Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32U575/585 microcontrollers memory and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

STM32U575/585 microcontrollers include ST state-of-the-art patented technology.

  5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1) .... 192
  5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2) .... 194
  5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3) .... 195
  5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4) .... 197
  5.7.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1) ........ 199
  5.7.6 GTZC1 TZIC status register 2 (GTZC1_TZIC_SR2) .......... 201
  5.7.7 GTZC1 TZIC status register 3 (GTZC1_TZIC_SR3) ........ 202
5.7.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4) ........................................... 204
5.7.9 GTZC1 TZIC flag clear register 1 (GTZC1_TZIC_FCR1) ................................. 205
5.7.10 GTZC1 TZIC flag clear register 2 (GTZC1_TZIC_FCR2) ............................. 207
5.7.11 GTZC1 TZIC flag clear register 3 (GTZC1_TZIC_FCR3) ............................. 208
5.7.12 GTZC1 TZIC flag clear register 4 (GTZC1_TZIC_FCR4) ............................. 210
5.7.13 GTZC1 TZIC register map ................................................................. 212

5.8 GTZC1 MPCBBz registers (z = 1 to 3) ......................................................... 214
5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3) ........ 214
5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1 (GTZC1_MPCBBz_CFGLOCKR1) (z = 1 to 3) ................................................................. 215
5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3) ........................................ 215
5.8.4 GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3) .............................. 216
5.8.5 GTZC1 MPCBBz register map (z = 1 to 3) .................................................. 217

5.9 GTZC2 TZSC registers ................................................................. 217
5.9.1 GTZC2 TZSC control register (GTZC2_TZSC_CR) ................................... 217
5.9.2 GTZC2 TZSC secure configuration register 1 (GTZC2_TZSC_SECCFGR1) ....... 218
5.9.3 GTZC2 TZSC privilege configuration register 1 (GTZC2_TZSC_PRIVCFGR1) .... 219
5.9.4 GTZC2 TZSC register map ................................................................. 221

5.10 GTZC2 TZIC registers ................................................................. 221
5.10.1 GTZC2 TZIC interrupt enable register 1 (GTZC2_TZIC_IER1) ..................... 221
5.10.2 GTZC2 TZIC interrupt enable register 2 (GTZC2_TZIC_IER2) ..................... 223
5.10.3 GTZC2 TZIC status register 1 (GTZC2_TZIC_SR1) .................................. 224
5.10.4 GTZC2 TZIC status register 2 (GTZC2_TZIC_SR2) .................................. 225
5.10.5 GTZC2 TZIC flag clear register 1 (GTZC2_TZIC_FCR1) ............................ 227
5.10.6 GTZC2 TZIC flag clear register 2 (GTZC2_TZIC_FCR2) ............................ 228
5.10.7 GTZC2 TZIC register map ................................................................. 229

5.11 GTZC2 MPCBB4 registers ............................................................... 230
5.11.1 GTZC2 SRAM4 MPCBB control register (GTZC2_MPCBB4_CR) ............... 230
5.11.2 GTZC2 SRAM4 MPCBB configuration lock register 1 (GTZC2_MPCBB4_CFGLOCKR1) ................................................................. 231
5.11.3 GTZC2 SRAM4 MPCBB security configuration for super-block 0 register (GTZC2_MPCBB4_SECCFGR0) .............................................. 232
5.11.4 GTZC2 SRAM4 MPCBB privileged configuration for super-block 0 register (GTZC2_MPCBB4_PRIVCFGR0) .............................................. 232
## 6 RAMs configuration controller (RAMCFG) ........................................... 234

6.1 Introduction ................................................................. 234

6.2 RAMCFG main features .................................................. 234

6.3 RAMCFG functional description .................................... 234

6.3.1 Internal SRAMs features ............................................ 234

6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM) .......... 235

6.3.3 Write protection (SRAM2) ......................................... 237

6.3.4 Read access latency ................................................ 238

6.3.5 Software erase ..................................................... 238

6.4 RAMCFG low-power modes ............................................ 238

6.5 RAMCFG interrupts ..................................................... 239

6.6 RAMCFG registers .......................................................... 239

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR) .... 239

6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER) 240

6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR) 241

6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxESEAR) 242

6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR) 242

6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR) 242

6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1) 243

6.6.8 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2) 243

6.6.9 RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR) 244

6.6.10 RAMCFG memory x erase key register (RAMCFG_MxERKEYR) 244

6.6.11 RAMCFG register map ............................................ 245

## 7 Embedded Flash memory (FLASH) ........................................... 248

7.1 Introduction ................................................................. 248

7.2 FLASH main features .................................................... 248

7.3 FLASH functional description ....................................... 249

7.3.1 Flash memory organization ...................................... 249

7.3.2 Error code correction (ECC) .................................... 250

7.3.3 Read access latency .............................................. 250
7.3.4 Bank power-down mode ........................................ 252
7.3.5 Flash memory program and erase operations .................. 253
7.3.6 Flash main memory erase sequences .......................... 255
7.3.7 Flash main memory programming sequences .................. 256
7.3.8 Flash memory endurance ....................................... 258
7.3.9 Flash memory errors flags ..................................... 259
7.3.10 Read-while-write (RWW) ..................................... 261
7.3.11 Power-down during Flash programming or erase operation .... 261
7.3.12 Reset during Flash programming or erase operation .......... 261

7.4 FLASH option bytes .................................................. 263
7.4.1 Option bytes description ........................................ 263
7.4.2 Option-byte programming ....................................... 264

7.5 FLASH TrustZone security and privilege protections .............. 265
7.5.1 TrustZone security protection ................................... 265
7.5.2 Watermark-based secure Flash memory area protection ........ 266
7.5.3 Secure hide protection (HDP) ................................... 267
7.5.4 Block-based secure Flash memory area protection ............. 268
7.5.5 Flash security attribute state ................................... 269
7.5.6 Block-based privileged Flash memory area protection ........ 269
7.5.7 Flash memory registers privileged and unprivileged modes .... 270
7.5.8 Flash memory bank attributes in case of bank swap ........... 270

7.6 FLASH memory protection ............................................. 271
7.6.1 Write protection (WRP) .......................................... 272
7.6.2 Readout protection (RDP) ........................................ 274

7.7 Summary of Flash memory and Flash memory registers access control 283

7.8 FLASH interrupts .................................................... 286

7.9 FLASH registers ....................................................... 287
7.9.1 FLASH access control register (FLASH_ACR) ................. 287
7.9.2 FLASH non-secure key register (FLASH_NSKEYR) .......... 289
7.9.3 FLASH secure key register (FLASH_SECKEYR) ................ 289
7.9.4 FLASH option key register (FLASH_OPTKEYR) ............... 290
7.9.5 FLASH bank 1 power-down key register (FLASH_PDKEY1R) ... 290
7.9.6 FLASH bank 2 power-down key register (FLASH_PDKEY2R) ... 291
7.9.7 FLASH non-secure status register (FLASH_NSSR) ............ 291
7.9.8 FLASH secure status register (FLASH_SECSR) ............... 293
7.9.9 FLASH non-secure control register (FLASH_NSCCR) ........ 295
7.9.10 FLASH secure control register (FLASH_SECCR) .......................... 297
7.9.11 FLASH ECC register (FLASH_ECCR) ................................. 298
7.9.12 FLASH operation status register (FLASH_OPSR) ...................... 299
7.9.13 FLASH option register (FLASH_OPTR) ................................. 300
7.9.14 FLASH non-secure boot address 0 register (FLASH_NSBOOTADD0R) ............... 303
7.9.15 FLASH non-secure boot address 1 register (FLASH_NSBOOTADD1R) ............ 304
7.9.16 FLASH secure boot address 0 register (FLASH_SECBOOTADD0R) ............ 305
7.9.17 FLASH secure watermark1 register 1 (FLASH_SECWM1R1) ............... 306
7.9.18 FLASH secure watermark1 register 2 (FLASH_SECWM1R2) ............... 307
7.9.19 FLASH WRP1 area A address register (FLASH_WRP1AR) ................. 308
7.9.20 FLASH WRP1 area B address register (FLASH_WRP1BR) ................. 309
7.9.21 FLASH secure watermark2 register 1 (FLASH_SECWM2R1) ............... 310
7.9.22 FLASH secure watermark2 register 2 (FLASH_SECWM2R2) ............... 311
7.9.23 FLASH WRP2 area A address register (FLASH_WRP2AR) ................. 312
7.9.24 FLASH WRP2 area B address register (FLASH_WRP2BR) ................. 313
7.9.25 FLASH OEM1 key register 1 (FLASH_OEM1KEYR1) ..................... 314
7.9.26 FLASH OEM1 key register 2 (FLASH_OEM1KEYR2) ..................... 314
7.9.27 FLASH OEM2 key register 1 (FLASH_OEM2KEYR1) ..................... 315
7.9.28 FLASH OEM2 key register 2 (FLASH_OEM2KEYR2) ..................... 315
7.9.29 FLASH secure block based bank 1 register x (FLASH_SECBB1Rx) ..... 316
7.9.30 FLASH secure block based bank 2 register x (FLASH_SECBB2Rx) ..... 316
7.9.31 FLASH secure HDP control register (FLASH_SECHDPCR) .............. 317
7.9.32 FLASH privilege configuration register (FLASH_PRIVCFGR) .......... 318
7.9.33 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rx) ..... 319
7.9.34 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rx) ..... 320
7.9.35 FLASH register map .................................................. 320

  12.4.4 Frequency error evaluation and automatic trimming .. 561
  12.4.5 CRS initialization and configuration ............... 561
12.5 CRS low-power modes .................................... 562
12.6 CRS interrupts ........................................... 562
12.7 CRS registers ............................................ 563
  12.7.1 CRS control register (CRS_CR) ..................... 563
  12.7.2 CRS configuration register (CRS_CFGR) ............. 564
  12.7.3 CRS interrupt and status register (CRS_ISR) ....... 565
  12.7.4 CRS interrupt flag clear register (CRS_ICR) ....... 567
  12.7.5 CRS register map .................................... 568

13 General-purpose I/Os (GPIO) .............................. 569
13.1 Introduction ............................................. 569
13.2 GPIO main features ...................................... 569
13.3 GPIO functional description ............................. 569
  13.3.1 General-purpose I/O (GPIO) ......................... 571
  13.3.2 I/O pin alternate function multiplexer and mapping .. 572
13.3.3 I/O port control registers .................................................. 572
13.3.4 I/O port data registers ...................................................... 573
13.3.5 I/O data bitwise handling .................................................. 573
13.3.6 GPIO locking mechanism ................................................... 573
13.3.7 I/O alternate function input/output ...................................... 573
13.3.8 External interrupt/wakeup lines .......................................... 574
13.3.9 Input configuration .......................................................... 574
13.3.10 Output configuration ....................................................... 575
13.3.11 Alternate function configuration ....................................... 575
13.3.12 Analog configuration ....................................................... 576
13.3.13 Using the HSE or LSE oscillator pins as GPIOs .................... 576
13.3.14 Using the GPIO pins in the RTC supply domain .................... 577
13.3.15 Using PH3 as GPIO ........................................................ 577
13.3.16 OPAMPx_VINM dedicated pins .......................................... 577
13.3.17 TrustZone security ........................................................ 577
13.3.18 Privileged and unprivileged modes .................................... 578
13.3.19 High-speed low-voltage mode (HSLV) .................................. 578
13.3.20 I/O compensation cell ..................................................... 579
13.4 GPIO registers ................................................................. 579
13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I) .......... 579
13.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I) .. 580
13.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to I) .. 580
13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to I) .. 581
13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I) .......... 581
13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to I) ....... 582
13.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I) ..... 582
13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I) .. 583
13.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to I) .. 584
13.4.10 GPIO alternate function high register (GPIOx_AFRH) (x = A to H) .. 584
13.4.11 GPIO port bit reset register (GPIOx_BRR) (x = A to I) .......... 585
13.4.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A to I) .. 586
13.4.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A to I) .. 586
13.4.14 GPIO register map ....................................................... 587

14 Low-power general-purpose I/Os (LPGPIO) .............................. 589
14.1 Introduction ................................................................. 589
14.2 LPGPIO main features ..................................................... 589
14.3 LPGPIO functional description ........................................... 589
  14.3.1 LPGPIO and GPIO configuration ................................. 589
  14.3.2 LPGPIO control registers ......................................... 589
  14.3.3 LPGPIO I/O data registers ....................................... 589
  14.3.4 LPGPIO I/O data bitwise handling ............................... 589
  14.3.5 Security protection ............................................... 590
  14.3.6 Secure clock and reset management .............................. 590
14.4 LPGPIO registers .......................................................... 591
  14.4.1 LPGPIO port mode register (LPGPIO_MODER) .................. 591
  14.4.2 LPGPIO port input data register (LPGPIO_IDR) ............... 591
  14.4.3 LPGPIO port output data register (LPGPIO_ODR) ............. 592
  14.4.4 LPGPIO port bit set/reset register (LPGPIO_BSRR) .......... 592
  14.4.5 LPGPIO port bit reset register (LPGPIO_BRR) ............... 593
  14.4.6 LPGPIO register map ............................................. 593

15 System configuration controller (SYSCFG) .......................... 594
  15.1 SYSCFG main features .............................................. 594
  15.2 SYSCFG functional description ...................................... 594
    15.2.1 I/O compensation cell management ........................... 594
    15.2.2 SYSCFG TrustZone security and privilege ................... 595
  15.3 SYSCFG registers .................................................... 597
    15.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR) ... 597
    15.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1) .......... 598
    15.3.3 SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR) ..... 599
    15.3.4 SYSCFG CPU non-secure lock register (SYSCFG_CNSLCKR) ... 600
    15.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLOCKR) ...... 601
    15.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2) .......... 602
    15.3.7 SYSCFG memory erase status register (SYSCFG_MESR) ....... 603
    15.3.8 SYSCFG compensation cell control/status register (SYSCFG_CCCSR) ........................................... 604
    15.3.9 SYSCFG compensation cell value register (SYSCFG_CCVR) ... 605
    15.3.10 SYSCFG compensation cell code register (SYSCFG_CCCR) ... 606
    15.3.11 SYSCFG RSS command register (SYSCFG_RSSCMDR) ......... 607
    15.3.12 SYSCFG register map ....................................... 607

