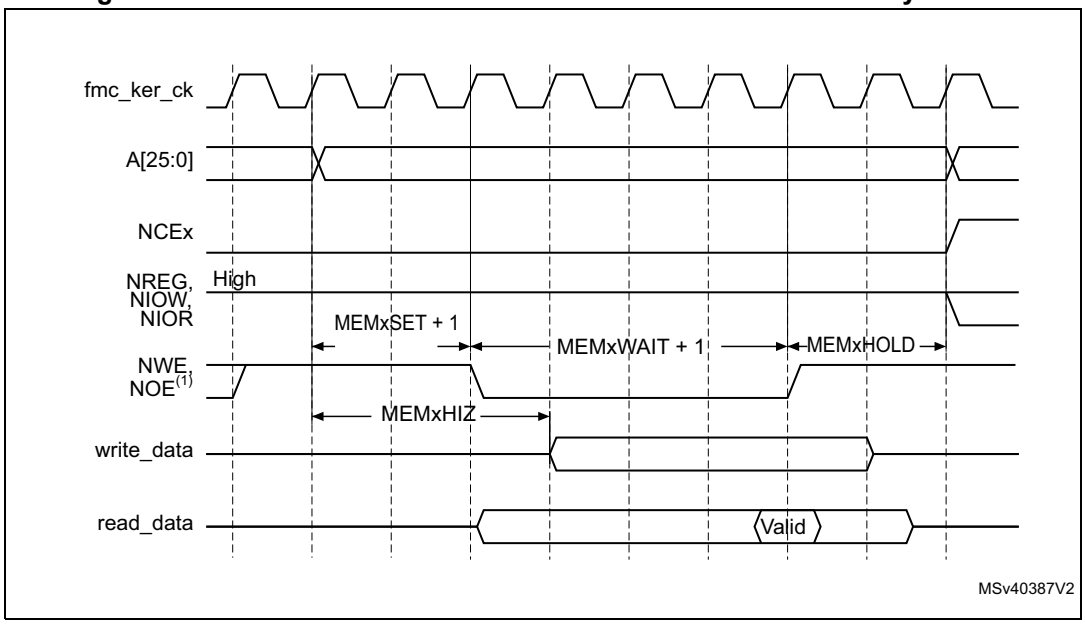
Table 175 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND flash controller are shown in gray.

Table 175. Supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses
	Asynchronous	R	32	8	Y	Split into 8 FMC accesses
	Asynchronous	W	32	8	Y	Split into 8 FMC accesses

Table 175. Supported memories and transactions (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	32	16	Y	Split into 4 FMC accesses
	Asynchronous	W	32	16	Y	Split into 4 FMC accesses



23.8.3 Timing diagrams for NAND flash memories

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the three phases of any NAND flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. *Figure 127* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 127. NAND flash controller waveforms for common memory access

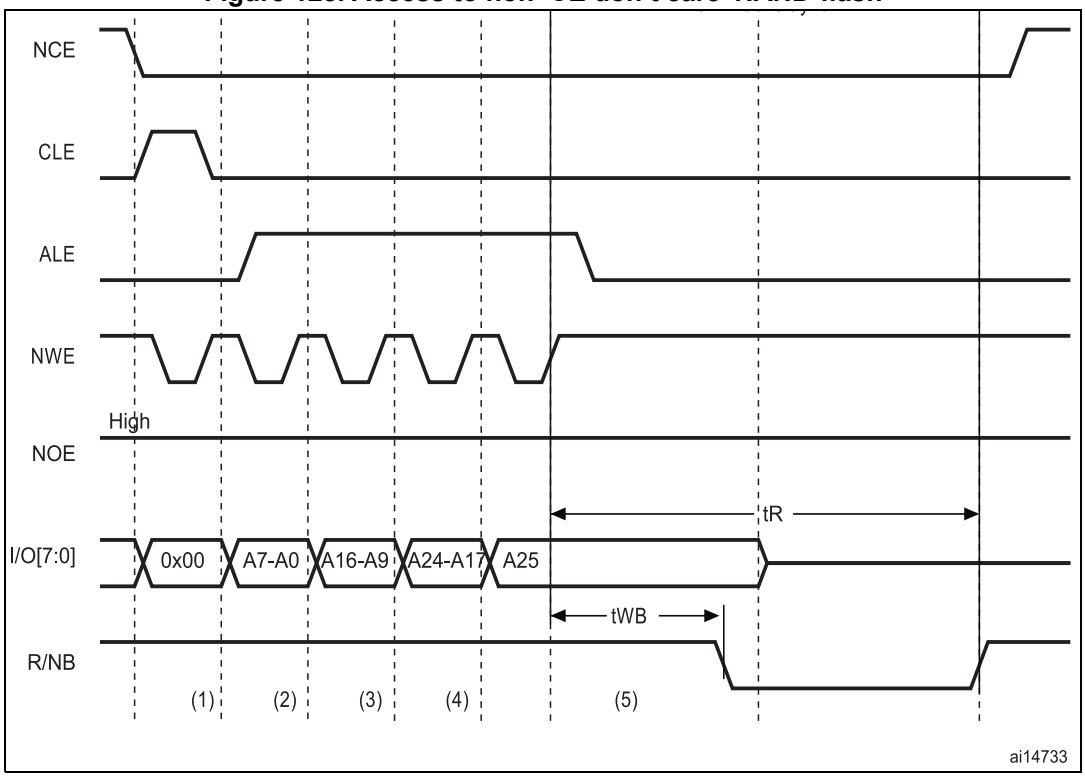
1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write accesses, the hold phase delay is (MEMHOLD) fmc_ker_ck cycles and for read access is (MEMHOLD + 1) fmc_ker_ck cycles.

23.8.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 23.8.5: NAND flash prewait feature*) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash memory, PWAITEN = 0 or 1 as needed, see *Section 23.6.2: NAND flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used



to implement the prewait functionality needed by some NAND flash memories (see details in *Section 23.8.5: NAND flash prewait feature*).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.
6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND flash device by restarting at step 2

23.8.5 NAND flash prewait feature

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see *Figure 128*).

Figure 128. Access to non 'CE don't care' NAND-flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000: FMC performs a write access using FMC_PATT2 timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × fmc_ker_ck = 112 ns > t_{WB} max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don't care).

When this function is required, it can be performed by programming the MEMHOLD value to meet the t_{WB} timing. However, any CPU read access to NAND flash memory has a hold delay of (MEMHOLD + 1) fmc_ker_ck cycles, and any CPU write access has a hold delay of (MEMHOLD) fmc_ker_ck cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t_{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

23.8.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software.The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:

- When accessing NAND flash bank, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

Execute below the sequence to perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

23.8.7 NAND flash controller registers

NAND flash control registers (FMC_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCPS[2:0]			TAR3
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAR[2:0]			TCLR[3:0]				Res.	Res.	ECCEN	PWID[1:0]		Res.	PBKEN	PWAITEN	Res.
rw	rw	rw	rw	rw	rw	rw			rw	rw	rw		rw	rw	

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]:** ECC page size.
These bits define the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]:** ALE to RE delay.
These bits set time from ALE low to RE low in number of fmc_ker_ck clock cycles.
Time is: t_ar = (TAR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the FMC clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 12:9 **TCLR[3:0]:** CLE to RE delay.
These bits set time from CLE low to RE low in number of fmc_ker_ck clock cycles. The time is give by the following formula:
t_clr = (TCLR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the fmc_ker_ck clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]:** Data bus width.
These bits define the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **PBKEN:** NAND flash memory bank enable bit.

This bit enables the memory bank. Accessing a disabled memory bank causes an ERROR on AXI bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN:** Wait feature enable bit.

This bit enables the Wait feature for the NAND flash memory bank:

0: disabled

1: enabled

Bit 0 Reserved, must be kept at reset value.

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

									r	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT:** FIFO empty.

Read-only bit that provides the status of the FIFO

0: FIFO not empty

1: FIFO empty

Bit 5 **IFEN:** Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled

1: Interrupt falling edge detection request enabled

Bit 4 **ILEN:** Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled

1: Interrupt high-level detection request enabled

Bit 3 **IREN:** Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled

1: Interrupt rising edge detection request enabled

Bit 2 **IFS:** Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred
Note: If this bit is written by software to 1 it is set.

Bit 1 **ILS:** Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred

Bit 0 **IRS:** Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred
Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)

Address offset: 0x88

Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZ[7:0]								MEMHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time
These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space. This is only valid for write transactions:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time
These bits define the number of fmc_ker_ck clock cycles for write accesses and fmc_ker_ck+1 clock cycles for read accesses during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: reserved.
0000 0001: 1 fmc_ker_ck cycle for write access / 3 fmc_ker_ck cycle for read access
1111 1110: 254 fmc_ker_ck cycles for write access / 257 fmc_ker_ck cycles for read access
1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

These bits define the minimum number of fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:
0000 0000: reserved
0000 0001: x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]:** Common memory x setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: fmc_ker_ck cycles
1111 1110: 255 x fmc_ker_ck cycles
1111 1111: reserved

Attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 23.8.5: NAND flash prewait feature*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for writ transaction:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

These bits define the number of fmc_ker_ck clock cycles during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space:
0000 0000: reserved
0000 0001: 1 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

These bits define the minimum number of x fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:

0000 0000: reserved

0000 0001: 2 x fmc_ker_ck cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space:

0000 0000: 1 x fmc_ker_ck cycle

1111 1110: 255 x fmc_ker_ck cycles

1111 1111: reserved.

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND flash memory page at the correct address (refer to *Section 23.8.6: Computation of the error correction code (ECC) in NAND flash memory*), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to ’1’.

23.9 SDRAM controller

23.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be fmc_ker_ck/2 or fmc_ker_ck/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

23.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

Table 177. SDRAM signals

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	-
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	-

23.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

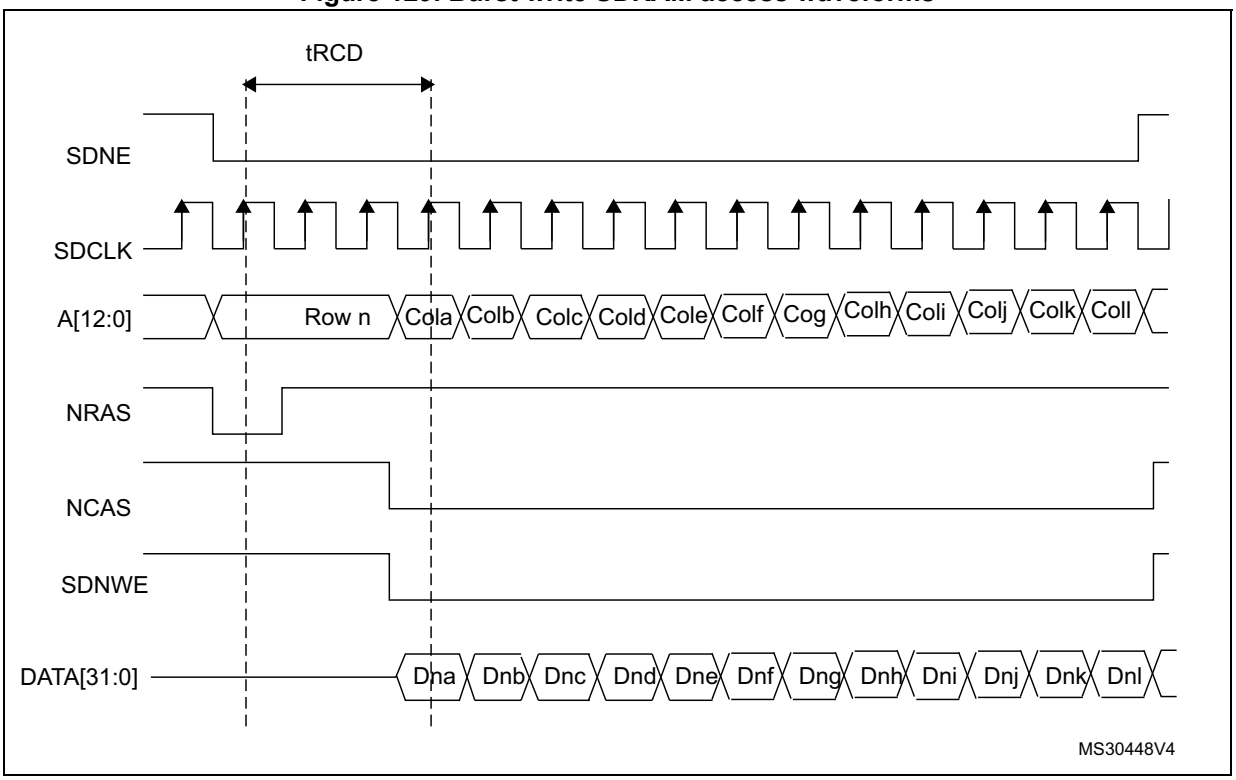
SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 µs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to ‘100’, and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Load Mode Register” command and program the SDRAM device. In particular the Burst Length (BL) has to be set to ‘1’) and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register”
8. Program the refresh rate in the FMC_SDRTR register

   The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefor the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.



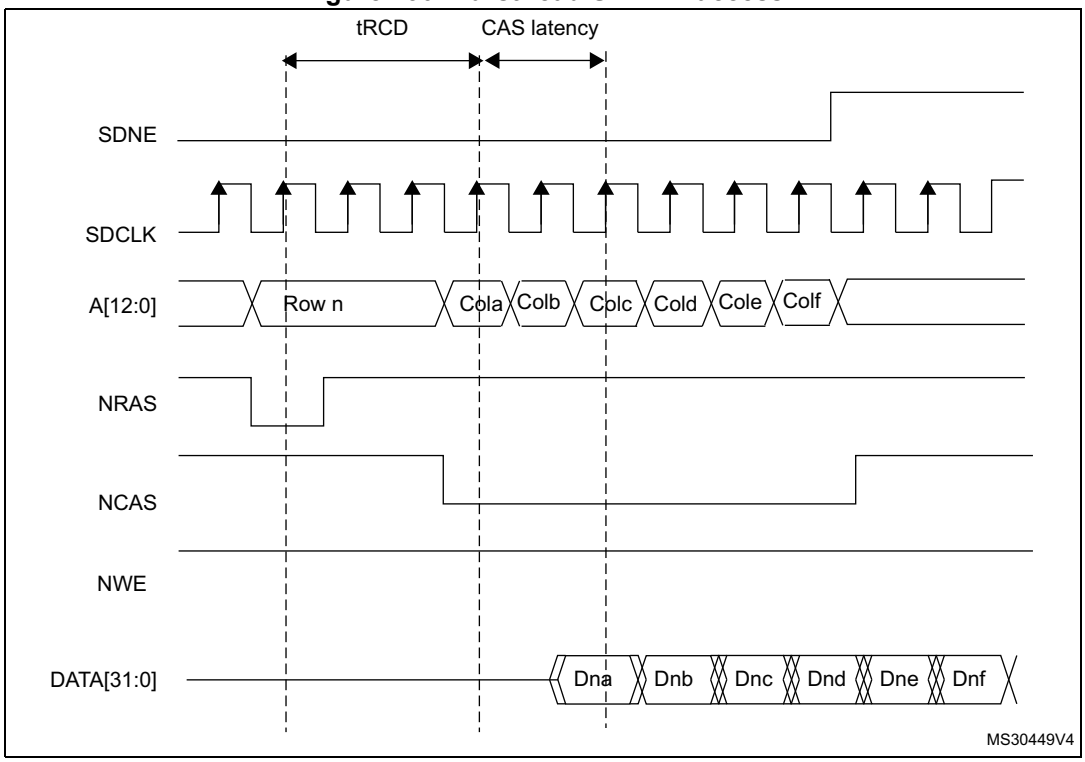
Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD andTRAS timings) in the FMC_SDTR1 register.

SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

Figure 129. Burst write SDRAM access waveforms



The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

SDRAM controller read cycle

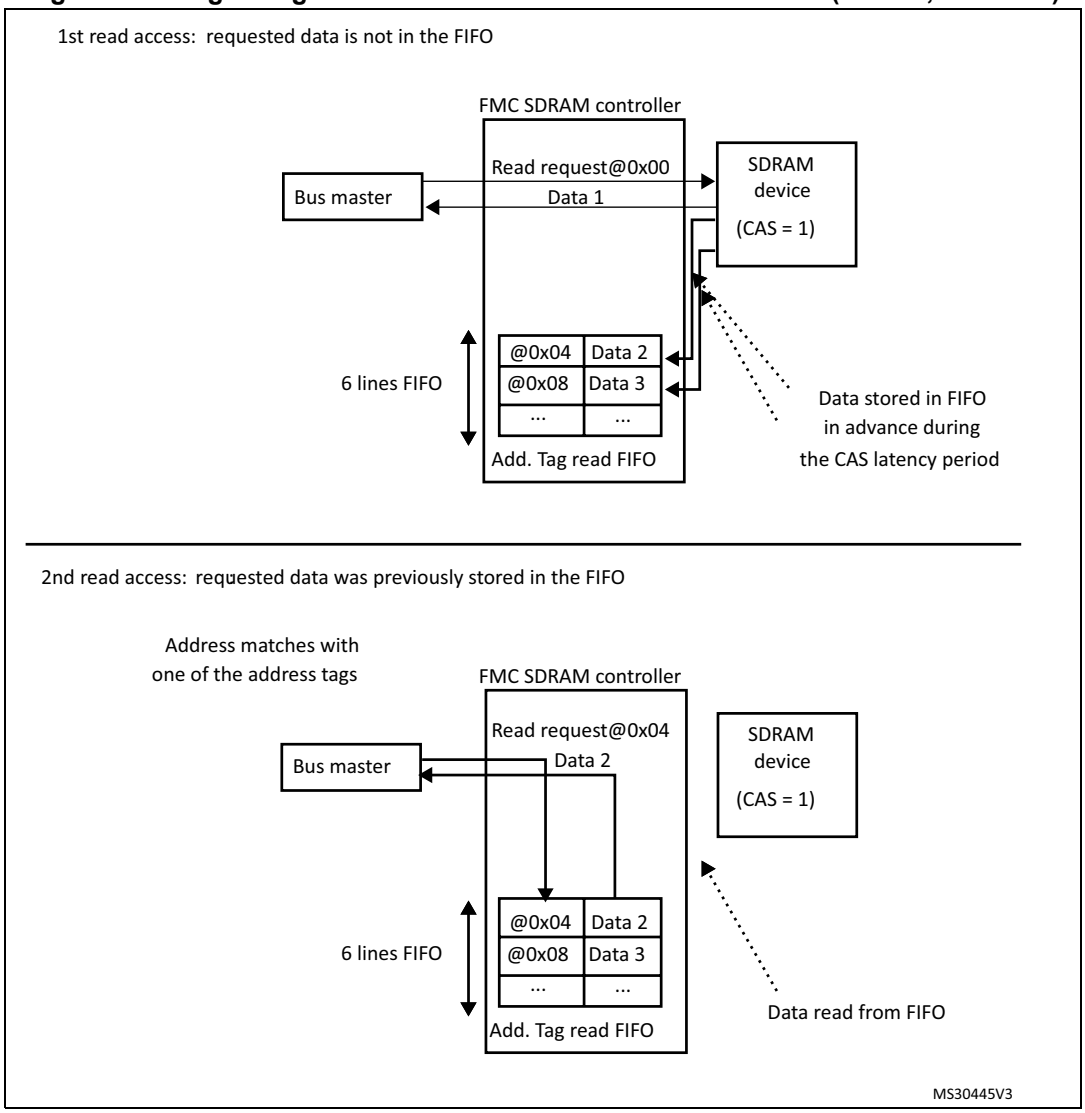
The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 130. Burst read SDRAM access

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC_SDCRx) and during the RPIPE delay when set to 2xfmc_ker_ck clock cycles as configured in FMC_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Examples:

- CAS=3, RPIPE= 2xfmc_ker_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc_ker_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)



The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

Figure 131. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.

The address management depends on the next AXI request:

- Next request is sequential (Burst access)

  In this case, the SDRAM controller increments the address.
- Next request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

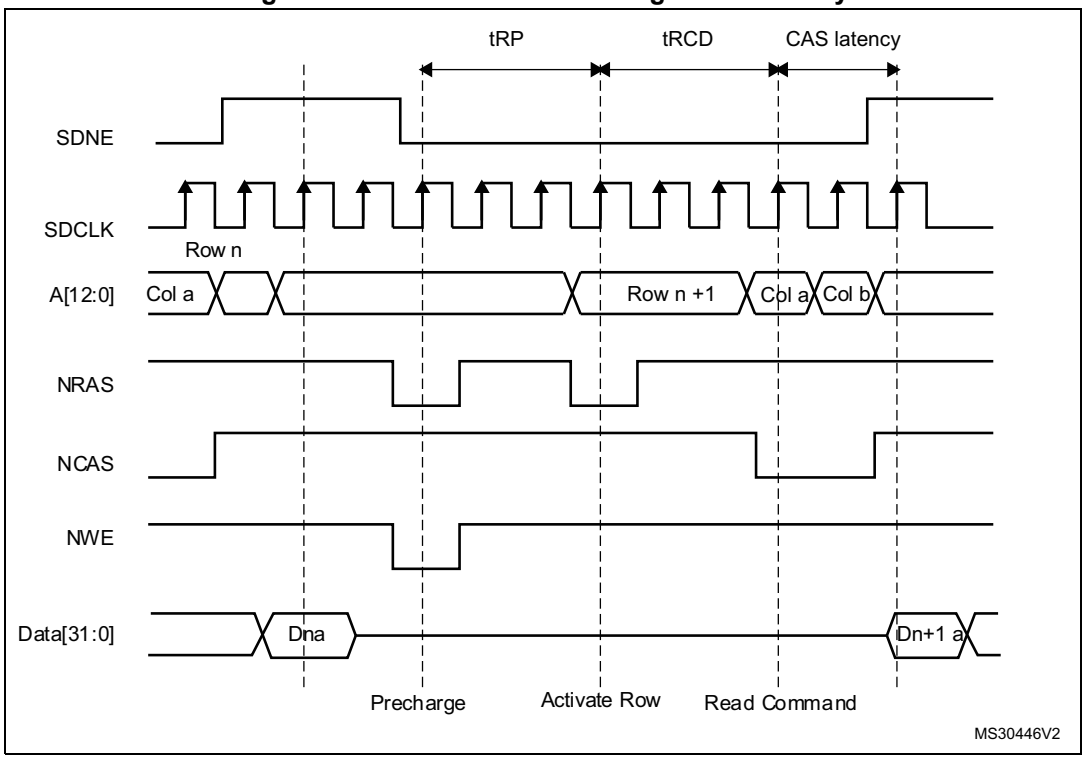
If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to *Figure 129* and *Figure 130* for read and burst write access crossing a row boundary.

Figure 132. Read access crossing row boundary



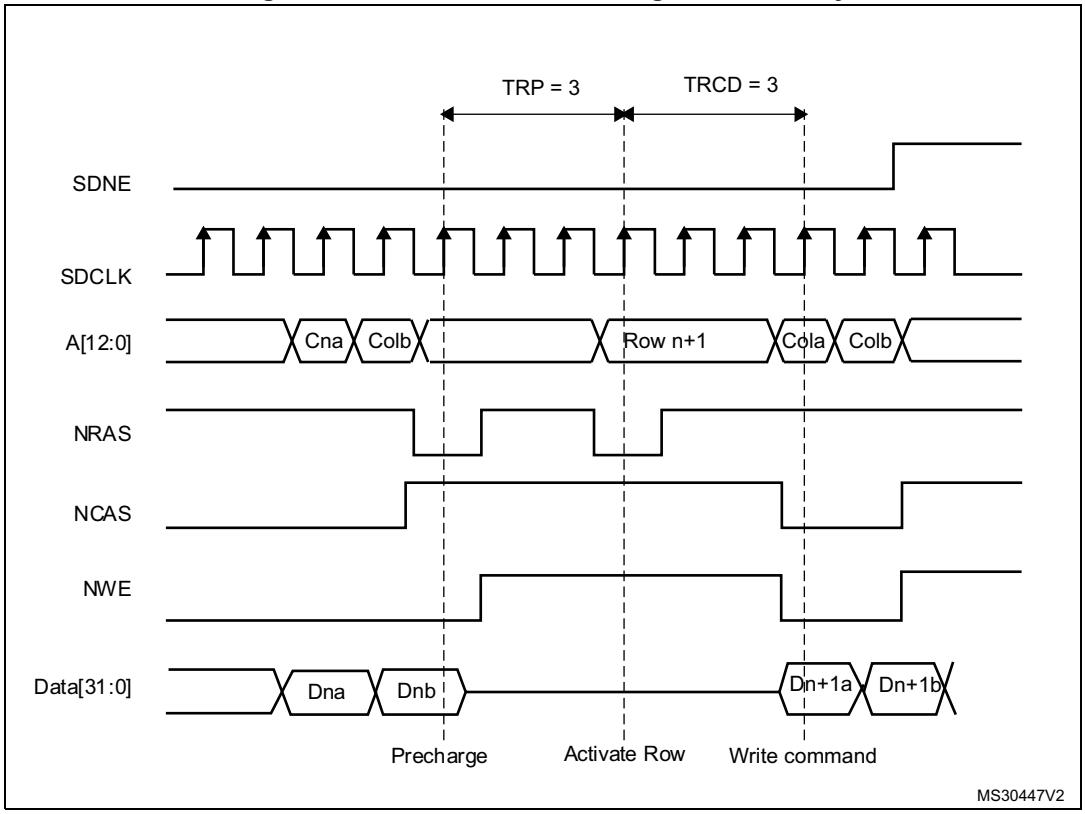


Figure 133. Write access crossing row boundary

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged.At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AXI slave error is generated.
- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits =’ 010’) must be issued first.

23.9.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode

  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode

  The auto-refresh cycles are performed by the SDRAM controller.

Self-refresh mode

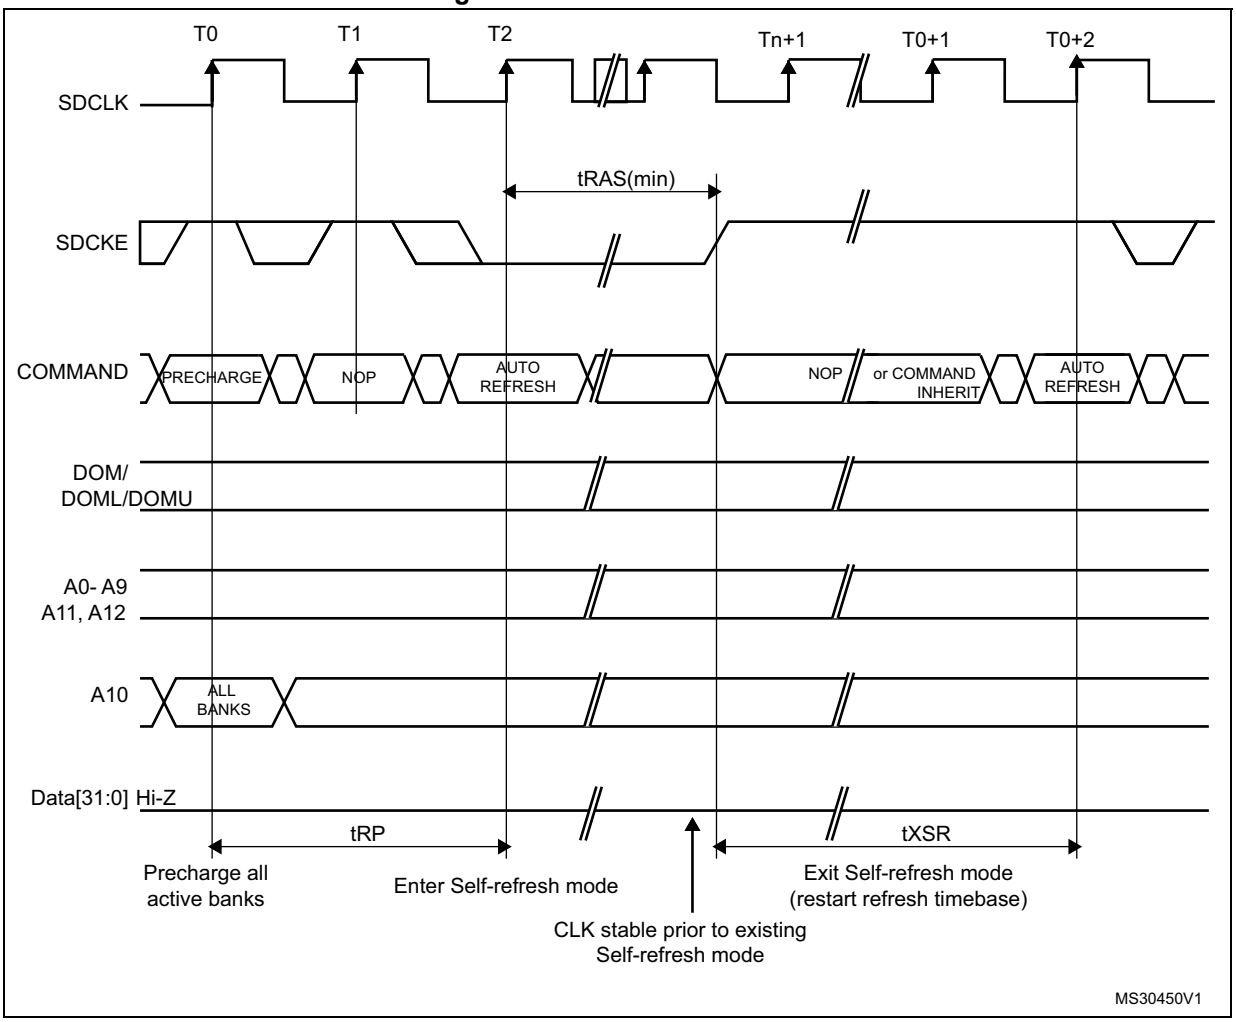
This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.



In Self-refresh mode, all SDRAM device inputs become don’t care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

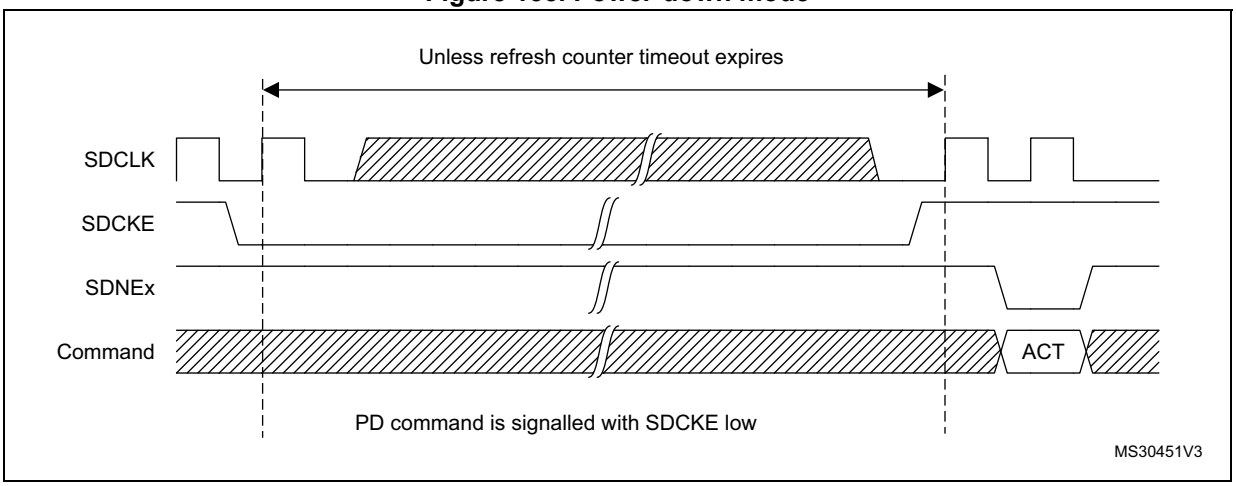


Figure 134. Self-refresh mode

Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

Figure 135. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

23.9.5 SDRAM controller registers

SDRAM Control registers for SDRAM memory bank x (FMC_SDCRx)

Address offset: 0x140+ 0x4* (x - 1), (x = 1 to 2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RPIPE[1:0]		RBURST	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]:** Read pipe

These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency.
00: No fmc_ker_ck clock cycle delay
01: One fmc_ker_ck clock cycle delay
10: Two fmc_ker_ck clock cycle delay
11: reserved.

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 12 **RBURST:** Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.
0: single read requests are not managed as bursts
1: single read requests are always managed as bursts

Note: The corresponding bit in the FMC_SDCR2 register is read only.

Bits 11:10 **SDCLK[1:0]:** SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.
00: SDCLK clock disabled
01: Reserved
10: SDCLK period = 2 x fmc_ker_ck periods
11: SDCLK period = 3 x fmc_ker_ck periods

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 9 **WP:** Write protection

This bit enables Write mode access to the SDRAM bank.
0: Write accesses allowed
1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles
00: reserved.
01: 1 cycle
10: 2 cycles
11: 3 cycles

Bit 6 **NB:** Number of internal banks

This bit sets the number of internal banks.
0: Two internal Banks
1: Four internal Banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: 32 bits
11: reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

Note: Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

SDRAM Timing registers for SDRAM memory bank x (FMC_SDTRx)

Address offset: 0x148 + 0x4 * (x - 1), (x = 1 to 2)

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD[3:0]				TRP[3:0]				TWR[3:0]			
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC[3:0]				TRAS[3:0]				TXSR[3:0]				TMRD[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]:** Row to column delay
These bits define the delay, tRCD, from the Activate command to a Read/Write command in number of memory clock cycles.
0000: 2 cycles
0001: 3 cycles
....
1111: 17 cycles
Note: tRCD delay is replaced by (TWR[3:0]+2) cycles when TWR[3:0] > TRCD[3:0].

Bits 23:20 **TRP[3:0]:** Row precharge delay

These bits define the delay, tRP, between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 19:16 **TWR[3:0]:** Recovery delay

These bits define the delay, tWR, between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TWR must be programmed to match the write recovery time (t_{WR}) defined in the SDRAM datasheet, and to guarantee that:

TWR ≥ TRAS - TRCD and TWR ≥ TRC - TRCD - TRP

Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR ≥ 2 cycles. TWR must be programmed to 0x1.

If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.

If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12 **TRC[3:0]:** Row cycle delay

These bits define the delay, tRC, between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 11:8 **TRAS[3:0]:** Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]:** Exit Self-refresh delay

These bits define the delay, tXSR, from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]:** Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.

The TRP and TRC timings are only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.

SDRAM Command mode register (FMC_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command is issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD[13:7]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD[6:0]							NRFS[3:0]				CTB1	CTB2	MODE[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	w	w	w	w

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:9 **MRD[13:0]:** Mode Register definition

This 14-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command. The MRD[13:0] bits are also used to program the extended mode register for mobile SDRAM.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh
These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.
0000: 1 Auto-refresh cycle
0001: 2 Auto-refresh cycles
....
1110: 15 Auto-refresh cycles
1111: 16 Auto-refresh cycles

Bit 4 **CTB1:** Command Target Bank 1
This bit indicates whether the command is issued to SDRAM Bank 1 or not.
0: Command not issued to SDRAM Bank 1
1: Command issued to SDRAM Bank 1

Bit 3 **CTB2:** Command Target Bank 2
This bit indicates whether the command is issued to SDRAM Bank 2 or not.
0: Command not issued to SDRAM Bank 2
1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]:** Command mode
These bits define the command issued to the SDRAM device.
000: Normal Mode
001: Clock Configuration Enable
010: PALL ("All Bank Precharge") command
011: Auto-refresh command
100: Load Mode Register
101: Self-refresh command
110: Power-down command
111: Reserved

Note: When a command is issued, at least one Command Target Bank bit (CTB1 or CTB2) must be set otherwise the command is ignored.

Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command is ignored.

Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the unused bank must be kept to 0.

SDRAM refresh timer register (FMC_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

Below an example of refresh rate calculation:

$$\text{Refresh rate} = 64\ \text{ms} / (8196\text{rows}) = 7.81\mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81\mu\text{s} \times 60\text{MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	COUNT[12:0]													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **REIE:** RES Interrupt Enable
0: Interrupt is disabled
1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]:** Refresh Timer Count
This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 58 SDRAM clock cycles (0x34).
Refresh rate = (COUNT + 1) x SDRAM frequency clock
COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE:** Clear Refresh error flag
This bit is used to clear the Refresh Error Flag (RE) in the Status Register.
0: no effect
1: Refresh Error flag is cleared

Note: The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles .

SDRAM Status register (FMC_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **MODES2[1:0]:** Status Mode for Bank 2
These bits define the Status Mode of SDRAM Bank 2.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bits 2:1 **MODES1[1:0]:** Status Mode for Bank 1
These bits define the Status Mode of SDRAM Bank 1.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bit 0 **RE:** Refresh error flag
0: No refresh error has been detected
1: A refresh error has been detected
An interrupt is generated if REIE = 1 and RE = 1

23.9.6 FMC register map

The following table summarizes the FMC registers.

Table 178. FMC register map

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 130* for the register boundary addresses.

24 Octo-SPI interface (OCTOSPI)

24.1 OCTOSPI introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

24.2 OCTOSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, and octal communication
- Dual memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI interface with transaction acceptance limited to one: the interface accepts the next transfer on AXI bus only once the previous is completed on memory side.

Signal name	Type	Description
octospi_dma	N/A	DMA request signal
octospi_it	Output	Global interrupt line (see *Table 185* for the multiple sources of interrupt)

24.4.3 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:

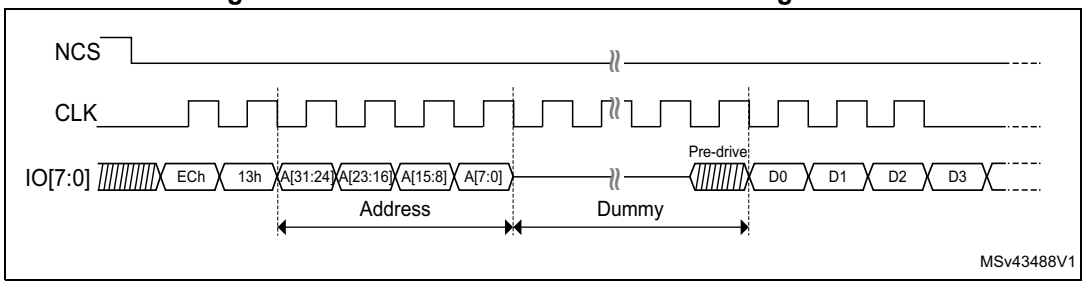
- regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

24.4.4 OCTOSPI regular-command protocol

When in regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:



- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 139. SDR read command in octal configuration

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR, and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in OCTOSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in OCTOSPI_AR. In memory-mapped mode, the address is given directly via the AXI (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO single in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR, and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-SPI, the quad-SPI, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR, and the data received from the external device can be obtained by reading OCTOSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

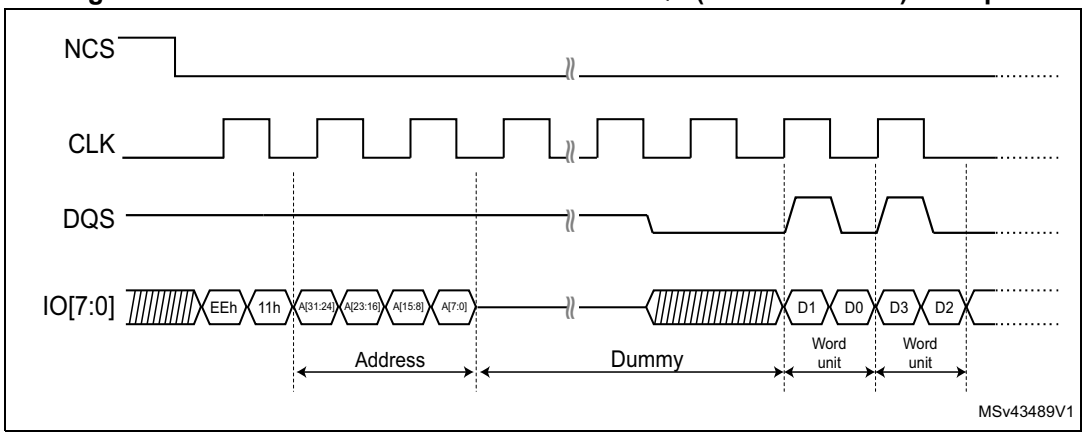
The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.



In memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in OCTOSPI_CCR.

Figure 140. DTR read in octal-SPI mode with DQS (Macronix mode) example

24.4.5 OCTOSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the OCTOSPI generating the clock.

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

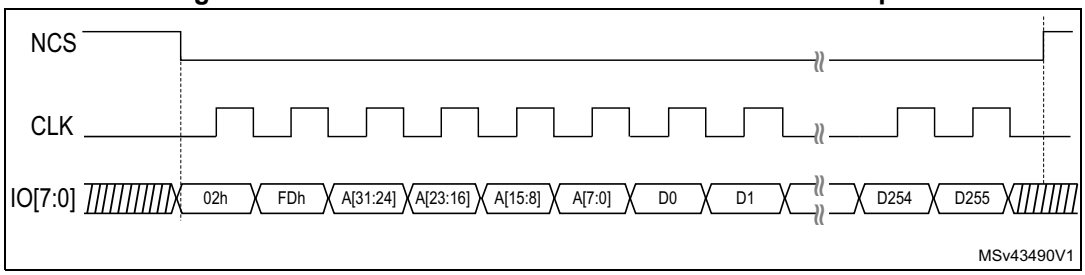
Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.



Single-data rate (SDR) mode

By default, all the phases operate in SDR mode.

In this mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

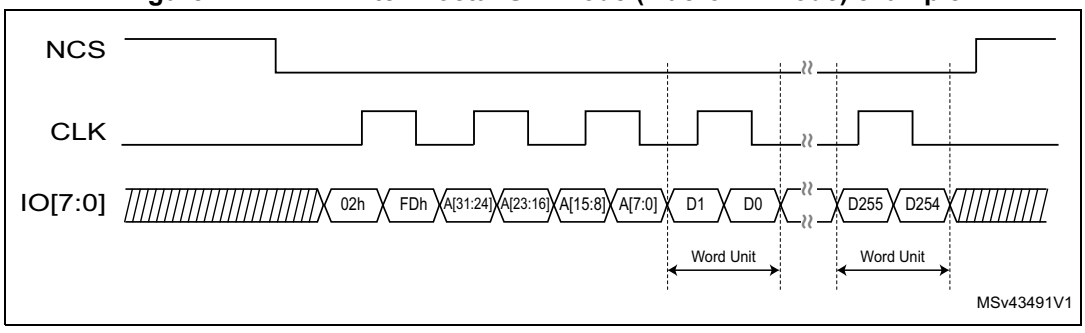
Figure 141. SDR write command in octo-SPI mode example

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.



In DTR mode, when the OCTOSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 142. DTR write in octal-SPI mode (Macronix mode) example

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 011, two external Quad-SPI devices (device A and device B) are used in order to

send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in OCTOSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

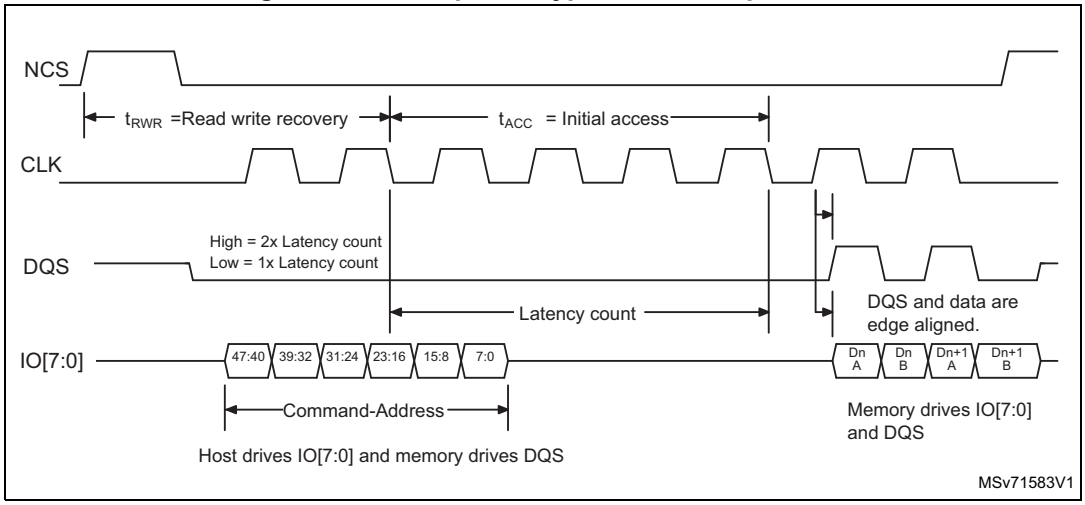
Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

24.4.6 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)



The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 143. Example of HyperBus read operation

Note: Due to internal synchronization, up to six extra dummy clock cycles may be generated by the Octo-SPI interface after the last data is read.

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 182. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

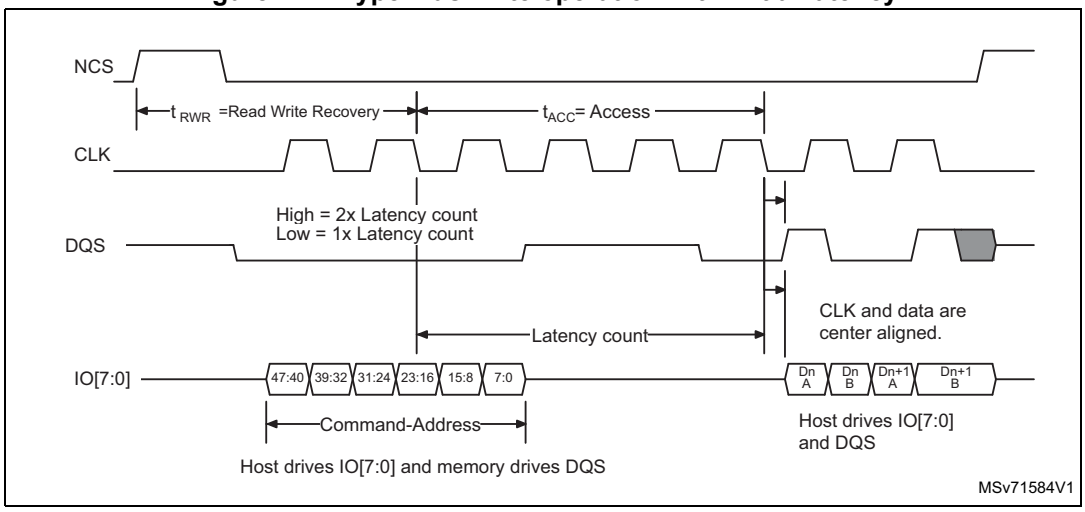
The address space is configured through the memory type MTYP[2:0] in OCTOSPI_DCR1.

The total size of the device must be configured through DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in OCTOSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in OCTOSPI_HLCR) according to the memory latency



During the read operation, the DQS is used by the device, in two ways (see *Figure 143*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

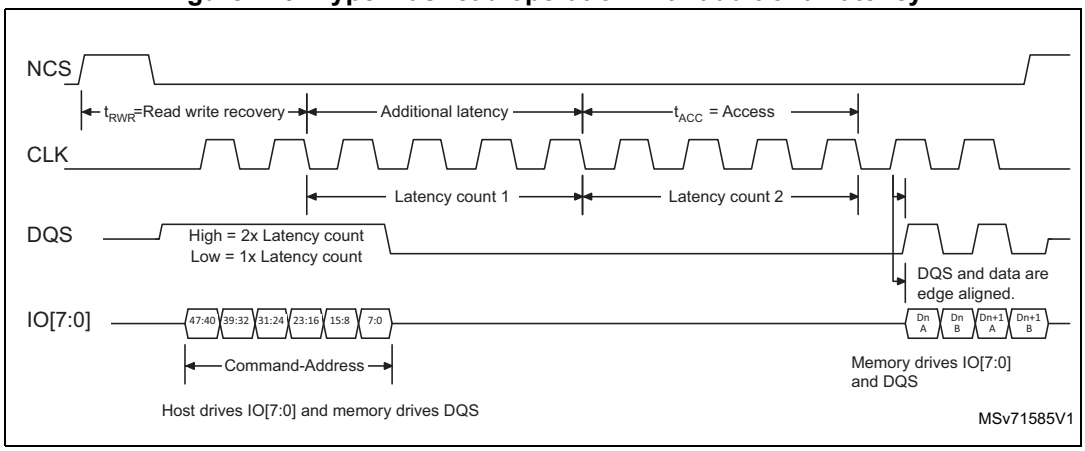
Figure 144. HyperBus write operation with initial latency

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the OCTOSPI to meet the device request.

Figure 145. HyperBus read operation with additional latency



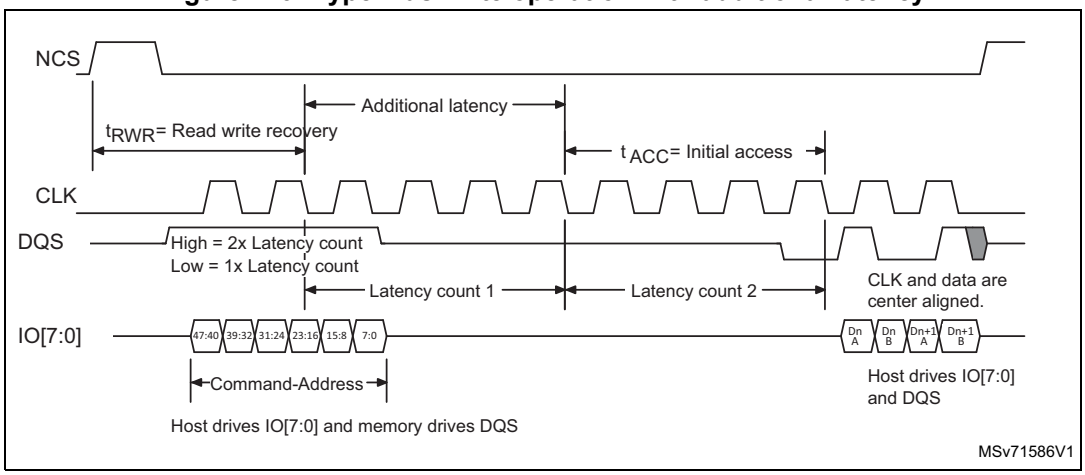


Figure 146. HyperBus write operation with additional latency

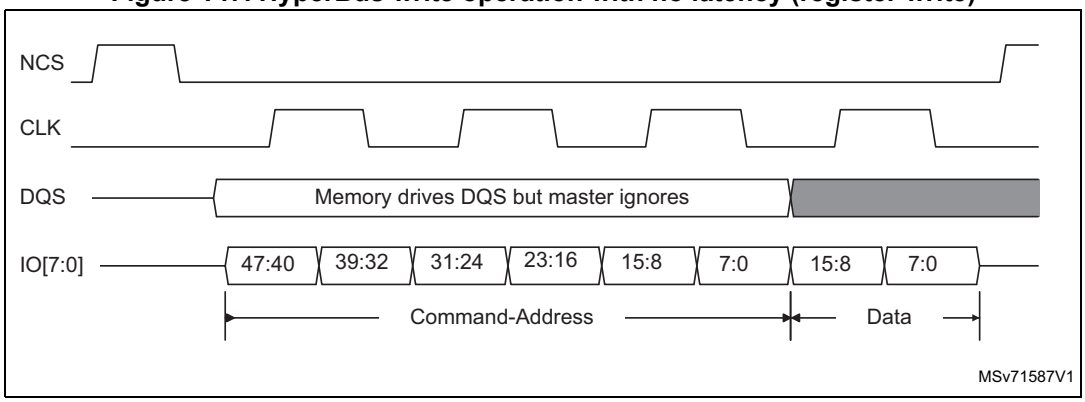
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.



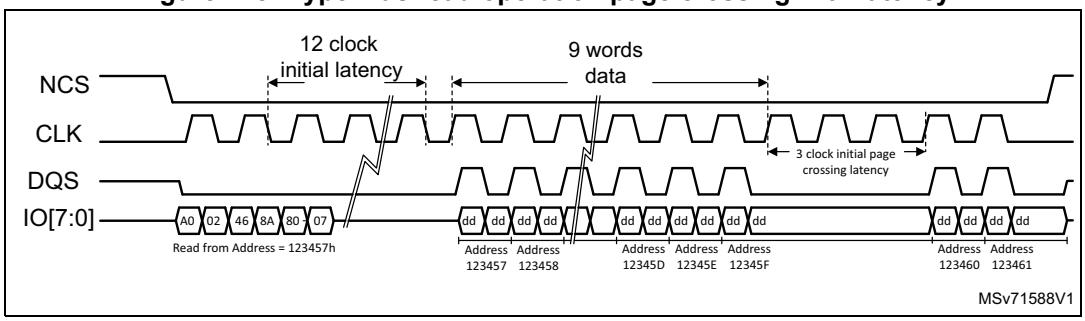
The latency can be forced to 2 x t_{ACC} by setting LM in OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the DQS signal is not taken into account by the OCTOSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 147. HyperBus write operation with no latency (register write)



Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 148. HyperBus read operation page crossing with latency

24.4.7 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

Wrap support

The OCTOSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated OCTOSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (OCTOSPI_CCR, OCTOSPI_TCR, OCTOSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in OCTOSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature limits the maximum length of a transaction to the value programmed by MAXTRAN[7:0] in OCTOSPI_DCR3.

If the number of clock cycles reaches the MAXTRAN + 1 value, and if the second OCTOSPI requests access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the flash memory devices that require extra command to reenable the write operation after the NCS is active again.

If NCS boundary, refresh, and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, reissues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

24.4.8 OCTOSPI operating mode introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

24.4.9 OCTOSPI indirect mode

In indirect mode, the commands are started by writing to the OCTOSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in OCTOSPI_CR, the OCTOSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading OCTOSPI_DR.

In indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in OCTOSPI_SR, and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

24.4.10 OCTOSPI automatic status-polling mode

In automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. The memory must then be configured in fixed latency.

24.4.11 OCTOSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the OCTOSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

24.4.12 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

24.4.13 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

24.4.14 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[2:0]
- the clock mode with FRCK and CKMODE
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{\text{DEVSIZE+1}}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

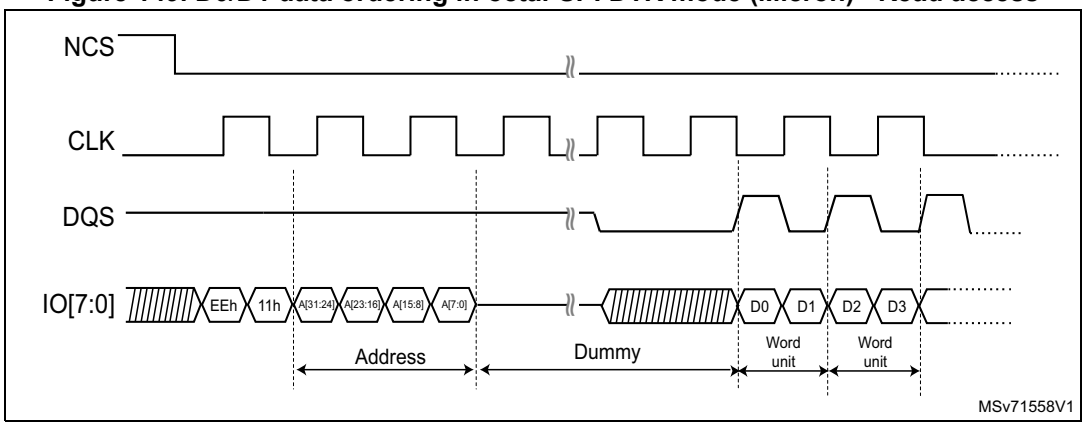
If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[2:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in OCTOSPI_HLCR.



Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the OCTOSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 149. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 140: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 183: OctaRAM command address bit assignment (based on 64-Mbyte OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock one when reading data from the memory.

Figure 150. OctaRAM read operation with reverse data ordering D1/D0

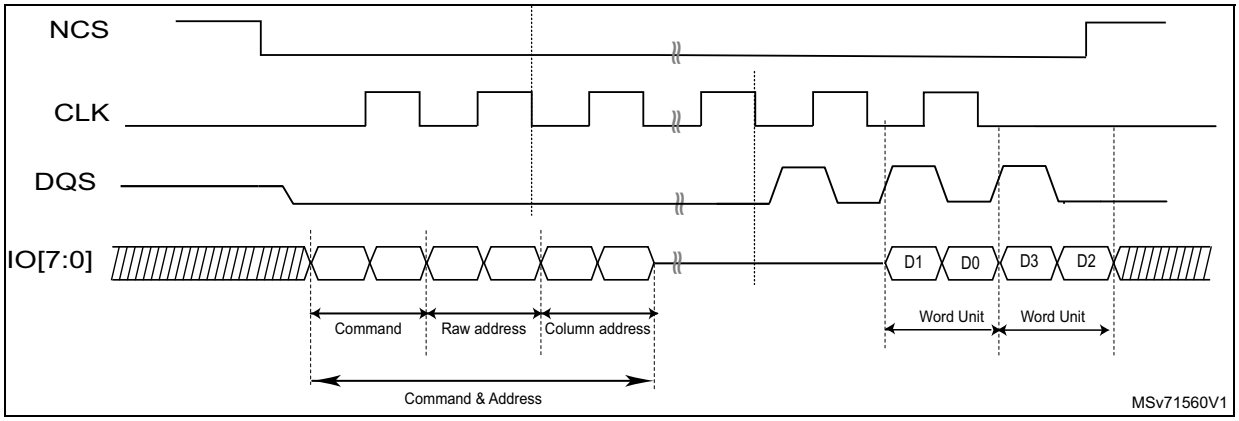


Table 183. OctaRAM command address bit assignment (based on 64-Mbyte(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64-Mbyte OctaRAM address assignment:
Row Address [RA12:RA0]: 8K. Column address [CA9:CA0]: 1K. 64-Mbyte density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.
- Standard mode. It is the mode to use whenever the targeted memory is not corresponding to any others configurations described in this section. MTYP[2:0] = 010 for this standard mode.

24.4.15 OCTOSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.

2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

When the OCTOSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the OCTOSPI becomes

busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

Memory-mapped write operations are not supported without write strobe.

OCTOSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

OCTOSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay.

This shift is performed by a delay hardware element located outside of the controller into the RCC (RCC_DLYCFGR) or implemented on an external dedicated block delay peripheral depending on the product (refer to the product reference manual for information about how to manage and configure the delay).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

Sending the instruction only once (SIOO)

A flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

The SIOO mode is not supported when any of the communication regulations, NCS boundary, or refresh features are used.

24.4.16 OCTOSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the OCTOSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Enable the DMA channel if needed.

4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

24.4.17 OCTOSPI error management

The following errors set the TEF flag in OCTOSPI_SR and generates an interrupt if enabled (TEIE = 1 in OCTOSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]).
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.

In memory-mapped mode, the OCTOSPI generates an AXI slave error in the following situations:

- The memory-mapped mode is disabled and an AXI read or write request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing.
- The OCTOSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in OCTOSPI_WCCR in octal DTR mode, in dual-memory configuration, in HyperBus mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the AXI bus Transfer size (ARSIZE) is different from 8 bytes (only for memory-mapped mode).
- Bit DMM is set in OCTOSPI_CR (dual-memory configuration) and octal mode is set.

24.4.18 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

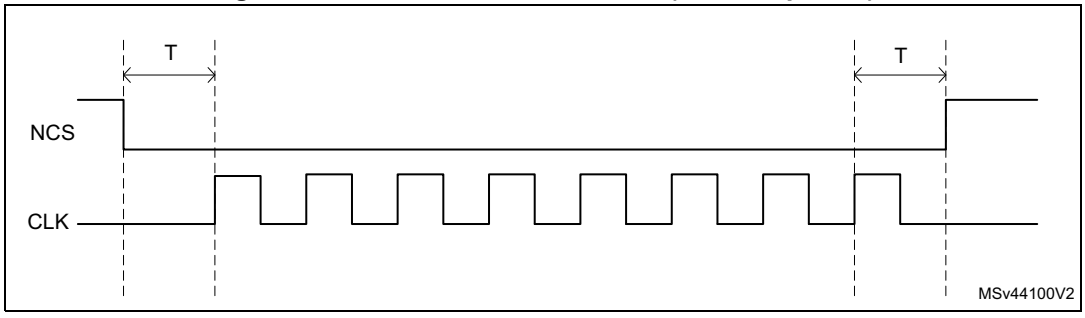
Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in OCTOSPI_DR, it is recommended to disable the DMA channel before aborting the OCTOSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

24.4.19 OCTOSPI reconfiguration or deactivation

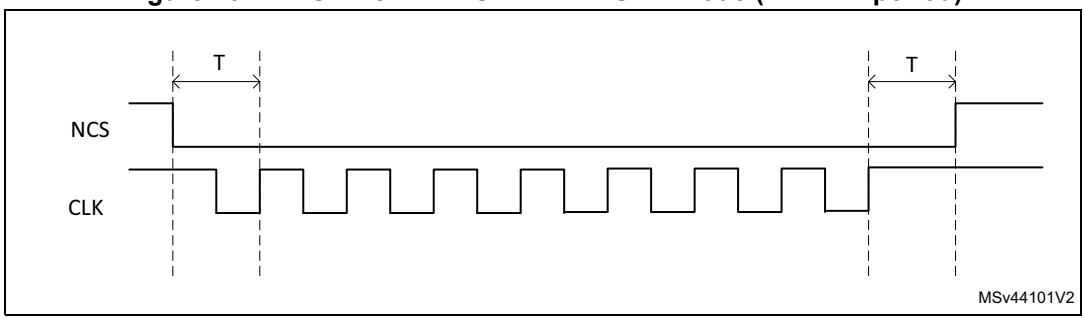
Before any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:



- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

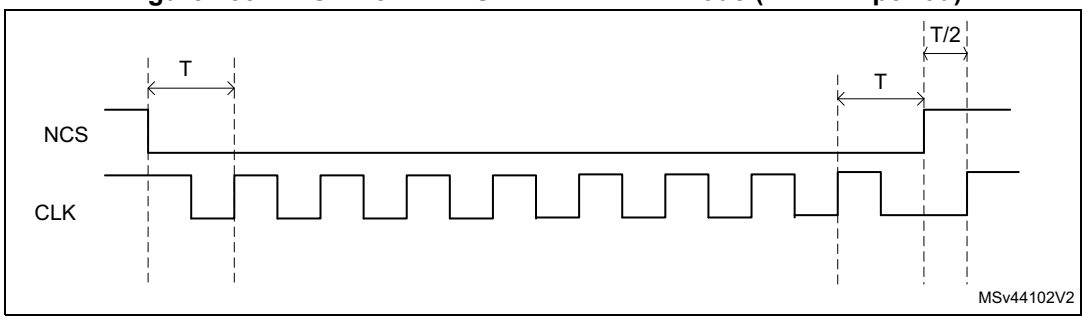
24.4.20 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.



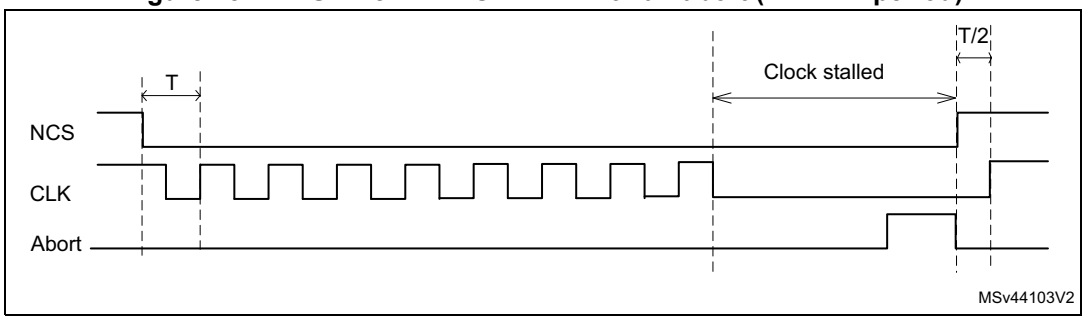
When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 151. NCS when CKMODE = 0 (T = CLK period)



When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 152. NCS when CKMODE = 1 in SDR mode (T = CLK period)



When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 153. NCS when CKMODE = 1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 154. NCS when CKMODE = 1 with an abort (T = CLK period)

24.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 184. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.

7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

24.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 185. OCTOSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

24.7 OCTOSPI registers

24.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	FMODE[1:0]		Res.	Res.	Res.	Res.	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
		rw	rw					rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					FSEL	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the OCTOSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode

This bit indicates which method must be used to determine a match during the automatic status-polling mode.

0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.

1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop

This bit determines if the automatic status-polling mode is stopped after a match.

0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.

1: Automatic status-polling mode stops as soon as there is a match.

Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable

This bit enables the timeout interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable

This bit enables the status-match interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable

This bit enables the FIFO threshold interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable

This bit enables the transfer complete interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable

This bit enables the transfer error interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.

00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.

00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.

...

11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.

Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 **FSEL**: Flash select

This bit selects the flash memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).

0: FLASH 1 selected (data exchanged over IO[3:0])

1: FLASH 2 selected (data exchanged over IO[7:4])

This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the OCTOSPI.

0: OCTOSPI disabled

1: OCTOSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

24.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	Res.	DEVSIZE[4:0]				
					rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CSHT[2:0]			Res.	Res.	Res.	Res.	DLY BYP	Res.	FRCK	CKMODE
					rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect-read/write modes must be used.

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **CSHT[2:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.
000: NCS stays high for at least 1 cycle between external device commands.
001: NCS stays high for at least 2 cycles between external device commands.
...
111: NCS stays high for at least 8 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).
1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.
0: CLK is not free running.
1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set. Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).
0: CLK must stay low while NCS is high (chip-select released). This is referred to as clock mode 0.
1: CLK must stay high while NCS is high (chip-select released). This is referred to as clock mode 3.

24.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

24.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAXTRAN[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer

This bitfield enables the communication regulation feature. The NCS is released every MAXTRAN+1 clock cycles when the other OCTOSPI request the access to the bus.

0: Maximum communication disabled

Others: Maximum communication is set to MAXTRAN + 1 bytes.

24.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Others: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the divided clock period: if OCTOSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

24.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

24.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the OCTOSPI_SR register.

Bit 3 **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the OCTOSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the OCTOSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the OCTOSPI_SR register.

24.7.8 OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

24.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

24.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

24.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

24.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match
Value to be compared with the masked status register to get a match

24.7.13 OCTOSPI polling interval register (OCTOSPI_PIR)

Address offset: 0x0090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval
Number of CLK cycles between a read during the automatic status-polling phases

24.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR)

Address offset: 0x0100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SIOO	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **SIOO**: Send instruction only once mode
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIOO)*).
0: Send instruction on every transaction
1: Send instruction only for the first command

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

24.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

0: No delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).
It is recommended to have at least six dummy cycles when using memories with DQS activated.

24.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

24.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR)

Address offset: 0x00130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period
After each access in memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.
This bitfield indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

24.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

010: Data on two lines
011: Data on four lines
100: Data on eight lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: no alternate bytes
001: alternate bytes on a single line
010: alternate bytes on two lines
011: alternate bytes on four lines
100: alternate bytes on eight lines
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

24.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR)

Address offset: 0x0148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle

Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

24.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.
0: Variable initial latency
1: Fixed latency

24.7.28 OCTOSPI register map

Table 186. OCTOSPI register map and reset values

25 Octo-SPI I/O manager (OCTOSPIM)

25.1 Introduction

The Octo-SPI I/O manager is a low-level interface that enables an efficient OCTOSPI pin assignment with a full I/O matrix (before alternate function map), and multiplex of single/dual/quad/octal SPI interfaces over the same bus.

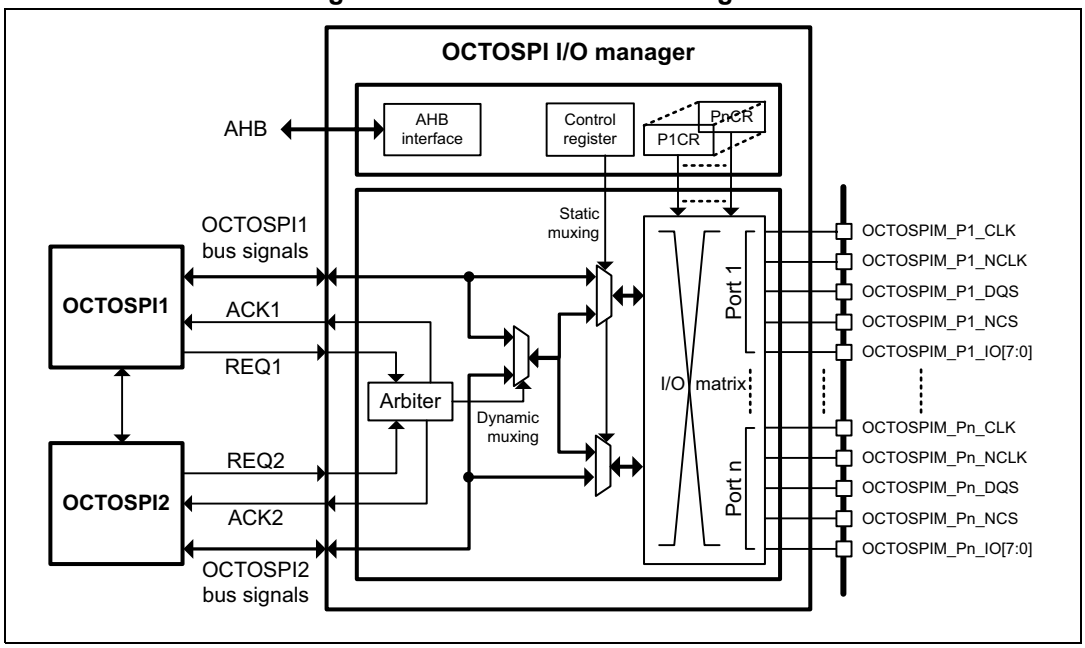
25.2 OCTOSPIM main features

- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

25.3 OCTOSPIM implementation

The following table describes the OCTOSPIM implementation.

Table 187. OCTOSPIM implementation



OCTOSPI feature	Available on the devices
Supports up to two single/dual/quad interfaces	X
Fully I/O multiplexing capability	X
Supports time-multiplexed mode	X
Supports high-speed interface	-
Chip select selection if OCTOSPI provides dual chip select	-
Supports 16-bit data interface and dual-octal mode	-

25.4 OCTOSPIM functional description

25.4.1 OCTOSPIM block diagram

The block diagram of the OCTOSPI I/O manager is shown in *Figure 155*.

Figure 155. OCTOSPIM block diagram

1. The number of ports (n) is 2.
2. Arbitration is possible for both I/O matrix input ports.

25.4.2 OCTOSPIM input/output pins

Table 188. OCTOSPIM input/output pins

Pin name(1)	Signal type	Description
OCTOSPIM_Px_NCLK	Output	OCTOSPI inverted clock to support 1.8 V HyperBus protocol
OCTOSPIM_Px_CLK		OCTOSPI clock
OCTOSPIM_Px_IOn (n = 0 to 7)	Input/output	OCTOSPI data pins
OCTOSPIM_Px_NCS	Output	Chip select for the memory
OCTOSPIM_Px_DQS	Input/output	Data strobe/write mask signal from/to the memory

1. x = 1 to 2.

25.4.3 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable premapping of functions:

- Any OCTOSPIM_Pn_CLK / OCTOSPIM_Pn_NCLK pair can be mapped independently to OCTOSPI1_CLK/OCTOSPI1_NCLK or OCTOSPI2_CLK/OCTOSPI2_NCLK
- Any OCTOSPIM_Pn_DQS can be mapped independently to OCTOSPI1_DQS or OCTOSPI2_DQS
- Any OCTOSPIM_Pn_NCS can be mapped independently to OCTOSPI1_NCS or OCTOSPI2_NCS
- Any OCTOSPIM_Pn_IO[3:0] and OCTOSPIM_Pn_IO[7:4] can be mapped independently to OCTOSPI1_IO[3:0], OCTOSPI1_IO[7:4], OCTOSPI2_IO1[3:0] or OCTOSPI2_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM_PnCR).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when all OCTOSPIs are disabled.

25.4.4 OCTOSPIM multiplexed mode

When this mode is set, the OCTOSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to manage accurately the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPI(s). When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when another OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPIn_NCS are not part of the multiplexing.Only OCTOSPIn_IOs, OCTOSPIn_DQS and OCTOSPIn_CLK / OCTOSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may increase.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.

This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting one).

The REQ2ACK_TIME field of the configuration register OCTOSPIM_CR defines the duration.

Pin mapping in multiplexed mode

In multiplexed mode, the mapping of the bus is done as described below:

- OCTOSPI1_NCS and OCTOSPI2_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSPI1.

25.5 OCTOSPIM registers

25.5.1 OCTOSPIM control register (OCTOSPIM_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REQ2ACK_TIME[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUXEN
															rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REQ2ACK_TIME[7:0]**: REQ to ACK time
In multiplexed mode (MUXEN = 1), this field defines the time between two transactions.
The value is the number of OCTOSPI clock cycles - 1

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MUXEN**: Multiplexed mode enable
This bit enables the multiplexing of the two OCTOSPIs.
0: No multiplexing, hence no arbitration
1: OCTOSPI1 and OCTOSPI2 are multiplexed over the same bus.

25.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR)

Address offset: 0x0000 + 0x4 * n (n = 1 to 2)

Reset value: 0x0301 0111, 0x0705 0333

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	IOHSRC[1:0]		IOHEN	Res.	Res.	Res.	Res.	Res.	IOLSRC[1:0]		IOLEN
					rw	rw	rw						rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

						rw	rw			rw	rw			rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:25 **IOHSRC[1:0]**: IO[7:4] source for Port n
This bits select the source of Port n IO[7:4].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
01: OCTOSPI1_IO[7:4] in non multiplexed mode / multiplexed_IO[7:4] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 24 **IOHEN**: IO[7:4] enable for Port n
This bit enables the Port n IO[7:4].
0: IO[7:4] for Port n disabled
1: IO[7:4] for Port n enabled

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:17 **IOLSRC[1:0]**: IO[3:0] source for Port n
This bits select the source of Port n IO[3:0].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
01: OCTOSPI1_IO[7:4] in non multiplexed mode / multiplexed_IO[7:4] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16 **IOLEN**: IO[3:0] enable for Port n
This bit enables the Port n IO[3:0].
0: IO[3:0] for Port n disabled
1: IO[3:0] for Port n enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **NCSSRC**: NCS source for Port n
This bit selects the source of Port n NCS.
0: OCTOSPI1_NCS
1: OCTOSPI2_NCS

Bit 8 **NCSEN**: NCS enable for Port n
This bit enables the Port n NCS.
0: NCS for Port n is disabled
1: NCS for Port n is enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **DQSSRC**: DQS source for Port n
This bit selects the source of Port n DQS.
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4 **DQSEN**: DQS enable for Port n
This bit enables the Port n DQS.
0: DQS for Port n is disabled
1: DQS for Port n is enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **CLKSRC**: CLK/NCLK source for Port n
This bit selects the source of Port n CLK/NCLK.
0: OCTOSPI1_CLK/NCLK in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode
1: OCTOSPI2_CLK/NCLK in non multiplexed mode / unused port in multiplexed mode

Bit 0 **CLKEN**: CLK/NCLK enable for Port n
This bit enables the Port n CLK/NCLK.
0: CLK/NCLK for Port n is disabled
1: CLK/NCLK for Port n is enabled

25.5.3 OCTOSPIM register map

Refer to *Section 2.3 on page 130* for the register boundary addresses.