16 Peripherals interconnect matrix ........................................ 609
  16.1 Introduction .......................................................... 609
16.2 Connection summary ........................................... 610
16.3 Interconnection details ....................................... 612
  16.3.1 Master to slave interconnection for timers ............ 612
  16.3.2 Triggers to ADCs ........................................ 613
  16.3.3 ADC analog watchdogs as triggers to timers .......... 614
  16.3.4 Triggers to DAC ......................................... 614
  16.3.5 Triggers on MDF1 or ADF1 ............................... 615
  16.3.6 Timer break from MDF1 ................................ 615
  16.3.7 Internal clock sources to timers ....................... 616
  16.3.8 Triggers to low-power timers .......................... 617
  16.3.9 Blanking sources to comparators ...................... 618
  16.3.10 RTC wakeup as inputs to timers ...................... 618
  16.3.11 USB OTG SOF as trigger to timers .................... 619
  16.3.12 Comparators as inputs, trigger or break signals to timers .... 619
  16.3.13 System errors as break signals to timers .......... 620
  16.3.14 Timers generating IRTIM signal ..................... 621
  16.3.15 Triggers for communication peripherals ............. 621
  16.3.16 Triggers to GPDMA/LPDMAs .......................... 622
  16.3.17 Internal analog signals to analog peripherals ...... 622
  16.3.18 ADC data filtering by the MDF1 ..................... 623
  16.3.19 Clock source for the DAC sample and hold mode ... 623
  16.3.20 Internal tamper sources ............................. 624
  16.3.21 Output from tamper to RTC .......................... 624
  16.3.22 Encryption keys to AES/SAES ......................... 624

17 General purpose direct memory access controller (GPDMA) .... 626
  17.1 Introduction ............................................ 626
  17.2 GPDMA main features ..................................... 626
  17.3 GPDMA implementation .................................... 627
    17.3.1 GPDMA channels ...................................... 627
    17.3.2 GPDMA autonomous mode in low-power modes ....... 628
    17.3.3 GPDMA requests ...................................... 628
    17.3.4 GPDMA block requests ............................... 632
    17.3.5 GPDMA triggers ..................................... 632
  17.4 GPDMA functional description .............................. 634
    17.4.1 GPDMA block diagram ............................... 634
17.4.2 GPDMA channel state and direct programming without any linked-list 634
17.4.3 GPDMA channel suspend and resume .............................. 635
17.4.4 GPDMA channel abort and restart ............................... 636
17.4.5 GPDMA linked-list data structure ................................. 637
17.4.6 Linked-list item transfer execution ............................. 640
17.4.7 GPDMA channel state and linked-list programming
  in run-to-completion mode ......................................... 641
17.4.8 GPDMA channel state and linked-list programming in link step mode 644
17.4.9 GPDMA channel state and linked-list programming .......... 651
17.4.10 GPDMA FIFO-based transfers .................................. 653
17.4.11 GPDMA transfer request and arbitration ..................... 660
17.4.12 GPDMA triggered transfer ...................................... 664
17.4.13 GPDMA circular buffering with linked-list programming ................. 665
17.4.14 GPDMA secure/non-secure channel ......................... 667
17.4.15 GPDMA privileged/unprivileged channel ..................... 668
17.4.16 GPDMA error management ..................................... 668
17.4.17 GPDMA autonomous mode ...................................... 670
17.5 GPDMA in debug mode ............................................... 671
17.6 GPDMA in low-power modes ......................................... 671
17.7 GPDMA interrupts .................................................. 672
17.8 GPDMA registers ..................................................... 673
  17.8.1 GPDMA secure configuration register (GPDMA_SECCFGR) ..... 673
  17.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR) ..... 674
  17.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR) ..... 675
  17.8.4 GPDMA non-secure masked interrupt status register
        (GPDMA_MISR) ............................................... 675
  17.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR) .... 676
  17.8.6 GPDMA channel x linked-list base address register
        (GPDMA_CxLBAR) ............................................. 677
  17.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR) .......... 677
  17.8.8 GPDMA channel x status register (GPDMA_CxSR) ............ 678
  17.8.9 GPDMA channel x control register (GPDMA_CxCR) ............ 680
  17.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1) ...... 682
  17.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2) ...... 686
  17.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1) .......... 690
  17.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1) 691
  17.8.14 GPDMA channel x source address register (GPDMA_CxSAR) .... 694
18 Low-power direct memory access controller (LPDMA) .............. 705

18.1 Introduction ........................................ 705
18.2 LPDMA main features .................................. 705
18.3 LPDMA implementation ................................. 706
  18.3.1 LPDMA channels .................................. 706
  18.3.2 LPDMA autonomous mode in low-power modes .......... 706
  18.3.3 LPDMA requests .................................. 707
  18.3.4 LPDMA block requests .............................. 707
  18.3.5 LPDMA triggers ................................... 708
18.4 LPDMA functional description ......................... 709
  18.4.1 LPDMA block diagram ............................. 709
  18.4.2 LPDMA channel state and direct programming without
       any linked-list ....................................... 709
  18.4.3 LPDMA channel suspend and resume .................. 711
  18.4.4 LPDMA channel abort and restart .................... 712
  18.4.5 LPDMA linked-list data structure .................... 713
  18.4.6 Linked-list item transfer execution .................. 714
  18.4.7 LPDMA channel state and linked-list programming
       in run-to-completion mode ............................ 715
  18.4.8 LPDMA channel state and linked-list programming in link
       step mode ........................................... 719
  18.4.9 LPDMA channel state and linked-list programming ..... 725
  18.4.10 LPDMA direct transfers ........................... 727
  18.4.11 LPDMA transfer request and arbitration .............. 729
  18.4.12 LPDMA triggered transfer ........................... 733
  18.4.13 LPDMA circular buffering with linked-list programming .. 734
  18.4.14 LPDMA secure/non-secure channel .................... 736
  18.4.15 LPDMA privileged/unprivileged channel ............... 737
  18.4.16 LPDMA error management ........................... 738
  18.4.17 LPDMA autonomous mode ............................ 739

1 Documentation conventions

1.1 General information

The STM32U575/585 devices have an Arm® Cortex®-M33 core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

- **read/write (rw)**: Software can read and write to this bit.
- **read-only (r)**: Software can only read this bit.
- **write-only (w)**: Software can only write to this bit. Reading this bit returns the reset value.
- **read/clear write0 (rc_w0)**: Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
- **read/clear write1 (rc_w1)**: Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
- **read/clear write (rc_w)**: Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
- **read/clear by read (rc_r)**: Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
- **read/set by read (rs_r)**: Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
- **read/set (rs)**: Software can read as well as set this bit. Writing 0 has no effect on the bit value.
- **read/write once (rwo)**: Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
- **toggle (t)**: The software can toggle this bit by writing 1. Writing 0 has no effect.
- **read-only write trigger (rt_w1)**: Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
- **Reserved (Res.)**: Reserved bit, must be kept at reset value.

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.
2 Memory and bus architecture

2.1 System architecture

The STM32U575/585 architecture relies on an Arm Cortex-M33 core optimized for execution thanks to an instruction cache having a direct access to the embedded Flash memory.

This architecture also features a 32-bit multilayer AHB bus matrix that interconnects:

- **up to 11 masters:**
  - Fast C-bus, connecting Cortex-M33 with TrustZone® mainline and FPU core C-bus to the internal SRAMs through the instruction cache
  - Slow C-bus, connecting Cortex-M33 with TrustZone mainline and FPU core C-bus to the external memories through the instruction cache
  - Cortex-M33 with TrustZone mainline and FPU core S-bus (three masters connected to three internal SRAMs without latency)
  - Cortex-M33 with TrustZone mainline and FPU core S-bus connected to the external memories through the data cache
  - GPDMA1 (general purpose DMA featuring two master ports)
  - DMA2D
  - SDMMC1
  - SDMMC2

- **up to 10 slaves:**
  - internal Flash memory (2 Mbytes)
  - internal SRAM1 (192 Kbytes)
  - internal SRAM2 (64 Kbytes)
  - internal SRAM3 (512 Kbytes)
  - AHB1 peripherals and backup RAM (2-Kbyte BKPSRAM) including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - FSMC (flexible static memory controller)
  - OCTOSPI1
  - OCTOSPI2
  - SmartRun domain (SRD) AHB3 peripherals and SRAM4 (16 Kbytes), including AHB to APB bridge and APB peripherals (connected to APB3)
The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

![Figure 1. System architecture](image)

### 2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal Flash memory and to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in code region. This bus targets the internal Flash memory and the internal SRAMs (SRAM1, SRAM2 and SRAM3).

SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.
2.1.2 **Slow C-bus**

This bus connects the C-bus of the Cortex-M33 core to the bus matrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. This bus targets the external memories (FSMC and OCTOSPIs).

2.1.3 **S-bus**

This bus connects the system bus of the Cortex-M33 core to the bus matrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4 and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the SRD peripherals. SRAM1, SRAM2 and SRAM3 are accessible on this bus with a continuous mapping.

*Note:* The bus matrix has a zero latency when accessing SRAM1, SRAM2 and SRAM3.

2.1.4 **DCache S-bus**

This bus connects the system bus of the Cortex-M33 core to the bus matrix via the data cache. This bus is used for instruction fetch and data access to the external memories mapped in data region. This bus targets the external memories (FSMC and OCTOSPIs).

*Note:* Fetching instructions through this bus is less efficient than fetching instructions through the slow C-bus.

2.1.5 **GPDMA-bus**

These buses connect the two AHB master interfaces of the GPDMA to the bus matrix. These buses target the internal Flash memory, the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4 and BKPSRAM), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the external memories through FSMC or OCTOSPIs.

2.1.6 **SDMMC1 and SDMMC2 controllers DMA buses**

These buses connect the SDMMC1 and SDMMC2 DMA master interfaces to the bus matrix. These buses are used only by the SDMMC1 and SDMMC2 DMA to load/store data from/to the memory. These buses target the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2 and SRAM3) and external memories through FSMC or OCTOSPIs.

2.1.7 **Bus matrix**

The bus matrix manages the access arbitration between masters. The arbitration uses a Round-Robin algorithm. This bus matrix features a fast bus multiplexer used to connect each master to a given slave without latency (see Figure 1). For the same master, other slaves undergo a latency of at least one cycle at each new access.

2.1.8 **AHB/APB bridges**

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to Section 2.3.2: Memory map and register boundary addresses for the address mapping of the peripherals connected to these bridges.
After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and Flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When a 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.9 SmartRun domain (SRD)

The SRD architecture relies on a DMA allowing autonomous operation during low-power modes down to Stop 2.

This architecture also features a 32-bit AHB bus matrix that interconnects:

- two masters:
  - the main AHB bus matrix
  - LPDMA1 (low-power DMA featuring one master port)

- two slaves:
  - AHB3 peripherals including AHB to APB bridge connected to APB3
  - internal SRAM4

This architecture is shown in the figure below.

Figure 2. SmartRun domain architecture

2.2 TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register. When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and non-secure states.

- SAU: Up to eight SAU configurable regions are available for security attribution.
- IDAU: provides a first memory partition as non-secure or non-secure callable attributes. The IDAU memory map partition is not configurable and fixed by hardware implementation (refer to Figure 3: Memory map based on IDAU mapping). It is then combined with the results from the SAU security attribution and the higher security state is selected.
Based on IDAU security attribution, the Flash memory, system SRAMs and peripherals memory space are aliased twice for secure and non-secure states. However, the external memories space is not aliased.

The table below shows an example of typical eight SAU regions mapping based on IDAU regions. The user can split and choose the secure, non-secure or NSC regions for external memories as needed.

**Table 1. Example of memory map security attribution versus SAU configuration regions**

<table>

</table>

1. NSC = non-secure callable
2.2.1 Default TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- **CPU:**
  - Cortex-M33 is in secure state after reset. The boot address must be at a secure address.

- **Memory map:**
  - SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to height SAU configurable regions are available for security attribution.

- **Flash memory:**
  - The Flash memory security area is defined by watermark user options.
  - Flash block-based security attributions are non-secure after reset.

- **SRAMs:**
  - All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.

- **External memories:**
  - FSMC and OCTOSPIs banks are secure after reset. MPCWMx (watermark-based memory protection controller) are secure.

- **Peripherals (see Table 2 and Table 3 for a list of securable and TrustZone-aware peripherals):**
  - Securable peripherals are non-secure after reset.
  - TrustZone-aware peripherals are non-secure after reset. Their secure configuration registers are secure.

- **All GPIO are secure after reset.**

- **Interrupts:**
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and non-secure state.
  - TZIC: All illegal access interrupts are disabled after reset (see GTZC TrustZone system architecture).

2.2.2 TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- **Securable:** peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties

- **TrustZone-aware:** peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to GTZC TrustZone system architecture for more details.
The tables below list the securable and TrustZone-aware peripherals within the system.

1. Always secure when TZEN = 1.
2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.
2.3.2 Memory map and register boundary addresses

Figure 3. Memory map based on IDAU mapping
All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. The following table gives the boundary addresses of the peripherals available in the devices.