26 Delay block (DLYB)

26.1 DLYB introduction

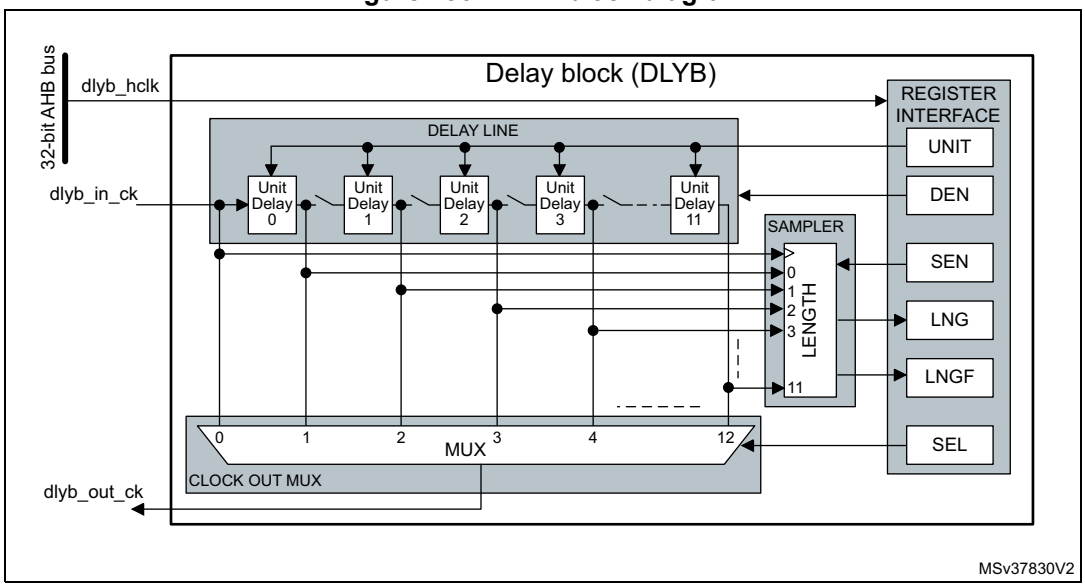
The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

26.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.



26.3 DLYB functional description

26.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 156. DLYB block diagram

26.3.2 DLYB pins and internal signals

Table 190 lists the DLYB internal signals.

Table 190. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

26.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 191. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don’t care	Don’t care	Don’t care	Don’t care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don’t care	Don’t care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

26.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

26.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

Octo-SPI use case:

The delay block is used in conjunction with Octo-SPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small "Unit" gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

26.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

26.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

26.4.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

26.4.3 DLYB register map

Table 192. DLYB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

27 Analog-to-digital converters (ADC)

27.1 ADC introduction

This section describes the ADC implementation:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 16-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

27.2 ADC main features

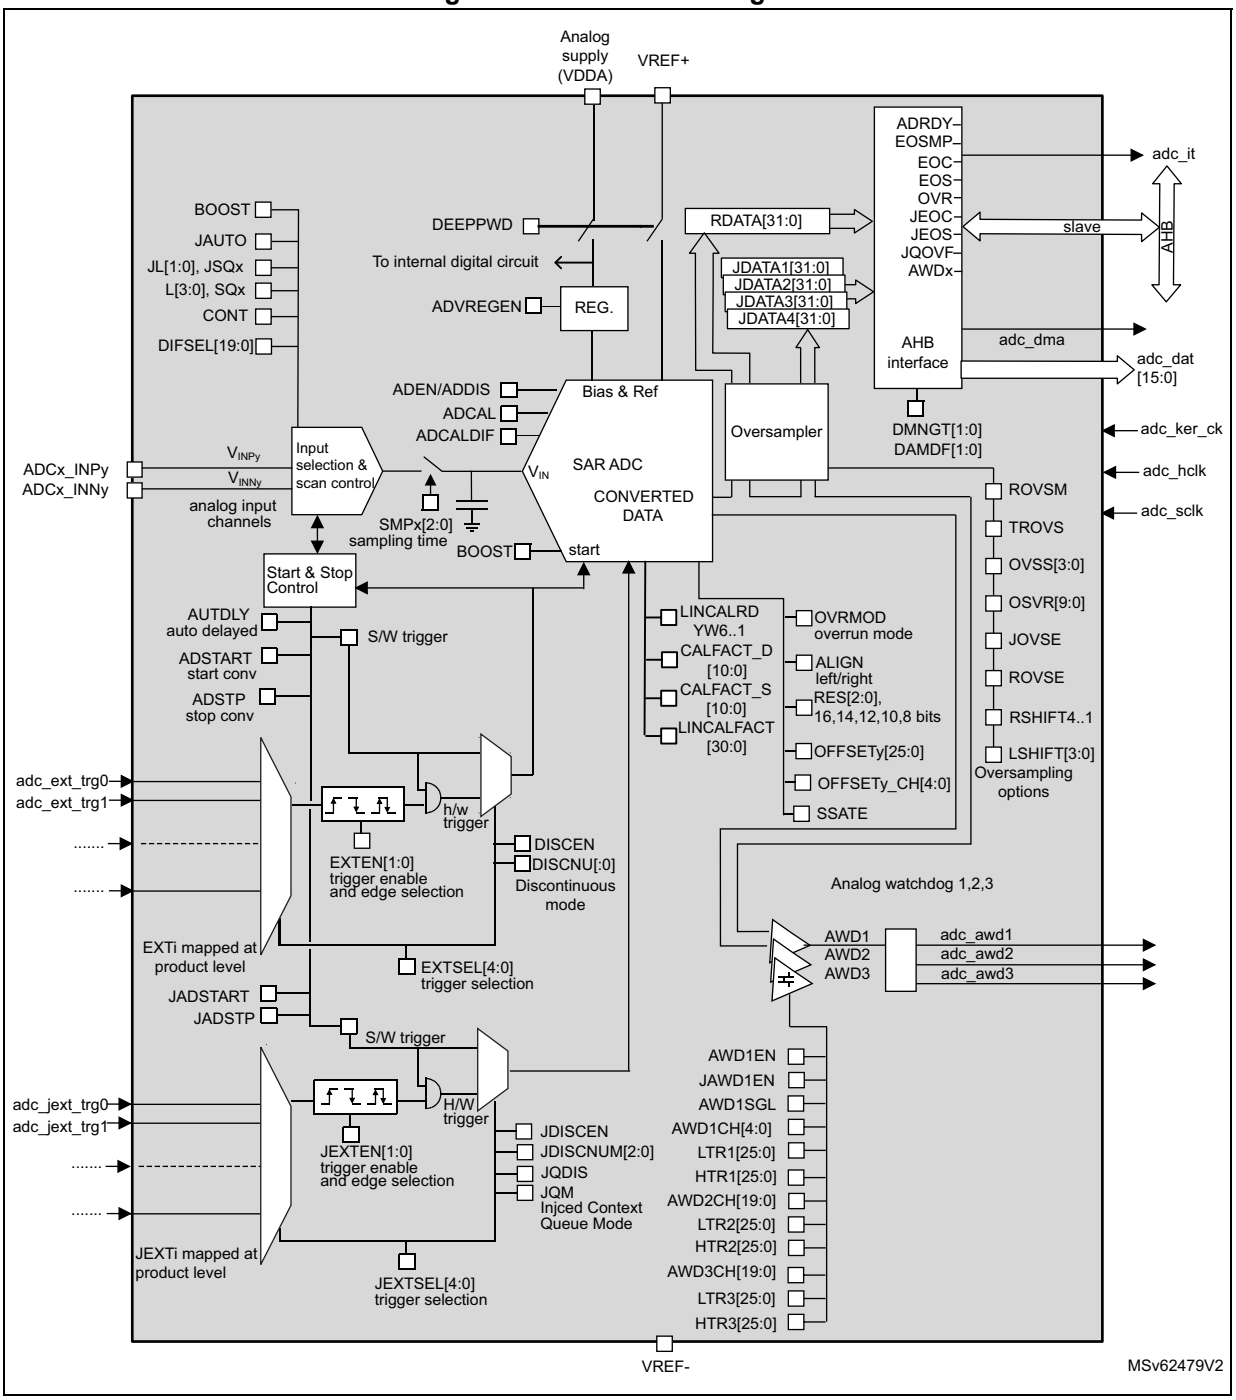
- High-performance features
  - Up to 2x ADCs which can operate in dual mode
  - 16, 14, 12, 10 or 8-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Can manage single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by GP-DMA for regular channel conversions with FIFO
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024x
  - Programmable data right and left shift
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)
- Each ADC features an external analog input channel
  - Up to 6 fast channels from dedicated GPIO pads
  - Up to 14 slow channels from dedicated GPIO pads
- In addition, there are 6 internal dedicated channels
  - Internal reference voltage (V_{REFINT})
  - Internal temperature sensor (V_{SENSE})
  - V_{BAT} monitoring channel ($V_{BAT}/4$)
  - Connection to DAC internal channels
- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels

  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Dual ADC mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{REF-} \leq V_{IN} \leq V_{REF+}$

Figure 157 shows the block diagram of one ADC.

27.3 ADC implementation

Table 193. ADC features



ADC modes/features	ADC1	ADC2
Dual mode	X (coupled together)	
DFSDM interface	X	X
Extended sample time option (SMPPLUS control)	-	-

27.4 ADC functional description

27.4.1 ADC block diagram

Figure 157 shows the ADC block diagram and *Table 194* gives the ADC pin description.

Figure 157. ADC block diagram

27.4.2 ADC pins and internal signals

Table 194. ADC input/output pins

Name	Signal type	Description
VREF+	Input, analog reference positive	The higher/positive reference voltage for the ADC.
VDDA	Input, analog supply	Analog power supply equal V_{DDA}
VREF-	Input, analog reference negative	The lower/negative reference voltage for the ADC.
VSSA	Input, analog supply ground	Ground for analog power supply equal to V_{SS}
ADCx_INPy	External analog inputs	Up to 20 analog input channels (x = ADC number= 1 to 2): – ADCx_INP[0:5] fast channels – ADCx_INP[6:19] slow channels
ADCx_INNy		Up to 20 analog input channels (x = ADC number= 1 to 2): – ADCx_INN[0:5] fast channels – ADCx_INN[6:19] slow channels

Table 195. ADC internal input/output signals

Internal signal name	Signal type	Description
V_{INP}[y]	Analog inputs	Positive input analog channels for each ADC, connected either to ADCx_INP*i* external channels or to internal channels.
V_{INN}[y]	Analog inputs	Negative input analog channels for each ADC, connected either to V_{REF-} or to ADCx_INN*i* external channels
adc_ext_trgy	Inputs	Up to 21 external trigger inputs for the regular conversions (can be connected to on-chip timers). These inputs are shared between the ADC master and the ADC slave.
adc_jext_trgy	Inputs	Up to 21 external trigger inputs for the injected conversions (can be connected to on-chip timers). These inputs are shared between the ADC master and the ADC slave.
adc_awd1 adc_awd2 adc_awd3	Outputs	Internal analog watchdog output signal connected to on-chip timers. (x = Analog watchdog number 1,2,3)
adc_it	Output	ADC interrupt
adc_hclk	Input	AHB clock
adc_sclk	Input	ADC synchronous clock input from RCC
adc_ker_ck_input	Input	ADC kernel clock input from RCC
adc_dma	Output	ADC DMA requests
adc_dat[15:0]	Outputs	ADC data outputs

Table 196. ADC interconnection

Signal name	Source/destination
ADC2 V_{INP}[18]	V_{SENSE} (output voltage from internal temperature sensor)
ADC2 V_{INP}[19]	V_{REFINT} (output voltage from internal reference voltage)
ADC2 V_{INP}[14]	V_{BAT}/4 (external battery voltage supply voltage)
ADC2 V_{INP}[16]	dac1_out1
ADC2 V_{INP}[17]	dac1_out2
ADC2 V_{INP}[15]	dac2_out1
adc_dat[15:0]	dfsdm_dat_adc[15:0]

27.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see *Figure 158: ADC Clock scheme*):

1. The ADC clock can be a specific clock source, named adc_ker_ck_input which is independent and asynchronous with the AHB clock.

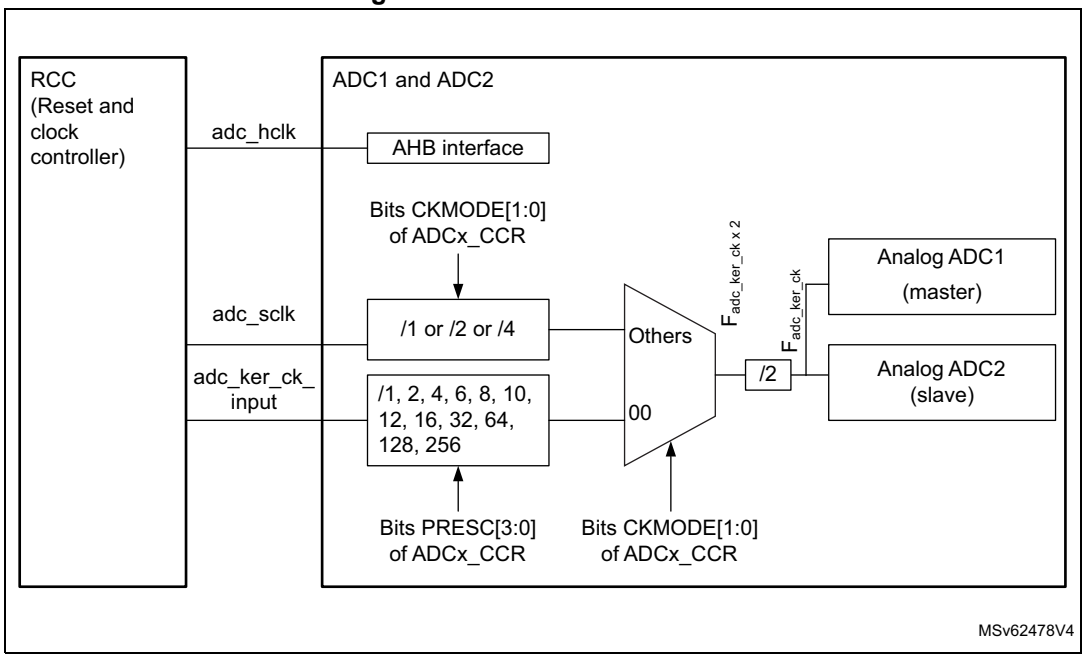
   It can be configured in the RCC (refer to RCC Section for more information on how to generate the ADC clock (adc_ker_ck_input) dedicated clock).

   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the system clock or system clock divided by two (adc_sclk). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).

   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be different from “00”. adc_sclk is equal to sys_ck when HPRE is set to 0, otherwise it corresponds to sys_ck/2.

In both case, the clock divider factor of 2 is applied to the clock provided to the ADC analog block ($f_{adc_ker_ck}$).



Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of using the system without additional PLL. In addition, when adc_sclk is twice faster than the adc_hclk clock, the latency between the trigger and the start of conversion is fixed. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock configured through CKMODE[1:0] bits must be compliant with the analog ADC operating frequency specified in the product datasheet.

Note: adc_sclk is the system clock or system clock divided by two: when the AHB prescaler is set to 1 (HPRE[3:0] = 0XXX in RCC_CFGR register), adc_sclk is equal to sys_ck, otherwise adc_sclk corresponds to sys_ck/2.

Figure 158. ADC Clock scheme

1. Refer to the RCC section to see how adc_hclk and adc_ker_ck_input can be generated.

Clock ratio constraint between ADC clock and AHB clock

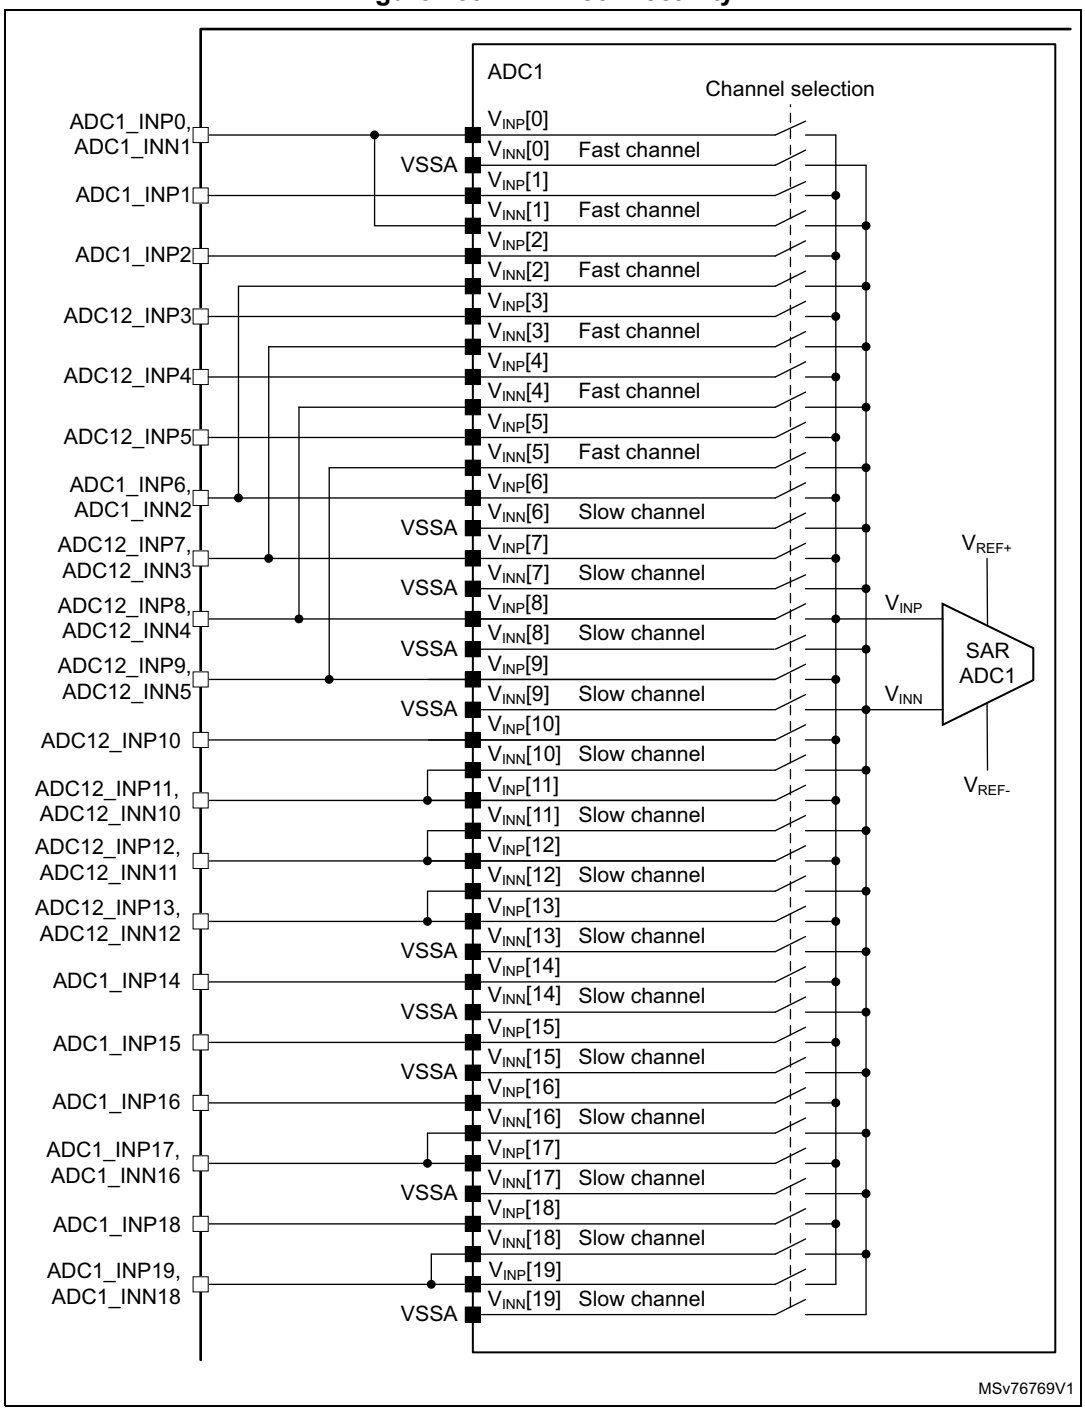
There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{adc_hclk} \geq F_{adc_ker_ck} / 4$ if the resolution of all channels are 16-bit, 14-bit,12-bit or 10-bit
- $F_{adc_hclk} \geq F_{adc_ker_ck} / 3$ if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)

Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio, for all ADC interfaces.

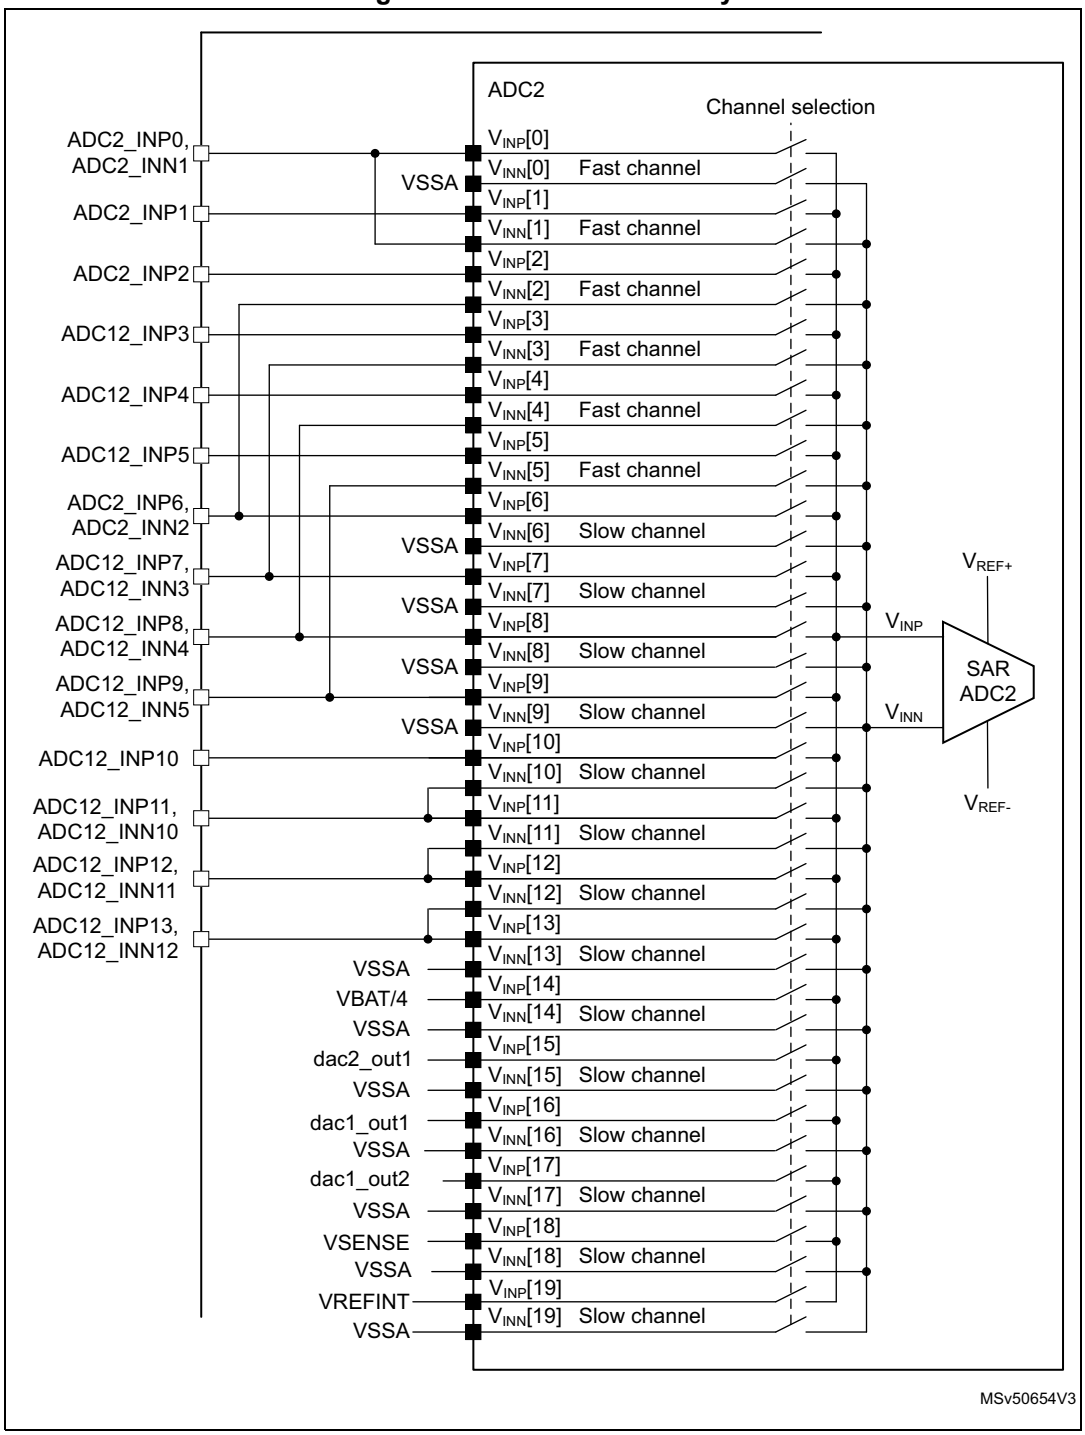
BOOST control



The ADC boost mode can be controlled through the BOOST bitfield in the ADC_CR register.

This bitfield must be set according to the ADC clock setting. Refer to the ADC_CR register description.

27.4.4 ADC1/2 connectivity



ADC1 and ADC2 are tightly coupled and share some external channels as described in the following figures.

Figure 159. ADC1 connectivity

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.

Figure 160. ADC2 connectivity

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.

27.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

27.4.6 ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit deep-power-down mode by clearing bit DEEPPWD=0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN=1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

The LDO status can be verified by checking the LDORDY bit in ADC_ISR register (refer to *Section 27.3: ADC implementation* for the availability of the LDO regulator status).

For the startup time of the ADC voltage regulator, refer to device datasheet for $T_{ADCVREG_STUP}$ parameter.

After ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC deep-power-down mode by setting bit DEEPPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

Note: When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or apply again the calibration factor which was previously saved (refer to *Section 27.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)*).

27.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by writing into bits DIFSEL[19:0] in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and V_{REF-} (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

The output data for the differential mode is an unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x0000 (16-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFFF.

$$\text{Converted value} = \frac{\text{ADC_Full_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When ADC is configured as differential mode, both input should be biased at V_{REF+} / 2 voltage.

The input signal are supposed to be differential (common mode voltage should be fixed).

For a complete description of how the input channels are connected for each ADC, refer to *Section 27.4.4: ADC1/2 connectivity*.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage is connected to $V_{INN[i]}$. As a consequence, channel “*i+n*”, which is connected to $V_{INN[i]}$, should not be converted at same time by different ADCs. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable.

27.4.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 11-bits of offset or 160-bits of linearity and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

The calibration is preliminary to any ADC operation. It removes the systematic errors which may vary from chip to chip and allows to compensate offset and linearity deviation.

The calibration factor for the offset to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which is applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which is applied for differential input conversions.

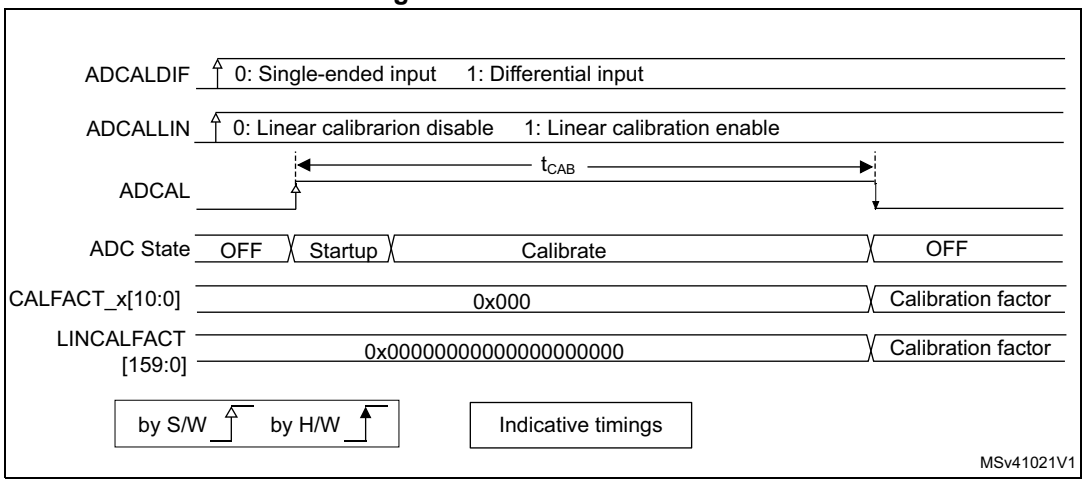
The linearity correction must be done once only, regardless of single / differential configuration.

- Write ADCALLIN = 1 before launching a calibration which runs the linearity calibration same time as the offset calibration.
- Write ADCALLIN = 0 before launching a calibration which does not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting bit ADCAL=1. It can be initiated only when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[10:0] or CALFACT_D[10:0] of ADC_CALFACT register (depending on single-ended or differential input calibration). The 160-bit linearity calibration factor can be accessed using the ADC_CALFACT2 register with ADEN set to 1.

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, it is recommended that a new offset calibration cycle is run before enabling again the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or V_{BAT} mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT and ADC_CALFACT2 register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.



The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when V_{REF+} voltage changed more than 10%.

Refer to the datasheets for the clock cycle requirement for both linear and offset calibration.

Software procedure to calibrate the ADC

1. Ensure DEEPPWD=0, ADVREGEN=1 and verify that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to *Section 27.3: ADC implementation* for the availability of the LDO regulator status).
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (single-ended input) or ADCALDIF=1 (Differential input). Select if Linearity calibration enable or not by ADCALLIN=1(enabled) or ADCALLIN=0(disabled).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The offset calibration factor can be read from ADC_CALFACT register.
7. The linearity calibration factor can be read from ADC_CALFACT2 register, following the procedure described in *Section : Linearity calibration reading procedure* (ADEN must be set to 1 prior to accessing ADC_CALFACT2 register).

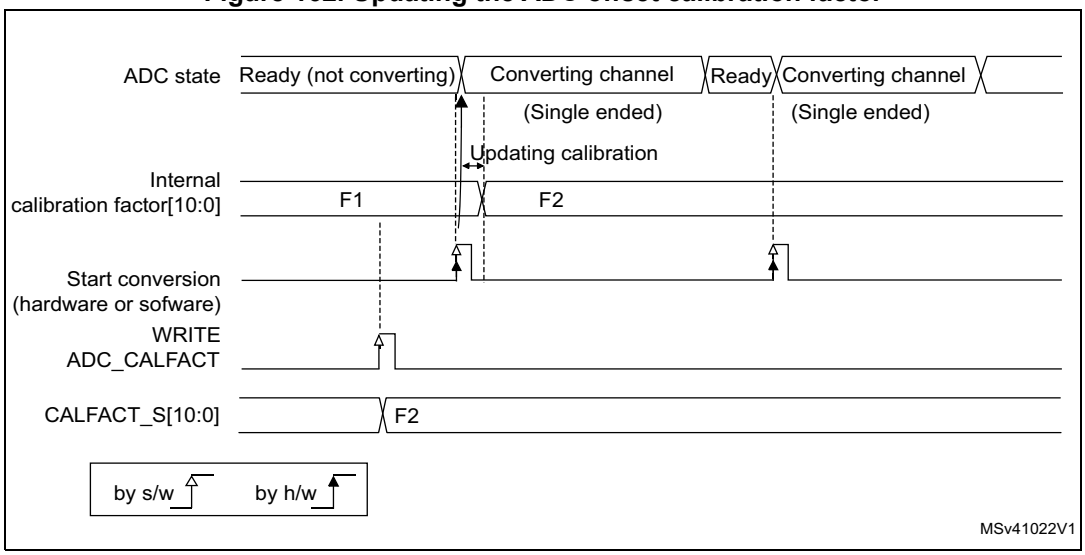


Figure 161. ADC calibration

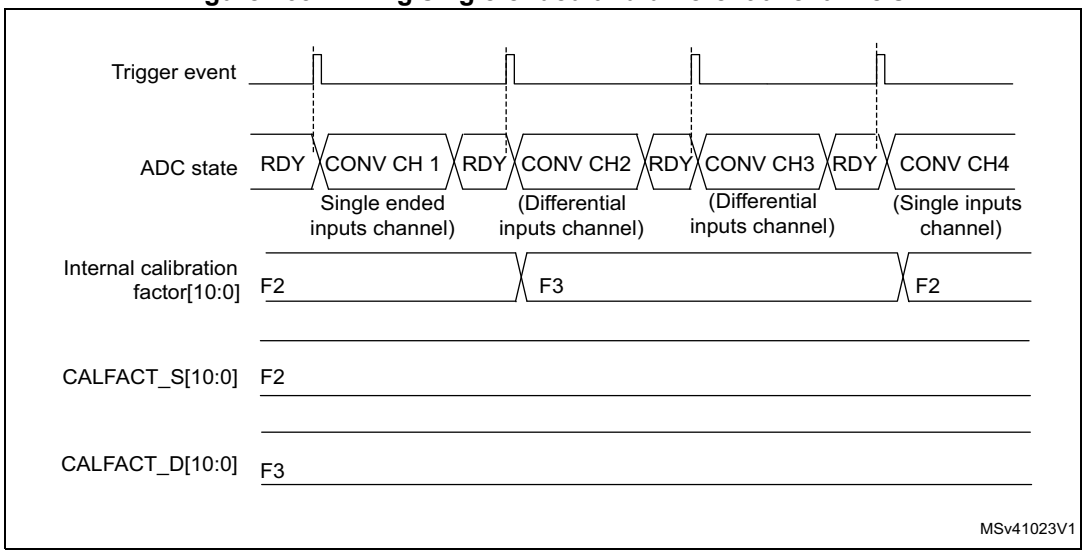
Software procedure to re-inject a calibration factor into the ADC

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new offset calibration factors.
3. Write LINCALFACT bits with the new linearity calibration factors, following the procedure described in *Section : Linearity calibration writing procedure*.
4. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 162. Updating the ADC offset calibration factor



Calibrating single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0) and Linearity calibration enable (with ADCALLIN=1). This updates the registers CALFACT_S[10:0] and LINCALFACT[159:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF=1) and Linearity calibration disable (with ADCALLIN=0). This updates the register CALFACT_D[10:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.

Figure 163. Mixing single-ended and differential channels

Linearity calibration reading procedure

Once the calibration is done (ADCAL bit cleared by hardware) with ADCALLIN=1, the 160-bit linearity correction factor can be read using the ADC_CALFACT2 30-bit registers (6 read accesses are necessary).

The six LINCALRDYW1..6 control/status bits in ADC_CR are set when the calibration is complete. When ADEN is set to 1, clearing one of these bits launches the transfer of part of the linearity factor into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit is reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared). The complete procedure is as following:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that the ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to *Section 27.3: ADC implementation* for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
3. Clear LINCALRDYW6 bit (Linearity calibration ready Word 6).
4. Poll LINCALRDYW6 bit until returned value is zero, indicating linearity correction bits[159:150] are available in ADC_CALFACT2[29:0].
5. Read ADC_CALFACT2[29:0].
6. Clear LINCALRDYW5 bit.
7. Poll LINCALRDYW5 bit until returned value is zero, indicating linearity correction bits[149:120] are available in ADC_CALFACT2[29:0].
8. Read ADC_CALFACT2[29:0].
9. Clear LINCALRDYW4 bit.
10. Poll LINCALRDYW4 bit until returned value is zero, indicating linearity correction bits[119:90] are available in ADC_CALFACT2[29:0].
11. Read ADC_CALFACT2[29:0].
12. Clear LINCALRDYW3 bit.
13. Poll LINCALRDYW3 bit until returned value is zero, indicating linearity correction bits[89:60] are available in ADC_CALFACT2[29:0].
14. Read ADC_CALFACT2[29:0].
15. Clear LINCALRDYW2 bit.
16. Poll LINCALRDYW2 bit until returned value is zero, indicating linearity correction bits[59:30] are available in ADC_CALFACT2[29:0].
17. Read ADC_CALFACT2[29:0].
18. Clear LINCALRDYW1 bit.
19. Poll LINCALRDYW1 bit until returned value is zero, indicating linearity correction bits[29:0] are available in ADC_CALFACT2[29:0].
20. Read ADC_CALFACT2[29:0].

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software can access the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

Linearity calibration writing procedure

The six LINCALRDYW1..6 control/status bits in ADC_CR are reset when the calibration has not yet been done or a new linearity calibration factor have been rewritten. It is possible to force directly a linearity calibration factor or re-inject it using the following procedure:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed by checking the LDORDY bit in ADC_ISR (refer to *Section 27.3: ADC implementation* for the availability of the LDO regulator status).
2. Set ADEN = 1 and wait until ADRDY=1.
3. Write ADC_CALFACT2[9:0] with previously saved linearity correction factor bits[159:150].
4. Set LINCALRDYW6 bit.
5. Poll LINCALRDYW6 bit until returned value is one, indicating linearity correction bits[159:150] have been effectively written.
6. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[149:120].
7. Set LINCALRDYW5 bit.
8. Poll LINCALRDYW5 bit until returned value is one, indicating linearity correction bits[149:120] have been effectively written.
9. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[119:90].
10. Set LINCALRDYW4 bit.
11. Poll LINCALRDYW4 bit until returned value is one, indicating linearity correction bits[119:90] have been effectively written.
12. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[89:60].
13. Set LINCALRDYW3 bit.
14. Poll LINCALRDYW3 bit until returned value is one, indicating linearity correction bits[89:60] have been effectively written.
15. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[59:30].
16. Set LINCALRDYW2 bit.
17. Poll LINCALRDYW2 bit until returned value is one, indicating linearity correction bits[59:30] have been effectively written.
18. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[29:0].
19. Set LINCALRDYW1 bit.
20. Poll LINCALRDYW1 bit until returned value is one, indicating linearity correction bits[29:0] have been effectively written.

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software is allowed to update the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

27.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

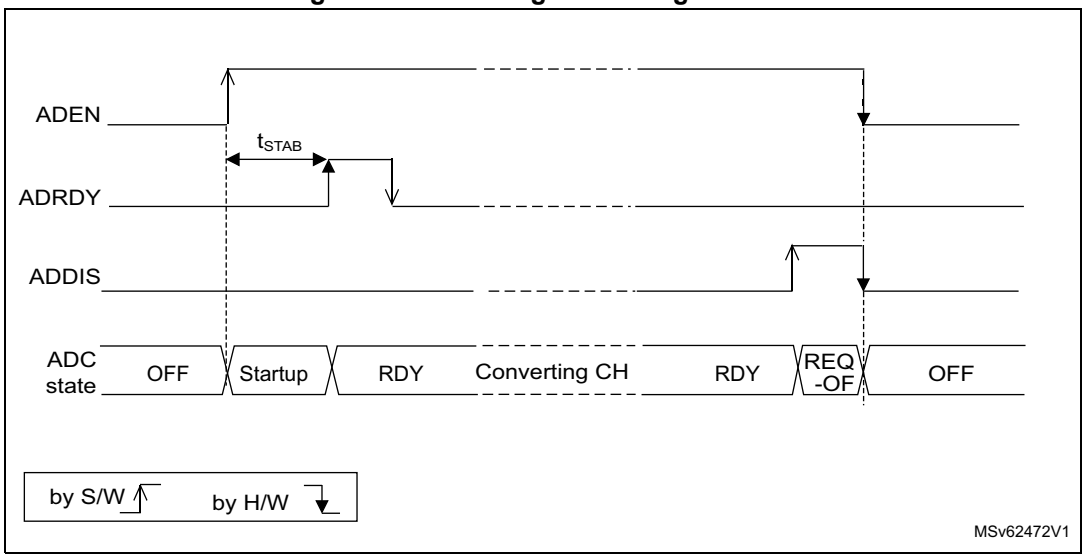
First of all, follow the procedure explained in *Section 27.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of t_{STAB} before it starts converting accurately, as shown in *Figure 164*. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to *Section 27.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.



Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN=0).

Figure 164. Enabling / Disabling the ADC

27.4.10 Constraints when writing the ADC control bits

The software can write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the control bits DIFSEL in the ADC_DIFSEL register, ADCx_CCR register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRy, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and eventually converting and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1).

The software is allowed to write the ADC_JSQR register only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).

27.4.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:

- 6 fast analog inputs coming from Analog PADs and GPIO pads (ADCx_INP/INN[0..5])
- Up to 14 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6..19]).
- The ADCs are connected to 6 internal analog inputs:
  - the internal temperature sensor (V_{SENSE})
  - the internal reference voltage (V_{REFINT})
  - the V_{BAT} monitoring channel ($V_{BAT}/4$)
  - DAC internal channels

Refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to external ADC pins or internal signals.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to *Section 27.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)*).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 only when the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Temperature sensor, V_{REFINT} and V_{BAT} internal channels

The internal reference voltage (V_{REFINT}), the temperature sensor (V_{SENSE}), and the V_{BAT} channel are connected to ADC internal channels. Refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals* for details.

Note: To convert one of the internal analog channels, enable the corresponding analog sources by programming VREFEN, TSEN and VBATEN bits in the ADCx_CCR registers.

27.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx, the corresponding ADC_PCSEL bit must be previously configured.

This ADC_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input MUX selects the ADC input according to the SQRx and JSQRx with very high speed, the analog switch integrated in the IO cannot react as fast as ADC mux does. To avoid the delay on analog switch control on IO, it is necessary to preselect the input channels which are selected in the SQRx, JSQRx.

The selection is based on the $V_{INP[i]}$ of each ADC input. If ADC1 converts the ADC12_INP2($V_{INP[2]}$) as differential mode, ADC12_INP6($V_{INP[6]}$) also needs to be selected in ADC_PCSEL.

Some I/Os are connected to several $V_{INP[i]}$ of the ADCx. The control inputs of the analog switch are ORed with the corresponding ADC_PCSEL register bits.

27.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 8.5 ADC clock cycles
- SMP = 011: 16.5 ADC clock cycles
- SMP = 100: 32.5 ADC clock cycles
- SMP = 101: 64.5 ADC clock cycles
- SMP = 110: 387.5 ADC clock cycles
- SMP = 111: 810.5 ADC clock cycles

The total conversion time is calculated as follows:

T_{CONV} = Sampling time + 7.5 ADC clock cycles

Example:

With $F_{adc_ker_ck}$ = 24 MHz and a sampling time of 1.5 ADC clock cycles (14-bit mode):

T_{CONV} = (1.5 + 7.5) ADC clock cycles = 9 ADC clock cycles = 0.375 µs (14 bit mode for fast channels)

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time for fast and slow channels

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the V_{DDA} voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low V_{DDA} voltage by enabling an internal voltage booster through the BOOSTE bit of the PWR_CR1 register.

27.4.14 Single conversion mode (CONT=0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)

  ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

27.4.15 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).

27.4.16 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN /= 0x0

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN /= 0x0

Note: In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software trigger (CONT=0, EXTEN=0x0)
  - at any end of conversion sequence (EOS =1)
- In discontinuous mode with software trigger (CONT=0, DISCEN=1, EXTEN=0x0)
  - at end of conversion (EOC=1)
- In all other cases (CONT=x, EXTEN=x)
  - after execution of the ADSTP procedure asserted by the software.

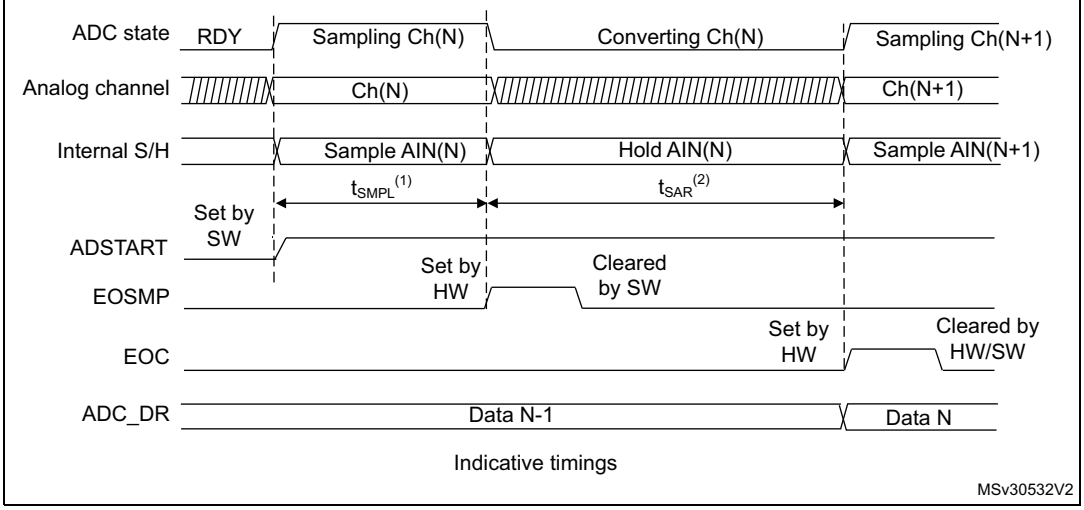
Note: In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTEN /=0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:

- in single mode with software injected trigger (JEXTEN=0x0)
  - at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN=1
- in all cases (JEXTEN=x)
  - after execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.



27.4.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [1.5\ _{|min} + 7.5\ _{|14bit}] \times T_{adc_ker_ck}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 62.5\ ns\ _{|min} + 312.5\ ns\ _{|14bit} = 375.0\ ns$ (for $F_{adc_ker_ck} = 24$ MHz)

Figure 165. Analog-to-digital conversion time

1. t_{SMPL} depends on SMP[2:0]
2. t_{SAR} depends on RES[2:0]

27.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

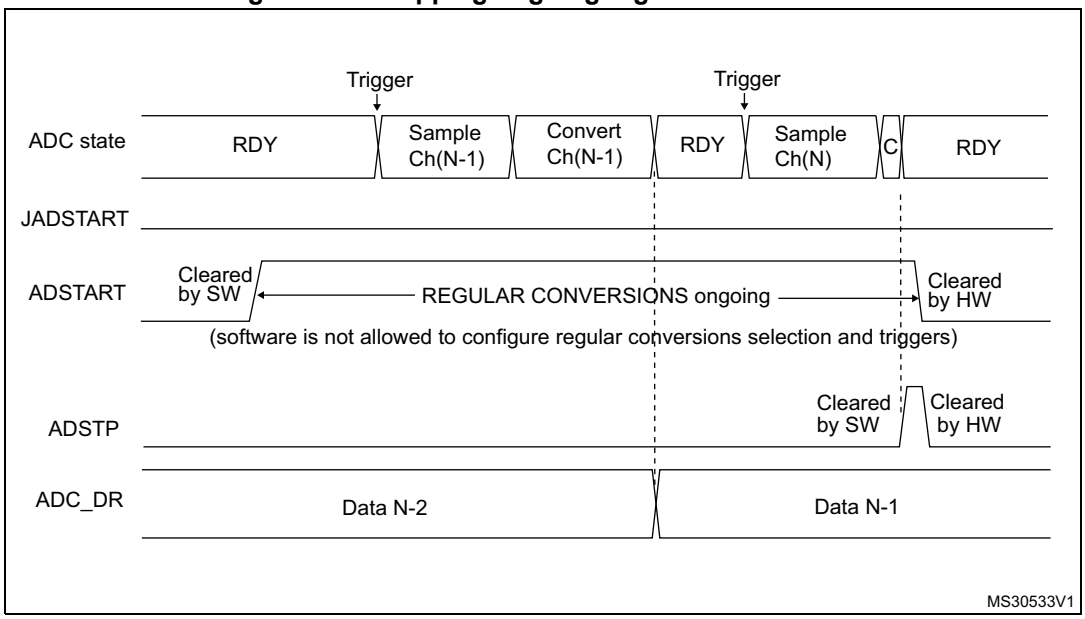
When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would re-start a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 166. Stopping ongoing regular conversions



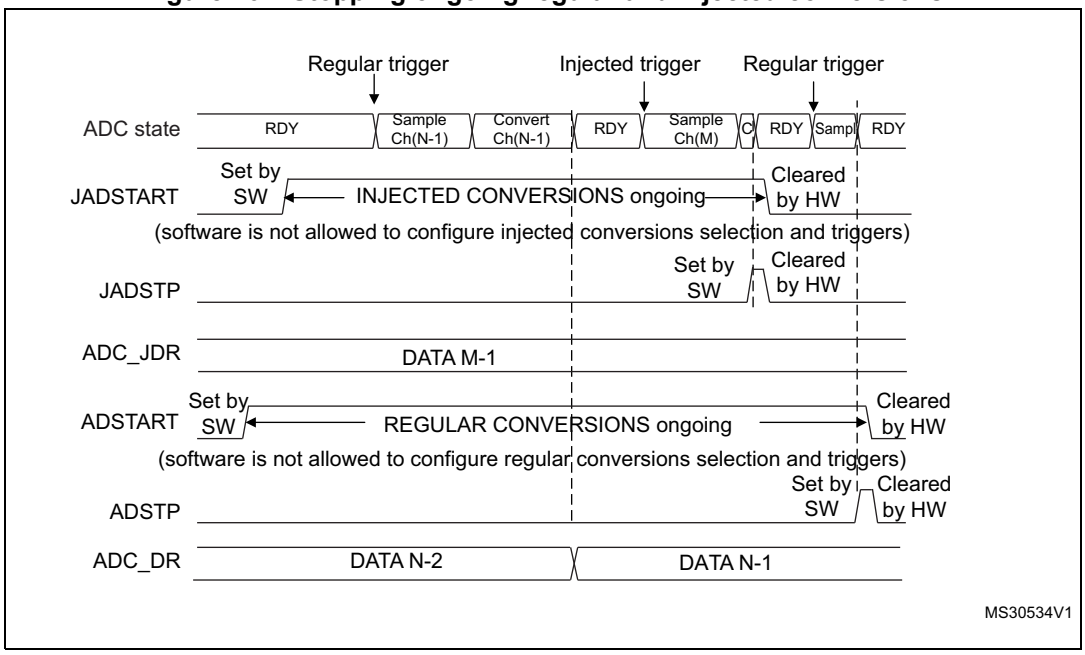


Figure 167. Stopping ongoing regular and injected conversions

27.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 197 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 197. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

Table 198. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	– If JQDIS=1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled – If JQDIS=0 (Queue enabled), Hardware and software trigger detection disabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 27.4.22: Queue of context for injected conversions.

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which out of 21 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Note: The regular trigger selection cannot be changed on-the-fly.
The injected trigger selection can be anticipated and changed on-the-fly. Refer to *Section 27.4.22: Queue of context for injected conversions on page 961*

Each ADC master shares the same input triggers with its ADC slave as described in *Figure 168*.

Figure 168. Triggers are shared between ADC master and ADC slave

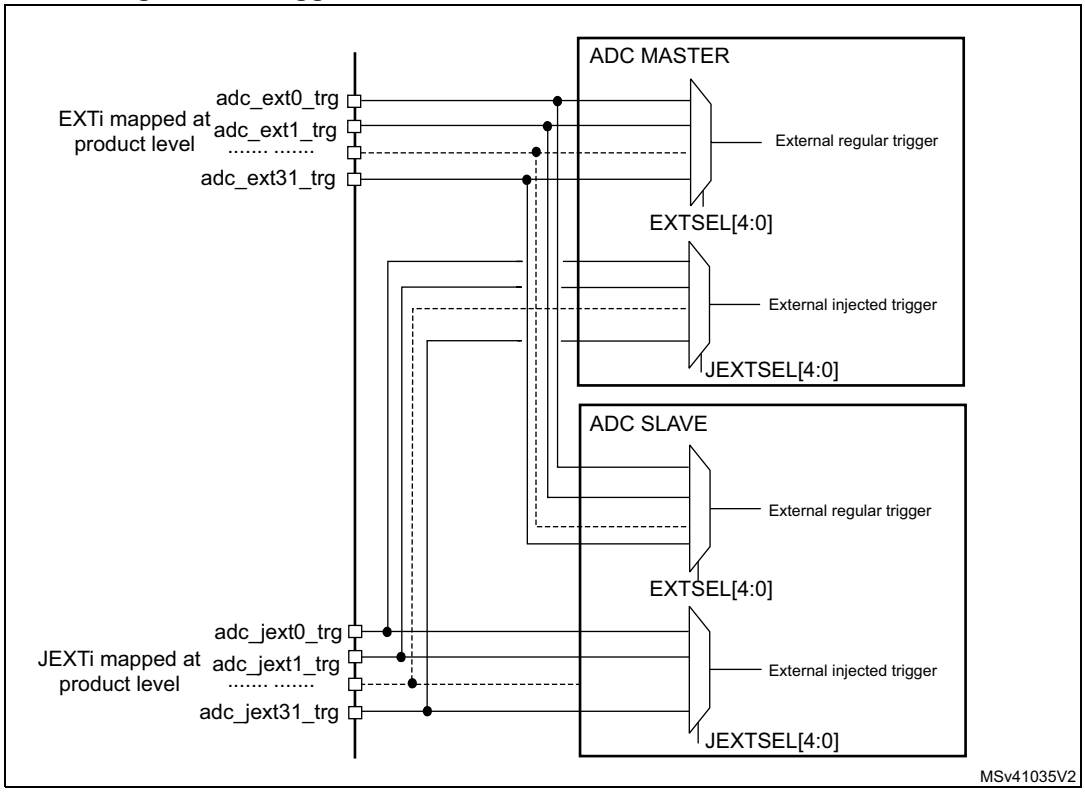

Table 199 and *Table 200* give all the possible external triggers of the three ADCs for regular and injected conversion.

27.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is

reset and the injected channel sequence switches are launched (all the injected channels are converted once).

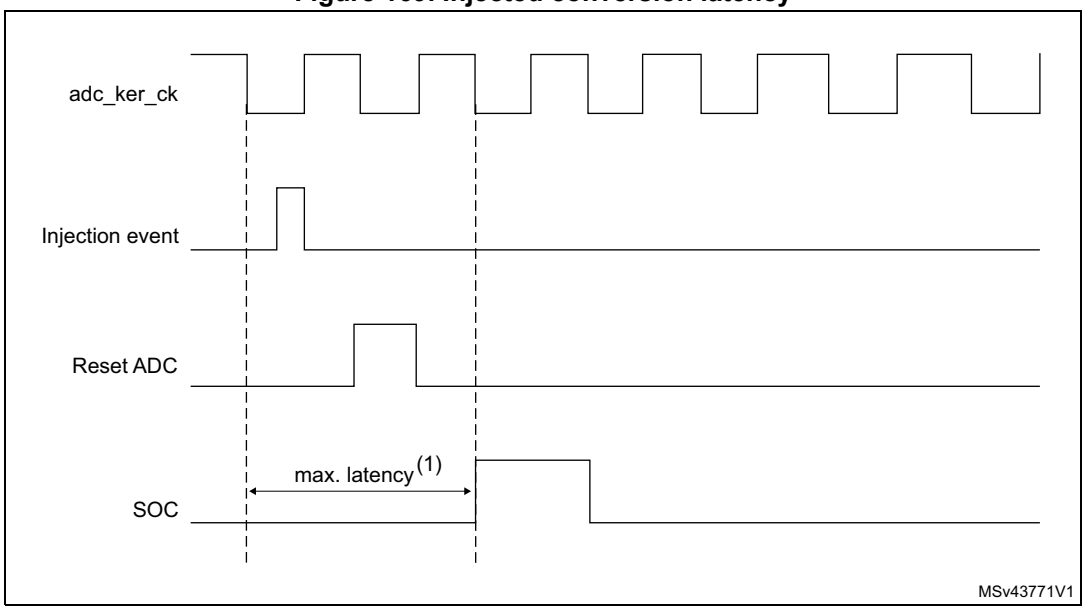
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 169* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 20 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 21 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).



In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer's data in JAUTO mode, it is necessary to program it in circular mode. If the single-shot mode is selected, the JAUTO sequence is stopped upon DMA Transfer Complete event.

Figure 169. Injected conversion latency

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

27.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (sub-group) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQR registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN=1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - all the next trigger events relaunch the complete sequence.

Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

27.4.22 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL[4:0] in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)

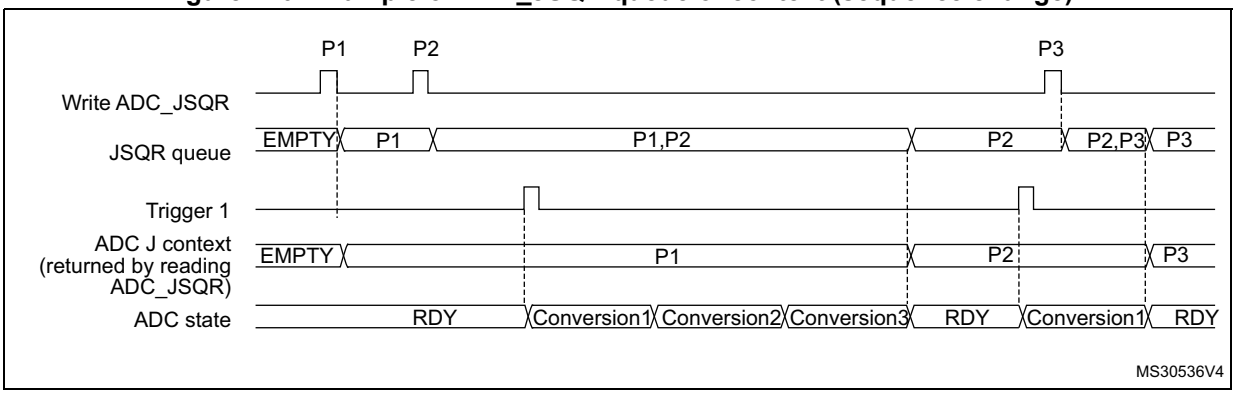
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The ADC_JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the ADC_JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the ADC_JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next ADC_JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into ADC_JSQR register while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of ADC_JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers

are ignored until the software re-writes a new injected context into ADC_JSQR register.

- Reading ADC_JSQR register returns the current ADC_JSQR context which is active at that moment. When the ADC_JSQR context is empty, JSQi is read as 0x00.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

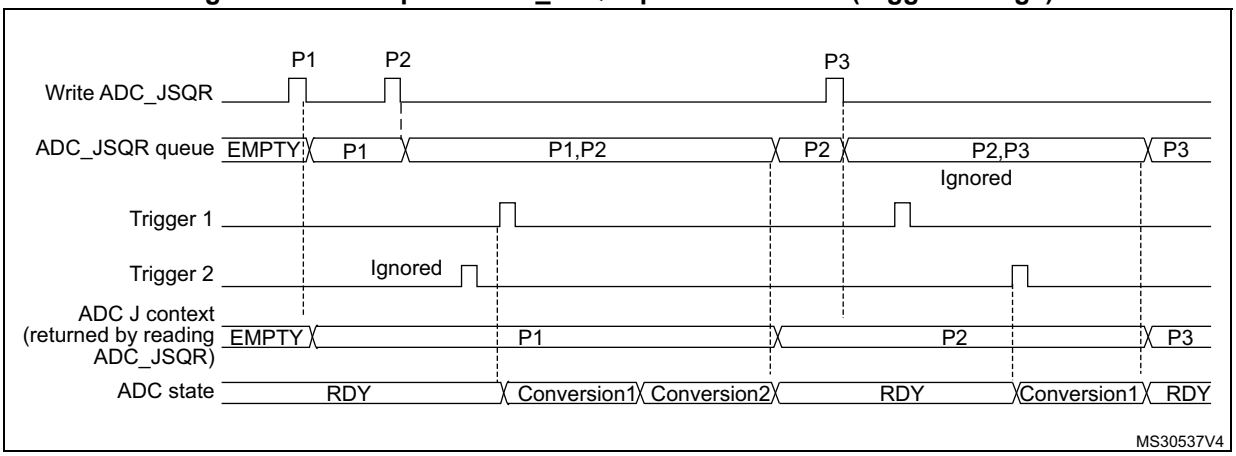
Note: When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue.The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):



- *1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out*
- *2nd trigger, disc. Sequence 1: 2nd conversion.*
- *3rd trigger, discontinuous. Sequence 1: 3rd conversion.*
- *4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.*
- *5th trigger, discontinuous. Sequence 2: 2nd conversion.*
- *6th trigger, discontinuous. Sequence 2: 3rd conversion.*

Note: When queue of context enabled (bit JQDIS=0), only hardware trigger can be used.

Behavior when changing the trigger or sequence context

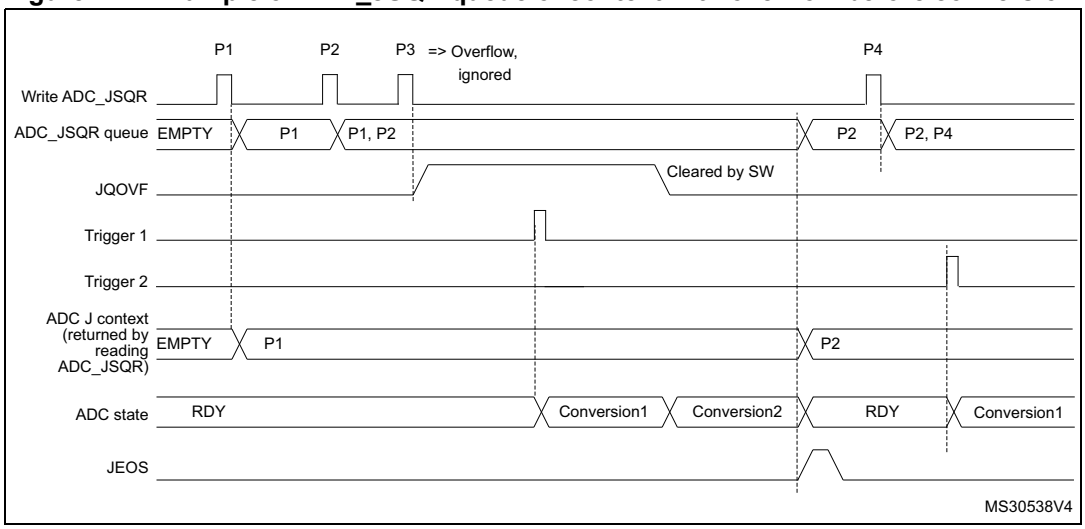


The *Figure 170* and *Figure 171* show the behavior of the context Queue when changing the sequence or the triggers.

Figure 170. Example of ADC_JSQR queue of context (sequence change)

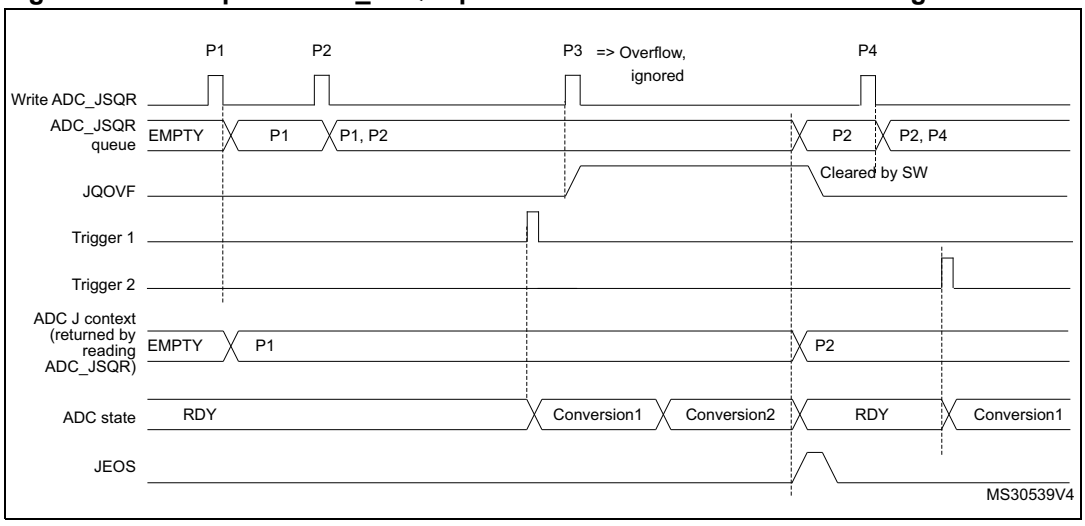
1. Parameters:
   P1: sequence of 3 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 4 conversions, hardware trigger 1

Figure 171. Example of ADC_JSQR queue of context (trigger change)



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs



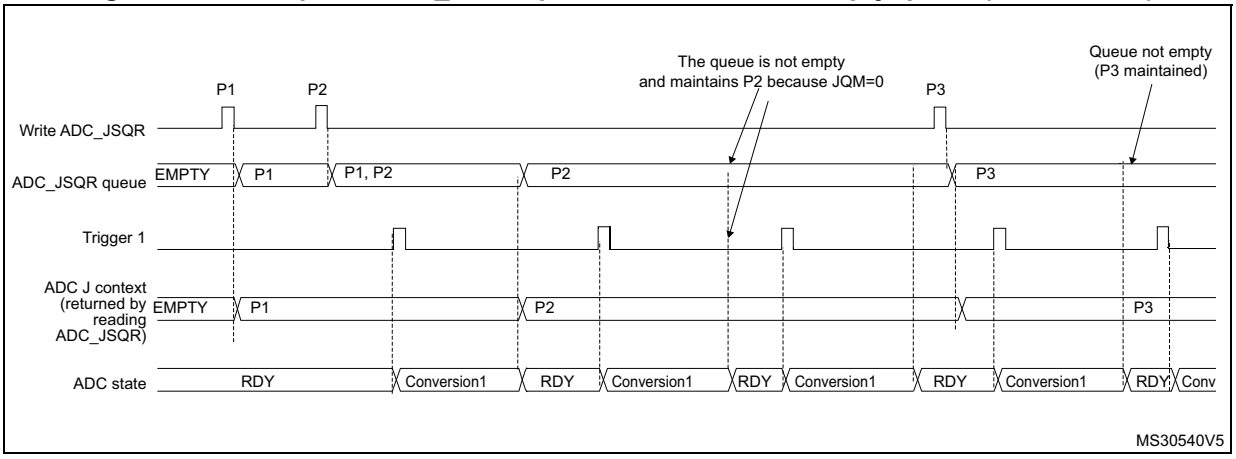
The *Figure 172* and *Figure 173* show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 172. Example of ADC_JSQR queue of context with overflow before conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

Figure 173. Example of ADC_JSQR queue of context with overflow during conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1



It is recommended to manage the queue overflows as described below:

- After each P context write into ADC_JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 174 and *Figure 175* show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

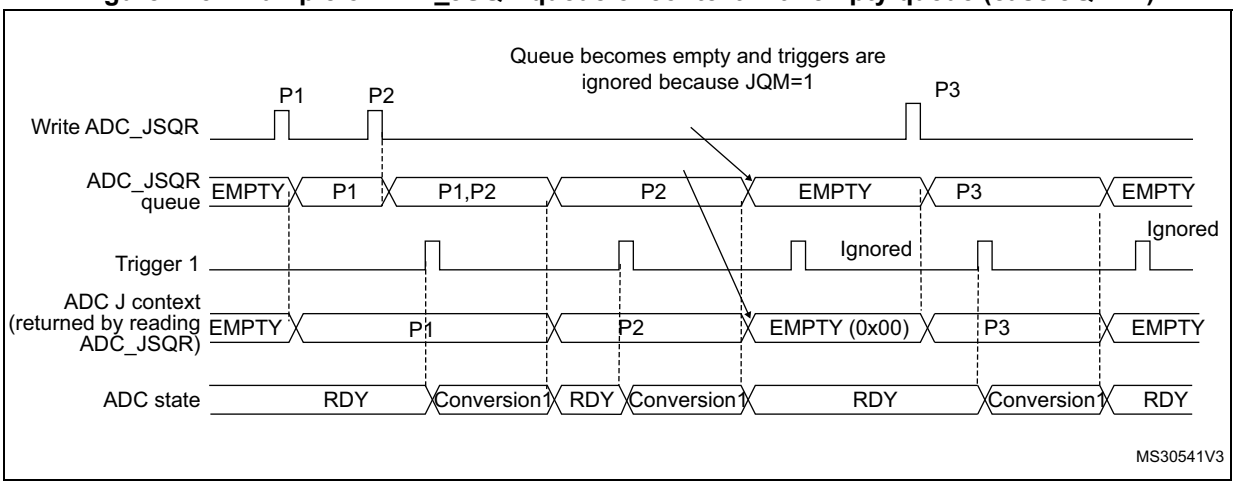


Figure 174. Example of ADC_JSQR queue of context with empty queue (case JQM=0)

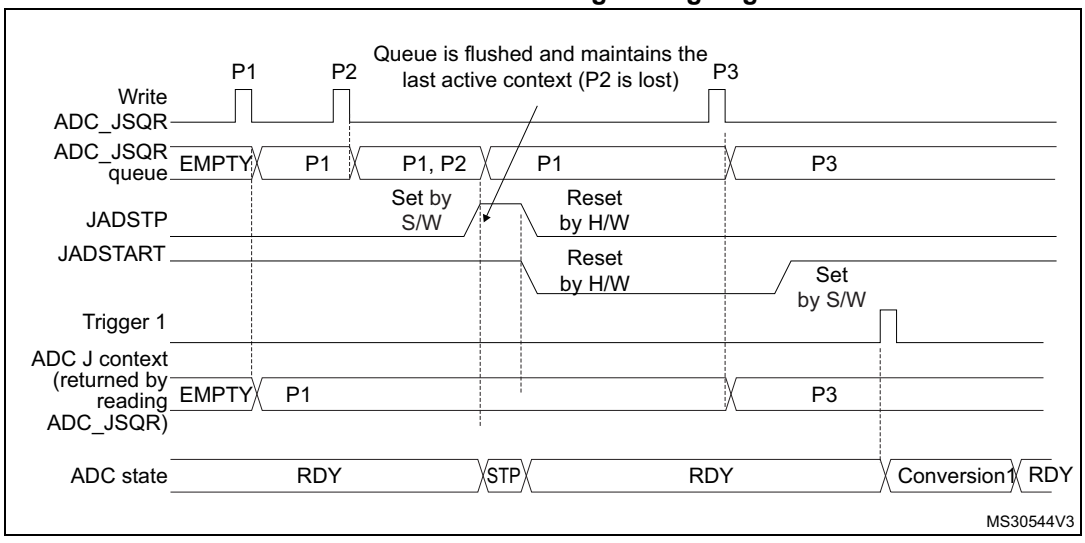
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

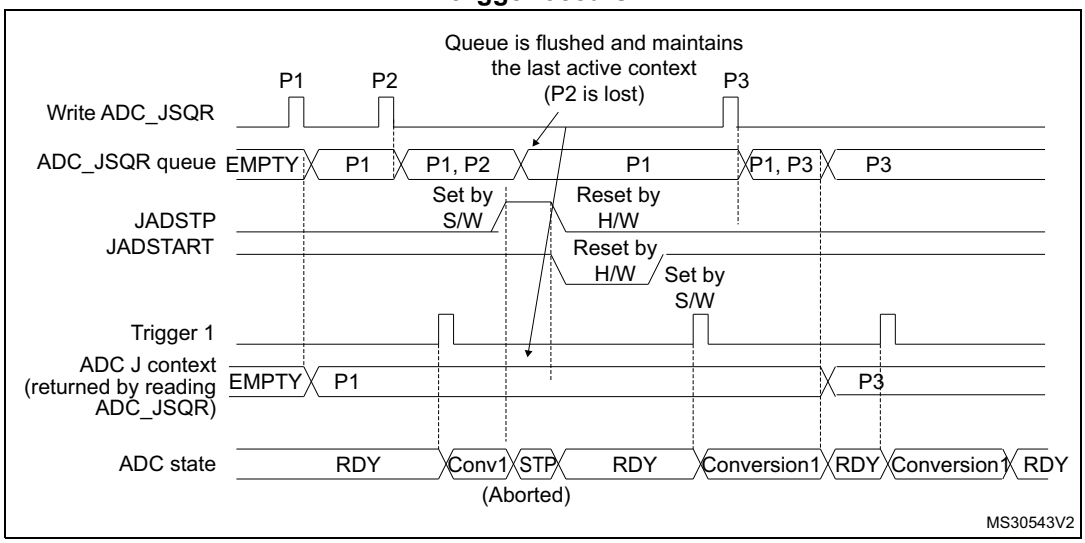
Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

Figure 175. Example of ADC_JSQR queue of context with empty queue (case JQM=1)



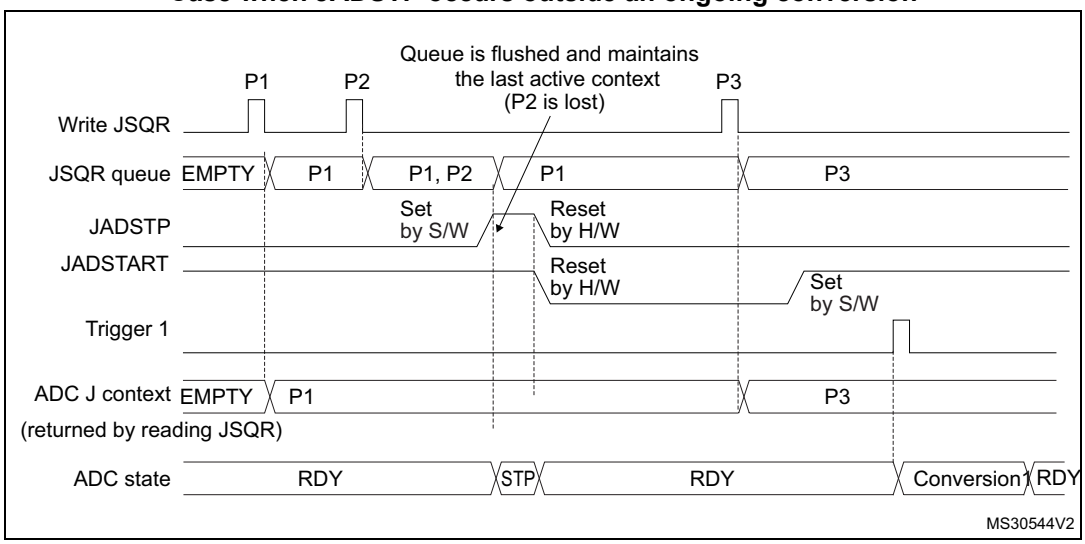
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Flushing the queue of context



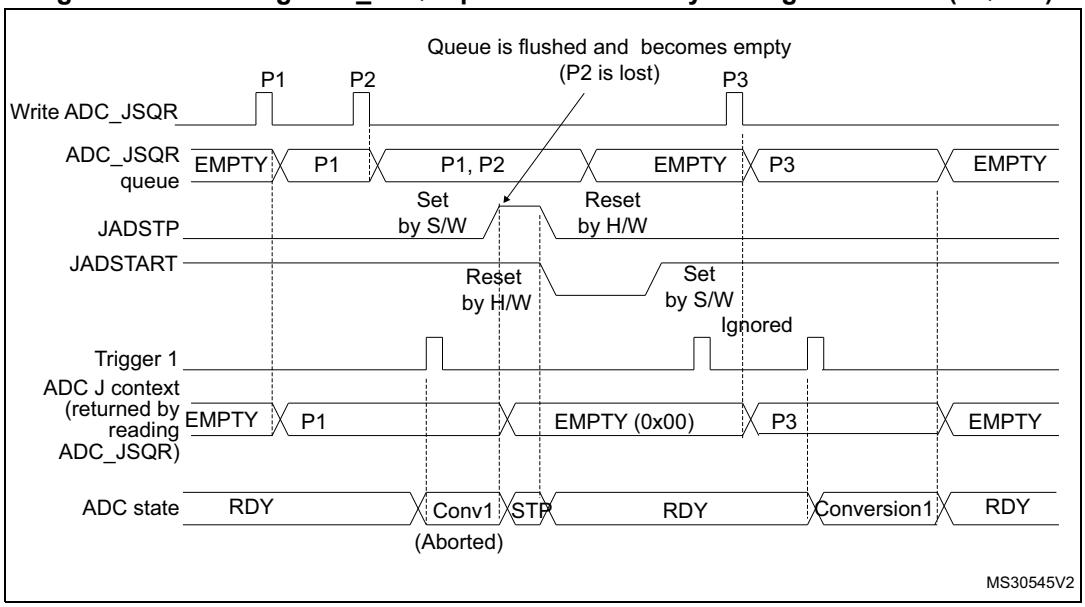
The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 176. Flushing ADC_JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.



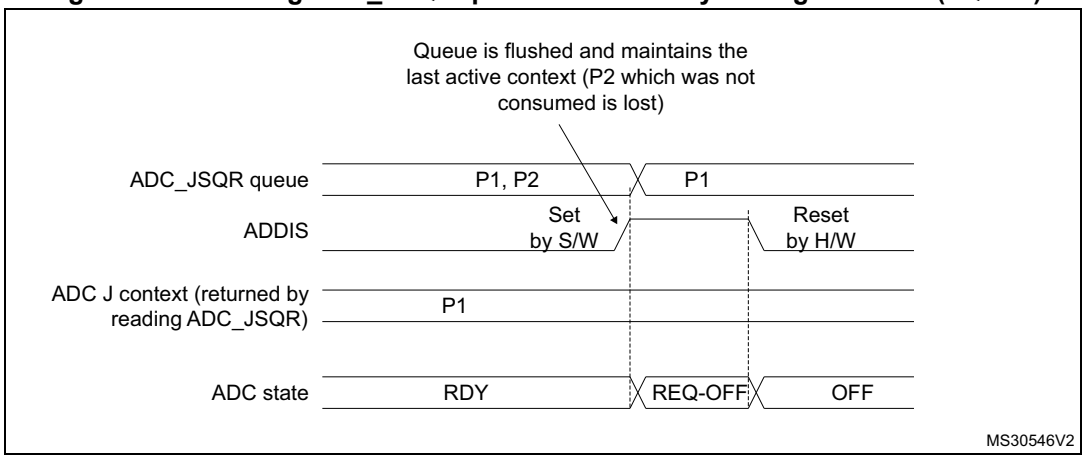
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 177. Flushing ADC_JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.



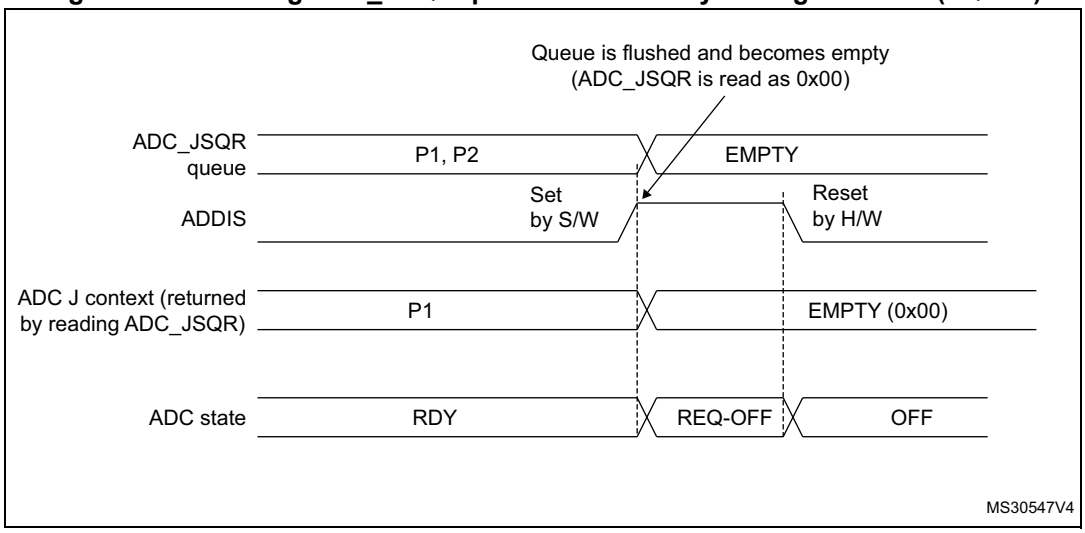
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 178. Flushing ADC_JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs outside an ongoing conversion



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 179. Flushing ADC_JSQR queue of context by setting JADSTP=1 (JQM=1)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 180. Flushing ADC_JSQR queue of context by setting ADDIS=1 (JQM=0)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 181. Flushing ADC_JSQR queue of context by setting ADDIS=1 (JQM=1)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy ADC_JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFGR register.

Queue of context: Programming of the register ADC_JSQR

When the injected conversion queue of context is enabled (JQDIS=0), the ADC_JSQR must be programmed at one register write access. As JL[1:0] register define the number of the injected sequence, corresponding JSQ1 to JSQ4 must be written at same time. If ADC_JSQR is reprogrammed before the injected conversion start, reprogrammed data is put on the queue. When queue of context is empty, ADC_JSQR read back as 0x0000. Register access should not use the ‘read modify write’ sequence.

When ADC_JSQR is programmed when already two contexts are queued, it raises JQOVF flag and generate the interrupt.

27.4.23 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 16, 14, 12, 10, 8 bits by programming the control bits RES[1:0]. *Figure 186*, *Figure 187*, *Figure 188* and *Figure 189* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 201*.

Table 201. T_{SAR} timings depending on resolution

RES [2:0]	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$=24 MHz	$T_{adc_ker_ck}$ (ADC clock cycles) (with Sampling Time= 1.5 ADC clock cycles)	$T_{adc_ker_ck}$ (ns) at $F_{adc_ker_ck}$=24 MHz
16 bits	8.5 ADC clock cycles	354.2	10 ADC clock cycles	416.7
14 bits	7.5 ADC clock cycles	312.5	9 ADC clock cycles	375
12 bits	6.5 ADC clock cycles	270.8	8 ADC clock cycles	333.3
10 bits	5.5 ADC clock cycles	229.2	7 ADC clock cycles	291.7
8 bits	4.5 ADC clock cycles	187.5	6 ADC clock cycles	250.0

27.4.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

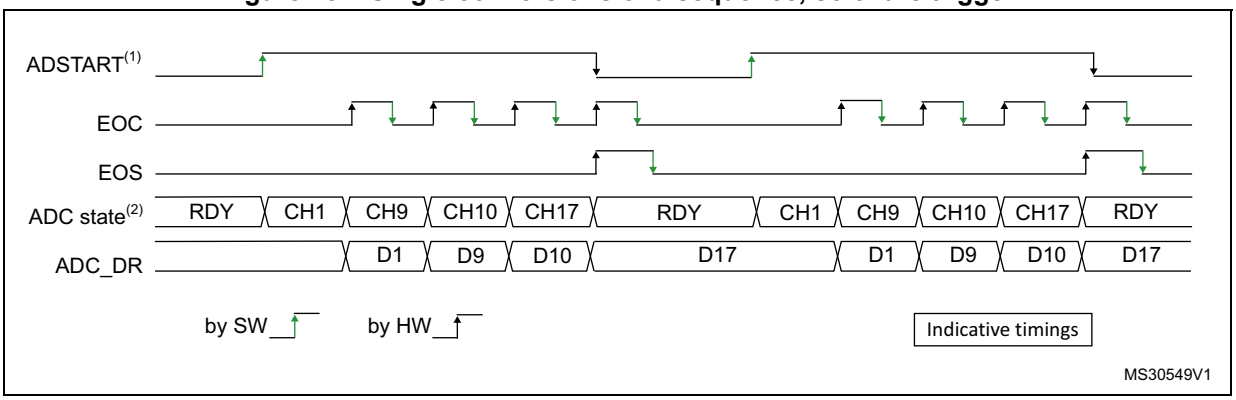
The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

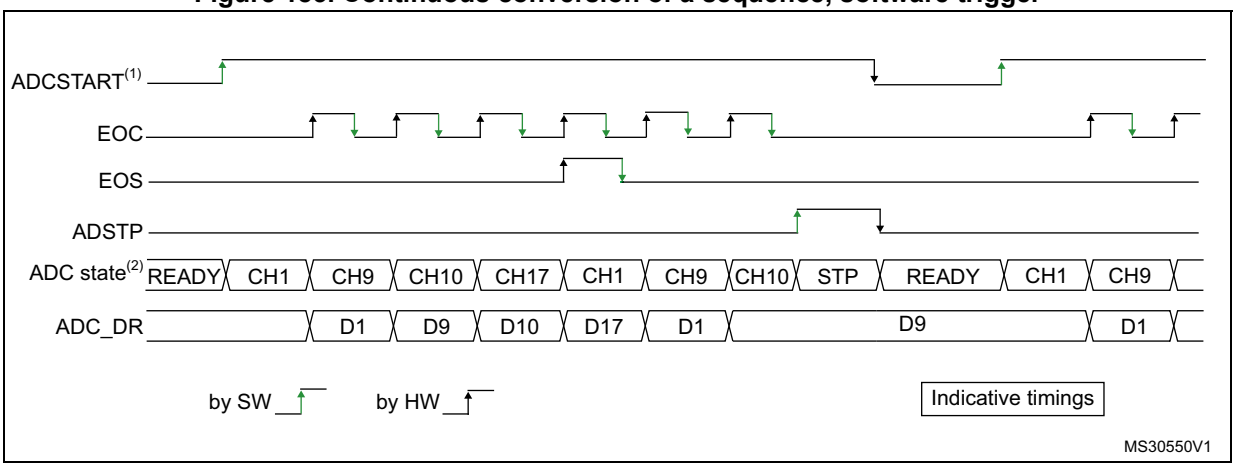
27.4.25 End of conversion sequence (EOS, JEOS)



The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

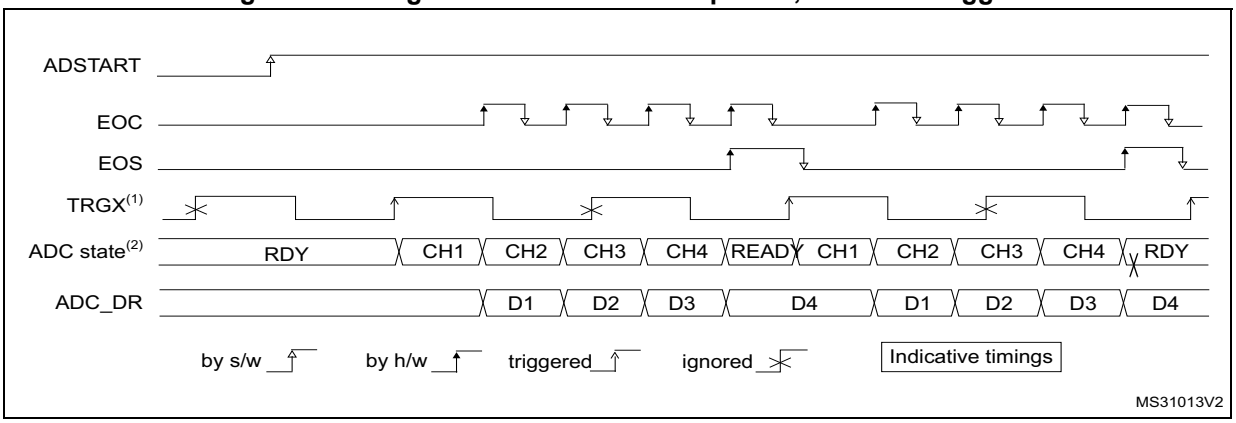
The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.



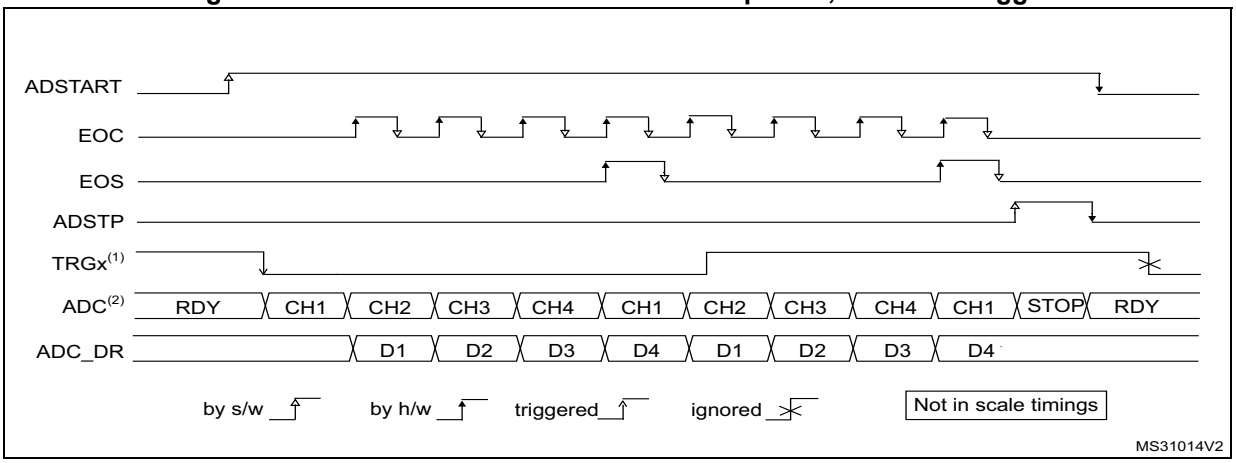
27.4.26 Timing diagrams example (single/continuous modes, hardware/software triggers)

Figure 182. Single conversions of a sequence, software trigger



1. EXTEN=0x0, CONT=0
2. Channels selected = 1,9, 10, 17; AUTDLY=0.

Figure 183. Continuous conversion of a sequence, software trigger



1. EXTEN=0x0, CONT=1
2. Channels selected = 1,9, 10, 17; AUTDLY=0.

Figure 184. Single conversions of a sequence, hardware trigger

1. TRGx (over-frequency) is selected as trigger source, EXTEN = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY=0.

Figure 185. Continuous conversions of a sequence, hardware trigger

1. TRGx is selected as trigger source, EXTEN = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY=0.

27.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in *Figure 186*, *Figure 187*, *Figure 188* and *Figure 189*.

Note: The data can be re-aligned in normal and in oversampling mode.

Offset

An offset y (y=1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in OFFSETy[25:0] bitfield into ADC_OFRy register. The channel to which the offset is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[25:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

The offset value should be lower than the max conversion value (ex. 16bit mode, offset value max is 0xFFFF).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 202 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

Table 202. Offset computation versus data resolution

Resolution (bits RES[2:0])	Subtraction between raw converted data and offset:		Result	Comments
	Raw converted Data, left aligned	Offset		
16 bits	DATA[15:0]	OFFSET[25:0]	signed 27-bit data	-
14 bits	DATA[15:2],00	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[1:0] to 00
12 bits	DATA[15:4],0000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[3:0] to 0000
10 bits	DATA[15:6],000000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[5:0] to 000000
8 bits	DATA[15:8],000000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[7:0] to 00000000

When reading data from ADC_DR (regular channel) or from ADC_JDRy (injected channel, y=1,2,3,4), the offset compensation is disabled when ADC_OFRy [25:0] bitfield is reset. Otherwise, the offset for ADC_OFRy[30:26] channel is enabled.

Figure 186, *Figure 187*, *Figure 188* and *Figure 189* show alignments for signed and unsigned data together with corresponding OVSS and LSHIFT values.

Figure 186. Right alignment (offset disabled, unsigned value)

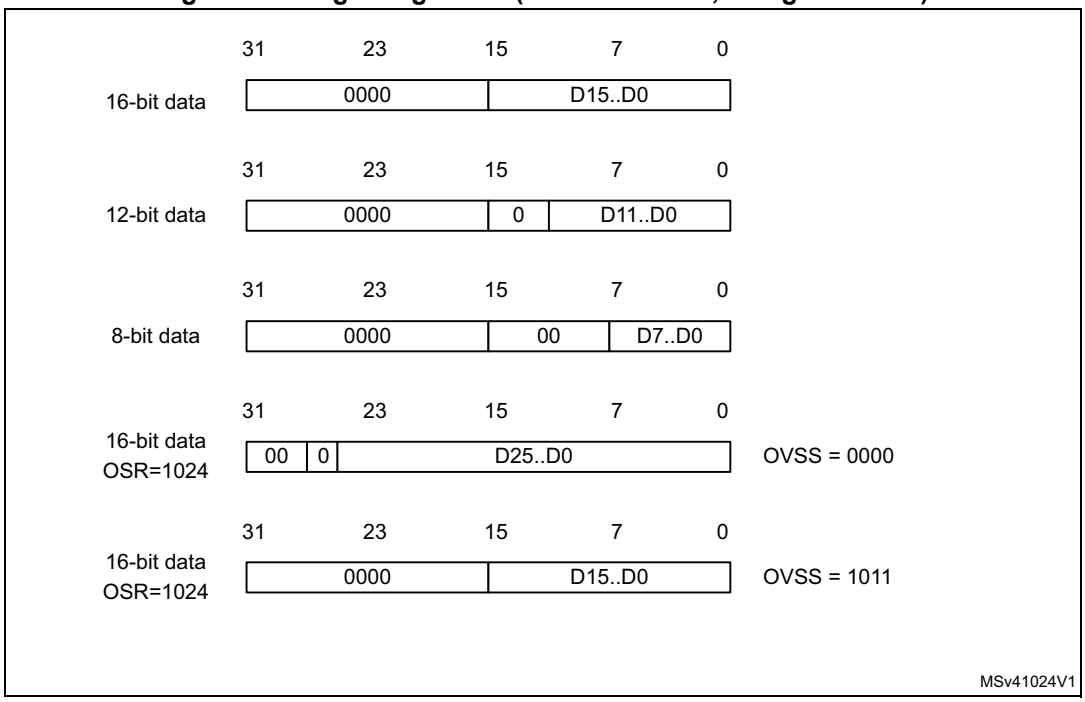


Figure 187. Right alignment (offset enabled, signed value)

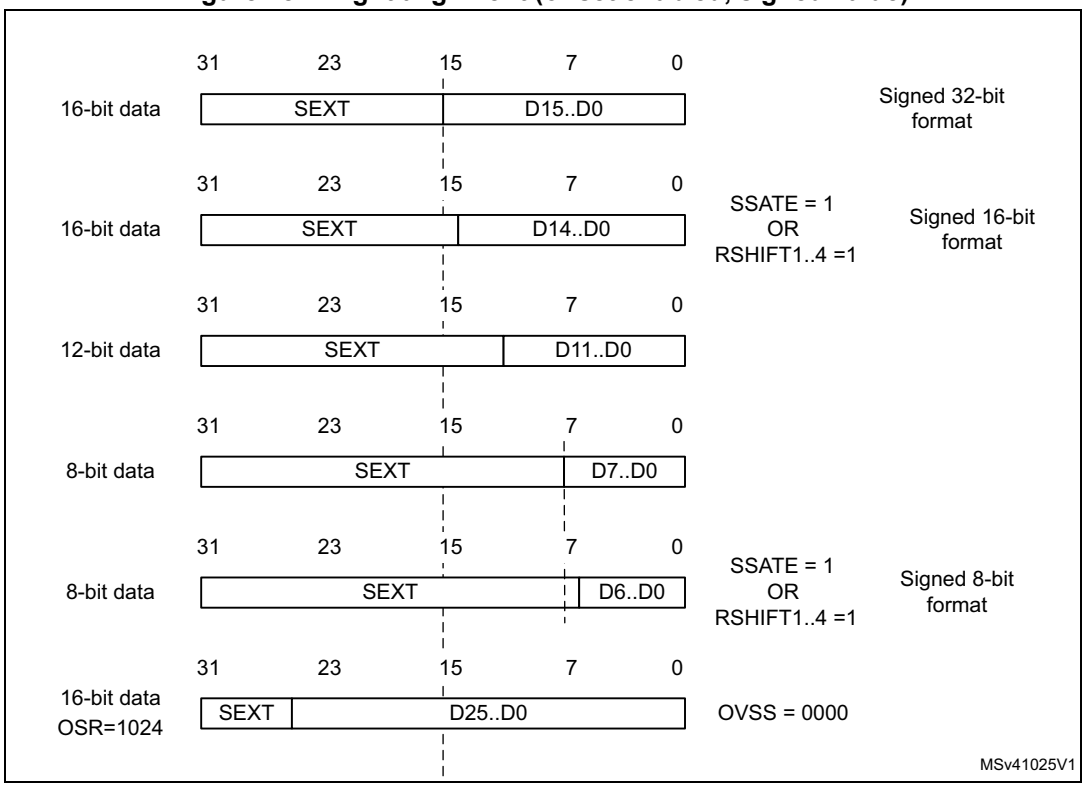

Figure 188. Left alignment (offset disabled, unsigned value)

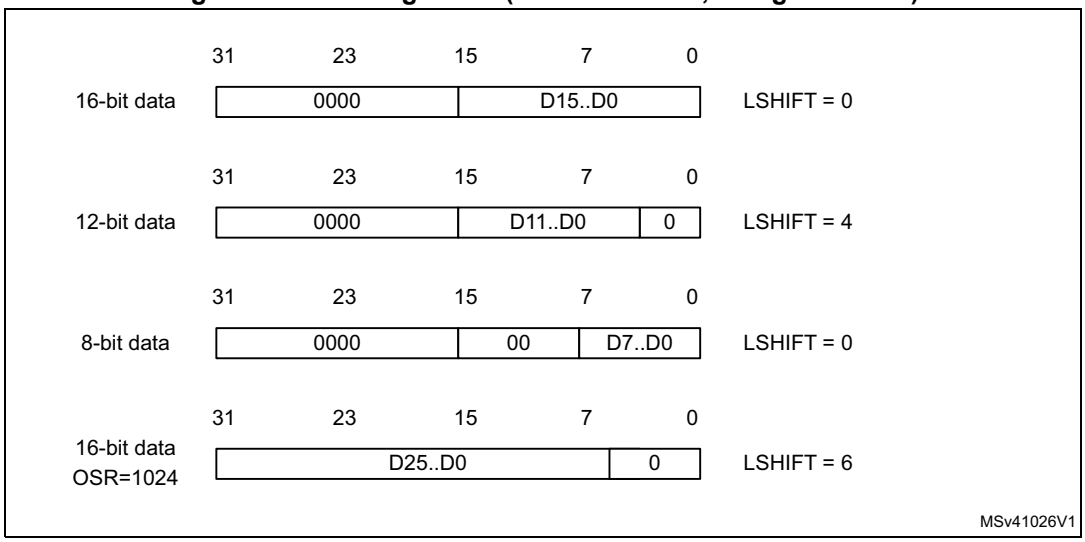

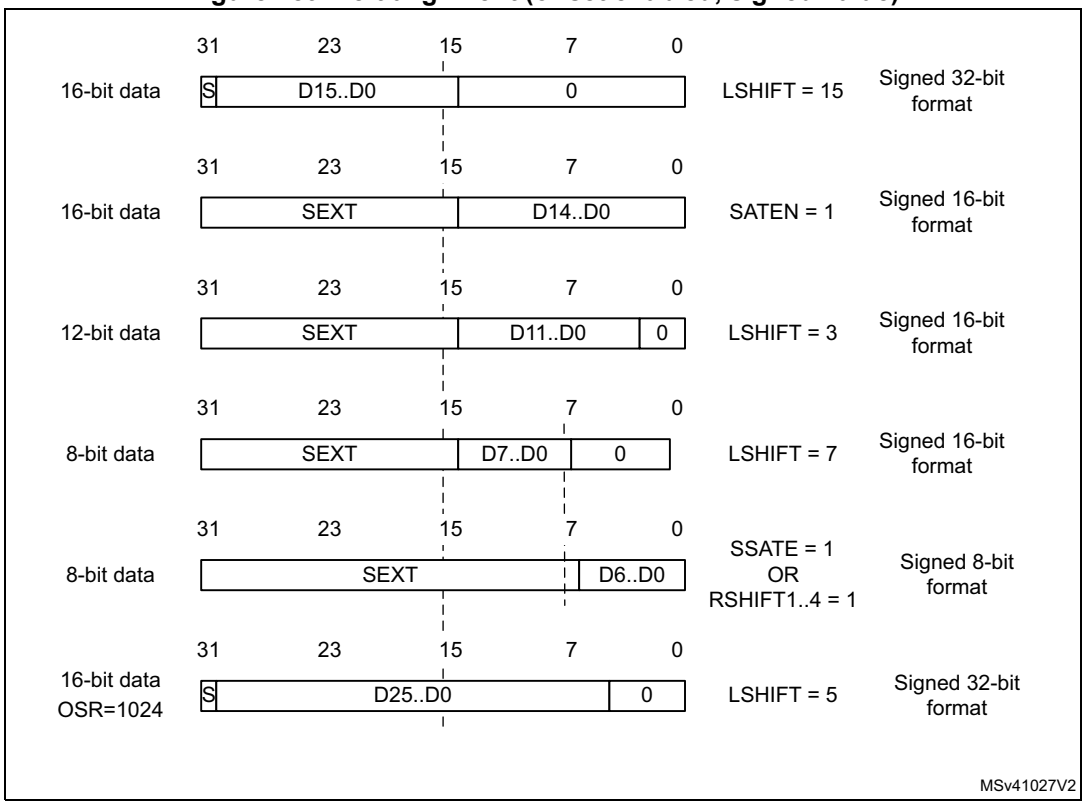

Figure 189. Left alignment (offset enabled, signed value)

16-bit and 8-bit signed format management: RSHIFTx,SSATE

The offset correction sign-extends the data format, resulting in an unsigned 16-bit conversion being extended to 17-bit signed format, for instance.

Three options are offered for formatting 8-bit and 16-bit conversion results.

For each offset correction channel 1 to 4, a RSHIFT1..4 bit in the ADC_CFGR2 register allows to have the result right-shifted 1-bit and have it fitting a standard 8 or 16-bit format.

Another option is to have the result saturated to the 16-bit and 8-bit signed formats, for the following cases only: RES[2:0] = 000 (16-bit format) and RES[2:0] = 111 (8-bit format).

This mode is enabled with the SSATE bit in the ADC_OFRy register.

The table below summarizes the 3 available use case for 16-bit format.

Table 203. 16-bit data formats

SSATE	RSHIFTx	Format	Data range (offset = 0x8000)
0	0	Sign-extended 17-bit significant data SEXT[31:16] DATA[15:0]	0x00007FFF - 0x FFFF8000
0	1	Sign-extended right-shifted 16-bit significant data SEXT[31:15] DATA[14:0]	0x3FFF - 0xC000
1	0	Sign-extended saturated 16-bit significant data SEXT[31:15] DATA[14:0]	7FFF - 0x8000
1	1	Reserved	-

Numerical examples are given in *Table 204* with 3 different offset values.

Table 204. Numerical examples for 16-bit format (bold indicates saturation)

Raw conversion result	Offset value	Result SSATE = 0 RSHIFT = 0	Result SSATE = 0 RSHIFT = 1	Result SSATE = 1 RSHIFT = 0
0xFFFF	0x8000	0x0000 7FFF	3FFF	7FFF
0x8000		0x0000 0000	0	0
0x0000		0xFFFF 8000	C000	8000
0xFFFF	0x8020	0x0000 7FDF	3FEF	7FDF
0x8000		0xFFFF FFE0	FFF0	FFE0
0x0000		0xFFFF 7FE0	BFF0	8000
0xFFFF	0x7FF0	0x0000 800F	4007	7FFF
0x8000		0x0000 0010	8	0010
0x0000		0xFFFF 8010	C008	8010

When oversampling mode is active, the SSATE and RSHIFT1..4 bits are not supported.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies of a buffer overrun event when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue to convert unless the software decides to stop and reset the sequence by setting ADSTP to 1.

OVR flag is cleared by software by writing 1 to it.

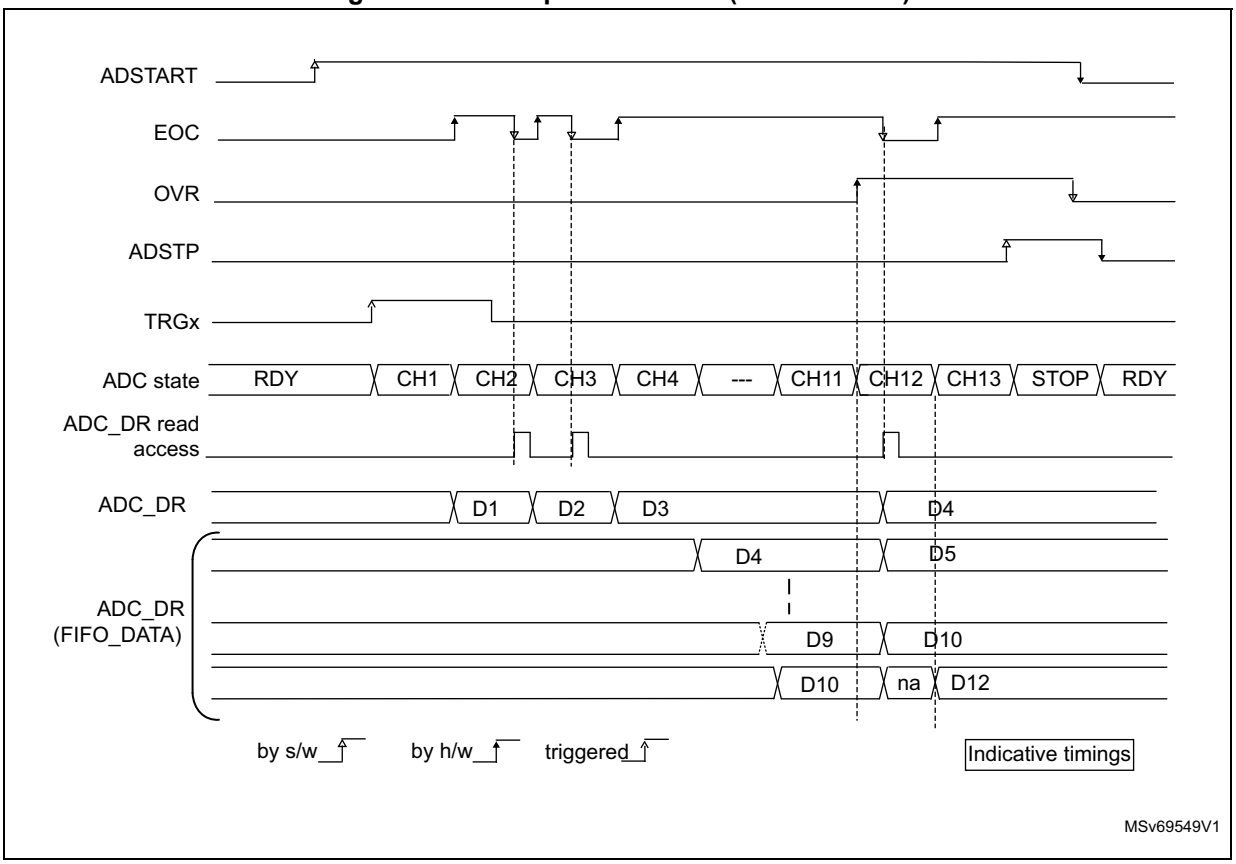
Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFGR register:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (8 data) and the new conversion is discarded and lost. If OVR remains at 1, any further conversion is be performed but the resulting data is also dicarded.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data.

Figure 190. Example of overrun (OVRMOD = 0)



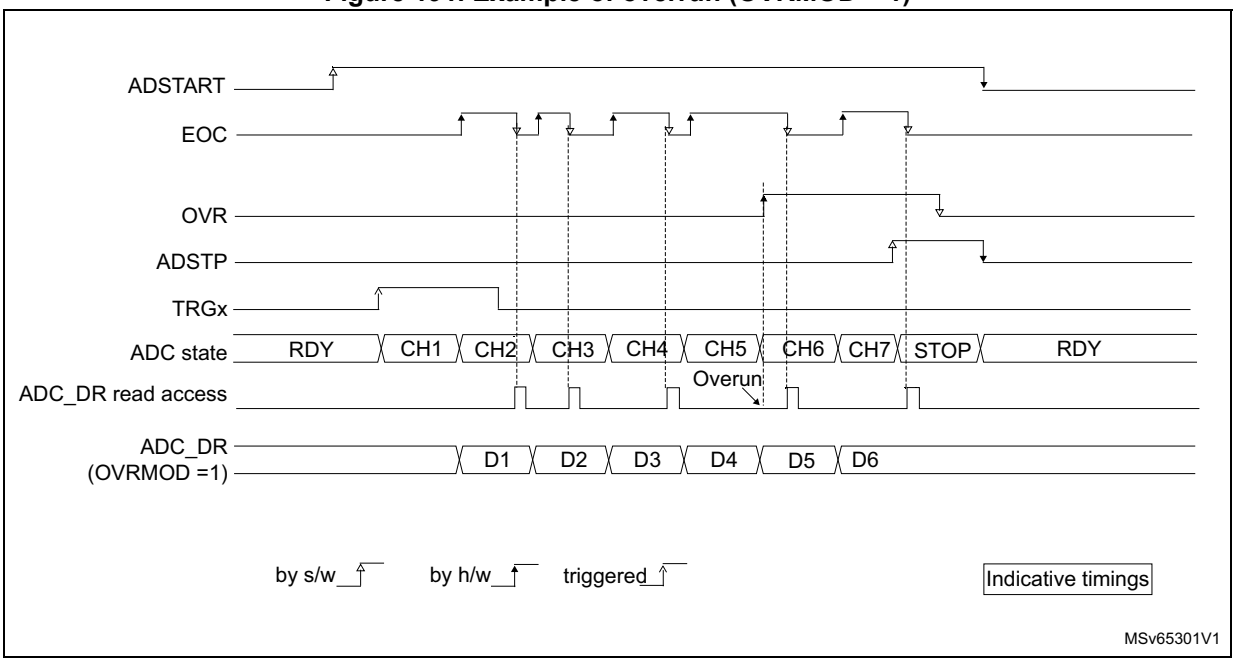


Figure 191. Example of overrun (OVRMOD = 1)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversion without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events or FIFO overflows as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert, and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT bit = 01 or 11 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMNGT of the ADC_CFGR register in single ADC mode, or with bit DAMDF of the ADCx_CCR register in dual ADC mode:

- DMA one shot mode (DMNGT bit = 01).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT bit = 11)
  This mode is suitable when programming the DMA in circular mode.

DMA one shot mode (DMNGT=01)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMNGT=11)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register has eight-stage FIFO. Two different DMA requests are generated parallel. When a data is available, “SREQ single request” generated, when 4 data are available, “BREQ burst request” generated. DMA2 can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA2. Please refer to the DMA2 chapter for further information.

27.4.28 Managing conversions using the DFSDM

The ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers 16 least significant bits of the regular data register data to the DFSDM, which in turns resets the EOC flag once the transfer is effective.

The data format must be 16-bit signed:

ADC_DR[31:16] = don’t care

ADC_DR[15] = sign

ADC_DR[14:0] = data

Any value above 16-bit signed format is truncated.

27.4.29 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see *Figure 192*).
- For an injected conversion: when the JEOS bit has been cleared (see *Figure 193*).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

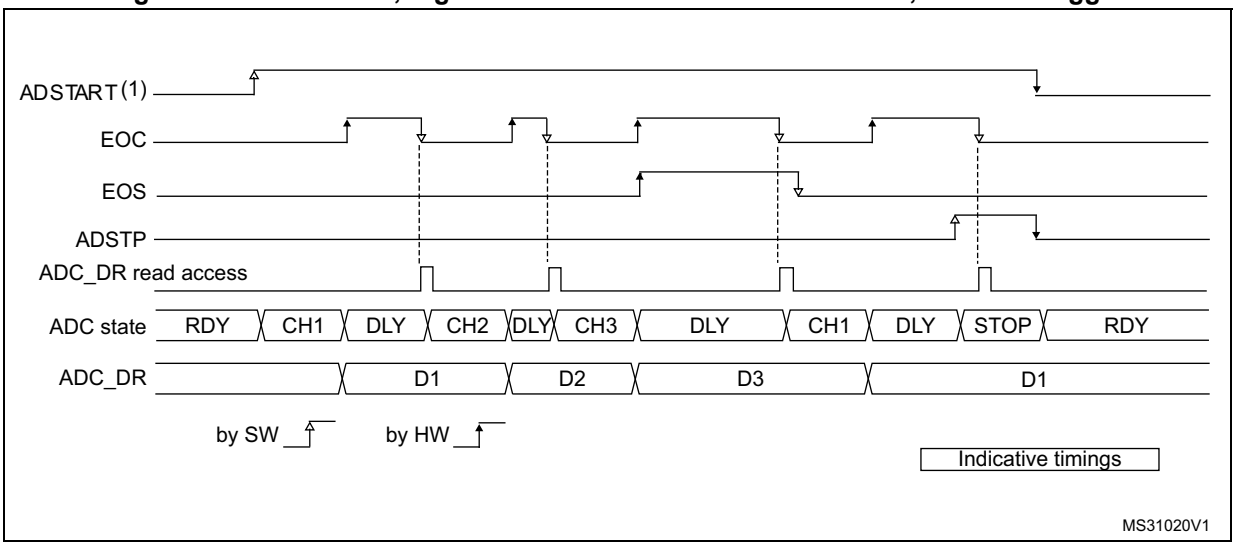
Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 193*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 195*).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 196*).

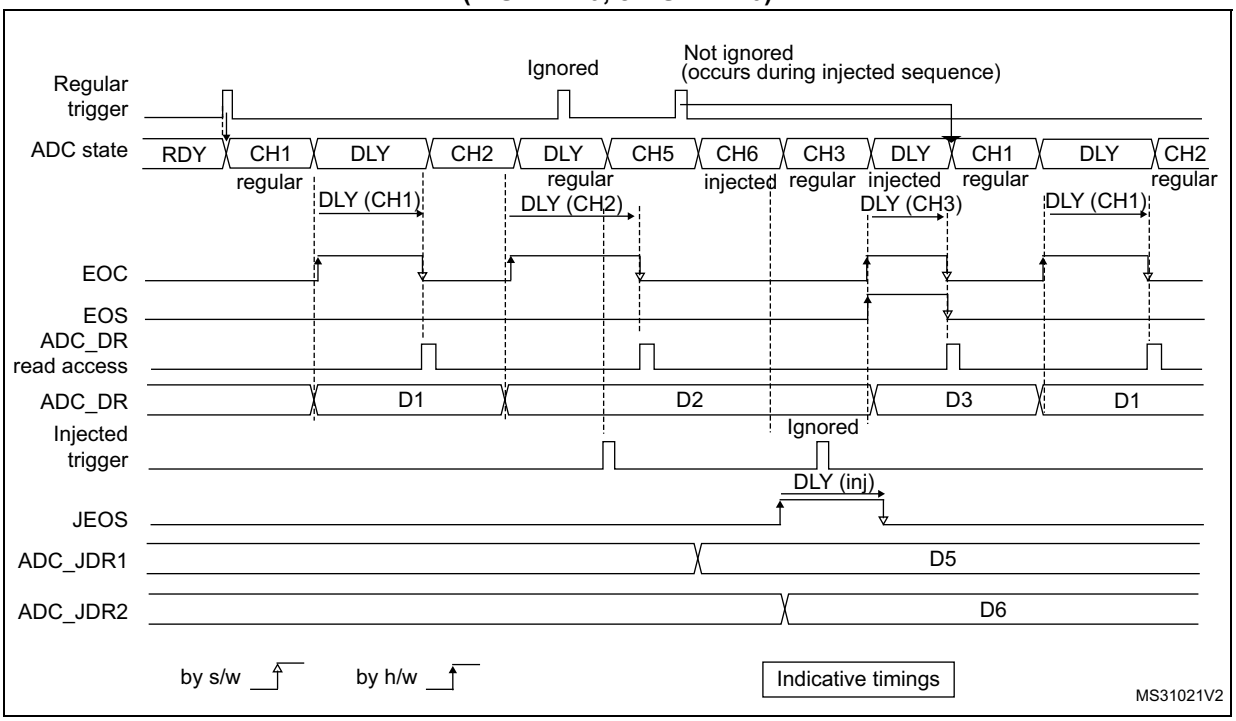
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:



1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.