**Table 4. Memory map and peripheral register boundary addresses**

2.3.3 Embedded SRAM

The devices feature up to 786-Kbyte SRAMs:

- 192-Kbyte SRAM1
- 64-Kbyte SRAM2
- 512-Kbyte SRAM3
- 16-Kbyte SRAM4
- 2-Kbyte BKPSRAM

These SRAMs can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1, SRAM2 and SRAM3 through the system bus or through the C-bus depending on the selected address. The CPU can access the SRAM4 and BKPSRAM through the system bus only.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as non-secure with a block granularity. For more details, refer to Section 5: Global TrustZone controller (GTZC).

SRAM features are detailed in Section 6.3.1: Internal SRAMs features.

2.3.4 Flash memory overview

The Flash memory is composed of two distinct physical areas:

- The main Flash memory block, that contains the application program and user data.
- The information block, that is composed of the following parts:
  - option bytes for hardware and memory protection user configuration
  - system memory that contains ST proprietary code
  - OTP (one-time programmable) area
The Flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the Flash memory operations (program/erase) controlled through the Flash registers plus security access control features. Refer to Section 7: Embedded Flash memory (FLASH) for more details.
3 System security

The STM32U575/585 are designed with a comprehensive set of security features, some of which being based on the standard Arm TrustZone technology.

These security features simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEM and third-party developers, by facilitating the re-use, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on the STM32U575/585 devices.

3.1 Key security features

- Resource isolation using privilege mode and Armv8-M mainline security extension of Cortex-M33, extended to securable I/Os, memories and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of image through USART, USB, I²C, SPI, FDCAN and JTAG
- Secure boot thanks to the unique boot entry feature and hide-protect area (HDP) mechanism
- Secure storage, featuring:
  - Non-volatile on-chip secure storage, protected with secure and HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID and JTAG 32-bit device-specific ID
  - On-chip enhance storage technology, using hardware secret non-volatile unique keys (DHUK), and application-defined volatile hardware secret key (BHK), both loadable by hardware to the DPA-resistant AES engine
- General purpose cryptographic acceleration
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM and CCM chaining modes
  - Secure AES 256-bit security co-processor, supporting ECB and CBC chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting MD5/SHA-1 checksums and SHA-2 secure hash
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
- On-the-fly decryption of encrypted image stored on external Flash memory connected through the OCTOSPI
  - Almost-zero latency with standard NOR Flash memories
  - Can be used to encrypt the image using device-unique secret keys
  - Automatic key erase in case of tamper
• Flexible life-cycle scheme with readout protection (RDP), including support for product decommissioning (auto-erase)
  – Debug protection, depending on the RDP level
  – Optional password-based RDP level regressions, including for RDP Level 2
• Protected firmware distribution scheme, using TrustZone, on-the-fly decryption and RDP Level 0.5
• Active tamper and protection against temperature, voltage and frequency attacks
  – Eight active inputs, eight active output tamper pins, available in all power modes

3.2 Secure install

The secure firmware install (SFI) is an immutable secure service embedded by STMicroelectronics in the devices. The SFI allows secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written either in the internal Flash memory or encrypted in an external Flash memory, is also protected, using the AES.

The SFI native service leverages the following hardware security features:
• secure boot (see Section 3.3)
• resource isolation using TrustZone (see Section 3.5)
• temporal isolation using hide protection (see Section 3.6.1)
• secure execution (see Section 3.7)
• secure storage, with associated cryptographic engines (see Section 3.8 and Section 3.9)

Further information can be found in the application note Overview secure firmware install (SFI) (AN4992).

3.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The actual functions of the secure boot depend on the availability of TrustZone features, and on the firmware stored in the device. However, the secure boot typically initializes the secure storage, and installs on-the-fly decryption keys in the OTFDEC, to be able to use encrypted firmware stored in an external Flash memory.

The device Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, provides a root of trust solution including secure boot functions.
In the devices, the secure boot takes benefit of hardware security features such as:

- resource isolation using TrustZone (see Section 3.5)
- temporal isolation using hide protection (see Section 3.6.1)
- secure execution (see Section 3.7)
- secure install and update (see Section 3.2 and Section 3.4)
- secure storage, with associated cryptographic engines if available (see Section 3.8 and Section 3.9)

This section describes the features specifically designed for secure boot.

### 3.3.1 Unique boot entry and BOOT_LOCK

When TrustZone is activated (TZEN = 1) and BOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system Flash memory (see the next section), or in the secure user Flash memory, at the address defined by SECBOOTADD0 option bytes.

When TrustZone is activated (TZEN = 1) and BOOT_LOCK secure option bit is set, the device unique boot entry is the unmodifiable secure address defined by SECBOOTADD0 option bytes. All these option bytes cannot be modified by the application anymore when BOOT_LOCK is set.

**Note:** As long as it is cleared, the BOOT_LOCK option bit can be set without any constraint. But once set, the BOOT_LOCK option bit cannot be cleared when RDP level > 0.

For more information on the boot mechanisms, refer to Section 4: Boot modes.

### 3.3.2 Immutable root of trust in system Flash memory

The immutable root-of-trust code stored in the system Flash memory is first used to perform SFI, allowing secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SYSCFG_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set.

### 3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

The device Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, allows the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

A firmware update can be done either on a single firmware image including both secure and non-secure parts, or on the secure (respectively non-secure) part of the firmware image, independently.
In the devices, the secure update application leverages the same hardware security as the firmware install described in Section 3.2.

3.5 Resource isolation using TrustZone

In the STM32U575/585 devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the non-secure world, as shown in the figure below.

Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after reset of the device.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the non-secure world.

Note: The secure code is typically small and rarely modified, while non-secure code is more exposed, and prone to firmware updates.

3.5.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- the Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- the dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- a global TrustZone framework (GTZC), extending the TrustZone protection against transactions coming from other masters in the system than the Cortex-M33
- TrustZone-aware embedded Flash memory and peripherals
Note: The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

3.5.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vectored interrupt controller (NVIC).

The Armv8-M TrustZone implementation in STM32U575/585 devices is composed of the following features:

- a new processor state, with almost no additional code-cycle overhead, as opposed to Armv8-A TrustZone that uses a dedicated exception routine for triggering a secure/non-secure world change
- two memory map views of a shared 4-Gbyte address space
- a low interrupt latency for both secure and non-secure domains, and a new interrupt configuration for security grouping and priority setting
- separated exception vector tables for the secure and non-secure exceptions
- micro-coded context preservation
- banking of specific registers across secure/non-secure states, including stack pointers with stack-limit checkers
- banking of following Cortex-M33 programmable components (two separate units for secure and non-secure):
  - SysTick timer
  - MPU configuration registers (eight MPU regions in secure, eight in non-secure)
  - some of the system control block (SCB) registers
- new system exception (SecureFault) for handling of security violations
- configurable debug support, as defined in Section 3.11

For more information, refer to Cortex-M33 programming manual (PM0264).

3.5.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on Figure 5, the Armv8-M non-secure memory view is similar to Armv7-M (that can be found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the Flash memory, SRAM and peripherals that are only accessible while the Cortex processor executes in Secure state.

Note: The figure below shows the 32-bit address space viewed after the SAU configuration by the secure code.
The Cortex processor state (and associated rights) depends on the security attribute assigned to the memory region where it is executed:

- A processor in a non-secure state only executes from non-secure (NS) program memory, while a processor in a secure state only executes from secure (S) program memory.
- While running in secure state, the processor can access data from both S and NS memories. Running in non-secure state, the CPU is limited to non-secure memories.

In order to manage transitions to the secure world, developers must create non-secure callable (NSC) regions that contain valid entry points to the secure libraries. The first instruction in these entry points must be the new secure gate (SG) instruction, used by the non-secure code to call a secure function (see the figure below).

**Figure 5. Sharing memory map between CPU in secure and non-secure state**

**Figure 6. Secure world transition and memory partitioning**
Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS or NSC) to a specific address, as shown in the table below.

Table 5. Configuring security attributes with IDAU and SAU

<table>
<thead>
<tr>
<th>IDAU security attribution</th>
<th>SAU security attribution(1)</th>
<th>Final security attribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Non-secure</td>

<td>Secure</td>
</tr>
<tr>
<td></td>
<td>Non-secure</td>
<td>Secure-NSC</td>
</tr>
<tr>
<td></td>
<td>Non-secure</td>
<td>Secure-NSC</td>
</tr>
</tbody>
</table>

1. Defined regions are aligned to 32-byte boundaries.

The SAU can only be configured by the Cortex-M33 in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in the previous table.

Note: The SAU/IDAU settings are applicable only to the Cortex-M33. The other masters like DMA are not affected by these policies.

For more information on memory security attribution using IDAU/SAU, refer to the application note TrustZone features on STM32L5 and STM32U5 Series (AN5347).

3.5.4 Memory and peripheral allocation using GTZC

Global TrustZone framework architecture

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between the secure and the non-secure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against non-secure transactions coming from other masters than the Cortex-M33.
Figure 7. Global TrustZone framework and TrustZone awareness

Securing peripherals with TZSC

When the TrustZone security is active, a peripheral is either securable through the GTZC, or is natively TrustZone-aware, as shown in the previous figure:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, that is controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers or a secure memory area.

When a securable peripheral is made secure-only with the GTZC, if this peripheral is master on the interconnect (SDMMC), it automatically issues secure transactions. The SDMMC is an example of securable master. TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.
Note: Like with TrustZone, a peripheral can be made privileged-only with TZSC (see Section 3.6.2). In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.

Securing memories with TZSC and MPCBB

The TZSC block in GTZC provides the capability to manage the security and privilege for all securable external memories, programming the MPCWM resources as defined in the table below.

### Table 6. MPCWMx resources

<table>
<thead>
<tr>

</tbody>
</table>

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, non-secure unprivileged otherwise.

### Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:
- statically programmed during the secure boot, locked and not changed afterwards
- dynamically re-programmed using a specific application code or real-time kernel
When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks or MPCWM non-secure region size can be changed by a secure software. This software must be privileged for MPCWM, can be unprivileged if the particular block is not privileged-only.
- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

**Securing peripherals with TZSC**

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of these peripherals can be found in [Section 5: Global TrustZone controller (GTZC)](#).

*Note:* When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only (see [Section 3.6.2](#)).

*When the TrustZone is activated, peripherals are set as non-secure and unprivileged after reset.*

**TrustZone-aware peripherals**

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOI, configured in LPGPIO alternate function or not
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- OTFDEC1/2, writable only in secure if TZEN = 1
- EXTI
- Flash memory
- RCC and PWR
- GPDMA and LPDMA
- SYSCFG registers
- RTC and TAMP
- MCU debug unit DBGMCU

The way illegal accesses to those peripherals are monitored through the TZIC registers is described in [Section 5: Global TrustZone controller (GTZC)](#).

For more details, refer to [Section 3.5.5](#).

**TrustZone illegal access controller (TZIC)**

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 1). All accesses to TZIC registers must be secured.

For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

*Note:* By default, all events are masked.
3.5.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

**Embedded Flash memory**

When the TrustZone security is enabled through option bytes (TZEN = 1), the whole Flash memory is secure after reset and the following protections, shown in the figure below, are available to the application:

- non-volatile user secure areas, defined with non-volatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as non-secure (example: outside watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

*Note:* All areas are aligned on the Flash memory page granularity.

The Flash memory area can be configured as secure while it is tagged as non-secure in Cortex-M33 IDAU/SAU. In this case, non-secure accesses by the CPU to the Flash memory are denied.

Erase or program operations can be available to secure (resp. non-secure) code only for secure (resp. non-secure) pages or memory. A Flash memory is considered secure if at least one page is secure.

**Figure 8. Flash memory TrustZone protections**

As shown above, when TrustZone is activated (TZEN = 1), the application code can use the HDP area that is part of the Flash watermark-based secure area. Indeed, when the
application sets the HDPx_ACCDIS bit, data read, write and instruction fetch on this HDP area are denied until next system reset.

For example, the software code in the secure Flash HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any Flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is deactivated (TZEN = 0), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See Section 7: Embedded Flash memory (FLASH) for more details.

**On-the-fly encryption/decryption (OTFDEC)**

When the TrustZone security is activated (TZEN = 1), the OTFDEC can only be initialized by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until next power-on-reset.

*Note:* Any application (secure or non-secure) can verify the initialization context of each OTFDEC region (including CRC of the keys), by reading the peripheral registers.

Key registers in each OTFDEC are write-only.

See Section 3.9.3 for more details on this cryptographic engine.

**Direct memory access controllers (LPDMA and GPDMA)**

When a DMA channel x is defined as secure (SECx = 1 in LP/GPDMA_SECCFG), the source and destination transfers can be independently set as secure or non-secure by a secure application using SSEC and DSEC bits in LP/GPDMA_CxTR1. The table below summarizes these security options available in each DMA channel.

<table>
<thead>
<tr>
<th>Destination type</th>
<th>Secure DMA channel x (SECx = 1)</th>
<th>Non-secure DMA channel y (SECy = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure source</td>
<td>OK</td>
<td>Transfer blocked</td>
</tr>
<tr>
<td>Non-secure source</td>
<td>OK(3)</td>
<td>OK(4)</td>
</tr>
</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros. Also an illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.

2. If the source is a memory, the transfer is only possible if SSEC = 0, otherwise the transfer is blocked.

3. If the destination is a memory, the transfer is only possible if DSEC = 0, otherwise the transfer is blocked.

4. If the transfer is memory-to-memory, the transfer is only possible if SSEC = 0 and DSEC = 0, otherwise the transfer is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding LP/GPDMA_SECCFG, LP/GPDMA_PRIVCFG and LP/GPDMA_RCFGLOCKR) are read as zero. Write are ignored for non-secure accesses. A secure illegal access event may also be triggered toward the TZIC peripheral.

  - Writes to LP/GPDMA_SECCFG and LP/GPDMA_RCFGLOCKR must be secure. For each bits in LP/GPDMA_PRIVCFG, write must be secure if corresponding bit in LP/GPDMA_SECCFG is set.
• In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.
• When switching to a non-secure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

Note: DMA secure channels are not available when TrustZone is deactivated.