In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

27.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 197. Analog watchdog guarded area

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (x=1,2,3).

AWDy (y=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels(1) remain within a configured voltage range (window).

Table 205 shows how the ADC_CFGRy registers should be configured to enable the analog watchdog on one or more channels.

Table 205. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in bits HTR1[25:0] of the ADC_HTR1 register and LTR1[25:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024).

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

Table 206 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

Table 206. Analog watchdog 1,2,3 comparison

Resolution (bit RES[2:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
16 bits	DATA[15:0]	LTR1[25:0] and HTR1[25:0]	-
14 bits	DATA[15:2],00	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[1:0] and HTR1[1:0] to 00
12 bits	DATA[15:4],0000	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[3:0] and HTR1[3:0] to 0000
10 bits	DATA[15:6],000000	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[5:0] and HTR1[5:0] to 000000
8 bits	DATA[15:8],00000000	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[7:0] and HTR1[7:0] to 00000000

1. The watchdog comparison is performed on the raw converted data before any alignment calculation and before applying any offsets (the data which is compared is not signed).

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCx_AWDy_OUT (x=ADC number, y=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCx_AWDy_OUT signal as ETR.

ADCx_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADCx_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCx_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCx_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS=1). Note that stopping regular or injected conversions (setting ADSTP=1 or JADSTP=1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCx_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

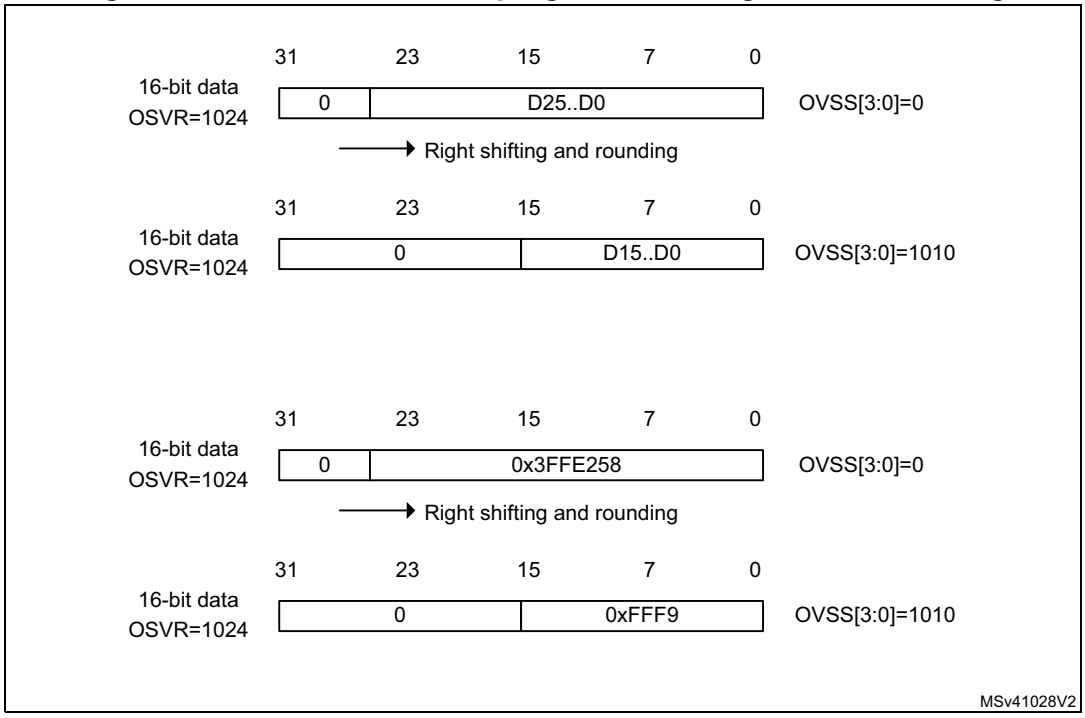
27.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 26-bit (16-bit values and OSVR[9:0] = 1024).

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$



It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OSVR[9:0] bits in the ADC_CFGR2 register, and can range from 2x to 1024x. The division coefficient M consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 26 bits (1024 x 16-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

The *Table 202* gives a numerical example of the processing, from a raw 26-bit accumulated data to the final 16-bit result.

Figure 202. 16-bit result oversampling with 10-bits right shift and rouding

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversions, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follow:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- the end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)

Single ADC operating modes support when oversampling

In oversampling mode, most of the ADC operating modes are maintained:

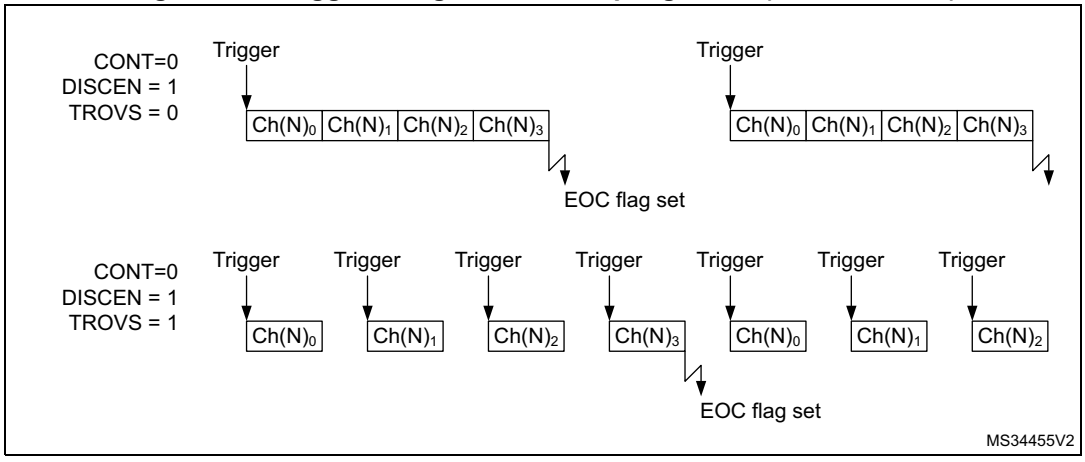
- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[2:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 16-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- the RES[2:0] bits are ignored, comparison is always done on using the full 26-bit values HTRx[25:0] and LTRx[25:0]
- *the comparison is performed on the oversampled accumulated value before shifting*



Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

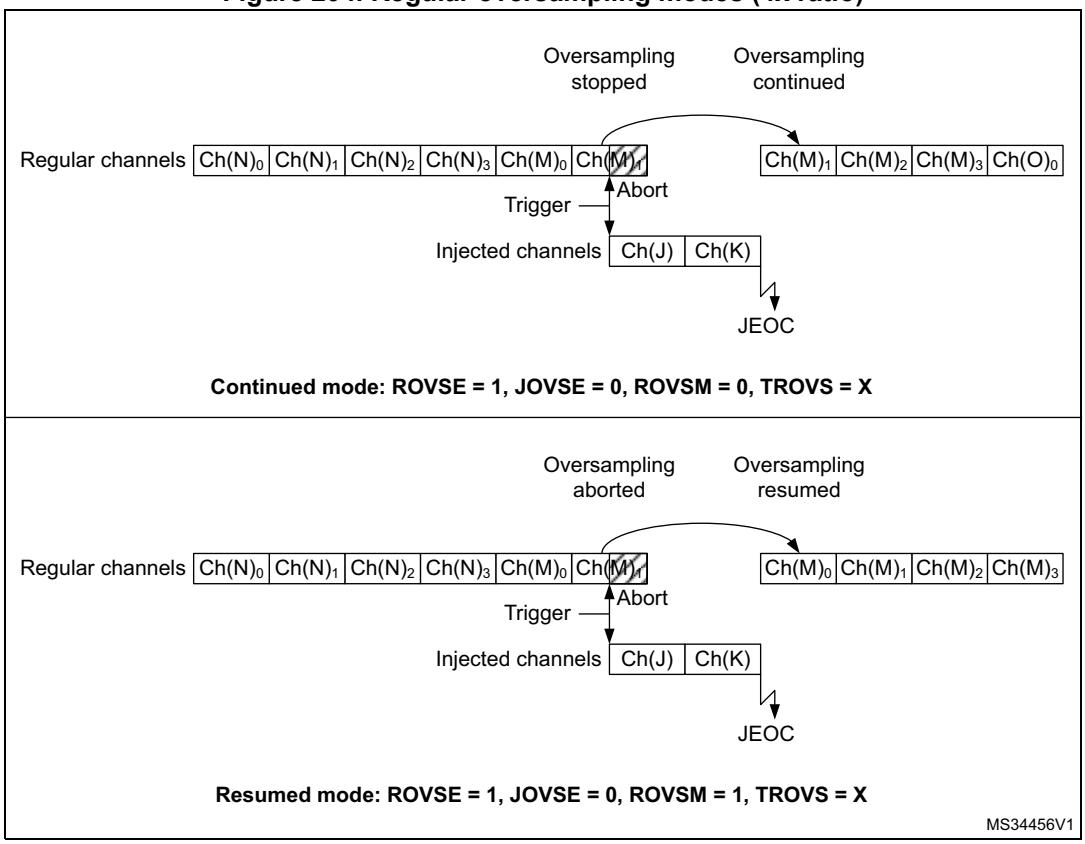
The *Figure 203* below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 203. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).



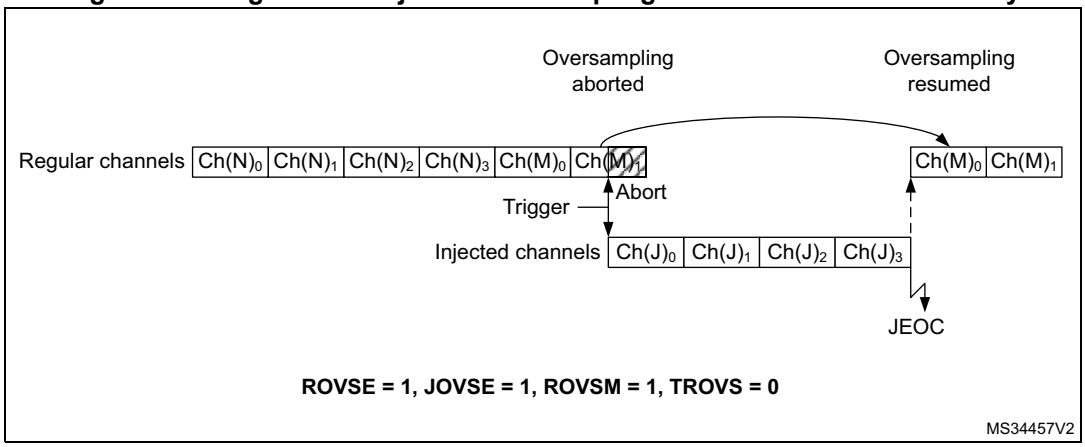
Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- in continued mode, the accumulation re-starts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- in resumed mode, the accumulation re-starts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequencer is blocked.

The *Figure 204* gives examples for a 4x oversampling ratio.

Figure 204. Regular oversampling modes (4x ratio)



Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on *Figure 205* below.

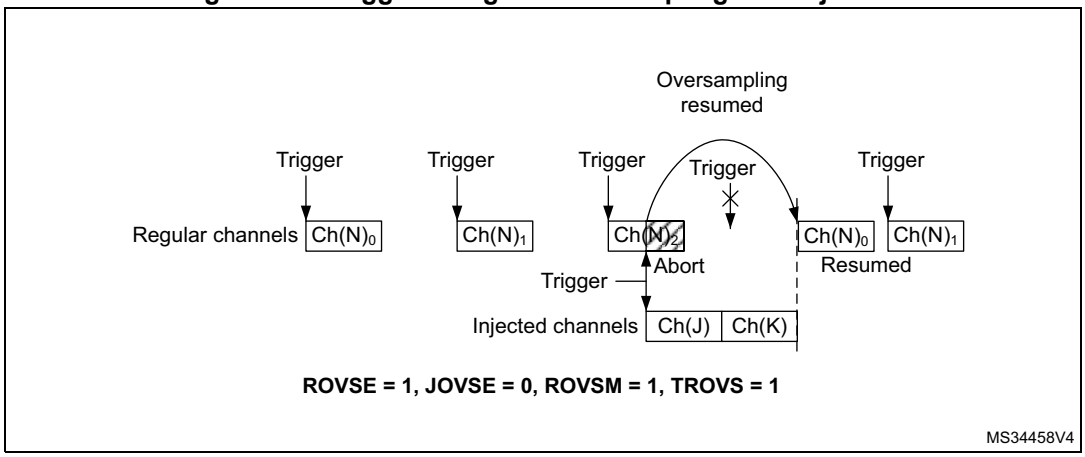


Figure 205. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on *Figure 206* below.

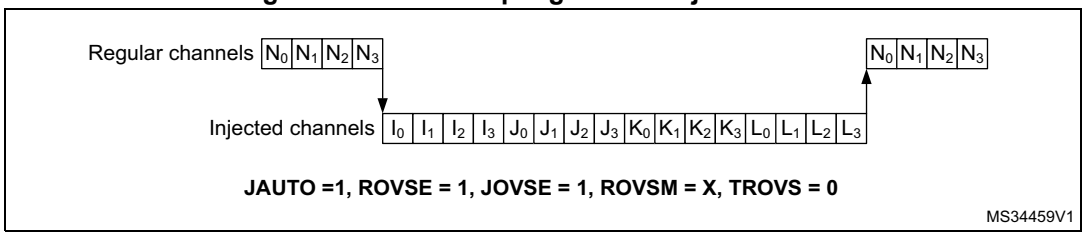

Figure 206. Triggered regular oversampling with injection

Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The *Figure 207* below shows how the conversions are sequenced.

Figure 207. Oversampling in auto-injected mode

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO=1, DISCEN=0, JDISCEN=0, ROVSE=1, JOVSE=1 and TROVSE=1.

Dual ADC modes support when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The *Table 207* below summarizes all combinations, including modes not supported.

Table 207. Oversampler operating modes summary

Regular Over-sampling ROVSE	Injected Over-sampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered Regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

27.4.32 Dual ADC modes

In devices with two ADCs or more, dual ADC modes can be used (see *Figure 208*):

- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

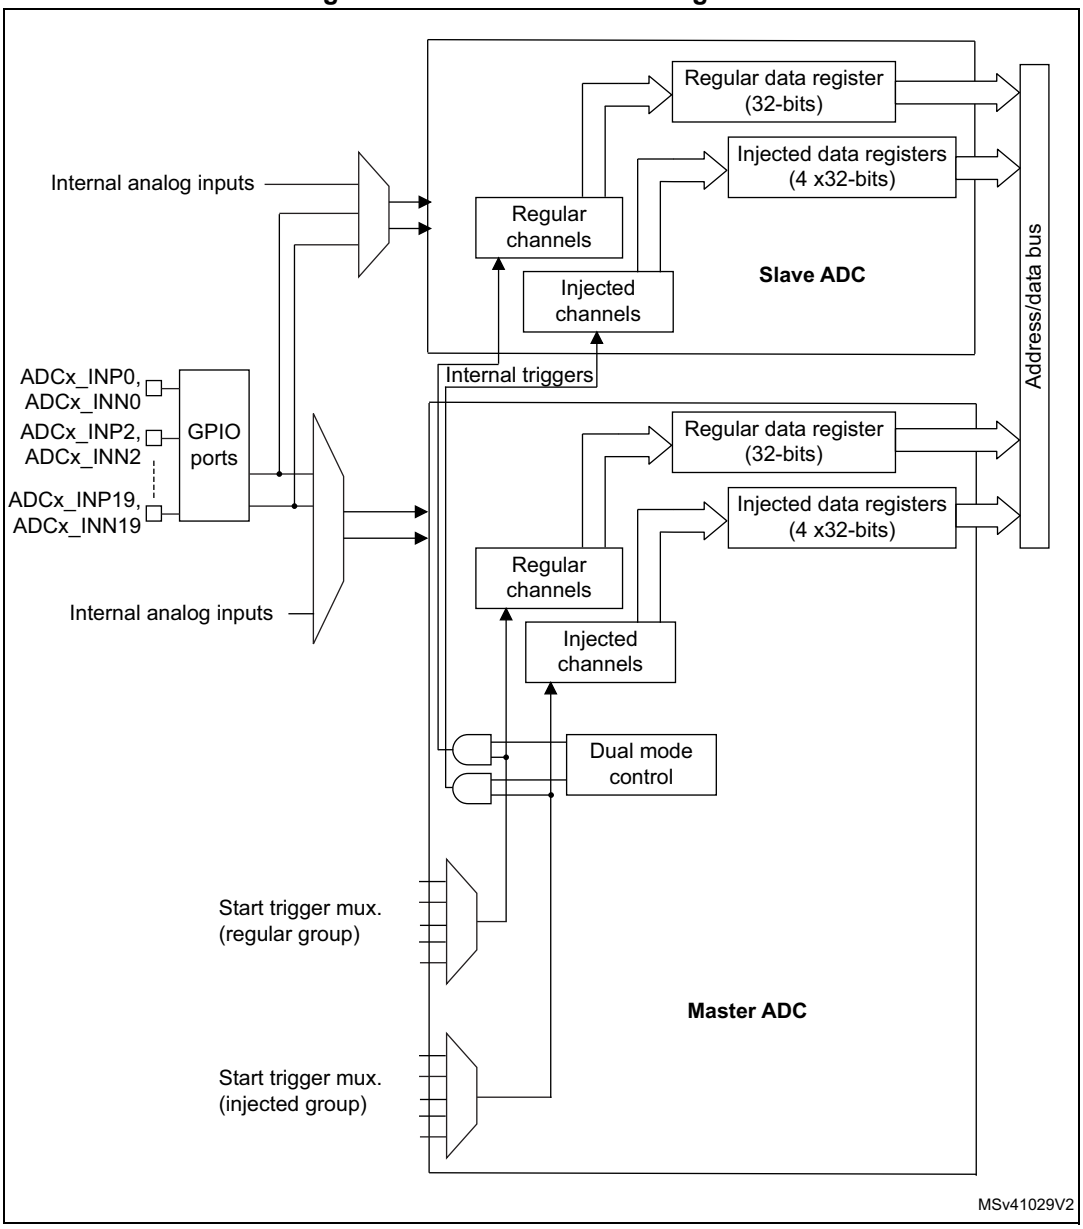
Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.



To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).

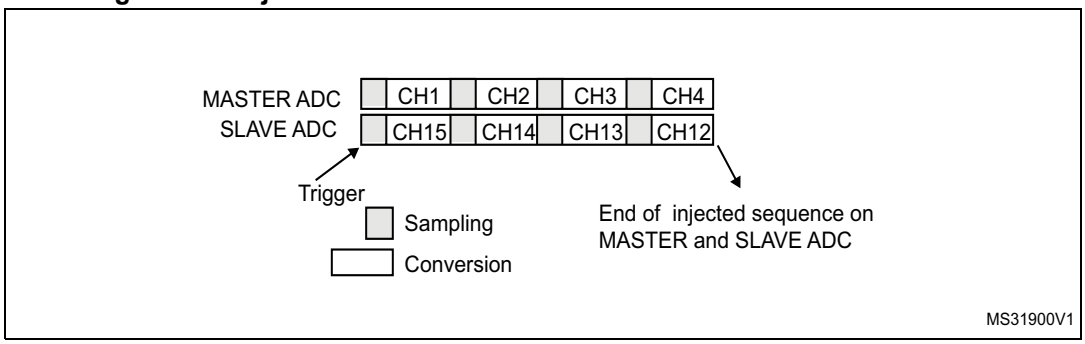
Figure 208. Dual ADC block diagram(1)

1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADC_JSQR register).



Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in *Figure 209*), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 209. Injected simultaneous mode on 4 channels: dual ADC mode

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored.
  There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

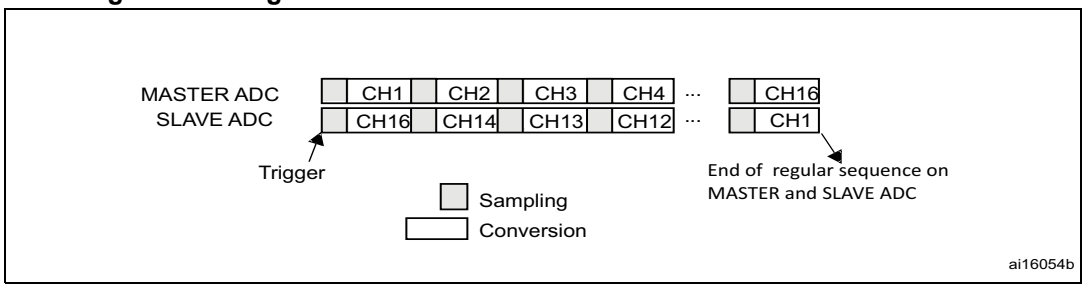
This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are re-started once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master ans slave must be configured with the same sampling time.

Software is notified by interrupts when it can read the data:



- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in *Figure 210*), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configuring dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CDR register.
  - both EOC flags are cleared when the DMA reads the ADCx_CDR register.

Note: When DAMDF[1:0]=0b10 or 0b11, the user must program the same number of conversions in the master's sequence as in the slave's sequence. Otherwise, the remaining conversions do not generate a DMA request.

Figure 210. Regular simultaneous mode on 16 channels: dual ADC mode

If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multiple-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

Interleaved mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the

complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

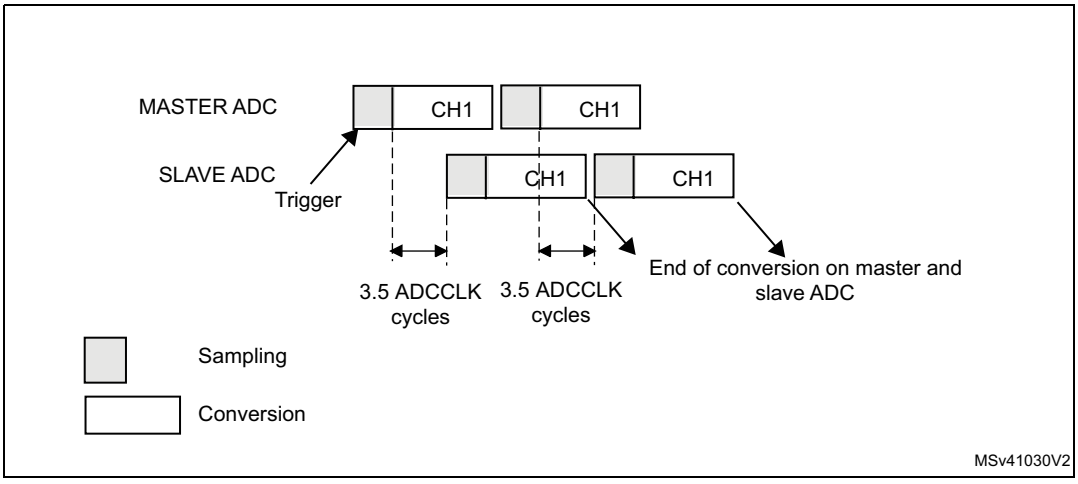
The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

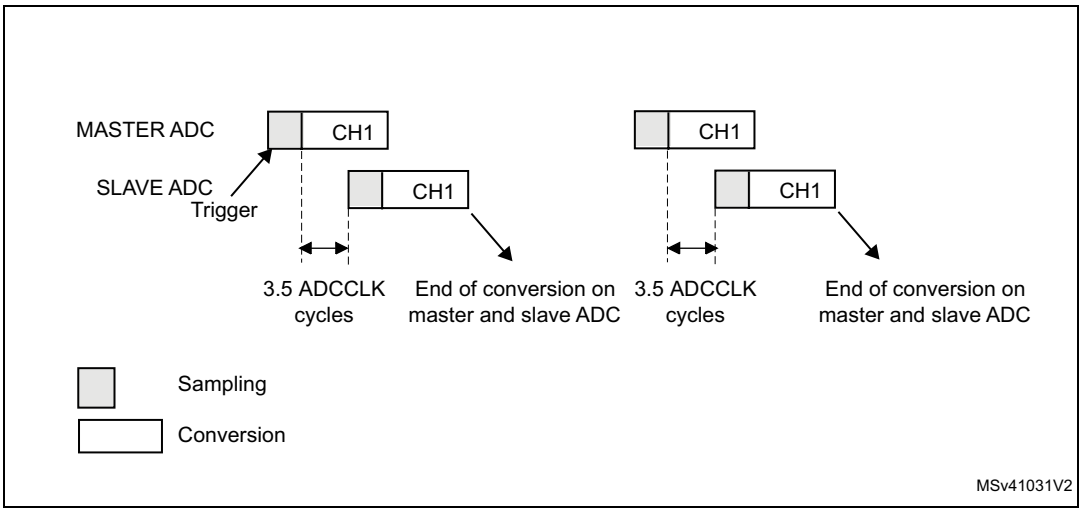
Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

Figure 211. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode





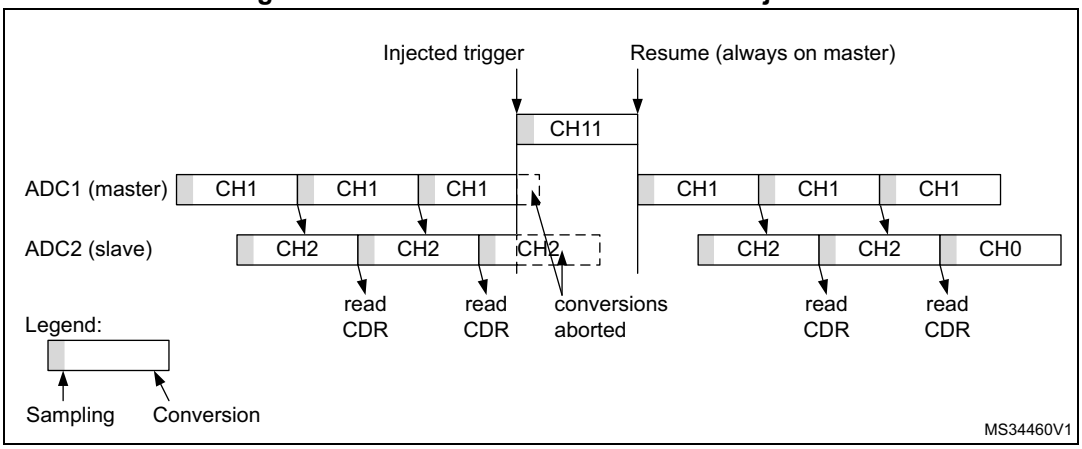


Figure 212. Interleaved mode on 1 channel in single conversion mode: dual ADC mode

If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is re-started from the master (see *Figure 213* below).

Figure 213. Interleaved conversion with injection

Alternate trigger mode

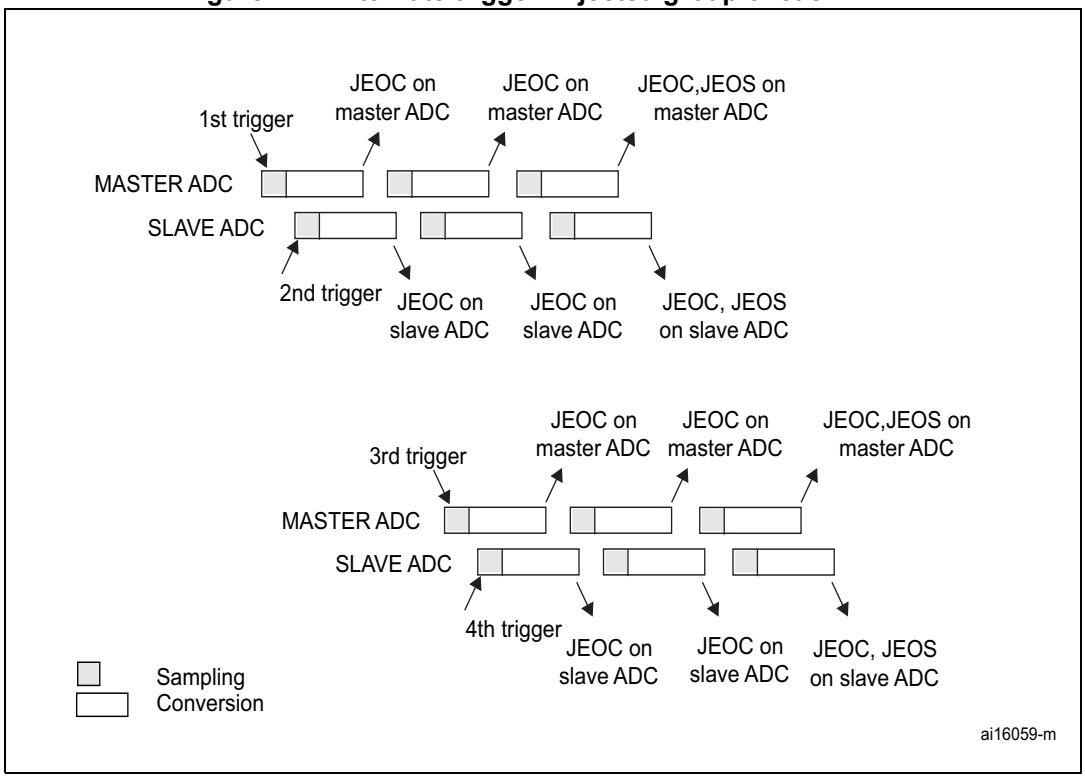
This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.

Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.



A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 214. Alternate trigger: injected group of each ADC

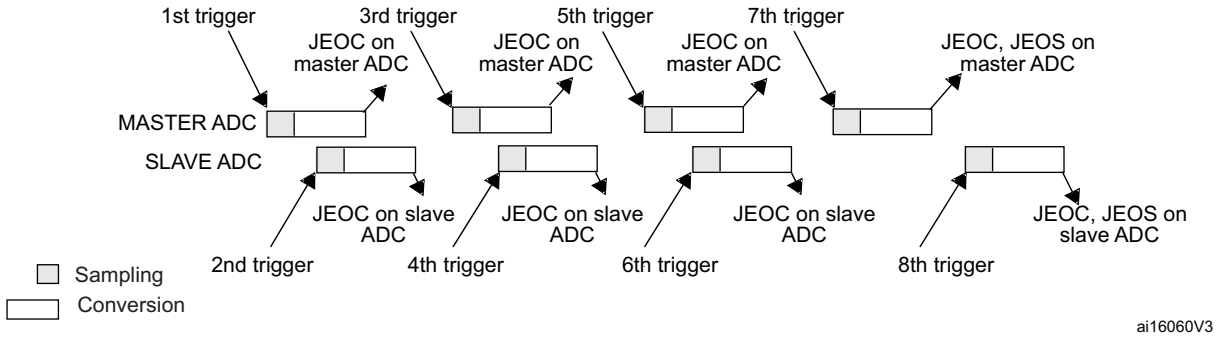
Note: Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN=1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.



A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

Figure 215. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode

Combined regular/injected simultaneous mode

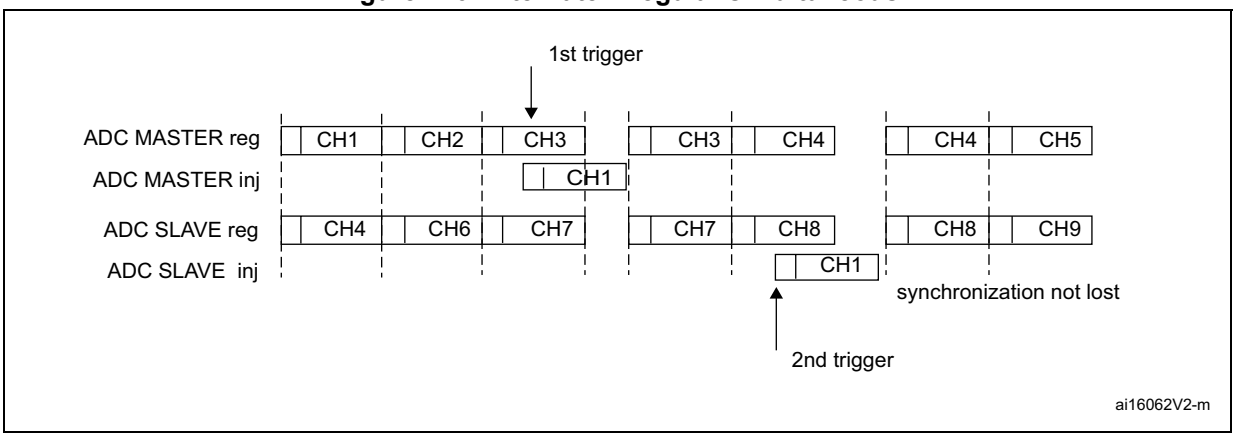
This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

Note: The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

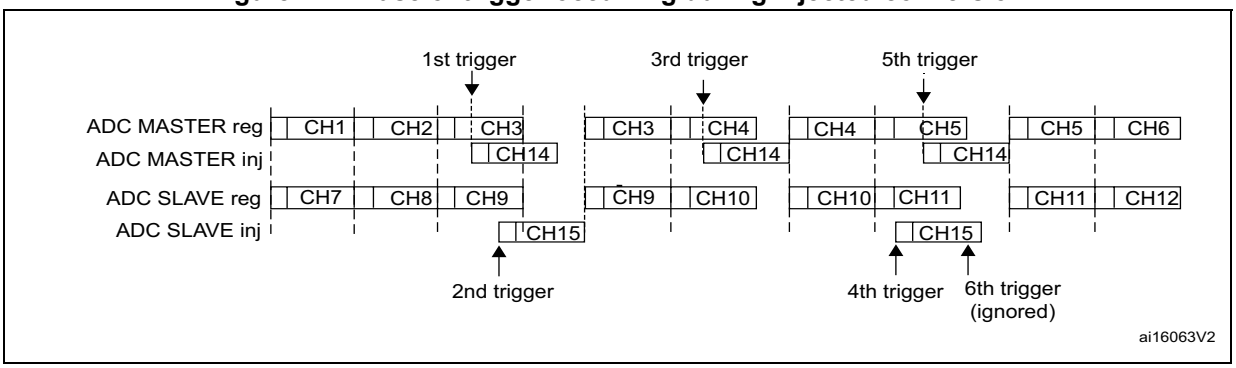
This mode is selected by programming bits DUAL[4:0]=00010.



It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. *Figure 216* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected

conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.



Note: The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Figure 216. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 217* shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 217. Case of trigger occurring during injected conversion

Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0]=00011.

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is alway the master's one. *Figure 218*, *Figure 219* and *Figure 220* show the behavior using an example.

Caution: In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.