When a channel is configured as non-secure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with non-secure transfers.

See Section 18: Low-power direct memory access controller (LPDMA) and Section 17: General purpose direct memory access controller (GPDMA) for more details.

Power control (PWR)

When the TrustZone security is activated (TZEN = 1), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:
• low-power mode setup
• wakeup (WKUP) pins definition
• voltage detection and monitoring
• Backup domain control

Other PWR configuration bits become secure:
• when the system clock selection is secure in the RCC: the voltage scaling (VOS) and the regulator booster (BOOSTEN) configurations become secure.
• when a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
• when the USB Type-C/USB power delivery interface (UCPD) is configured as secure in TZSC: PWR_UCPDR register becomes secure.

See Section 10: Power control (PWR) for details.

Secure clock and reset (RCC)

When the TrustZone security is activated (TZEN = 1) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:
• If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
• If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure as soon as at least one function is configured as secure inside the peripheral.

Note: Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

The SHSI configuration and status bits are secured when the SAES is configured as secure. Additionally, the following configurations can be made secure-only using RCC_SECCFGR:
• external clock (such as HSE or LSE), internal oscillator (such as HSI, MSI, or LSI)
• main PLL and AHB prescaler
• system clock source selection
• MCO clock output
• reset flag
• automatic internal oscillator waking up configuration

See Section 11: Reset and clock control (RCC) for details.
Real time clock (RTC)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a Backup domain power-on reset, all RTC registers can be read or written in both secure and non-secure modes. The secure boot code can then change this security setup, making registers Alarm A, alarm B, wakeup timer and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:
- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIMCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and non-secure modes. All the other RTC registers can be read only in secure mode.

When SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See Section 54: Real-time clock (RTC) for more details.

Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a non-secure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a Backup domain power-on reset, all TAMP registers can be read or written in both secure and non-secure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:
- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (with the exception of TAMP_SECCFGR, TAMP_PRIMCFGR and TAMP_MISR) returns zero if the access is non-secure. Backup registers have their own read protection (see below).

The application can also:
- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- in backup registers increase security for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read non-secure, write non-secure
  - protection zone 2 is read non-secure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See Section 55: Tamper and backup registers (TAMP) for more details.
General-purpose I/Os (GPIO)

When the TrustZone security is activated (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin of GPIO is set as secure.

When an I/O is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of non-secure access.

When digital alternate function is used (input/output mode), in order to protect the data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- If the peripheral is secure, the I/O pin must also be secure to allow input/output of data.
- If the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

The TrustZone-aware logic around GPIO ports, used as alternate function, is summarized in the table below.

<table>
<thead>
<tr>
<th>Table 9. Secure alternate function between peripherals and allocated I/Os</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, the table below summarizes the list of I/Os that do not have any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral is non-secure.
For example, when a secure application sets PA4 as secure to be used as LPTIM2_OUT, if the DAC is non-secure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is non-secure, it can be programmed to capture the USART input traffic through the TAMP_IN signal.

It is important that, for each case described in the table below, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if it is not used by the secure application.

**Note:** How to make a peripheral secure is summarized in the right column of the table below.

</table>

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to Section 13: General-purpose I/Os (GPIO) for more details.

### Extended interrupts and event controller (EXTI)

When the TrustZone security is activated (TZEN = 1), the EXTI is able to protect event register bits from being modified by non-secure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR1. When an input event is configured as secure, only a secure application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 can be globally locked after reset in EXTI_LOCKR.

See Section 21: Extended interrupts and event controller (EXTI) for more details.

### System configuration controller (SYSCFG)

Like all TrustZone-aware peripherals, when the TrustZone security is activated (TZEN = 1), a non-secure read/write access to a secured SYSCFG register is RAZ/WI. Such access
also generates an illegal access event that triggers a secure illegal access interrupt if the SYSCFG illegal access event is not masked in the TZIC.

See Section 15: System configuration controller (SYSCFG) for more details.

**Microcontroller debug unit (DBGMCU)**

The MCU debug component (DBGMCU) helps the debugger, providing support for:
- low-power mode behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWDG, timers, low-power timers, and LP/GPDMA channels

The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in the table below.

### Table 12. TrustZone-aware DBGMCU non-secure accesses management

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from debugger is converted to non-secure access in the device.

Refer to Section 65.11: Microcontroller debug unit (DBGMCU) for more details.

### 3.5.6 Activating TrustZone security

The TrustZone is deactivated by default in all STM32U575/585 devices. It can be activated by setting the TZEN option bit in FLASH_OPTR when RDP Level 0. Once TZEN has changed from 0 to 1, the default security state, after reset, is always the following:

- **CPU subsystem**
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.

- **Embedded Flash memory**
  - Flash memory non-volatile secure areas (with their HDP zone), are defined with non-volatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user Flash secure, without HDP area defined.
  - Volatile block-based security attributions of the Flash memory are non-secure.

- **Embedded SRAM memories**
  - All SRAMs are secure, as defined in GTZC/MPCBB (see Section 3.5.4). The secure boot code can change this security setup, making blocks secure or not.

- **External memories**
– All memory devices connected to the FSMC and OCTOSPIs are secure, as defined in GTZC/MPCWM (see Section 3.5.4). The secure-boot code can change this security setup, making components secure or not.

- All GPIOs are secure.
- All LP/GPDMA channels are non-secure.
- Backup registers are non-secure.
- Peripherals and GTZC:
  – Securable peripherals are non-secure and unprivileged.
  – TrustZone-aware peripherals are non-secure, with their secure configuration registers being secure.
  – All illegal access interrupts in GTZC/TZIC are disabled.

*Note:* Refer to Section 3.5.4 for the list of securable and TrustZone-aware peripherals.

### 3.5.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during a RDP regression to Level 0.

*Note:* Such RDP regression triggers the erase of embedded memories (SRAM2, Flash memory), and the reset of all peripherals, including the OTFDEC and all crypto engines.

After the TrustZone deactivation, most features mentioned in Section 3.5 are no more available:

- The non-volatile secure area of the embedded Flash memory is deactivated, including the HDP area.
- Only the NVIC manages non-secure interrupts.
- All secure registers in TrustZone-aware peripherals are RAZ/WI.

*Note:* When the TrustZone is deactivated, the resource isolation using privilege stays available (see Section 3.6.2 for details).

### 3.6 Other resource isolations

These are hardware mechanisms offering an additional level of isolation on top of the TrustZone technology.

#### 3.6.1 Temporal isolation using secure hide protection (HDP)

When the TrustZone security is enabled (TZEN = 1), the embedded Flash memory allows an HDP area per watermarked-secure area of each bank (8-Kbyte page granularity) to be defined. The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset. The hide protection principle is pictured on the figure below.
When the HDPxEN and HDPx_ACCDIS bits (x = 1, 2) are set, data read, write and instruction fetch on the area defined by SECWMx_PWRST and HDPx_PEND option bytes, are denied until the next device reset.

Note:  
*Bank erase aborts when it contains a write-protected area (WRP or HDP area).*  
The HDP area can be resized by a secure application if the area is not hidden and if RDP Level $\neq 2$.

### 3.6.2 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in Section 3.5, the hardware and software resources of STM32U575/585 devices can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is deactivated (TZEN = 0), critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

**Memory and peripheral privileged allocation using MPU**

The Cortex-M33 MPU divides the unified memory into eight regions, each aligned to a multiple of 32 bytes. Each memory regions can be programmed to generate faults when accessed inappropriately by unprivileged software.

**Memory and peripheral privileged allocation using GTZC**

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.
For masters other than the Cortex-M33, the GTZC can assign them as unprivileged initiators, automatically protecting resources defined as privileged against this master.

- **Securing peripherals with TZSC (privileged-only)**
  In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:
  - A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate that is controlled by the TZSC.
  - A privileged-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific behavior such as a subset of registers or a memory area is privilege-only.

  When such peripheral is made privileged-only with GTZC, if it is master on the interconnect (SDMMC), it automatically issues privileged transactions. Privilege-aware masters like GPDMA or LPDMA, drive privileged signal in the AHB interconnect according to their internal privileged mode, independently to the GTZC.

  The list of securable peripherals can be found in *Section 5: Global TrustZone controller (GTZC)*.

- **Securing memories with TZSC and MPCBB (privileged-only)**
  The TZSC logic in GTZC provides the capability to manage the privilege level for all securable external memories, programming the MPCWM resources defined in *Section 3.5.4*.

  Similarly, the TZSC logic in GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources defined in *Section 3.5.4*.

- **Error management (privileged-only)**
  - Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.
  - The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write.
  - When an illegal unprivileged access occurs, no bus error is generated, except when this access is an instruction fetch, accessing a privileged memory or a peripheral register.
Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TZEN = 0:

- **Embedded Flash memory**
  By default all embedded Flash registers can be read or programmed in both privileged and unprivileged modes.
  When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the Flash secure registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is deactivated (TZEN = 0).
  When non-secure privileged bit NSPRIV is set in FLASH_PRIVCFGR, reading and writing the Flash non-secure registers are possible only in privileged mode.

Regarding privileged protection of the embedded Flash memory, the devices offer the following features:
- The system Flash memory can be accessed both in privileged and unprivileged modes.
- Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.
- Each 8-Kbyte page of the embedded Flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by a privileged or unprivileged access.

Note: **Switching a page from privileged to unprivileged does not erase the content of the page.**

When applicable, an erase or program operation is always available to privileged code, and is available to unprivileged code only for unprivileged pages or unprivileged memory.

- **On-the-fly encryption/decryption (OTFDEC)**
  When privileged bit PRIV is set in OTFDEC_PRIVCFGR, the OTFDEC can only be initialized by a privileged application.

Note: **OTFDEC_PRIVCFGR can be read by both privileged and unprivileged code.**

- **Direct memory access controllers (LPDMA and GPDMA)**
  When a DMA channel x is defined as privileged (PRIVx = 1 in LP/GPDMA_PRIVCFGR), special rules apply when accessing privileged/unprivileged source or destination. Those rules are summarized on the table below.

### Table 13. DMA channel use (privilege)

<table>
<thead>
<tr>
<th>Destination</th>
<th>Privileged DMA channel x (PRIVx = 1)</th>
<th>Unprivileged DMA channel y (PRIVy = 0)</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros.

See **Section 18: Low-power direct memory access controller (LPDMA)** and **Section 17: General purpose direct memory access controller (GPDMA)** for more details.
- **Power control (PWR)**
  By default, after a power-on or a system reset, all PWR registers but PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

  When non-secure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR non-secure registers are possible only in privileged mode.

  See *Section 10: Power control (PWR)* for details.

- **Secure clock and reset (RCC)**
  By default, after a power-on or a system reset, all RCC registers but RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0).

  When non-secure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC non-secure bits are possible only in privileged mode.

  See *Section 11: Reset and clock control (RCC)* for details.

- **Real time clock (RTC)**
  By default after any Backup domain reset, all RTC registers but RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

    When PRIV bit is set in privileged-only RTC_PRIVCFGR:
    - Writing the RTC registers is possible only in privileged mode.
    - Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

    All the other RTC registers can be read only in privileged mode.

    When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALPRPRV or ALRBPRIV.

    See *Section 54: Real-time clock (RTC)* chapter for details.

- **Tamper and backup registers (TAMP)**
  By default after any Backup domain reset, all TAMP registers but TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

    When PRIV bit is set in privileged-only TAMP_PRIVCFGR:
    - Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.
    - Reading the TAMP_SECCFGR or TAMP_PRIVCFGR is always possible in privilege and unprivileged modes. All the other TAMP registers can be read only in privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.
The application can also:

- make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR
- increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:
  - Make protection zone 1 read privileged, write privileged.
  - Make protection zone 2 read privileged or unprivileged, write privileged.
  - Protection zone 3 is always read and write privileged or unprivileged.

- **General-purpose I/Os (GPIO)**
  All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

- **Extended interrupts and event controller (EXTI)**
  The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGR1 register. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

  The security configuration in EXTI_PRIVCFGR1 can be globally locked after reset in EXTI_LOCKR.

  See Section 21: Extended interrupts and event controller (EXTI) for more details.

- **System configuration controller (SYSCFG)**
  All SYSCFG registers can be read and written in both privileged and unprivileged modes, except:
  - FPUSEC bit in SYSCFG_SECCFGR registers (privileged only)
  - SYSCFG registers for CPU configuration: SYSCFG_CSLOCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR

  See Section 15: System configuration controller (SYSCFG) for more details.

## 3.7 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

### 3.7.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the non-secure and secure MPUs split memory into regions (up to eight per MPU). Secure MPU is only available when TrustZone is activated.
3.7.2 Embedded Flash memory write protection

The embedded Flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded Flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses: two write-protected areas can be defined in each bank, with the granularity of a 8-Kbyte page.

WRP areas can be modified through option byte changes unless corresponding FLASH_WRPxABR has its UNLOCK option bit cleared (meaning ROM emulation). UNLOCK can be set only when regressing from RDP Level 1 to Level 0.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

3.7.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: V_{BAT}, V_{DDA}), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with V_{DD} or V_{BAT}

See Section 55: Tamper and backup registers (TAMP) for more details.

Tamper detection sources

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os). The active-tamper balls are mapped in the center of packages that can be used in POS market (such as WLCSP90).

The active pins are clocked by the LSE, and are functional in all system operating modes (Run, Sleep, Stop, Standby or Shutdown), and in V_{BAT} mode.

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparison in four consecutive comparison samples).

Note: Timestamps are automatically generated when a tamper event occurs.
The internal tamper sources are listed in the table below.

Table 14. Internal tampers in TAMP

</tr>
</tbody>
</table>

1. LSE missing or over frequency detection (> 2MHz), Glitch filter (> 2 MHz).

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxNOER bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in SAES, AES, HASH and OTFDEC (encrypted Flash memory regions are read as zero)
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erased when V_{DD} is present)
  - non-volatile information used to derive the DHUK in SAES is zeroed until complete SRAM2 erase
  - 2-Kbyte backup SRAM (depending on configuration bit), erased when V_{DD} is present
  - ICACHE and DCACHE erased when V_{DD} is present

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present, are only erased at the next V_{DD} power on.
Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2, or by performing a RDP regression as defined in Section 3.10.1. Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxNOER bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:
- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM, SRAM2: read-as-zero, write-ignored
- AES, SAES and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:
- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset triggers automatically the erase of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection are summarized on the table below.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on tamper detection features</td>

<td>No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE</td>
</tr>
<tr>
<td></td>
<td>Tamper events cause the device to exit the Shutdown mode.</td>
</tr>
</tbody>
</table>

3.8 Secure storage

A critical feature of any security system is how long term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.
Figure 10 shows how key management service application can use the AES engine for example to compute external image decryption keys. A non-volatile key can be stored in the embedded secure HDP area (see Section 3.6.1), while volatile key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone-aware TAMP.

Figure 10 also shows keys that are manipulated by software (like OTFDEC keys), or keys that are managed only by hardware (like DHUK). More information on those hardware keys can be found in Section 3.8.1.

Figure 10. Key management principle

Details on tamper protection is found in Section 3.7.3, while TAMP TrustZone features are briefly described in Section 3.5.5.

3.8.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys, using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in case of tamper.

There are three different sources of hardware secret keys:

- **DHUK**: derived keys based on 256-bit non-volatile device unique secret in Flash memory. The generation of this key takes into account the TrustZone state and key use state (KMOD).
- **BHK**: 256-bit application key stored in tamper-resistant volatile storage in TAMP. This key is written at boot time, then read/write locked to application until next reset.
- **XORK**: result of a XOR of BHK and DHUK
Those keys can be used in the following modes:

- as a normal key, loading in write-only key registers (software key mode)
- as an encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as an encryption/decryption key for another key, to be used in a faster AES engine (shared key mode)

3.8.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see Section 66.1: Unique device ID register (96 bits)).

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see Section 3.8.1).

3.9 Crypto engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The crypto engines embedded in STM32 reduces weaknesses on the implementation of critical cryptographic functions, preventing for example the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provides certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

3.9.1 Crypto engines features

The table below lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available (both can be reserved to secure application only).

**Note:** Additional operations can be added using firmware.

The PKA can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 45: Public key accelerator (PKA) for more details.
Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

### 3.9.2 Secure AES co-processor (SAES)

The devices provide an additional on-chip hardware AES encryption and decryption engine, that implements counter-measures and mitigations against power and electromagnetic side-channel attacks.

Clocked by a dedicated 48 MHz SHSI clock, SAES is also slower than the AES, in order to provide best-in-class side-channel protections. The SAES engine supports 128-bit or 256-bit key in electronic code book (ECB) or cipher block chaining (CBC) mode.

As shown in Section 3.8, the SAES can be used for extra-secure on-chip storage for sensitive information. It can also be made secure-only.

For more information, refer to Section 42: Secure AES coprocessor (SAES).
3.9.3 On-the-fly decryption engine (OTFDEC)

The OTFDEC TrustZone-aware peripheral proposes on-the-fly decryption of encrypted images stored on external Flash memory, connected through the OCTOSPI. This decryption process introduces almost no additional cycle overhead when the standard NOR Flash memory is used. The OTFDEC can also be used to encrypt Flash memory images on the device (for example to encrypt with a device unique secret key).

When a tamper event is confirmed in TAMP, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

An OTFDEC typical use is detailed in Section 3.12.2. For more details on the peripheral programming, refer to Section 44: On-the-fly decryption engine (OTFDEC).

3.10 Product life-cycle

A typical IoT device life-cycle is summarized in the figure below. For each step, the devices propose secure life-cycle management mechanisms embedded in the hardware.

![Figure 11. Device life-cycle security](MSv64454V1)
More details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in the table below.

### Table 17. Main product life-cycle transitions

<table>
<thead>
<tr>
<th>Transitions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device manufacturing</td>
<td>STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.</td>
</tr>
<tr>
<td>Vendor manufacturing</td>
<td>One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“productization” transition) or he/she can use the platform for software development (“user provisioning” transition).</td>
</tr>
<tr>
<td>Productization</td>
<td>The end user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.</td>
</tr>
<tr>
<td>User provisioning</td>
<td>Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.</td>
</tr>
<tr>
<td>Field return or decommissioning</td>
<td>Those are one-way transitions, with devices kept in user premises or returned to the manufacturer. In both cases, all data including user data are destroyed, therefore the devices lose the ability to operate securely (like connecting to a managed IoT network).</td>
</tr>
</tbody>
</table>

The features described hereafter contribute to secure the device life-cycle.

### 3.10.1 Life-cycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the devices debug, test and provisioned secrets, as summarized in the table below.

### Table 18. Typical product life-cycle phases

<table>
<thead>
<tr>
<th>RDP protection level</th>
<th>Debug</th>
<th>Comments</th>
</tr>

</tr>
<tr>
<td>Level 2 Device closed (JTAG fuse)</td>
<td>None</td>
<td>Boot address must target the user Flash memory (secure if TZEN = 1). Option bytes are read-only, hence RDP level 2 cannot be changed, unless OEM2 unlocking key is activated (see Table 19).</td>
</tr>
</tbody>
</table>
1. Debug is not available when executing RSS code.
2. Only applicable when TrustZone security is activated in the product.
3. External Flash memory area decrypted on-the-fly with the OTFDEC.

Note: OEM1KEY option byte can be modified when OEM1LOCK = 0 (RDP = 0.5 or 1 only).
OEM2KEY option byte can be modified when OEM2LOCK = 0 (RDP = 1 only).

The supported transitions, summarized in the figure below, can be requested (when available) through the debug interface or via the system bootloader.

Figure 12. RDP level transition scheme

As shown in the previous figure, the user Flash memory is automatically erased, either partially or in totality, during a RDP regression from RDP1. Those regressions can be conditioned to dedicated 64-bit password keys, if provisioned by the OEM (see next subsection). During the transition from RDP Level1 to RDP Level 0.5, only non-secure embedded Flash memory is erased, keeping functional, for example, the secure boot and the secure firmware update. In all regressions from Level 1, the OTP area in the Flash memory is kept, all SRAMS and targeted device secrets are erased. These secrets, also erased as response to tamper, are defined in Section 3.7.3.

Note: Enabling TrustZone using option byte TZEN is only possible when RDP level is 0.

For more details on RDP, refer to Section 7: Embedded Flash memory (FLASH).

RDP unlocking sequences

The use of the two OEM password keys described in the last figure, is further described hereafter.

Note: The devices support both permanent RDP Level 2 (legacy mode) or password-based RDP Level 2 regression to Level 1. This Level 2 regression does not erase the application code, and it does not change the RDP Level 1 protections in place.
Details on the password-based regression can be found in the table below.

Table 19. OEM1/2 RDP unlocking methods

<table>
<thead>

<td>Regression to Level 0.5 always granted</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>2</td>
<td>Regression to Level 1 never granted RDP remains a permanent state.</td>
</tr>
</tbody>
</table>

- **OEM1 unlock sequence**, starting at RDP Level 1:
  - Shift password key through JTAG/SWD (see the note below).
  - If this key matches the OEM1KEY provisioned in the device, the application can trigger a regression sequence to Level 0. After the regression is completed, the whole embedded Flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 1 protections are enforced until next power-on reset.

- **OEM2.1 unlock sequence**, starting at RDP Level 1:
  - Shift password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the application can trigger a regression sequence to Level 0.5. After the regression is completed, the non-secure embedded Flash memory and device secrets are erased. The OTP area is not erased.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 1 protections are enforced until next power-on reset.

- **OEM2.2 unlock sequence**, starting at RDP Level 2:
  - Shift password key through JTAG/SWD under reset (see the note below).
  - If this key matches the OEM2KEY provisioned in the device, the device automatically triggers a regression sequence to Level 1. After the regression is completed, a power-on reset has to be performed by the user.
  - In case of mismatch value, the RDP regression is blocked and RDP Level 2 protections are enforced until next power-on reset.

**Note:** Unlocking the device with a password is possible only once per power cycle.

*Shifting the password key through JTAG/SWD corresponds to writing two 32-bit key words, AUTH_KEY[31:0], then AUTH_KEY[63:32], in DBGMCU_DBG_AUTH_HOST register.*
JTAG 32-bit device specific ID

Unless the JTAG port is de-activated (OEM2LOCK = 0 and RDP Level = 2), a 32-bit device specific quantity can always be read through the JTAG port. This information is stored in DBGMCU_DBG_AUTH_DEVICE.

The OEM can use this 32-bit information to derive the expected OEM password keys to unlock this specific device.

3.10.2 Recommended option byte settings

Most of the time, the user threat model focuses mainly on software attacks. In this case, it may be sufficient to keep the RDP Level 1 as device protection.

For a more aggressive threat model, where the user fears physical attacks on the STM32 device, it is recommended to optimize the level of security by setting the RDP Level 2.

The recommended settings are detailed below:

- If TrustZone is disabled (TZEN = 0)
  - RDP Level 2
  - non-secure boot address option bytes set in user Flash memory

- If TrustZone is enabled (TZEN = 1)
  - RDP Level 2
  - BOOT_LOCK = 1
  - secure boot address option bytes set in user Flash memory

As described in the previous section, the customer can decide to allow any RDP Level 2 part to regress to RDP Level 1, provided the OEM Key2 has been successfully provisioned, and OEM2LOCK option bit is set.

3.11 Access controlled debug

The device restricts access to embedded debug features, in order to guarantee the confidentiality of customer assets against unauthorized usage of debug and trace features.

3.11.1 Debug protection with readout protection (RDP)

As described in Section 3.10.1, the hardware RDP mechanism automatically controls the accesses to the device debug and test. The protection of these debug features are defined in the table below. Possible password-based regressions are described in Section 3.10.1.
3.12 Software intellectual property protection and collaborative development

Thanks to software intellectual property protection and collaborative model, the devices allow the design of solutions integrating innovative third-party libraries.

Collaborative development is summarized on the figure below. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B, who does the same before deploying a final product to the end users.

Note: Each platform vendor can provision individual platforms for development not to be connected to a production cloud network (“Development Platform X”).

Figure 13. Collaborative development principle

MSv64455V1
The features described hereafter contribute to securing the software intellectual property within such a collaborative development.

### 3.12.1 Software intellectual property protection with RDP

As described in Section 3.10.1, the hardware RDP mechanism automatically controls the accesses to secrets provisioned in the device. The protection of these secrets are defined in the table below.

<table>
<thead>
<tr>
<th>RDP protection level</th>
<th>Secrets protection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Level 0</td>
<td>Device open</td>
</tr>
<tr>
<td></td>
<td>No special protections.</td>
</tr>
<tr>
<td>Level 0.5(1)</td>
<td>Device partially closed</td>
</tr>
<tr>
<td></td>
<td>All peripherals and memories mapped as secure during secure boot cannot be dumped, debugged or traced</td>
</tr>
<tr>
<td>Level 1</td>
<td>Device memories protected</td>
</tr>
<tr>
<td></td>
<td>Data and code stored in embedded Flash memory, encrypted external Flash memory[2], SRAM2 and backup registers are no more accessible via debugger.</td>
</tr>
<tr>
<td>Level 2</td>
<td>Device closed</td>
</tr>
<tr>
<td></td>
<td>All data and code stored in the device or encrypted in external Flash memory cannot be dumped clear-text, debugged or traced.</td>
</tr>
</tbody>
</table>

1. Only applicable when TrustZone security is activated in the product.
2. External Flash memory area decrypted on-the-fly with OTFDEC peripheral.

### 3.12.2 Software intellectual property protection with OTFDEC

As described in Section 3.9.3, the OTFDEC associated with the OCTOSPI is able to decrypt on the fly, the encrypted images stored in external SPI Flash memories.

Thanks to this feature, the devices allow the installation of intellectual properties, in one of the following ways:

- over the air, with the image already encrypted with a key provisioned in the device
- through a provisioning host located in a trusted or a non-trusted environment/facility

*Figure 14* illustrates this last case, with the provisioning, in a non-trusted environment, of software intellectual properties both in the embedded Flash memory and in an external SPI Flash memory (encrypted).

**Note:** Since the OTFDEC uses the AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed, the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR Flash memory.
Provisioning

Assuming the device is virgin, the first step is to provision both Flash memories, as detailed below:

1. The user creates a SFI image, composed of:
   - encrypted internal firmware and data (including external Flash memory drivers)
   - encrypted external firmware and data AES key (up to 4)
   - encrypted external firmware and data image

2. The secure bootloader stored in the system memory, loads the second part of the secure bootloader in SRAM2, through the supported communication ports (USART, SPI, I2C, FDCAN, USB and JTAG). This second part runs in the secure SRAM2 and is responsible for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.

3. The internal Flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES keys. Alternatively, device unique external firmware AES keys can be used instead of such global keys.
4. The OTFDEC is properly initialized with encrypted region information, including the corresponding external firmware and data AES key.

5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in the OTFDEC.

6. After a chunk OTFDEC re-encryption, the user external Flash memory programmer is responsible for programming the last encrypted chunks to the external SPI Flash memories through the OCTOSPI.

**Secure boot**

After provisioning, each time the device initializes on a trusted firmware, the following actions are required:

1. Secure-boot firmware executes, programming the external firmware and data AES keys to the OTFDEC write-only key registers, along with the other needed information.