Figure 218. Interleaved single channel CH0 with injected sequence CH11, CH12

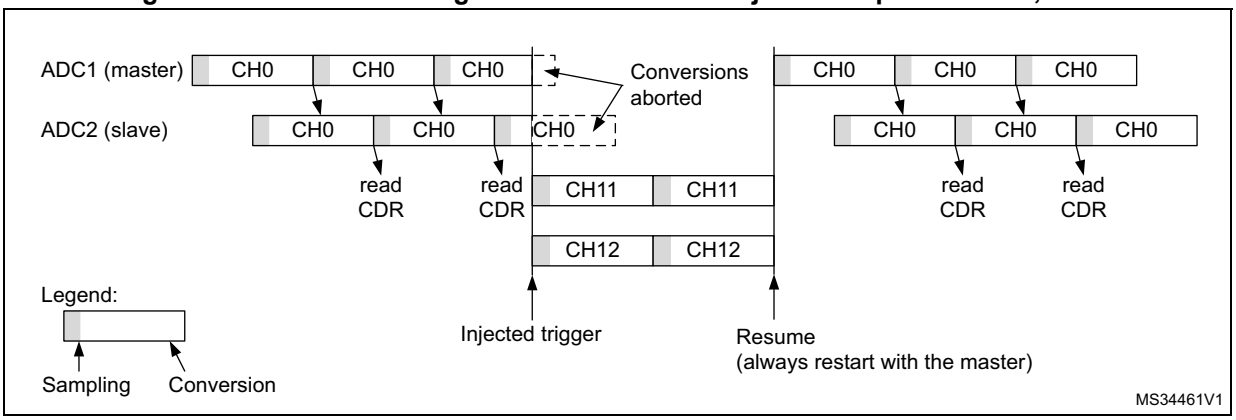


Figure 219. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first

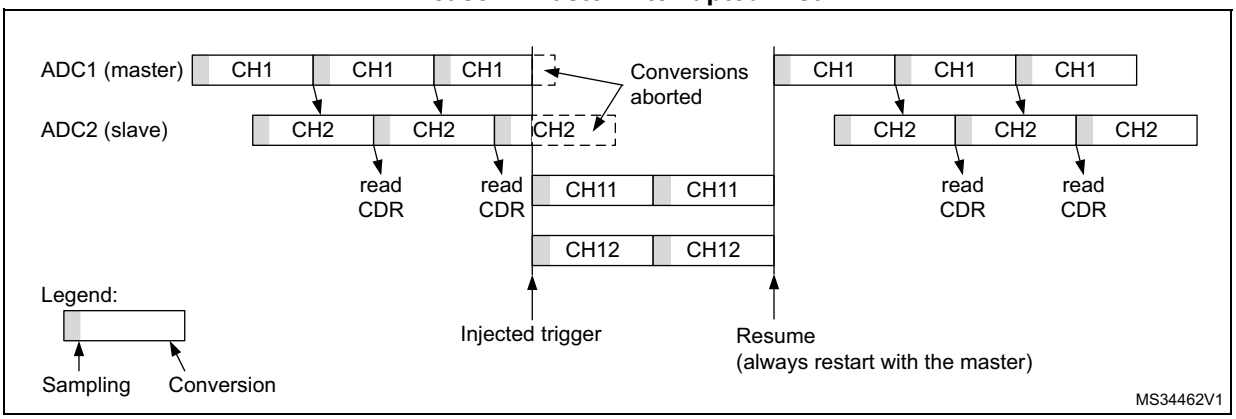

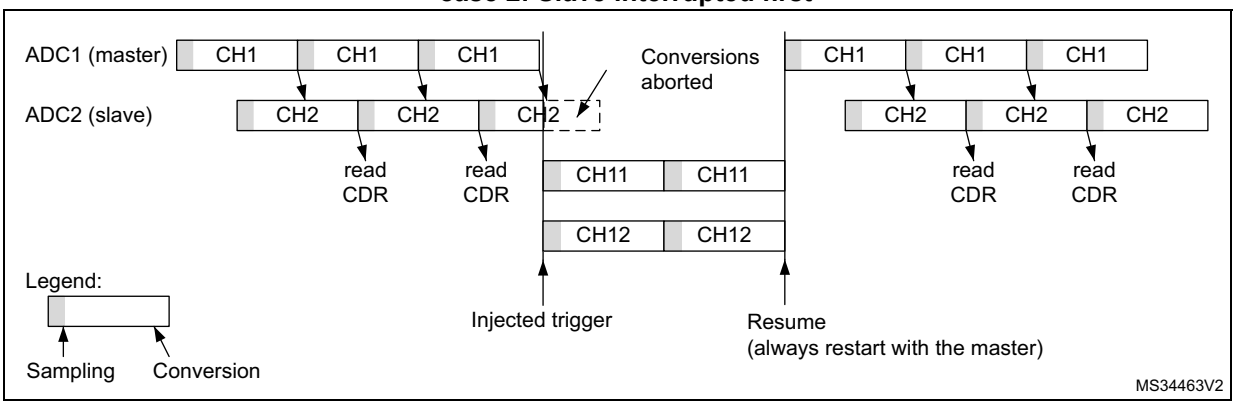

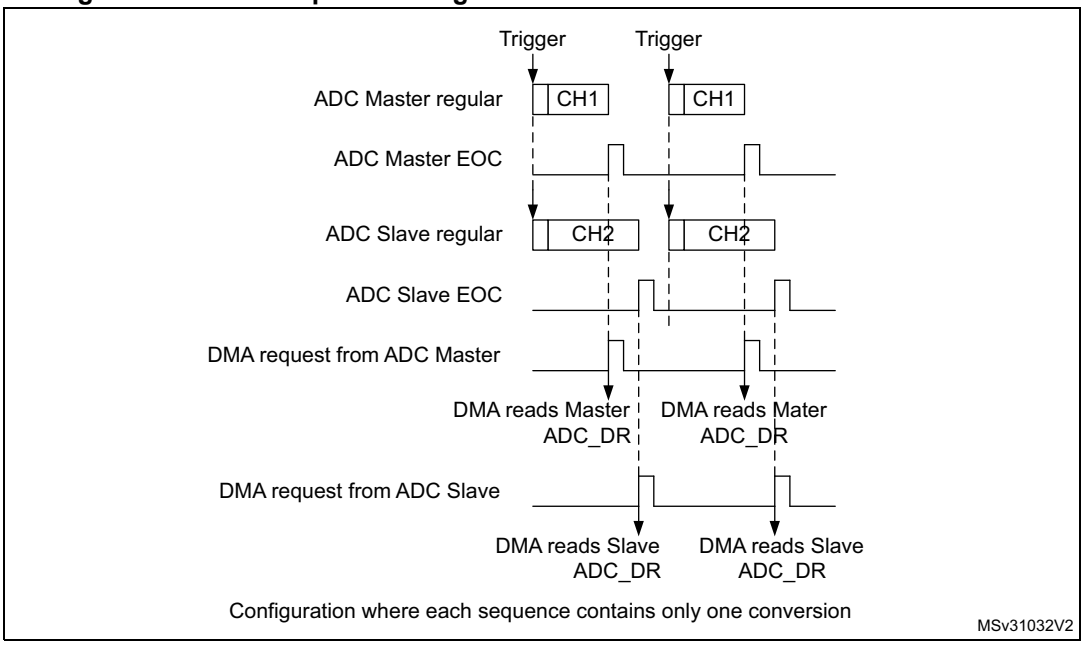

Figure 220. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first

DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 221: DMA Requests in regular simultaneous mode when DAMDF=0b00*).

Figure 221. DMA Requests in regular simultaneous mode when DAMDF=0b00

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this DAMDF bits must be configured in the ADCx_CCR register:

- **DAMDF=0b10, 32-bit format**: A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADCx_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit.
  Example:

  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:

  1st DMA request: ADCx_CDR2[31:0] = MST_ADC_DR[31:0]

  2nd DMA request: ADCx_CDR2[31:0] = SLV_ADC_DR[31:0]
- **DAMDF=0b10, 16-bit format**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-

converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter is truncated to the least 16 significant bits.

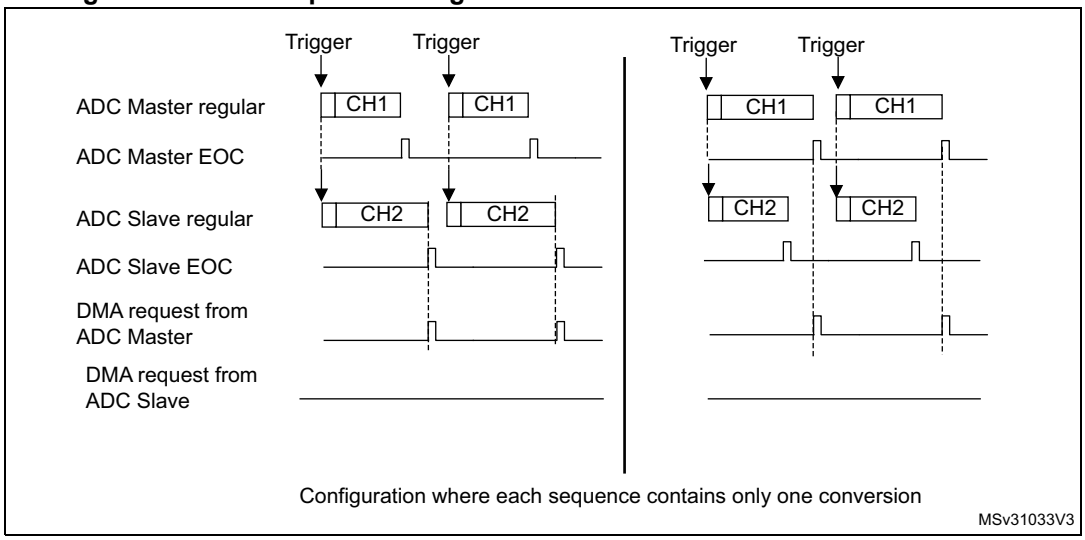
Example:

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

2nd DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 222. DMA requests in regular simultaneous mode when DAMDF=0b10



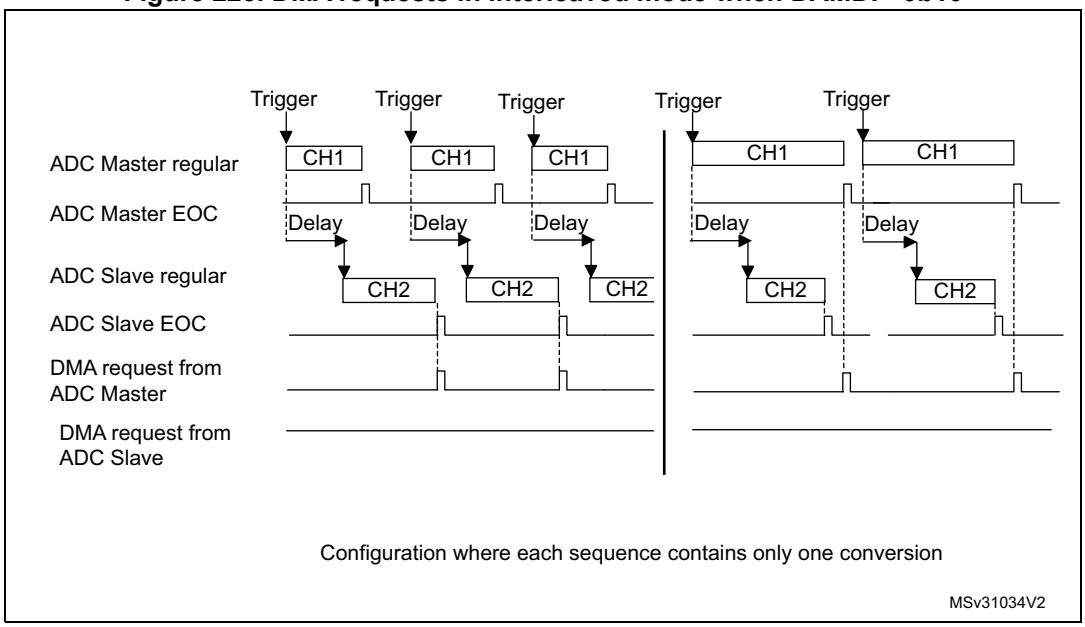


Figure 223. DMA requests in interleaved mode when DAMDF=0b10

Note: When using multiple-ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF=0b11**: This mode is similar to the DAMDF=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

  This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when 4 new 8-bit values are available.

  Example:

  Interleaved dual mode: a DMA request is generated each time 4 data items are available (t0, t1,... are corresponding to the consecutive sampling instants)

  1st DMA request:

  ADCx_CDR[7:0] = MST_ADC_DR[7:0]$_{t0}$

  ADCx_CDR[15:8] = SLV_ADC_DR[7:0]$_{t0}$

  ADCx_CDR[23:16] = MST_ADC_DR[7:0]$_{t1}$

  ADCx_CDR[31:24] = SLV_ADC_DR[7:0]$_{t1}$

  2nd DMA request:

  ADCx_CDR[7:0] = MST_ADC_DR[7:0]$_{t2}$

  ADCx_CDR[15:8] = SLV_ADC_DR[7:0]$_{t2}$

  ADCx_CDR[23:16] = MST_ADC_DR[7:0]$_{t3}$

  ADCx_CDR[31:24] = SLV_ADC_DR[7:0]$_{t3}$

Overrun detection

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

DMA one shot mode/ DMA circular mode when multiple-ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), bit DMNGT[1:0]=0b10 in the master ADC's ADCx_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA*.

Stopping the conversions in dual ADC modes

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

DFSDM mode in dual ADC mode interleaved mode

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

This mode is enabled by setting the bits DMNGT[1:0] = 0b10 in the master ADC's ADC_CFGR register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the DFSDM.

The data format must be 16-bit signed:

ADC_DR[31:16] = 0x0000

ADC_DR[15] = sign

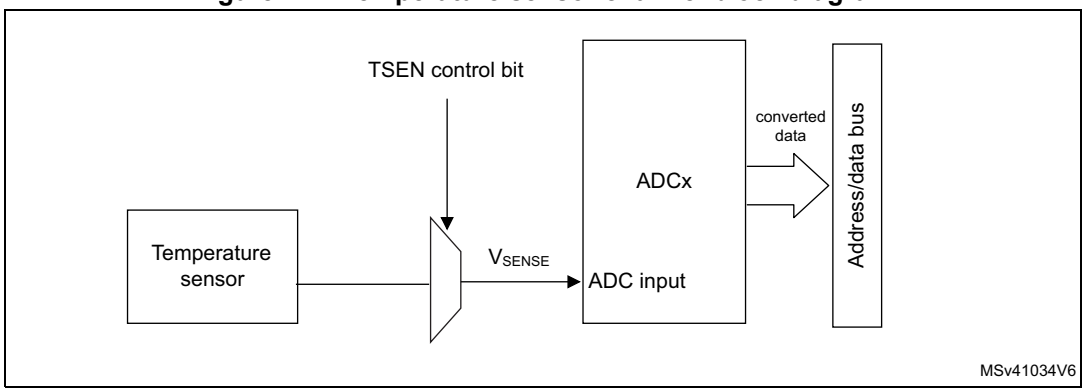
ADC_DR[14:0] = data

Any value above 16-bit signed format in any converter is truncated.

DFSDM mode in dual ADC simultaneous mode

The dual mode is not required to use DFSDM in dual ADC simultaneous mode since conversion data are treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with DFSDM interface.

27.4.33 Temperature sensor



The temperature sensor can measure the junction temperature (T_J) of the device in the –40 to 130 °C temperature range.

The temperature sensor is internally connected to an ADC internal channel which is used to convert the sensor's output voltage to a digital value (refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals*). The sampling time for the temperature sensor's analog pin must be greater than the stabilization time specified in the product datasheet.

When not in use, the sensor can be put in power-down mode.

Figure 224 shows the block diagram of the temperature sensor.

Figure 224. Temperature sensor channel block diagram

Note: The TSEN bit must be set to enable the conversion of the corresponding ADC internal channel (temperature sensor, V_{SENSE}).

Reading the temperature

To use the sensor:

1. Select the ADC input channels (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADCx_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V_{SENSE} data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$\text{emperature (in °C)} = \frac{\text{TS_CAL2_TEMP} - \text{TS_CAL1_TEMP}}{\text{TS_CAL2} - \text{TS_CAL1}} \times (\text{TS_DATA} - \text{TS_CAL1}) + \text{TS_CAL1_TEMP}$$

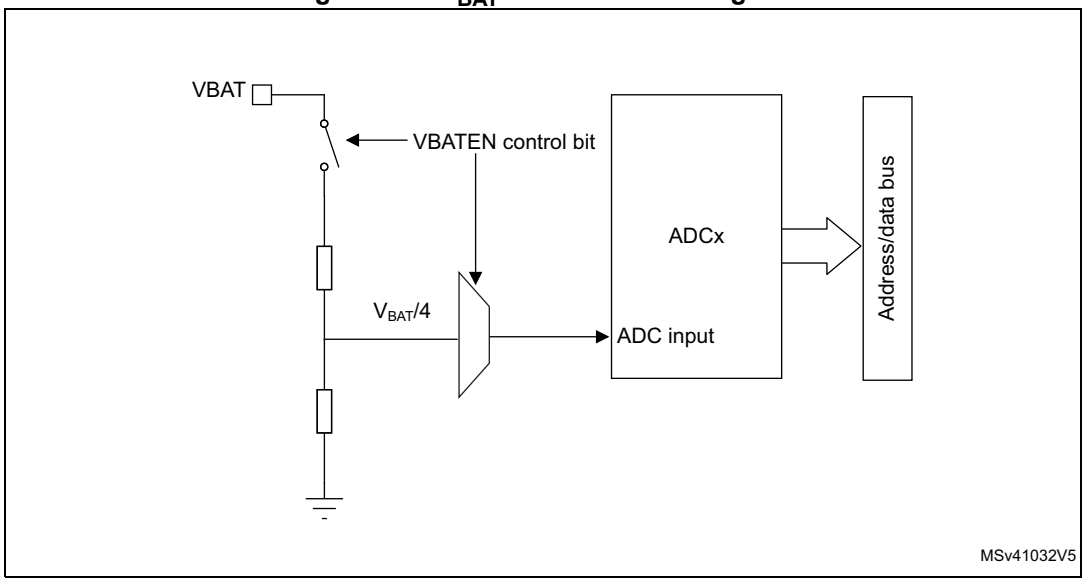
Where:

- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP
- TS_DATA is the actual temperature sensor output value converted by ADC

  Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and SENSEEN bits should be set at the same time.

27.4.34 V_{BAT} supply monitoring



The VBATEN bit of the ADCx_CCR register is used to switch to the battery voltage. As the V_{BAT} voltage could be higher than V_{DDA}, to ensure the correct operation of the ADC, the V_{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}/4$ to an ADC input channel (refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals*).

As a consequence, the converted digital value is one fourth of the V_{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

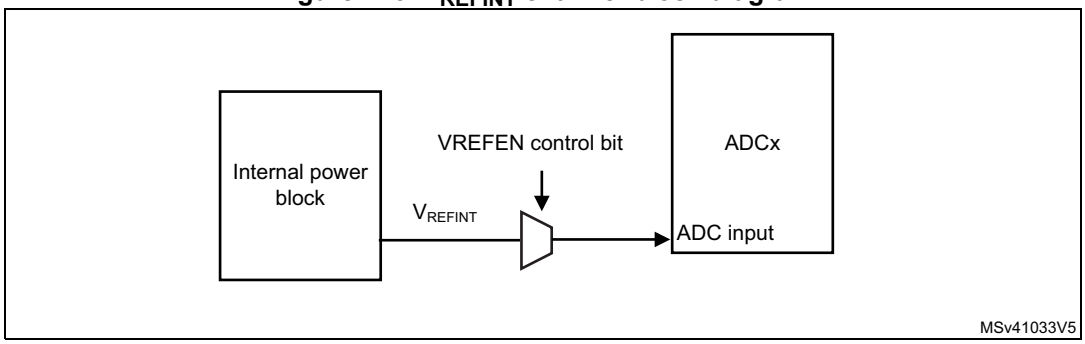
Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/4$ voltage.

Figure 225 shows the block diagram of the V_{BAT} sensing feature.

Figure 225. V_{BAT} channel block diagram

Note: The VBATEN bit in ADCx_CCR must be configured to enable the conversion of the corresponding ADC internal channel.

27.4.35 Monitoring the internal voltage reference



The internal voltage reference can be monitored to have a reference point for evaluating the ADC V_{REF+} voltage level.

The internal voltage reference is internally connected to an ADC input channel (refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals*).

The sampling time for this channel must be greater than the stabilization time specified in the product datasheet.

Figure 225 shows the block diagram of the V_{REFINT} sensing feature.

Figure 226. V_{REFINT} channel block diagram

Note: The VREFEN bit of the ADCx_CCR register must be configured to enable the conversion of the corresponding ADC internal channel (V_{REFINT}).

Calculating the actual V_{DDA} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{DDA} = 3.3 V can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{DDA} voltage supplying the device:

$$V_{REF+} = 3.3\ V \times VREFINT_CAL / VREFINT_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value
- VREFINT_DATA is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For most applications V_{DDA} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{DDA}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{3.3\ V \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{DDA} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{DDA}}{FULL_SCALE} \times ADC_DATA$$

Where:

- VREFINT_CAL is the VREFINT calibration value
- ADC_DATA is the value measured by the ADC on channel x (right-aligned)
- VREFINT_DATA is the actual VREFINT output value converted by the ADC
- FULL_SCALE is the maximum digital value of the ADC output. For example with 16-bit resolution, it is 2^{16} - 1 = 65535 or with 8-bit resolution, 2^8 - 1 = 255.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

27.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Table 208. ADC interrupts per each ADC

Interrupt event	Event flag	Enable control bit
ADC ready	ADRDY	ADRDYIE
End of conversion of a regular group	EOC	EOCIE
End of sequence of conversions of a regular group	EOS	EOSIE
End of conversion of a injected group	JEOC	JEOCIE
End of sequence of conversions of an injected group	JEOS	JEOSIE
Analog watchdog 1 status bit is set	AWD1	AWD1IE
Analog watchdog 2 status bit is set	AWD2	AWD2IE
Analog watchdog 3 status bit is set	AWD3	AWD3IE
End of sampling phase	EOSMP	EOSMPIE
Overrun	OVR	OVRIE
Injected context queue overflows	JQOVF	JQOVFIE

27.6 ADC registers (for each ADC)

Refer to *Section 1.2 on page 98* for a list of abbreviations used in register descriptions.

27.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	LDORDY	Res.	JQOVF	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
			r		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: ADC LDO output voltage ready bit

This bit is set and cleared by hardware. It indicates that the ADC internal LDO output is ready and that the ADC can be enabled or calibrated.

0: ADC LDO voltage regulator disabled

1: ADC LDO voltage regulator enabled

Note: Refer to Section 27.3: ADC implementation for the availability of the LDO regulator.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVF**: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to *Section 27.4.22: Queue of context for injected conversions* for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

27.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.

0: Injected Context Queue Overflow interrupt disabled

1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.3 ADC control register (ADC_CR)

Address offset: 0x08

Reset value: 0x2000 0000

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.

0: Writing ADCAL launches a calibration in single-ended inputs mode.

1: Writing ADCAL launches a calibration in differential inputs mode.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in deep-power-down mode.

0: ADC not in deep-power down

1: ADC in deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 28 **ADVREGEN**: ADC voltage regulator enable

This bits is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled

1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 27.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.

The software can program this bitfield only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 27 **LINCALRDYW6**: Linearity calibration ready Word 6

This control / status bit allows to read/write the 6th linearity calibration factor.

When the linearity calibration is complete, this bit is set. A bit clear launches the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit is reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared).

When the *LINCALRDYW6 bit is reset, a new linearity factor 6 value can be written into* the LINCALFACT[29:0] of the ADC_CALFACT2 register. A bit set launches the linearity factor 6 update and the bit is effectively set by hardware once the update is done (software must poll the bit until it is set to indicate the write is effective).

Note: ADC_CALFACT2[29:10] *contains 0.* ADC_CALFACT2[9:0] *corresponds linearity correction factor bits[159:150].*

The software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 27.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT) for details.

The software is allowed to update the linearity calibration factor by writing LINCALRDYWx only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 26 **LINCALRDYW5**: Linearity calibration ready Word 5

Refer to LINCALRDYW6 description.

Note: ADC_CALFACT2[29:0] *corresponds linearity correction factor bits[149:120].*

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 25 **LINCALRDYW4**: Linearity calibration ready Word 4

Refer to LINCALRDYW6 description.

Note: ADC_CALFACT2[29:0] *correspond linearity correction factor bits[119:90].*

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 24 **LINCALRDYW3**: Linearity calibration ready Word 3

Refer to LINCALRDYW6 description.

Note: ADC_CALFACT2[29:0] *corresponds linearity correction factor bits[89:60].*

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 23 **LINCALRDYW2**: Linearity calibration ready Word 2

Refer to LINCALRDYW6 description.

Note: ADC_CALFACT2[29:0] *corresponds linearity correction factor bits[59:30].*

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.

Bit 22 **LINCALRDYW1**: Linearity calibration ready Word 1

Refer to LINCALRDYW6 description.

Note: ADC_CALFACT2[29:0] corresponds linearity correction factor bits[29:0].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **ADCALLIN**: Linearity calibration

This bit is set and cleared by software to enable the Linearity calibration.

0: Writing ADCAL launches a calibration without the Linearity calibration.

1: Writing ADCAL launches a calibration with the Linearity calibration.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **BOOST[1:0]**: Boost mode control

This bitfield is set and cleared by software to enable/disable the boost mode.

00: used when ADC clock ≤ 6.25 MHz

01: used when 6.25 MHz < ADC clock frequency ≤ 12.5 MHz

10: used when 12.5 MHz < ADC clock ≤ 25.0 MHz

11: used when 25.0 MHz < ADC clock ≤ 50.0 MHz

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the BOOST bitfield of the slave ADC is no more writable and its content must be equal to the master ADC BOOST bitfield.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTEN=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTEN=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

27.6.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JQDIS	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	JQM	JDISCEN	DISCNUM[2:0]			DISCEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					RES[2:0]			DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **JQDIS**: Injected Queue disable

These bits are set and cleared by software to disable the Injected Queue mechanism:

0: Injected Queue enabled

1: Injected Queue disabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).

A set or reset of JQDIS bit causes the injected queue to be flushed and the ADC_JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel-0 monitored by AWD1

00001: ADC analog input channel-1 monitored by AWD1

.....

10010: ADC analog input channel-19 monitored by AWD1

others: Reserved, must not be used

Note: The channel selected by AWD1CH must be also selected into the SQi or JSQi bits.

The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 21 **JQM**: ADC_JSQR queue mode

This bit is set and cleared by software.

It defines how an empty Queue is managed.

0: ADC_JSQR Mode 0: The Queue is never empty and maintains the last written configuration into ADC_JSQR.

1: ADC_JSQR Mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to *Section 27.4.22: Queue of context for injected conversions* for more information.

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off

1: Auto-delayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: Event 0
00001: Event 1
00010: Event 2
00011: Event 3
00100: Event 4
00101: Event 5
00110: Event 6
00111: Event 7
...
11111: Event 31

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 4:2 **RES[2:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

000: 16 bits
001: 14 bits in legacy mode (not optimized power consumption)
010: 12 bits in legacy mode (not optimized power consumption)
101: 14 bits
110: 12 bits
011: 10 bits
111: 8 bits
Others: Reserved, must not be used.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data Management configuration

This bit is set and cleared by software to select how ADC interface output data are managed.

00: Regular conversion data stored in DR only
01: DMA One Shot Mode selected
10: DFSDM mode selected
11: DMA Circular Mode selected

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bit DAMDF of the ADCx_CCR register.

27.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSHIFT[3:0]				Res.	Res.	OSVR[9:0]

	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				rw	rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: Shift left 1-bit
0010: Shift left 2-bits
0011: Shift left 3-bits
0100: Shift left 4-bits
0101: Shift left 5-bits
0110: Shift left 6-bits
0111: Shift left 7-bits
1000: Shift left 8-bits
1001: Shift left 9-bits
1010: Shift left 10-bits
1011: Shift left 11-bits
1100: Shift left 12-bits
1101: Shift left 13-bits
1110: Shift left 14-bits
1111: Shift left 15-bits

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OSVR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RSHIFT4**: Right-shift data after Offset 4 correction

Refer to RSHIFT1 description.

Bit 13 **RSHIFT3**: Right-shift data after Offset 3 correction
Refer to RSHIFT1 description

Bit 12 **RSHIFT2**: Right-shift data after Offset 2 correction
Refer to RSHIFT1 description

Bit 11 **RSHIFT1**: Right-shift data after Offset 1 correction
This bitfield is set and cleared by software to right-shift 1-bit data after offset1 correction. This bit can only be used for 8-bit and 16-bit data format (see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)* for details).
0: Right-shifting disabled
1: Data is right-shifted 1-bit.

Bit 10 **ROVSM**: Regular Oversampling mode
This bit is set and cleared by software to select the regular oversampling mode.
0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)
Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bit 9 **TROVS**: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling
0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger
Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling right shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
0000: No right shift
0001: Shift right 1-bit
0010: Shift right 2-bits
0011: Shift right 3-bits
0100: Shift right 4-bits
0101: Shift right 5-bits
0110: Shift right 6-bits
0111: Shift right 7-bits
1000: Shift right 8-bits
1001: Shift right 9-bits
1010: Shift right 10-bits
1011: Shift right 11-bits
Others: Reserved, must not be used.
Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected Oversampling disabled

1: Injected Oversampling enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular Oversampling disabled

1: Regular Oversampling enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

27.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles

001: 2.5 ADC clock cycles

010: 8.5 ADC clock cycles

011: 16.5 ADC clock cycles

100: 32.5 ADC clock cycles

101: 64.5 ADC clock cycles

110: 387.5 ADC clock cycles

111: 810.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles
001: 2.5 ADC clock cycles
010: 8.5 ADC clock cycles
011: 16.5 ADC clock cycles
100: 32.5 ADC clock cycles
101: 64.5 ADC clock cycles
110: 387.5 ADC clock cycles
111: 810.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 PCSEL[19:0] :Channel x ($V_{INP[i]}$) pre selection (x = 0 to 19)

These bits are written by software to pre select the input channel at IO instance to be converted.

0: Input Channel x (Vinp x) is not pre selected for conversion, the ADC conversion result with this channel shows wrong result.

1: Input Channel x (Vinp x) is pre selected for conversion

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.9 ADC watchdog threshold register 1 (ADC_LTR1)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LTR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **LTR1[25:0]**: Analog watchdog 1 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 1.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.10 ADC watchdog threshold register 1 (ADC_HTR1)

Address offset: 0x24

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HTR1[25:16]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR1[25:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

27.6.12 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

27.6.13 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

27.6.14 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

27.6.15 ADC regular Data Register (ADC_DR)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular Data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 27.4.27: Data management*.

27.6.16 ADC injected sequence register (ADC_JSQR)

Address offset: 0x4C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled and If JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 27.4.22: Queue of context for injected conversions)

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: Event 0

00001: Event 1

00010: Event 2

00011: Event 3

00100: Event 4

00101: Event 5

00110: Event 6

00111: Event 7

...

11111: Event 31:

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bits 1:0 **JL[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

27.6.17 ADC injected channel y offset register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y-1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SSATE	OFFSET_CH[4:0]					OFFSET[25:16]									
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SSATE:** Signed saturation Enable

This bit is written by software to enable or disable the Signed saturation feature.

This bit can be enabled only for 8-bit and 16-bit data format (see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)* for details).

0: Offset is subtracted maintaining data integrity and extending result size (9-bit and 17-bit signed format).

1: Offset is subtracted and result is saturated to maintain result size.

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 30:26 **OFFSET_CH[4:0]:** Channel selection for the Data offset y

These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[25:0] applies.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 25:0 **OFFSET[25:0]:** Data offset y for the channel programmed into bits OFFSETy_CH[4:0]

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

When OFFSETy[25:0] bitfield is reset, the offset compensation is disabled.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.
Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[25:0] which is subtracted when converting channel 4.

27.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AWD2CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2

AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2

When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQi or JSQi bits.

The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD3CH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3

AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3

When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQi or JSQi bits.

The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.21 ADC watchdog lower threshold register 2 (ADC_LTR2)

Address offset: 0xB0

Reset value: 0x0000 0000

LTR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **LTR2[25:0]**: Analog watchdog 2 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 2.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.22 ADC watchdog higher threshold register 2 (ADC_HTR2)

Address offset: 0xB4

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

HTR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR2[25:0]**: Analog watchdog 2 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 2.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.23 ADC watchdog lower threshold register 3 (ADC_LTR3)

Address offset: 0xB8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LTR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **LTR3[25:0]**: Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.24 ADC watchdog higher threshold register 3 (ADC_HTR3)

Address offset: 0xBC

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HTR3[25:16]

HTR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR3[25:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.

Refer to *Section 27.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)*

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

27.6.25 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xC0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]**: Differential mode for channels 19 to 0

These bits are set and cleared by software. They allow to select if a channel is configured as single ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel-i is configured in single ended mode

DIFSEL[i] = 1: ADC analog input channel-i is configured in differential mode

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

27.6.26 ADC calibration factors register (ADC_CALFACT)

Address offset: 0xC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	CALFACT_D[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	CALFACT_S[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **CALFACT_D[10:0]**: Calibration Factors in differential mode

These bits are written by hardware or by software.

Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new differential conversion is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **CALFACT_S[10:0]**: Calibration Factors In single-Ended mode

These bits are written by hardware or by software.

Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended conversion is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

27.6.27 ADC calibration factor register 2 (ADC_CALFACT2)

Address offset: 0xC8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	LINCALFACT[29:16]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LINCALFACT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **LINCALFACT[29:0]**: Linearity Calibration Factor

These bits are written by hardware or by software.

They hold 30-bit out of the 160-bit linearity calibration factor.

Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new single-ended calibration is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

27.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

27.7.1 ADC xcommon status register (ADCx_CSR) (x=1/2)

Address offset: 0x00

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

ADC1 and ADC2 are controlled by the same interface.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					r	r	r	r	r	r	r	r	r	r	r

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **JQOVF_SLV:** Injected Context Queue Overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADCx+1_ISR register.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADCx+1_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADCx+1_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADCx+1_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC
This bit is a copy of the EOS bit in the corresponding ADCx+1_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADCx+1_ISR register.

Bit 17 **EOSMP_SLV:** End of Sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADCx+1_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADCx+1_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST:** Injected Context Queue Overflow flag of the master ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

27.7.2 ADC x common control register (ADCx_CCR) (x=1/2)

Address offset: 0x08

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	TSEN	VREFEN	PRESC[3:0]				CKMODE[1:0]	
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable

This bit is set and cleared by software to control V_{BAT} channel.

0: V_{BAT} channel disabled

1: V_{BAT} channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 23 **TSEN**: Temperature sensor voltage enable

This bit is set and cleared by software to control V_{SENSE} channel.

0: Temperature sensor channel disabled

1: Temperature sensor channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 22 **VREFEN**: V_{REFINT} enable

This bit is set and cleared by software to enable/disable the V_{REFINT} channel.

0: V_{REFINT} channel disabled

1: V_{REFINT} channel enabled

Note: The software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 21:18 **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
Others: Reserved, must not be used

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16 **CKMODE[1:0]:** ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

00: CK_ADCx (x=1 to 23) (Asynchronous clock mode), generated at product level (refer to *Section Reset and Clock Control (RCC)*)
01: adc_sclk/1 (Synchronous clock mode).
10: adc_sclk/2 (Synchronous clock mode)
11: adc_sclk/4 (Synchronous clock mode)

Whatever CKMODE[1:0] settings, an additional divider factor of 2 is applied to the clock delivered to the analog ADC block.

In synchronous clock mode, when adc_ker_ck = 2 x adc_hclk, there is no jitter in the delay from a timer trigger to the start of a conversion.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:14 **DAMDF[1:0]:** Dual ADC mode data format

This bit-field is set and cleared by software. It specifies the data format in the common data register ADCx_CDR.

00: Dual ADC mode without data packing (ADCx_CDR and ADCx_CDR2 registers not used).
01: Reserved.
10: Data formatting mode for 32 down to 10-bit resolution
11: Data formatting mode for 8-bit resolution

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to *Table 209* for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode.
All the ADCs are independent:
00000: Independent mode
The configurations 00001 to 01001 correspond to the following operating modes: dual mode, master and slave ADCs working together:
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined Interleaved mode + injected simultaneous mode
00100: Reserved.
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only
All other combinations are reserved and must not be programmed

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Table 209. DELAY bits versus ADC resolution

DELAY bits	16-bit resolution	14-bit resolution	12-bit resolution	10-bit resolution	8-bit resolution
0000	1.5 * $T_{adc_ker_ck}$	1.5 * $T_{adc_ker_ck}$	1.5 * $T_{adc_ker_ck}$	1.5 * $T_{adc_ker_ck}$	1.5 * $T_{adc_ker_ck}$

others: reserved	-	-	-	-	-

27.7.3 ADC x common regular data register for dual mode (ADCx_CDR) (x=1/2)

Address offset: 0x0C

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]

RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 27.4.32: Dual ADC modes*.

The data alignment is applied as described in *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 27.4.32: Dual ADC modes*.

The data alignment is applied as described in *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)*)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

27.7.4 ADC x common regular data register for 32-bit dual mode (ADCx_CDR2) (x=1/2)

Address offset: 0x10

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs

In dual mode, these bits alternatively contains the regular 32-bit data of the master and the slave ADC. Refer to *Section 27.4.32: Dual ADC modes*.

The data alignment is applied as described in *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)*.

27.8 ADC register map

The following table summarizes the ADC registers.

Table 210. ADC global register map

Offset	Register
0x000 - 0x0D0	Master ADC1
0x0D4 - 0x0FC	Reserved
0x100 - 0x1D0	Slave ADC2
0x1D4 - 0x2FC	Reserved
0x300 - 0x310	Master and slave ADC common registers (ADC1/2)

Table 211. ADC register map and reset values for each ADC (offset=0x000 for master ADC, 0x100 for slave ADC)

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 130* for the register boundary addresses.

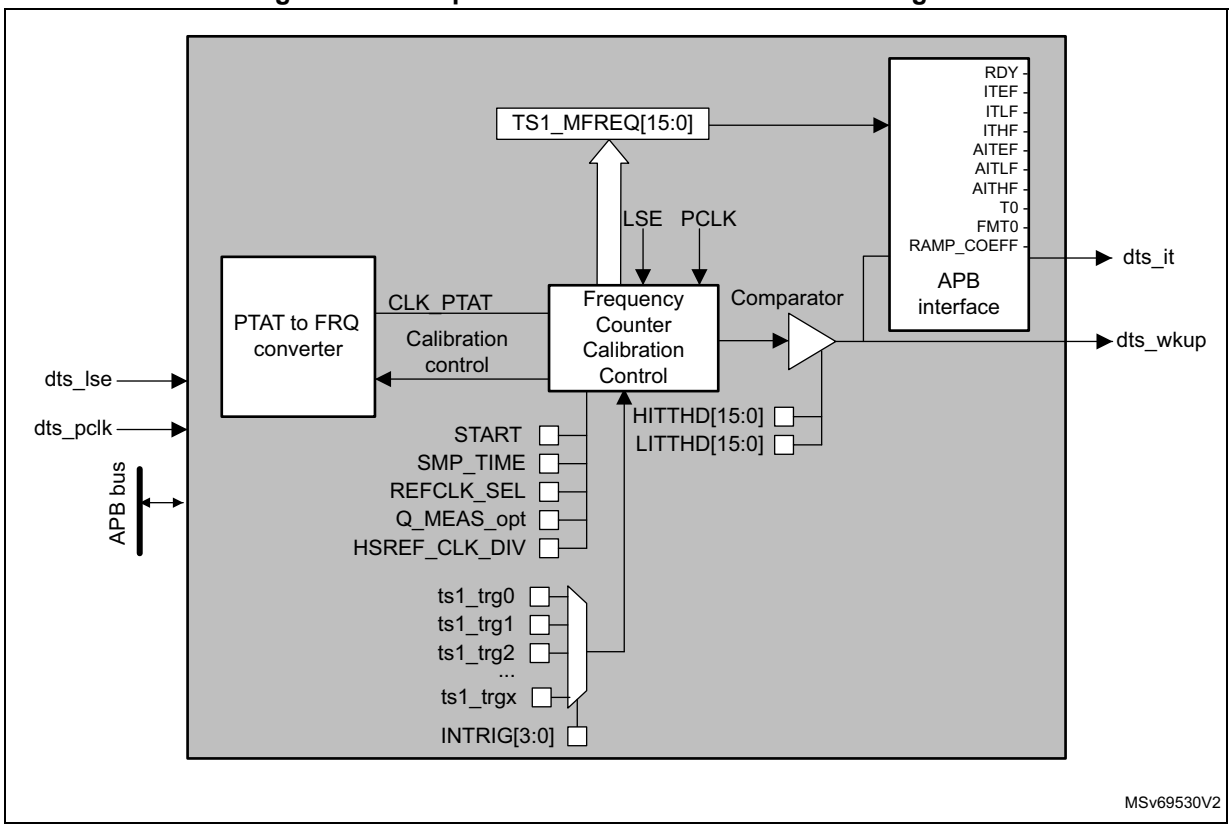
28 Digital temperature sensor (DTS)

28.1 DTS introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

28.2 DTS main features

The temperature sensor block main features are the following:



- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wake-up signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)

28.3 DTS functional description

28.3.1 DTS block diagram

The temperature sensor block diagram is shown in *Figure 227*.