2. The application reads or executes the encrypted external firmware and data through the Octo-SPI in Memory mapped mode, unless a tamper event is detected. In this case, all OTFDEC keys are erased and encrypted regions are read as zero until the OTFDEC is properly initialized again.

For more information on SFI solutions for the devices, refer to the application note *Overview secure firmware install (SFI)* (AN4992).

### 3.12.3 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.

- Non-invasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels such as timing, power and EM emissions.
# Boot modes

At startup, a BOOT0 pin, nBOOT0 and NSBOOTADDx[24:0]/SECBOOTADD0[24:0] option bytes are used to select the boot memory address that includes:

- Boot from any address in user Flash memory.
- Boot from system memory (bootloader).
- Boot from any address in embedded SRAM.
- Boot from root security service (RSS).

The BOOT0 value may come from the PH3-BOOT0 pin or from an option bit depending on the value of a user option bit to free the GPIO pad if needed.

The bootloader, located in the system memory, is used to reprogram the Flash memory by using USART, I2C, SPI, FDCAN or USB_FS in device mode through the DFU (device firmware upgrade).

*Table 22 and Table 23* detail the boot modes when TrustZone is disabled or enabled.

### Table 22. Boot modes when TrustZone is disabled (TZEN = 0)

<table>
<thead>
<tr>
<th>nBOOT0 FLASH_OPTR[27]</th>
<th>BOOT0 pin PH3</th>
<th>nSWBOOT0 FLASH_OPTR[26]</th>
<th>Boot address option-byte selection</th>
<th>Boot area</th>
<th>ST programmed default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>0</td>
<td>1</td>
<td>NSBOOTADD0[24:0]</td>
<td>Boot address defined by user option bytes NSBOOTADD0[24:0]</td>
<td>Flash: 0x0800 0000</td>
</tr>
<tr>
<td>-</td>
<td>1</td>
<td>1</td>

</tr>
<tr>
<td>0</td>
<td>-</td>
<td>0</td>
<td>NSBOOTADD1[24:0]</td>
<td>Boot address defined by user option bytes NSBOOTADD1[24:0]</td>
<td>Bootloader: 0x0BF9 0000</td>
</tr>
</tbody>
</table>

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address.

A unique boot entry option can be selected by setting the BOOT_LOCK option bit. All other boot options are ignored.
The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on Flash read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure Flash memory or the non-secure Flash memory depending on TrustZone security option as described in the table below.

### Table 23. Boot modes when TrustZone is enabled (TZEN = 1)

<table>
<thead>
<tr>
<th>BOOT_LOCK</th>
<th>nBOOT0 FLASH_OPTR[27]</th>
<th>BOOT0 pin</th>

<td>SECBOOTADD0 [24:0]</td>
<td>Flash: 0x0C00 0000</td>
<td></td>
</tr>
</tbody>
</table>

The boot address option bytes are used to program any boot memory address. However, the allowed address space depends on Flash read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced either in the secure Flash memory or the non-secure Flash memory depending on TrustZone security option as described in the table below.

### Table 24. Boot space versus RDP protection

</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The BOOT0 value (either coming from the pin or the option bit) is latched upon reset release. It is up to the user to set nBOOT0 or BOOT0 values to select the required boot mode.

The BOOT0 pin or user option bit (depending on nSWBOOT0 in FLASH_OPTR) is also resampled when exiting Standby mode. Consequently, the BOOT0 pin or user option bit must be kept in the required boot mode configuration in Standby mode. After startup delay, the selection of the boot area is done before releasing the processor reset.
PH3/BOOT0 GPIO is configured as follows:

- in input mode during the complete reset phase if the option bit nSWBOOT0 is set in FLASH_OPTR, and then switches automatically in analog mode after reset is released (BOOT0 pin)
- in input mode from the reset phase to the completion of the option byte loading if the bit nSWBOOT0 is cleared into FLASH_OPTR (BOOT0 value coming from the option bit), and then switches automatically to the analog mode even if the reset phase is not complete

**Embedded bootloader**

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note *STM32 microcontroller system memory boot mode* (AN2606).

**Embedded root security services (RSS)**

The embedded RSS are located in the secure information block, programmed by ST during production. Refer to the application note *Overview secure firmware install (SFI)* (AN4992).
5 Global TrustZone controller (GTZC)

5.1 Introduction

This section describes the global TrustZone controller (GTZC) block that contains the following sub-blocks:

- **TZSC**: TrustZone security controller
  This sub-block defines the secure/privileged state of slave peripherals. It also controls the sub-region area size and properties for the watermark memory peripheral controller (MPCWM). The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.

- **MPCBB**: memory protection controller - block based
  This sub-block configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.

- **TZIC**: TrustZone illegal access controller
  This sub-block gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These sub-blocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- on-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- off-chip memories with secure and/or privileged areas

5.2 GTZC main features

The GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, TZIC and MPCBB
- TZIC accessible only with secure transactions
- Secure and non-secure access supported for privileged and unprivileged part of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged regions for external memories and internal backup SRAM
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

GTZC TrustZone system architecture

The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located
- a non-secure or public world (such as usual non secure operating system and user space)
The TrustZone architecture is extended beyond AHB and Armv8-M with:

- AHB/APB bridge used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards APB agents
- PPC (peripheral protection controller) used as secure gate to block or propagate secure/non-secure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards internal SRAMs
- TrustZone watermark MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards external memories

AHB and APB Peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **non-secure and unprivileged**: peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/non-secure and/or privileged/unprivileged.

**Application information**

The TZSC, MPCBB and TZIC can be used in one of the following ways:

- programmed during secure boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. Same remark applies to the GTZC_TZSC_SECCFGRx/PRIVCFGRx registers that define secure/privileged state of each peripheral.
The Armv8-M security architecture with secure, securable and TrustZone-aware peripherals is shown in the figure below.

5.4 GTZC functional description

5.4.1 GTZC block diagram

The figure below describes the combined feature of TZSC, MPCBB and TZIC. Each sub-block is controlled by its own AHB configuration port.

The TZSC defines which peripheral is secure and/or privileged. The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (non-secure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given ram block can be modified only with a secure privileged transaction if the same RAM block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 16. GTZC block diagram
5.4.2 Illegal access definition

Three different types of illegal access exist:

- **Illegal non-secure access**
  
  Any non-secure transaction trying to write a secure resource is considered as illegal and thus the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. However some exceptions exist on secure and privileged configuration registers: these later ones authorize non secure read access to secure registers (see GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx).

- **Illegal secure access**
  
  Any secure transaction trying to access non-secure block in internal block-based SRAM or watermarked memory is considered as illegal.

  Correct TZIC settings allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write and execute access.

  Concerning the MPCBB controller, there is an option to ignore secure data read/write access on non-secure SRAM blocks, by setting the SRWILADIS bit in the GTZC_MPCBBz_CR register. Secure read and write data transactions are then allowed on non-secure SRAM blocks, while secure execution access remains not allowed.

  Any secure execute transaction trying to access a non-secure peripheral register is considered as illegal and generate a bus error.

- **Illegal unprivileged access**
  
  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write access. The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated. A bus error is generated when any unprivileged execute transaction tries to access a privileged memory.

5.4.3 TrustZone security controller (TZSC)

The TZSC is composed of a configurable set of registers, providing the following features:

- **Control of secure and privileged state for all peripherals**, done through:
  
  - GTZC_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  
  - GTZC_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals

- **For watermark memory protection controller (external memories and backup SRAM)**, two independent regions can be defined and the following fields are used to program:
  
  - the start of the first protected sub-region on external memory/backup SRAM: SUBA_START[10:0]
  
  - the length of the first protected sub-region on external memory/backup SRAM: SUBA_LENGTH[11:0]
  
  - the start of the second protected sub-region on external memory/backup SRAM: SUBB_START[10:0]
  
  - the length of the second protected sub-region on external memory/backup SRAM: SUBB_LENGTH[11:0]
A control register for each sub-region can be used to enable/disable the watermark memory protection controller as well as defining the right attributes of each sub-region.

**Figure 17. Watermark memory protection controller (region x/sub-regions A and B)**

In the figure above, region x represents the external memory or backup SRAM region (such as FSMC bank, OCTOSPI1, OCTOSPI2 or BKPSRAM). Secure and privileged attributes of sub-regions A and B are independently configurable. When no sub-regions are defined or enabled on the region x, then the default attribute of the region x is set as “secure-privileged”.

The tables below describe the secure/privileged properties of the common area of sub-region A and B when an overlap exists.

**Table 30. Secure properties of sub-regions A and B**

<table>

</table>
5.4.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAM memories. The security and privileged policy can be individually configured per each 512-byte block of SRAM.

Figure 18. MPCBB block diagram

In order to setup the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC_MPCBBz_PRIVCFGRx.

A MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC_MPCBBz_CFGLOCKR1. This lock remains active until the next system reset.

Note: The block size is 512 bytes. The super-block size is 512 * 32 = 16 Kbytes.

5.4.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 1).

TZIC allows the trace (flag) of which event triggered the secure illegal access interrupt. Register masks (GTZC_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC_TZIC_SRx and GTZC_TZIC_FCRx). The reset value of mask registers (GTZC_TZIC_IERx) is such that all events are masked.

5.4.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to non-secure and unprivileged.
For internal SRAMx (x = 1 to 4), all GTZC_MPCBBz_SECCFGRx and GTZC_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 1).
- to 0x0000 0000, making these internal memories block non-secure and unprivileged by default when TrustZone security is disabled at system level (TZEN = 0)

For external memories and backup SRAM, all GTZC_TZSC_MPCWMxzR registers are set:

- to 0x0000 0000, making these memories secure and privileged by default when TrustZone security is enabled at system level (TZEN = 1).
- to 0x0800 0000, making these memories non-secure and non-privilege by default when TrustZone security is disabled at system level (TZEN = 0)

Secure boot code can then program the security settings, making components secure or not as needed.

### 5.5 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when accessed by a non-secure access. The MPCBB and TZSC are TrustZone-aware peripherals, meaning that secure and non-secure registers co-exist within the peripheral.

5.6.7 GTZC1 TZSC privilege configuration register 3 (GTZC1_TZSC_PRIVCFGR3)

Address offset: 0x028
Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when corresponding GTZC1_TZSC_SECCFGR register signal is set to 1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

| Bit 31:23 Reserved, must be kept at reset value. |
| Bit 22 RAMCFGPRIV: privileged access mode for RAMCFG |
| Bit 21 OCTOSPI2_REGPRIV: privileged access mode for OCTOSPI2 |
| Bit 20 OCTOSPI1_REGPRIV: privileged access mode for OCTOSPI1 |
| Bit 19 FSMC_REGPRIV: privileged access mode for FSMC registers |
| Bit 18 SDMMC2PRIV: privileged access mode for SDMMC1 |

</table>

Bits 31:10  Reserved, must be kept at reset value.

Bit 9  **PRIV**: Privileged sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Privileged and unprivileged accesses are granted in sub-region z.
1: Only privileged accesses are granted in sub-region z of region x.

Bit 8  **SEC**: Secure sub-region z of base region x
This bit is taken into account only if SREN is set.
0: Only non-secure data accesses are granted to sub-region z of region x.
1: Only secure data accesses are granted to sub-region z of region x.
5.6.9 GTZC1 TZSC memory x sub-region A watermark register (GTZC1_TZSC_MPCWMxAR)

Address offset: 0x44 + 0x10 *(x - 1) (x = 1 to 5)
Reset value: 0x0000 0000
The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.
Secure privilege access only.
When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.
When an overlap of sub-region A and B exists, secure/privileged attributes of both sub-regions apply on the common section (see Section 5.4.3: TrustZone security controller (TZSC))

<td>0</td>
</tr>
</tbody>
</table>

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 SRLOCK: Sub-region z lock
This bit, once set, can be cleared only by a system reset.
0: GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR can be written.
1: Writes to GTZC1_TZSC_MPCWMxCFGR, GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR are ignored.

Bit 0 SREN: Sub-region z enable
0: Sub-region z is disabled. Access control of base region x applies to any access between this sub-region start- and end-addresses.
1: Sub-region z of region x is enabled. Access control defined in GTZC1_TZSC_MPCWMxCFGR applies to any access between this sub-region start- and end-addresses, both defined in GTZC1_TZSC_MPCWMxAR and GTZC1_TZSC_MPCWMxBR.
Note: External memories that are watermark controlled start fully non-secure/unprivileged at reset when TZEN = 0. When TZEN = 1, external memories start fully secure/fully privileged (inverted reset-value).
Bits 27:16  **SUBA_LENGTH[11:0]**: Length of sub-region A in region x
This field defines the length of the sub-region A, to be multiplied by the granularity defined in Table 28.
When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.
If SUBA_LENGTH = 0, the sub-region A is disabled (SREN bit in GTZC1_TZSC_MPCMWxACFGR is cleared).

Bits 15:11  Reserved, must be kept at reset value.

Bits 10:0  **SUBA_START[10:0]**: Start of sub-region A in region x
This field defines the address offset of the sub-region A, to be multiplied by the granularity defined in Table 28, versus the start of the region x.
External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).
5.6.10 **GTZC1 TZSC memory x sub-region B watermark register (GTZC1_TZSC_MPCWMxBR)**

Address offset: 0x4C + 0x10 *(x - 1) (x = 1, 2, 5)  
Reset value: 0x0000 0000  
The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.  
Secure privilege access only.  
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.  
When an overlap of sub-region A and B exists, secure/privileged attributes of both sub-regions apply on the common section (see Section 5.4.3: TrustZone security controller (TZSC))

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBB_LENGTH[11:0]: Length of sub-region B in region x**

This field defines the length of the sub-region B, to be multiplied by the granularity defined in Table 28.
When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.
If SUBB_LENGTH = 0, the sub-region B is disabled. (SREN bit in GTZC1_TZSC_MPCWMxBCFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBB_START[10:0]: Start of sub-region B in region x**

This field defines the address offset of the sub-region B, to be multiplied by the granularity defined in Table 28, versus the start of the region x.
External memories that are watermark controlled, start fully non-secure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).

Refer to Table 26: GTZC1 sub-blocks address offset.
5.7 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000
Reset value: 0x0000 0000
Secure privileged access only.

This register is used to enable interrupt of illegal access.

Reset value

Refer to Table 26: GTZC1 sub-blocks address offset.
5.8 GTZC1 MPCBBz registers (z = 1 to 3)

All registers are accessed only by words (32-bit).

5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

<table>
<thead>
<tr>

</tbody>
</table>
5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1  
(GTZC1_MPCBBz_CFGLOCKR1) (z = 1 to 3)

Address offset: 0x010
Reset value: 0x0000 0000
Secure privileged access only.

Bits 31:0 SPLCKy: Security/privilege configuration lock for super-block (y = 31 to 0)
This bit is set by software and can be cleared only by system reset.
0: GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy can be written.
1: Writes to GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy are ignored

5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x  
register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3)

Address offset: 0x100 + 0x04 * x, (x = 0 to 31)
Reset value: 0xFFFF FFFF
The given reset value is valid when TZEN = 1. The reset value is 0x0000 0000 when  
TZEN = 0.
Write access to this register is secure only. Any read is allowed.

Bits 31:0 SECy: Security configuration for block y (y = 31 to 0)
0: Non-secure access only to block y, belonging to super-block x. Secure access is also  
allowed if the SRWILADIS bit is set in GTZC1_MPCBBz_CR.
1: Secure access only to block y, belonging to super-block x.
Unprivileged write to this bit is ignored if PRIVy bit is set in GTZC1_MPCBBz_PRIVCFGRx.  
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCKR1.
5.8.4 **GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3)**

Address offset: $0x200 + 0x04 \times x$, (x = 0 to 31)

Reset value: $0xFFFFFFFF$

The given reset value is valid when TZEN = 1. The reset value is $0x0000 0000$ when TZEN = 0.

Write access to this register is privileged only. Any read is allowed.

Bits 31:1 Reserved, must be kept at reset value.
5.9.2 GTZC2 TZSC secure configuration register 1
(GTZC2_TZSC_SECCFGR1)

Address offset: 0x010
Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when corresponding GTZC2_TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.9.3 GTZC2 TZSC privilege configuration register 1 (GTZC2_TZSC_PRIVCFGR1)

Address offset: 0x020
Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privilege transaction when corresponding GTZC2_TZSC_SECCFGR register signal is set to 1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

Refer to Table 27: GTZC2 sub-blocks address offset.

5.10 GTZC2 TZIC registers

All registers are accessed only by words (32-bit).

5.10.1 GTZC2 TZIC interrupt enable register 1 (GTZC2_TZIC_IER1)

Address offset: 0x000
Reset value: 0x0000 0000
Secure privilege access only.
This register is used to enable interrupt of illegal access.
Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **ADF1IE**: illegal access interrupt enable for ADF1
0: interrupt disabled
1: interrupt enabled

Bit 11 **DAC1IE**: illegal access interrupt enable for DAC1
0: interrupt disabled
1: interrupt enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **VREFBUFIE**: illegal access interrupt enable for VREFBUF
0: interrupt disabled
1: interrupt enabled

Bit 8 **ADC4IE**: illegal access interrupt enable for ADC4
0: interrupt disabled
1: interrupt enabled

Bit 7 **COMPIE**: illegal access interrupt enable for COMP
0: interrupt disabled
1: interrupt enabled

Bit 6 **OPAMPIE**: illegal access interrupt enable for OPAMP
0: interrupt disabled
1: interrupt enabled

Bit 5 **LPTIM4IE**: illegal access interrupt enable for LPTIM4
0: interrupt disabled
1: interrupt enabled

Bit 4 **LPTIM3IE**: illegal access interrupt enable for LPTIM3
0: interrupt disabled
1: interrupt enabled

Bit 3 **LPTIM1IE**: illegal access interrupt enable for LPTIM1
0: interrupt disabled
1: interrupt enabled

Bit 2 **I2C3IE**: illegal access interrupt enable for I2C3
0: interrupt disabled
1: interrupt enabled

Bit 1 **LPUART1IE**: illegal access interrupt enable for LPUART1
0: interrupt disabled
1: interrupt enabled

Bit 0 **SPI3IE**: illegal access interrupt enable for SPI3
0: interrupt disabled
1: interrupt enabled
5.10.2 GTZC2 TZIC interrupt enable register 2 (GTZC2_TZIC_IER2)

Address offset: 0x004
Reset value: 0x0000 0000

Secure privileged access only.

Refer to Table 27: GTZC2 sub-blocks address offset.

#### Bit 31 SRWILADIS: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a non-secure blocks of the block-based SRAM (secure fetch on non-secure block is always considered illegal).

0: enabled, secure read/write access not allowed on non-secure SRAM block
1: disabled, secure read/write access allowed on non-secure SRAM block
Bit 30 **INVSECSTATE**: SRAMx clocks security state  
This bit is used to define the internal SRAMs clocks control in RCC as secure or not.  
0: SRAMs clocks are secure if a secure area exists in the MPCBB. It is non secure if there is no secure area.  
1: SRAMs clocks are non-secure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: lock the control register of the MPCBB until next reset  
This bit is cleared by default and once set, it can not be reset until system reset.  
0: control register not locked  
1: control register locked

### 5.11.2 GTZC2 SRAM4 MPCBB configuration lock register 1

**(GTZC2_MPCBB4_CFGLOCKR1)**

Address offset: 0x010  
Reset value: 0x0000 0000

Secure privileged access only.

Table 38. GTZC2 MPCBB4 register map and reset values

Refer to Table 27: GTZC2 sub-blocks address offset.
6 RAMs configuration controller (RAMCFG)

6.1 Introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1, SRAM2, SRAM3, SRAM4, and BKPSRAM).

6.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Error code correction (ECC):
  - Single error detection and correction with interrupt generation
  - Double error detection with interrupt or NMI generation
  - Status with failing address

- Write protection (1-Kbyte granularity)
- Programmable wait states for voltage scaling range 4
- SRAM software erase

6.3 RAMCFG functional description

6.3.1 Internal SRAMs features

Five SRAMs are embedded in the devices, each with specific features:

- SRAM1, SRAM2, SRAM3 are the main SRAMs. SRAM4 is in the SRAM used for peripherals low-power background autonomous mode (LPBAM) in Stop 2 mode. These SRAMs are made of several blocks that can be powered down in Stop mode to reduce consumption:
  - SRAM1: three 64-Kbyte blocks (total 192 Kbytes)
  - SRAM2: 8-Kbyte + 56-Kbyte blocks (total 64 Kbytes). In addition SRAM2 blocks can be retained in Standby mode.
  - SRAM3: eight 64-Kbyte blocks (total 512 Kbytes)
  - SRAM4: 16-Kbyte

The backup SRAM (BKPSRAM) can be retained in all low-power modes and when V_{DD} is off in V_{BAT} mode. Refer to Section 10: Power control (PWR) for more details.

- All internal SRAMs are erased by hardware in case of Readout protection (RDP) level regression to Level 0.5 or Level 0. Refer to Section 7: Embedded Flash memory (FLASH) for more details.

- SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the Flash memory user option bytes. SRAM1, SRAM3 and SRAM4 are erased when a system reset occurs if the SRAM134_RST option bit is selected in the Flash memory.
user option bytes. Refer to Section 7: Embedded Flash memory (FLASH) for more details.

- SRAM2 and optionally backup SRAM are protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a Backup domain reset. Refer to Section 55: Tamper and backup registers (TAMP) for more details.

- The RAMCFG embeds the registers related to the internal SRAMs ECC, write protection, wait state configuration and software erase.

The table below summarizes the features supported by each internal SRAM

**Table 39. Internal SRAMs features**

1. Optional: BKPSRAM can be configured to be erased or not on tamper detection.

### 6.3.2 Error code correction (SRAM2, SRAM3, BKPSRAM)

The ECC is supported by SRAM2, SRAM3 and BKPSRAM when enabled with the SRAM2_ECC, SRAM3_ECC and BKPRAM_ECC user option bits. Refer to Section 7: Embedded Flash memory (FLASH) for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing two bits error detection and one bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is \(WSC[2:0] + 2\) AHB clock cycles (refer to Section 6.3.4: Read access latency).

**Caution:** In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when SRAM is no more accessed).
Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDC/CSED C bits are set in the RAMCFG memory interrupt status register (RAMCFG_MxISR) and RAMCFG memory x interrupt clear register x (RAMCFG_MxICR) respectively. An interrupt is generated if enabled by the SEIE bit in the RAMCFG memory x interrupt enable register (RAMCFG_MxIER). The failing address is stored in the RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR) if the ALE bit is set in the RAMCFG memory x control register (RAMCFG_MxCR).

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, the DED and CDED bits are set in the RAMCFG memory interrupt status register (RAMCFG_MxISR) and RAMCFG memory x interrupt clear register x (RAMCFG_MxICR) respectively. An interrupt or NMI is generated if enabled by the DEIE or ECCNMI bit in the RAMCFG memory x interrupt enable register (RAMCFG_MxIER). The failing address is stored in the RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR) if the ALE bit is set in the RAMCFG memory x control register (RAMCFG_MxCR).

Caution: Double errors cannot be detected when the DED bit is set.

SRAM3 ECC specific management

When the ECC is enabled for SRAM3, only the first 256 Kbytes of SRAM3 are with ECC. The next 192 Kbytes are without ECC, and the last block is used to store the ECC, so cannot be used for application.
The figure below shows the SRAM areas, when SRAM2 and SRAM3 ECC are enabled.

**Figure 19. SRAM1, SRAM2 with ECC and SRAM3 with ECC memory map**

When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in the related RAMCFG memory x control register (RAMCFG_MxCR).

The ECC can be deactivated by executing the following software sequence:
1. Write 0xAE in the RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR).
2. Write 0x75 in the RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR).
3. Write 0 in the ECCE bit of the RAMCFG memory x control register (RAMCFG_MxCR).

When ECC is deactivated (ECCE = 0), the SRAM3 ECC storage area can be read and written for ECC user test purpose. When the ECC is activated (ECCE = 1), this area is reserved for ECC storage purpose and cannot be read nor written.

### 6.3.3 Write protection (SRAM2)

The SRAM2 is made of 64 1-Kbyte pages. Each 1-Kbyte page can be write-protected by setting its corresponding PxWP (x = 0 to 63) bit in the RAMCFG memory 2 write protection register 1 (RAMCFG_M2WPR1) and RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2).
6.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states must be correctly programmed in the WSC[2:0] field of the RAMCFG memory x control register (RAMCFG_MxCR), depending on AHB clock frequency (HCLK) and voltage scaling range, as shown in the table below.

<table>
<thead>
<tr>
<th>Wait states (WS) (Latency)</th>
<th>HCLK (MHz)</th>
<th>VCORE range 1</th>
<th>VCORE range 2</th>
<th>VCORE range 3</th>
<th>VCORE range 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 AHB cycle)</td>
<td>≤ 160</td>
<td>≤ 110</td>
<td>≤ 55</td>
<td>≤ 16</td>
<td></td>
</tr>
<tr>
<td>1 WS (2 AHB cycle)</td>
<td></td>
<td>-</td>
<td>-</td>
<td>≤ 25</td>
<td></td>
</tr>
</tbody>
</table>

1. LPBAM: low-power background autonomous mode. The system clock can be requested in Stop mode to perform DMA transfers.

6.3.5 Software erase

SRAM erase can be requested by executing this software sequence:
1. Write 0xCA in the RAMCFG memory x erase key register (RAMCFG_MxERKEYR).
2. Write 0x53 in the RAMCFG memory x erase key register (RAMCFG_MxERKEYR).
3. Write 1 in the SRAMER bit of the RAMCFG memory x control register (RAMCFG_MxCR).

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is ongoing.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is ongoing, wait states are inserted on the AHB bus until the end of the erase operation.

6.4 RAMCFG low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. RAMCFG interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The content of RAMCFG registers is kept. The ECC is functional and ECC error interrupt or NMI causes the device to exit from Stop 0 and Stop 1 modes.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RAMCFG peripheral is powered down and must be reinitialized after exiting Standby.</td>
</tr>
</tbody>
</table>
6.5 RAMCFG interrupts

The table below gives the list of RAMCFG interrupt requests.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>

1. Stop 0 and Stop 1 modes only

6.6 RAMCFG registers

In the registers described below, x refers to:
- SRAM1/2/3/4 when x = 1/2/3/4 respectively
- BKPSRAM when x = 5

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x040 * (x - 1), (x = 1 to 5)
Reset value: 0x0000 000X
ECCE reset value depends on ECC enable user option bit.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 WSC[2:0]: Wait state configuration
This field is used to program the number of wait states inserted on the AHB when reading the SRAM, depending on its access time.
000: 0 wait state
001: 1 wait state
... 111: 7 wait states (not needed)

Bits 15:9 Reserved, must be kept at reset value.
Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation on going
1: Erase operation on going

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in the SRAMx ECC single/double error address registers
1: Failing address stored in the SRAMx ECC single/double error address registers

*Note*: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 control registers.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable.

This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.

0: ECC disabled
1: ECC enabled

*Note*: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 control registers.

### 6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER)

**Address offset**: 0x004 + 0x040 * (x - 1), (x = 2, 3, 5)

**Reset value**: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCNMI**: Double error NMI

This bit is set by software and cleared only by a global RAMCFG reset.

0: NMI not generated in case of ECC double error
1: NMI generated in case of ECC double error

*Note*: if ECCNMI is set, the RAMCFG maskable interrupt is not generated whatever DEIE bit value.