Figure 227. Temperature sensor functional block diagram

28.3.2 DTS internal signals

Table 213. DTS internal input/output signals

Signal name	Signal type	Description
dts_lse	Digital input	LSE clock
dts_pclk	Digital input	APB clock
dts_it	Digital output	Temperature sensor interrupt
dts_wkup	Digital output	Temperature sensor wake-up

28.3.3 DTS block operation

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

28.3.4 Operating modes

Several operating modes can be selected by setting the REFCLK_SEL bit in *Temperature sensor configuration register 1 (DTS_CFGR1)*:

- PCLK only (REFCLK_SEL = 0)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock
- PCLK and LSE (REFCLK_SEL = 1)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.
- LSE only (REFCLK_SEL = 1) and PCLK OFF

  The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

28.3.5 Calibration

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered .

28.3.6 Prescaler

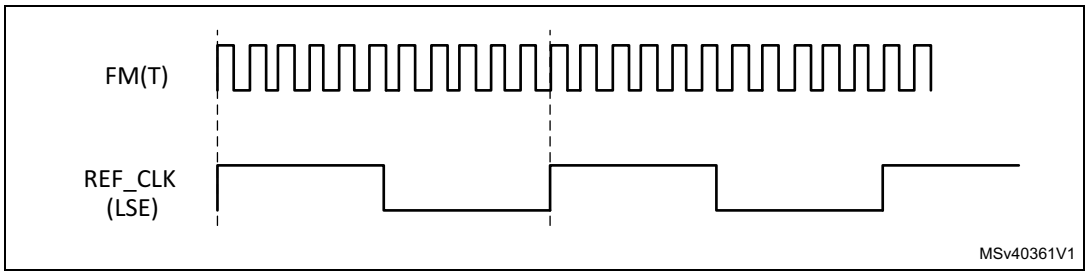
When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).
- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.

28.3.7 Temperature measurement principles

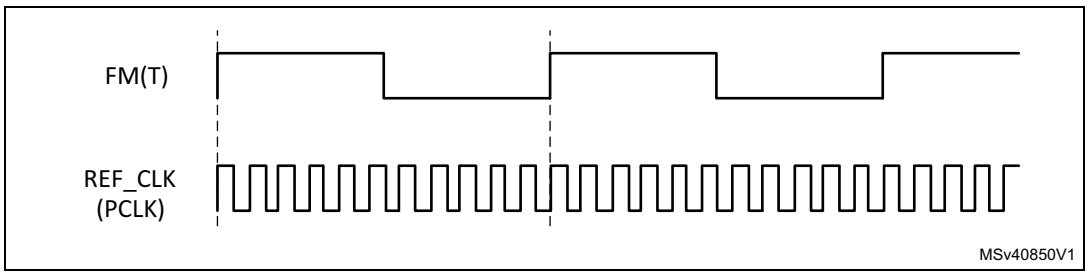
The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent.



Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFGR1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.



This counter behavior is shown in *Figure 228* and *Figure 229*.

Figure 228. Method for low REF_CLK frequencies

1. To increase the precision, FM(T) measurement can be done on several LSE periods.

Figure 229. Method for high REF_CLK frequencies

1. To increase the precision, PCLK measurement can be done on several FM(T) periods.

The counting result is stored in the DTS_DR register (see *Temperature sensor data register (DTS_DR)*.

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:

$$T = T_0 + ((F_{PCLK} / TS1_MFREQ) \times TS1_SMP_TIME - 100 \times TS1_FMT0) / TS1_RAMP_COEFF$$

where

T0 (factory calibration temperature) is equal to 30 °C.

TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.

TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

$$T = T_0 + ((F_{LSE} \times TS1_MFREQ / TS1_SMP_TIME) - (100 \times TS1_FMT0)) / TS1_RAMP_COEFF$$

28.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see *Table 214*).

Table 214. Sampling time configuration

TS1_SMP_TIME[3:0]	LSE or FM(T) clock cycle(s)
0000	1
0001	1
0010	2
0011	3
0100	4
0101	5
0110	6
0111	7
1000	8
1001	9
1010	10
1011	11
1100	12
1101	13
1110	14
1111	15

28.3.9 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFGR1.

Table 215. Trigger configuration

Name	TS1_INTRIG[3:0]				Comment
N.A	0	0	0	0	No hardware trigger
ts1_trg0	0	0	0	1	lptim1_out
ts1_trg1	0	0	1	0	lptim2_out
ts1_trg2	0	0	1	1	lptim3_out
ts1_trg3	0	1	0	0	exti13
ts1_trg4	0	1	0	1	Reserved
ts1_trg5	0	1	1	0	
ts1_trg6	0	1	1	1	
ts1_trg7	1	0	0	0	
ts1_trg8	1	0	0	1	
ts1_trg9	1	0	1	0	
ts1_trg10	1	0	1	1	
ts1_trg11	1	1	0	0	
ts1_trg12	1	1	0	1	
ts1_trg13	1	1	1	0	
ts1_trg14	1	1	1	1	

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 28.3.10: On-off control and ready flag), otherwise the trigger is ignored.

If a trigger source changes on-the-fly, the new trigger source signal should be low. If the new source signal is high, the temperature sensor detects a rising edge and start the measurement sequence.

28.3.10 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFGR1 register. The TS1_RDY flag in the *Temperature sensor status register (DTS_SR)* indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests are then ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.

28.3.11 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

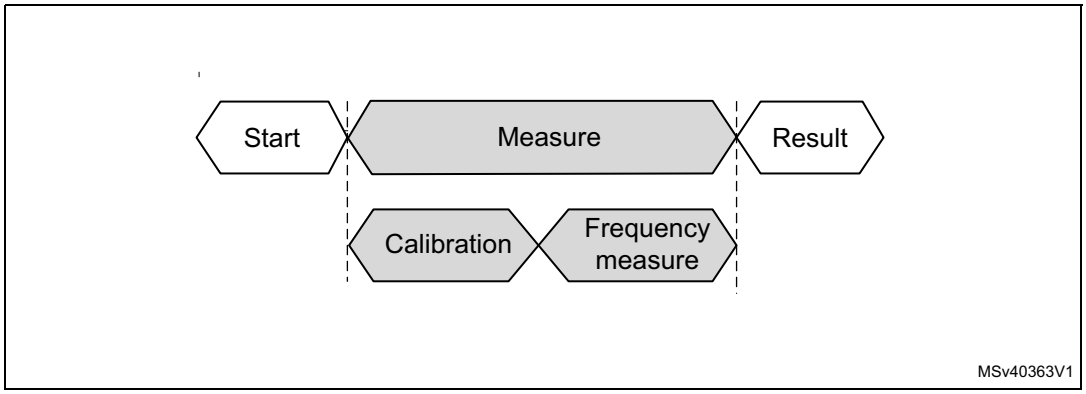
The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to ‘0000’ in DTS_CFGR1.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFGR1 starts the measurement.

If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.

If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag become 1 and the measurement restarts.

Hardware trigger



TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Temperature measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see *Section 28.3.5: Calibration*). The measurement period depends on the following DTS_CFGR1 bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

Figure 230. Temperature sensor sequence

28.4 DTS low-power modes

Table 216. Temperature sensor behavior in low-power modes

Mode	Description
Sleep	Only works in LSE mode. DTS interrupt causes the device to exit from Sleep mode.
Stop	Only works in LSE mode. DTS interrupt cause the device to exit from Stop mode.

28.5 DTS interrupts

There are two ways to use the DTS block as an interrupt source.The DTS interrupt line can be connected to the EXTI controller (see *Section 28.5.3: Asynchronous wake-up*) or to the CPU NVIC (see *Section 28.5.2: Synchronous interrupt*).

28.5.1 Temperature window comparator

The DTS_ITR1 register allows defining the high and low threshold that are used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ ITLF, TS1_ITHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see *Section 28.6.6*).

28.5.2 Synchronous interrupt

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 28.5.1: Temperature window comparator*).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see *Section 28.6.7*). All combinations of interrupts are allowed.

The TS1_ITEF, TS1_ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see *Section 28.6.8*).

28.5.3 Asynchronous wake-up

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 28.5.1: Temperature window comparator*).

Three asynchronous wake-up events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.

The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits an the their description.

Table 217. Interrupt control bits

Interrupt event	Interrupt flag	Enable control bit	Interrupt clear bit	Exit from Sleep mode	Synchronous/ Asynchronous
At the end of measurement	TS1_ITEF in DTS_SR	TS1_ITEEN in DTS_ITENR	TS1_CITEF in DTS_ICIFR	NO	Synchronous on PCLK
When the measure is equal or exceeds the low threshold	TS1_ITLF in DTS_SR	TS1_ITLEN in DTS_ITENR	TS1_CITLF in DTS_ICIFR	NO	
When the measure is equal or exceeds the high threshold	TS1_ITHF in DTS_SR	TS1_ITHEN in DTS_ITENR	TS1_CITHF in DTS_ICIFR	NO	
At the end of measurement	TS1_AITEF in DTS_SR	TS1_AITEEN in DTS_ITENR	TS1_CAITEF in DTS_ICIFR	YES	Asynchronous
When the measure is equal or exceeds the low threshold	TS1_AITLF in DTS_SR	TS1_AITLEN in DTS_ITENR	TS1_CAITLF in DTS_ICIFR	YES	
When the measure is equal or exceeds the high threshold	TS1_AITHF in DTS_SR	TS1_AITHEN in DTS_ITENR	TS1_CAITHF in DTS_ICIFR	YES	

28.6 DTS registers

The registers of this peripheral can only be accessed by-word (32-bit).

28.6.1 Temperature sensor configuration register 1 (DTS_CFGR1)

DTS_CFGR1 is the configuration register for temperature sensor 1.

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	HSREF_CLK_DIV[6:0]							Res.	Res.	Res.	REFCLK_SEL	TS1_SMP_TIME[3:0]			
	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TS1_INTRIG_SEL[3:0]				Res.	Res.	Res.	TS1_START	Res.	Res.	Res.	TS1_EN
				rw	rw	rw	rw				rw				rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSREF_CLK_DIV[6:0]**: High speed clock division ratio

These bits are set and cleared by software. They can be used to define the division ratio for the main clock in order to obtain the internal frequency lower than 1 MHz required for the calibration. They are applicable only for calibration when PCLK is selected as reference clock (REFCLK_SEL=0).

0000000: No divider

0000001: No divider

0000010: 1/2 division ratio

...

1111111: 1/127 division ratio

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **REFCLK_SEL**: Reference clock selection bit

This bit is set and cleared by software. It indicates whether the reference clock is the high speed clock (PCLK) or the low speed clock (LSE).

0: High speed reference clock (PCLK)

1: Low speed reference clock (LSE)

Bits 19:16 **TS1_SMP_TIME[3:0]**: Sampling time for temperature sensor 1

These bits allow increasing the sampling time to improve measurement precision.

When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement is performed at TS1_SMP_TIME period of CLK_PTAT.

When the LSE is selected as reference clock (REFCLK_SEL = 1), the measurement is performed at TS1_SMP_TIME period of LSE.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1

These bits are set and cleared by software. They select which input triggers a temperature measurement. Refer to *Section 28.3.9: Trigger input*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TS1_START:** Start frequency measurement on temperature sensor 1

This bit is set and cleared by software.

0: No software trigger.

1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TS1_EN:** Temperature sensor 1 enable bit

This bit is set and cleared by software.

0: Temperature sensor 1 disabled

1: Temperature sensor 1 enabled

Note: Once enabled, the temperature sensor is active after a specific delay time. The TS1_RDY flag is set when the sensor is ready.

28.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The reset value is factory trimmed.

Address offset: 0x08

Reset value: 0x000X XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_T0[1:0]	
														r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS1_FMT0[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **TS1_T0[1:0]**: Engineering value of the T0 temperature for temperature sensor 1.
00: 30 °C
01: 130 °C
Others: Reserved, must not be used.

Bits 15:0 **TS1_FMT0[15:0]**: Engineering value of the frequency measured at T0 for temperature sensor 1
This value is expressed in 0.1 kHz.

28.6.3 Temperature sensor ramp value register (DTS_RAMPVALR)

The DTS_RAMPVALR is the ramp coefficient for the temperature sensor. The reset value is factory trimmed.

Address offset: 0x10

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS1_RAMP_COEFF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TS1_RAMP_COEFF[15:0]**: Engineering value of the ramp coefficient for the temperature sensor 1.
This value is expressed in Hz/°C.

28.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1)

DTS_ITR1 contains the threshold values for sensor 1.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TS1_LITTHD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **TS1_HITTHD[15:0]:** High interrupt threshold for temperature sensor 1
These bits are set and cleared by software. They indicate the highest value than can be reached before raising an interrupt signal.

Bits 15:0 **TS1_LITTHD[15:0]:** Low interrupt threshold for temperature sensor 1
These bits are set and cleared by software. They indicate the lowest value than can be reached before raising an interrupt signal.

28.6.5 Temperature sensor data register (DTS_DR)

The DTS_DR contains the number of REF_CLK cycles used to compute the FM(T) frequency.

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TS1_MFREQ[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TS1_MFREQ[15:0]**: Value of the counter output value for temperature sensor 1

28.6.6 Temperature sensor status register (DTS_SR)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS1_RDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_AITHF	TS1_AITLF	TS1_AITEF	Res.	TS1_ITHF	TS1_ITLF	TS1_ITEF
r									r	r	r		r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **TS1_RDY:** Temperature sensor 1 ready flag
This bit is set and reset by hardware.
It indicates that a measurement is ongoing.
0: Temperature sensor 1 busy
1: Temperature sensor 1 ready

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHF:** Asynchronous interrupt flag for high threshold on temperature sensor 1
This bit is set by hardware when the high threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITHFEN bit is set

Bit 5 **TS1_AITLF:** Asynchronous interrupt flag for low threshold on temperature sensor 1
This bit is set by hardware when the low threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITLFEN bit is set

Bit 4 **TS1_AITEF:** Asynchronous interrupt flag for end of measure on temperature sensor 1
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS1_CAITEF bit in the DTS_ICIFR register.
0: End of measure not detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_AITEFEN bit is set

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHF:** Interrupt flag for high threshold on temperature sensor 1, synchronized on PCLK
This bit is set by hardware when the high threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITHFEN bit is set

Bit 1 **TS1_ITLF:** Interrupt flag for low threshold on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when the low threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITLFEN bit is set

Bit 0 **TS1_ITEF:** Interrupt flag for end of measurement on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS2_CITEF bit in the DTS_ICIFR register.
0: No end of measurement detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_ITEFEN bit is set

28.6.7 Temperature sensor interrupt enable register (DTS_ITENR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_ AITHEN	TS1_ AITLEN	TS1_ AITEEN	Res.	TS1_ ITHEN	TS1_ ITLEN	TS1_ ITEEN
									rw	rw	rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHEN:** Asynchronous interrupt enable flag on high threshold for temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is above the high threshold (only when REFCLK_SEL= 1")
0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

Bit 5 **TS1_AITLEN:** Asynchronous interrupt enable flag for low threshold on temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is below the low threshold (only when REFCLK_SEL= 1)
0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
1: Asynchronous interrupt on low threshold enabled for temperature sensor 1

Bit 4 **TS1_AITEEN:** Asynchronous interrupt enable flag for end of measurement on temperature sensor 1

This bit are set and cleared by software.
It enables the asynchronous interrupt for end of measurement (only when REFCLK_SEL = 1).
0: Asynchronous interrupt for end of measurement disabled on temperature sensor 1
1: Asynchronous interrupt for end of measurement enabled on temperature sensor 1

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHEN:** Interrupt enable flag for high threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the interrupt when the measure reaches or is above the high threshold.
0: Synchronous interrupt for high threshold disabled on temperature sensor 1
1: Synchronous interrupt for high threshold enabled on temperature sensor 1

Bit 1 **TS1_ITLEN:** Interrupt enable flag for low threshold on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt when the measure reaches or is below the low threshold.
0: Synchronous interrupt for low threshold disabled on temperature sensor 1
1: Synchronous interrupt for low threshold enabled on temperature sensor 1

Bit 0 **TS1_ITEEN:** Interrupt enable flag for end of measurement on temperature sensor 1, synchronized on PCLK.

This bit are set and cleared by software.
It enables the synchronous interrupt for end of measurement.
0: Synchronous interrupt for end of measurement disabled on temperature sensor 1
1: Synchronous interrupt for end of measurement enabled on temperature sensor 1

28.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR)

DTS_ICIFR is the control register for the interrupt flags.

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_ CAITHF	TS1_ CAITLF	TS1_ CAITEF	Res.	TS1_ CITHF	TS1_ CITLF	TS1_ CITEF
									rc_w1	rc_w1	rc_w1		rc_w1	rc_w1	rc_w1

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_CAITHF:** Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5 **TS1_CAITLF:** Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.

Bit 4 **TS1_CAITEF:** Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.
Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_CITHF:** Interrupt clear flag for high threshold on temperature sensor 1
Writing this bit to 1 clears the TS1_ITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF:** Interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF:** Interrupt clear flag for end of measurement on temperature sensor 1
Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

28.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

29 Digital-to-analog converter (DAC)

29.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features up to two output channels, each with its own converter. In dual DAC channel mode, conversions can be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, VREF+ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to *voltage reference buffer (VREFBUF)* section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the sample and hold mode.

29.2 DAC main features

The DAC main features are the following (see *Figure 231: Dual-channel DAC block diagram*)

- Two DAC interfaces, maximum two output channels each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from VREF+ pin or internal VREFBUF reference

Figure 231 shows the block diagram of a DAC channel and *Table 220* gives the pin description.

29.3 DAC implementation

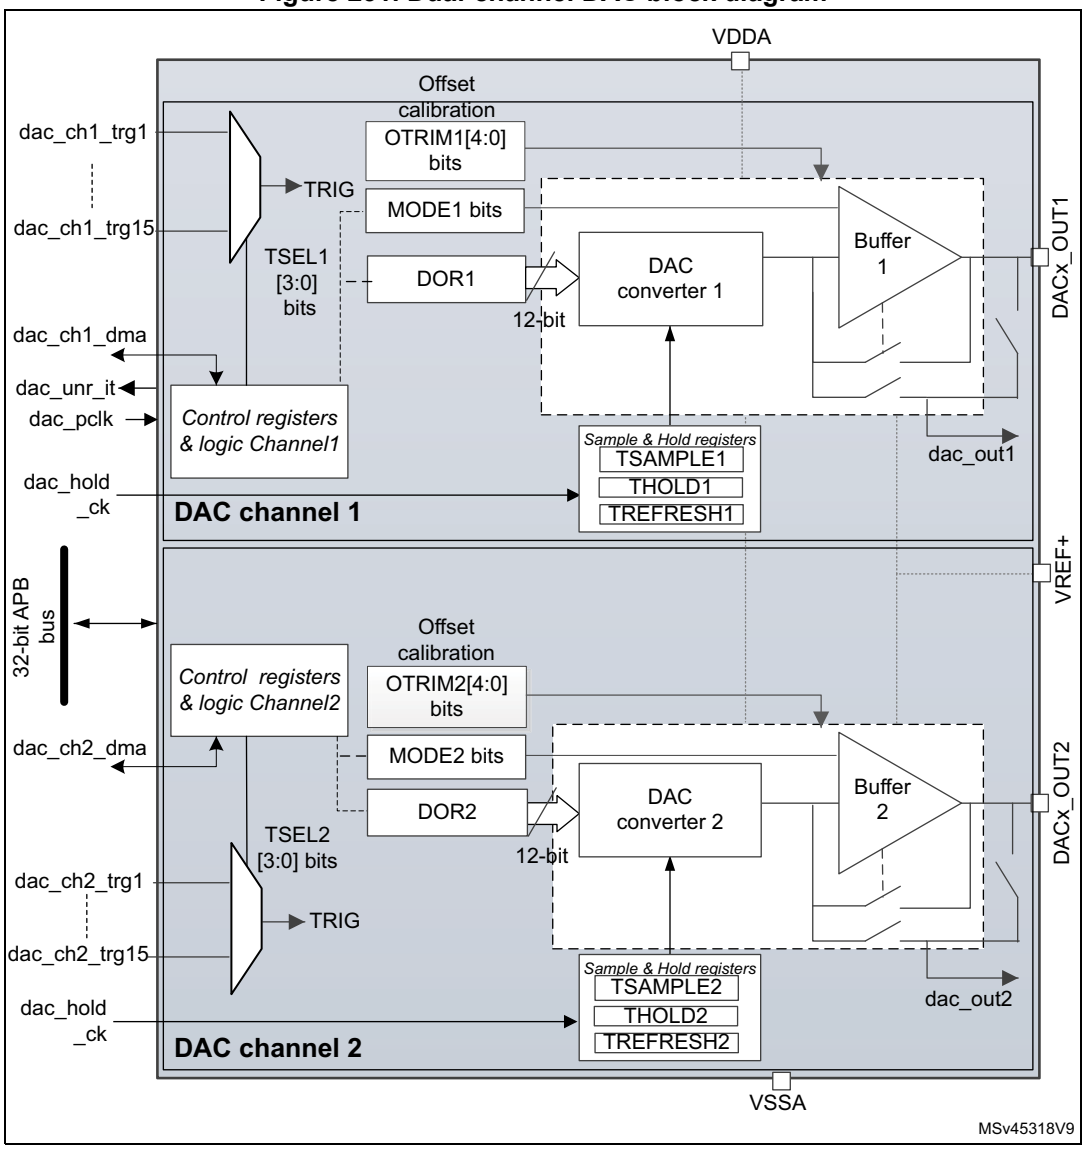

Table 219. DAC features

DAC features	DAC1	DAC2
Dual channel	X	-
Output buffer	X	
I/O connection	DAC1_OUT1 on PA4, DAC1_OUT2 on PA5	DAC2_OUT1 on PA6
Maximum sampling time	1 Msps	
VREF+ pin	X	

29.4 DAC functional description

29.4.1 DAC block diagram

Figure 231. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the normal mode in buffer/unbuffered configuration and the sample and hold mode.
2. DAC channel2 is available only on DAC1.

29.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The sample and hold block and its associated registers can run in Stop mode using the LSI clock source (dac_hold_ck).

Table 220. DAC input/output pins

Pin name	Signal type	Remarks
VREF+	Input, analog positive reference	The higher/positive reference voltage for the DAC, $V_{REF+} \leq V_{DDAmax}$ (refer to datasheet)
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUTy	Analog output signal	DACx channely analog output

Table 221. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch2_dma	Bidirectional	DAC channel2 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 15)	Inputs	DAC channel1 trigger inputs
dac_ch2_trgx (x = 1 to 15)	Inputs	DAC channel2 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_pclk	Input	DAC peripheral clock
dac_hold_ck	Input	DAC low-power clock used in sample and hold mode
dac_out1	Analog output	DAC channel1 output for on-chip peripherals
dac_out2	Analog output	DAC channel2 output for on-chip peripherals

Table 222. DAC1 interconnection

Signal name	Source	Source type
dac_hold_ck	lsi_ck (selected in the RCC)	LSI clock selected in the RCC
dac_chx_trg1 (x = 1, 2)	tim1_trgo	Internal signal from on-chip timers
dac_chx_trg2 (x = 1, 2)	tim2_trgo	Internal signal from on-chip timers
dac_chx_trg3 (x = 1, 2)	tim4_trgo	Internal signal from on-chip timers
dac_chx_trg4 (x = 1, 2)	tim5_trgo	Internal signal from on-chip timers
dac_chx_trg5 (x = 1, 2)	tim6_trgo	Internal signal from on-chip timers
dac_chx_trg6 (x = 1, 2)	tim7_trgo	Internal signal from on-chip timers
dac_chx_trg7 (x = 1, 2)	tim8_trgo	Internal signal from on-chip timers
dac_chx_trg8 (x = 1, 2)	tim15_trgo	Internal signal from on-chip timers
dac_chx_trg11 (x = 1, 2)	lptim1_out	Internal signal from on-chip timers
dac_chx_trg12 (x = 1, 2)	lptim2_out	Internal signal from on-chip timers
dac_chx_trg13 (x = 1, 2)	exti9	External pin
dac_chx_trg14 (x = 1, 2)	lptim2_out	Internal signal from on-chip timers

Table 223. DAC2 interconnection

Signal name	Source	Source type
dac_hold_ck	lsi_ck (selected in the RCC)	LSI clock selected in the RCC
dac_ch1_trg1	tim1_trgo	Internal signal from on-chip timers
dac_ch1_trg2	tim2_trgo	Internal signal from on-chip timers
dac_ch1_trg3	tim4_trgo	Internal signal from on-chip timers
dac_ch1_trg4	tim5_trgo	Internal signal from on-chip timers
dac_ch1_trg5	tim6_trgo	Internal signal from on-chip timers
dac_ch1_trg6	tim7_trgo	Internal signal from on-chip timers
dac_ch1_trg7	tim8_trgo	Internal signal from on-chip timers
dac_ch1_trg8	tim15_trgo	Internal signal from on-chip timers
dac_ch1_trg11	lptim1_out	Internal signal from on-chip timers
dac_ch1_trg12	lptim2_out	Internal signal from on-chip timers
dac_ch1_trg13	exti9	External pin
dac_ch1_trg14	lptim3_out	Internal signal from on-chip timers

29.4.3 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

Note: The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

29.4.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

  – 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DAC_DHRx (data holding registerx, which are internal non-memory-mapped registers). The DAC_DHRx register is then loaded into the DAC_DORx register either automatically, by software trigger or by an external event trigger.

Figure 232. Data registers in single DAC channel mode

- Dual DAC channels (when available)

  There are three possibilities:

  – 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)

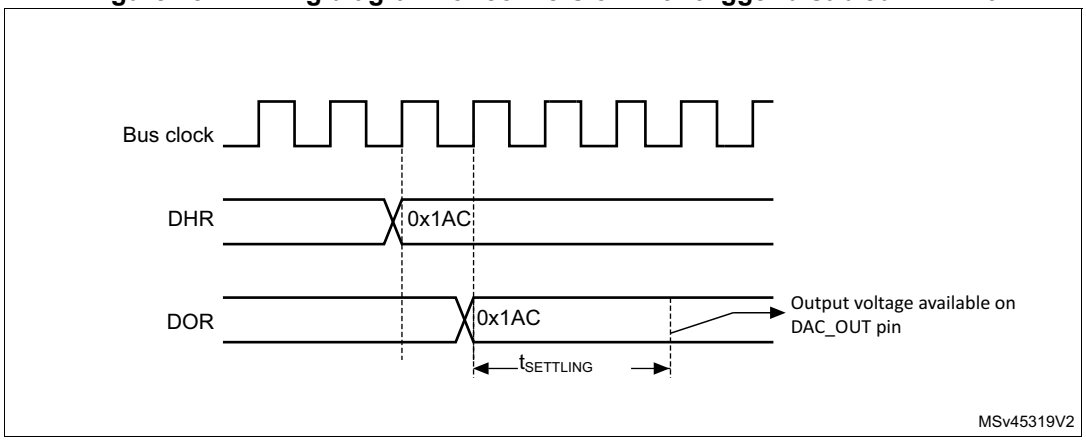
  – 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)

  – 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1

and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 233. Data registers in dual DAC channel mode



29.4.5 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_pclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_pclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

Figure 234. Timing diagram for conversion with trigger disabled TEN = 0

29.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and V_{REF+}.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DAC output} = V_{REF} \times \frac{DOR}{4096}$$

where all voltages are expressed in Volt.

29.4.7 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in *Section 29.4.2*.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_pclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_pclk clock cycle.

29.4.8 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

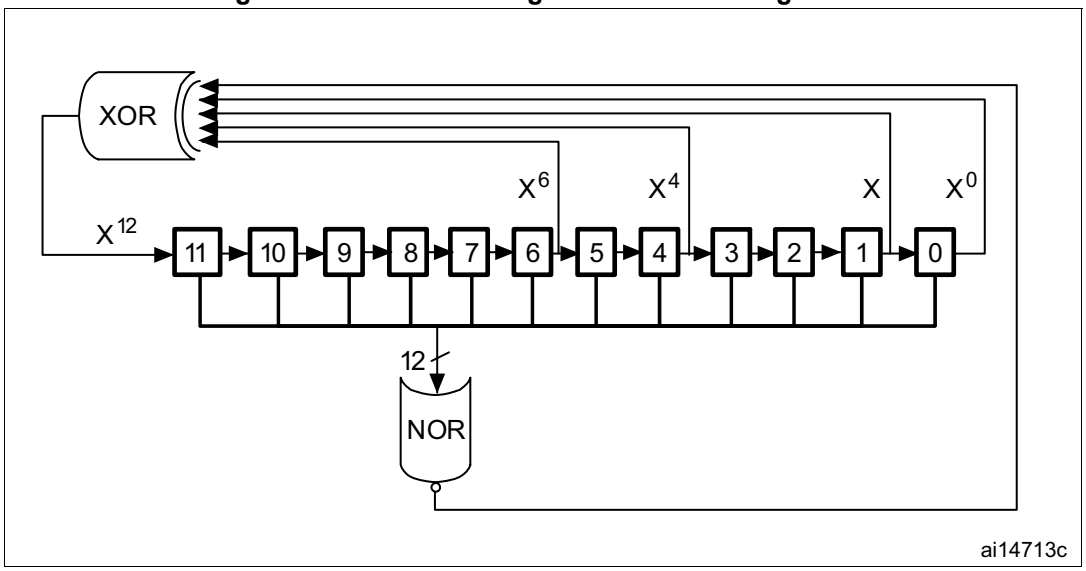
When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.



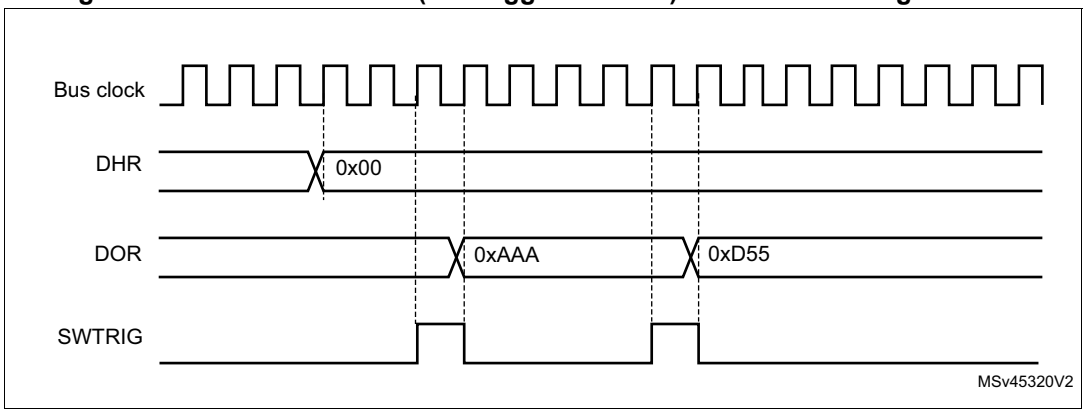
The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

29.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_pclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 235. DAC LFSR register calculation algorithm



The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a 1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 236. DAC conversion (SW trigger enabled) with LFSR wave generation

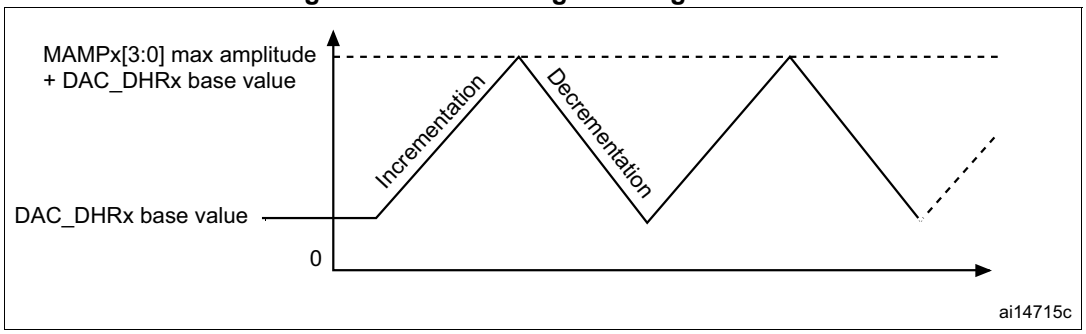
Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.

29.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_pclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 237. DAC triangle wave generation



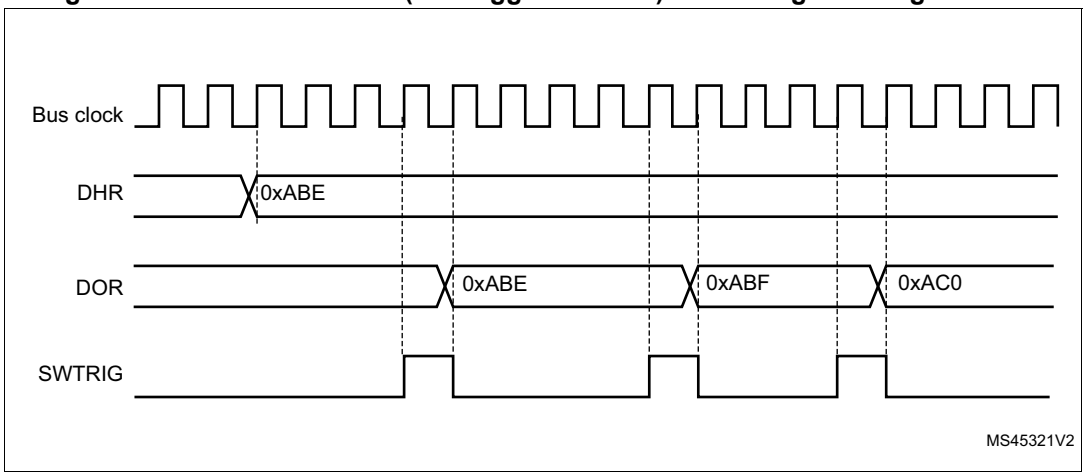


Figure 238. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

29.4.11 DAC channel modes

Each DAC channel can be configured in normal mode or sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI low-speed clock (dac_hold_ck) in addition to the dac_pclk clock, allowing using the DAC channels in deep low power modes such as Stop mode.

The LSI low-speed clock (dac_hold_ck) must not be stopped when the sample and hold mode is enabled.

The sample/hold mode operations can be divided into three phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11.
- 62 cycles are required for hold phase: THOLDx[9:0] = 62.
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 224. Sample and refresh timings

Buffer State	t_{SAMP}(1)(2)	$t_{REFRESH}$(2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula, the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8-bit resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Refer to the product datasheet for product data.

C_{SH} = 100 nF

= 3.0 V

Sampling phase:

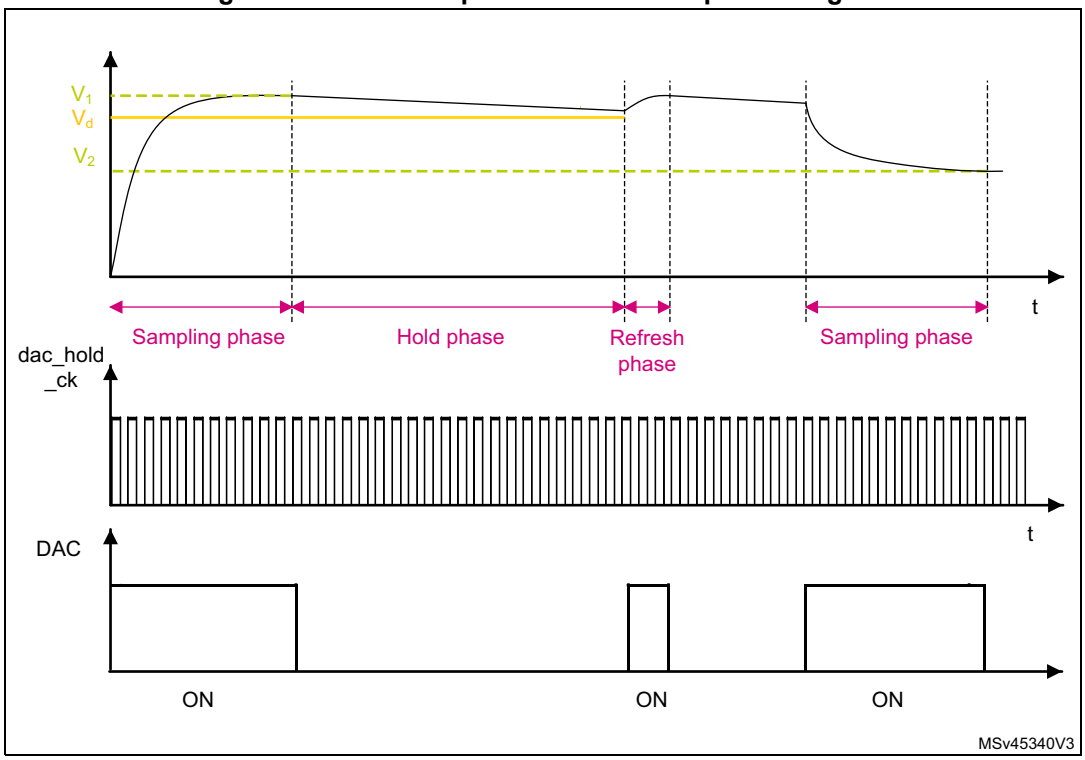
t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms

(where R_{BON} = 2 kΩ)

Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs

(where N_{LSB} = 10 (10 LSB drop during the hold phase)



Hold phase:

D_v = i_{leak} * t_{hold} / C_{SH} = 0.0073 V (10 LSB of 12bit at 3 V)

i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)

t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 239. DAC sample and hold mode phase diagram

Like in normal mode, the sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

  When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

Table 225. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (such as comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (such as comparators)

Table 225. Channel output modes summary (continued)

MODEx[2:0]			Mode	Buffer	Output connections
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (such as comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)
1	1	1			Connected to on chip peripherals (such as comparators)

29.4.12 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = \left((D / 2^N) \times G \times V_{REF}\right) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{REF} is the nominal full-scale voltage, and V_{OS} is the offset voltage. For an ideal DAC channel, G = 1 and V_{OS} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{OS}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to V_{REF+}/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, V_{REF+} values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the nominal factory trimming conditions.

In addition, when V_{DD} is removed (example the device enters in Standby or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 0b00000.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) Until the CAL_FLAGx is read as 1 or the maximum trimming code is reached, increment OTRIMx[4:0] and repeat substeps from (b) to (d).

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

Note: A t_{TRIM} delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, V_{REF+} and temperature conditions do not change during device operation while it enters more often in Standby and VBAT modes, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

29.4.13 DAC channel conversion modes

Four conversion modes are possible.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Load the DAC channel data into the desired DHR registers (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DHRx register is transferred into DAC_DORx (three dac_pclk clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bits, TENx.
2. Configure the trigger sources by setting different values in the TSELx[3:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).