---

240/3040  RM0456 Rev 1
Bit 2  Reserved, must be kept at reset value.
Bit 1  **DEIE**: ECC double error interrupt enable
  0: Double error interrupt disabled
  1: Double error interrupt enabled
Bit 0  **SEIE**: ECC single error interrupt enable
  0: Single error interrupt disabled
  1: Single error interrupt enabled

### 6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR)

Address offset: 0x008 + 0x040 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

Bit 8  **SRAMBUSY**: SRAM busy with erase operation
  0: No erase operation on going
  1: Erase operation on going

*Note: Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or readout protection regression. Refer to Table 39: Internal SRAMs features.*

Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **DED**: ECC double error detected
  0: No double error
  1: Double error detected

*Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 interrupt status registers.*

Bit 0  **SEDC**: ECC single error detected and corrected
  0: No single error
  1: Single error detected and corrected

*Note: This bit is reserved and must be kept at reset value in SRAM1 and SRAM4 interrupt status registers.*
6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)

Address offset: 0x00C + 0x040 * (x - 1), (x = 2, 3, 5)
Reset value: 0x0000 0000

Refer to Section 2.3 for the register boundary addresses.
7 Embedded Flash memory (FLASH)

7.1 Introduction

The Flash memory interface manages accesses to the Flash memory, maximizing throughput to the CPU, instruction cache and DMAs. It implements the Flash memory erase and program operations as well as the read and write protection mechanisms. It also implements the security and privilege access control features. It is optimized in terms of power consumption with dedicated modes when the MCU is in low-power modes.

7.2 FLASH main features

- Up to 2 Mbytes of Flash memory supporting read-while-write capability (RWW).
- Memory organization
  - Dual bank architecture (bank 1 and bank 2)
  - Main memory: up to 1 Mbyte per bank
  - Information block: 64.5 Kbytes in bank 1
- 128-bit wide data read with prefetch
- Standard and burst programming modes
- Read, program and erase operations in all voltage ranges
- 10 kcycles endurance on all Flash memory. 100 kcycles on 256 Kbytes per bank
- Page erase, bank erase and mass erase (both banks)
- Bank swapping: the user Flash memory address mapping of each bank can be swapped.
- Product security activated by TrustZone option bit (TZEN)
- Device life cycle managed by readout protection option byte (RDP)
- Four write protection areas (two per bank)
- TrustZone support:
  - Two secure areas (1 per bank)
  - Two secure HDP (hide protection) areas part of the secure areas (one per bank)
- Configurable protection against unprivileged accesses with Flash page granularity
- Error code correction: 9 bits ECC per 128-bit quad-word allowing two bits error detection and one bit error correction
- Option-byte loader
- Advanced low-power modes (low-power read mode, bank power-down mode)
7.3 FLASH functional description

7.3.1 Flash memory organization

The Flash memory has the following main features:

- Capacity up to 2 Mbytes
- Dual-bank mode:
  - 1 Mbyte per bank for main memory
  - 8 Kbytes page size
  - 137 bits wide data read and write (128 effective bits plus 9 ECC bits)
  - Page, bank and mass erase

The Flash memory is organized as follows:

- Main memory block organized as two banks of 1 Mbyte each containing 128 pages of 8 Kbytes
- An information block containing:
  - 32 Kbytes for system memory. This area is immutable and reserved for use by STMicroelectronics. It contains the bootloader that is used to reprogram the Flash memory through one of the user communication interfaces such as USB (DFU). The system memory is programmed by STMicroelectronics when the device is manufactured. For further details, refer to the application note STM32 microcontroller system memory boot mode (AN2606).
  - 32 Kbytes immutable secure area containing the root security services (RSS and RSS library) developed by STMicroelectronics
  - 512 bytes OTP (one-time programmable) bytes for user data (32 quad-words). The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire quad-word cannot be written anymore, even with the value 0x0000 0000 0000 0000 0000 0000 0000.
  - option bytes for user configuration. Unlike user Flash memory and system memory, it is not mapped to any memory address and can be accessed only through the Flash register interface.

The memory organization is based on a main area and an information block as shown in the table below.

<table>

</tbody>
</table>
Note: The secure information block is only accessible when TrustZone is active.

7.3.2 Error code correction (ECC)

Data in Flash memory are 137-bit words: Nine bits are added per quad-word (128 bits). The ECC mechanism supports:

- one error detection and correction
- two errors detection

When one error is detected and corrected, the ECCC flag (ECC correction) is set in the FLASH ECC register (FLASH_ECCR). If the ECCCIE bit is set, an interrupt is generated.

When two errors are detected, the ECCD flag (ECC detection) is set in the FLASH ECC register (FLASH_ECCR). In this case, a NMI is generated.

When an ECC error is detected, the address of the failing quad-word and its associated bank are saved in ADDR_ECC[19:0] and BK_ECC in the FLASH ECC register (FLASH_ECCR). ADDR_ECC[3:0] are always cleared.

When ECCC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Caution: When the ECCC flag is set, a further two-errors detection is not able to generate the NMI or break signal to timers. It is therefore recommended to clear the ECC flag as soon as a correction is operated, to preserve the ECC error detection capability. In case of a double ECC error detection (ECCD flag set and NMI triggered), the software must clean the cache in the NMI handler.

Note: For an erased Flash line, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

The following addresses in the system Flash memory are used to store words including ECC errors to allow run-time tests by software on ECC correction detection capability:

- 0x0BFA1F00 (embeds a word with 1-bit error)
- 0x0BFA1F80 (embeds a word with 2-bit error)

In case the second address is read, for instance by the debugger memory viewer, a NMI is generated.

7.3.3 Read access latency

To correctly read data from Flash memory, the number of wait states (latency) must be correctly programmed in the FLASH access control register (FLASH_ACR) according to the

<table>

</tbody>
</table>

The Flash memory supports a low-power read mode when setting the LPM bit in the FLASH access control register (FLASH_ACR). The table below shows the correspondence between wait states and CPU clock frequency when LPM bit is set.

Table 46. Number of wait states according to CPU clock (HCLK) frequency (LPM = 1)

<table>
<thead>
<tr>
<th>Wait states (WS) (Latency)</th>
<th>HCLK (MHz)</th>
<th>$V_{\text{CORE}}$ range 1/2/3</th>
<th>$V_{\text{CORE}}$ range 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 CPU cycle)</td>
<td></td>
<td>$\geq \text{HCLK (MHz)} / 10 -1$</td>
<td>$\leq 8$</td>

</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 4 MHz, 0 wait state (WS) is configured in the FLASH access control register (FLASH_ACR) and the normal read mode is selected (LPM = 0).

Instruction prefetch

The Cortex-M33 fetches instructions and literal pools (constants/data) over the C-Bus and through the instruction cache if it is enabled. The prefetch block aims at increasing the efficiency of C-Bus accesses in case the instruction cache is enabled by reducing the cache refill latency. Prefetch is efficient in case of sequential code; prefetch in the Flash memory allows the next sequential instruction line to be read from the Flash memory while the current instruction line is being filled in instruction cache and executed by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the FLASH access control register (FLASH_ACR). PRFTEN must be set only if at least one wait state is needed to access the Flash memory.

Note: Prefetch tends to increase the code execution performance at the cost extra Flash memory accesses. It must be used carefully in low-power applications.
When changing the CPU frequency, the software sequences detailed below must be applied in order to tune the number of wait states needed to access the Flash memory.

**Increase the CPU frequency**

1. Program the new number of wait states to the LATENCY bits in the *FLASH access control register (FLASH_ACR)*.
2. Check that the new number of wait states is taken into account to access the Flash memory by reading back the *FLASH access control register (FLASH_ACR)*.
3. Modify the CPU clock source by writing the SW bits in the RCC_CFGR1 register.
4. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR1 and RCC_CFGR2 registers.

**Decrease the CPU frequency**

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGR1 register.
2. Modify the CPU clock prescaler, if needed, by writing the HPRE bits in RCC_CFGR2.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR1 and RCC_CFGR2 registers.
4. Program the new number of wait states to the LATENCY bits in the *FLASH access control register (FLASH_ACR)*.
5. Check that the new number of wait states is used to access the Flash memory by reading back the *FLASH access control register (FLASH_ACR)*.

The software sequences detailed below must be applied in order to modify the read mode.

**From normal read mode to low-power read mode**

1. Set the LPM bit in the *FLASH access control register (FLASH_ACR)*.
2. Check that the low-power read mode is activated by reading the *FLASH access control register (FLASH_ACR)*.

**From low-power read mode to normal read mode**

1. Reset the LPM bit in the *FLASH access control register (FLASH_ACR)*.
2. Check that the normal read mode is activated by reading the *FLASH access control register (FLASH_ACR)*.

**7.3.4 Bank power-down mode**

After reset, both banks are in normal mode. In order to reduce power consumption, each bank can be independently put in power-down mode by setting the PDREQx bit in the *FLASH access control register (FLASH_ACR)*.
Request entry in power-down mode for bank x

- Check that bank x is not in power-down mode and no request to put it in power-down mode is pending (PDx bit in FLASH non-secure status register (FLASH_NSSR) and PDREQx bit in FLASH access control register (FLASH_ACR) must be reset).
- Unlock PDKEYxR with correct keys. Refer to FLASH bank 1 power-down key register (FLASH_PDKEY1R) or FLASH bank 2 power-down key register (FLASH_PDKEY2R).
- Set the PDREQx bit in the FLASH access control register (FLASH_ACR).
- Check that the PDx bit in the FLASH non-secure status register (FLASH_NSSR) is set. The PDREQx bit in the FLASH access control register (FLASH_ACR) is automatically reset and the PDKEYxR is locked.

Note: If bank x is currently being accessed, the power-down request is delayed until the access is completed.

Requesting power-down entry for a bank already in power-down mode has no effect. The PDREQx bit in the FLASH access control register (FLASH_ACR) is automatically reset and the PDKEYxR is locked.

Return to normal mode

Any access to a bank in power-down mode automatically wakes up the bank. A penalty of 5 µs minimum is taken to wake up the bank.

Wake up bank 1 (respectively bank 2) is done in one of the following cases:
- upon a valid read access to bank 1 (resp. bank 2)
- upon a valid write access to bank 1 (resp. bank 2)
- upon a valid bank erase on bank 1 (resp. bank 2)

Waking up both bank 1 and bank 2 is done in one of the following cases:
- upon a valid mass erase
- upon an option byte modification
- upon an option byte loading
- upon system reset

Note: The software can reduce the Flash bank wake-up time by enabling HSI16 before waking up the bank.

7.3.5 Flash memory program and erase operations

The embedded Flash memory can be programmed using in-circuit programming or in-application programming.

The in-circuit programming (ICP) method is used to update the entire contents of the Flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, in-application programming (IAP) can use any communication interface supported by the microcontroller (such as I/Os, USB, CAN, UART, I2C or SPI) to download programming data into the memory. IAP allows the user to re-program the Flash memory while the application is running. Nevertheless, part of the application must have been previously programmed in the Flash memory using ICP.

An ongoing Flash memory operation does not block the CPU as long as the CPU does not access the same Flash memory bank. Code or data fetches are possible on one bank while
a write/erase operation is performed to the other bank (refer to Section 7.3.10: Read-while-write (RWW)).

On the contrary, during a program/erase operation to the Flash memory, any attempt to read the same Flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has been completed.

The MCU supports TrustZone that defines secure and non-secure areas in the Flash memory. All program and erase operations can be performed in secure mode through the secure registers or in non-secure mode through the non-secure registers. For more information, refer to Section 7.5: FLASH TrustZone security and privilege protections.

Unlock the secure/non-secure Flash control registers

After reset, write is not allowed in the Flash control registers (FLASH secure control register (FLASH_SECCR) and FLASH non-secure control register (FLASH_NSCR)) in order to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances.

The following sequence is used to unlock these registers:
1. Write KEY1 = 0x45670123 in the FLASH secure key register (FLASH_SECKEYR) or FLASH non-secure key register (FLASH_NSKEYR).
2. Write KEY2 = 0xCDEF89AB in the FLASH secure key register (FLASH_SECKEYR) or FLASH non-secure key register (FLASH_NSKEYR).

Any wrong sequence locks up the FLASH secure control register (FLASH_SECCR) or FLASH non-secure control register (FLASH_NSCR) register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a hard fault interrupt is generated.

The FLASH_NSCR (resp. FLASH_SECCR) register can be locked again by software by setting the LOCK bit in the FLASH_NSCR (resp. FLASH_SECCR) register.

Note: The FLASH_NSCR and FLASH_SECCR registers cannot be written when the BSY bits are set. Any attempt to write them with the BSY bits set, causes the AHB bus to stall until the BSY bits are cleared.

Wait for data-to-write flags (WDW)

The WDW flags in the FLASH non-secure status register (FLASH_NSSR) and FLASH secure status register (FLASH_SECSR) are both set when a secure or non-secure write access has been done in the write buffer. They are cleared when the BSY flags are set (meaning that the write buffer is freed and the programming operation actually starts in the Flash memory) or in case of error.

It is the software responsibility to ensure that the four words in the same quad-word are all written.
Flash secure and non-secure busy flags

The BSY flags in the Flash non-secure status register (FLASH_NSSR) and Flash secure status register (FLASH_SECSR) are both set when a secure or non-secure Flash operation is started:

- **Erase operation:** setting the STRT bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR)
- **Write operation:** setting the PG bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR) and writing a quad-word in the Flash memory
- **Option-byte programming:** setting the OPTSTRT in the FLASH non-secure control register (FLASH_NSCR)

7.3.6 Flash main memory erase sequences

The Flash memory erase operation can be performed at page level, bank level or on the whole Flash memory (mass erase). Mass erase does not affect the information block (system Flash, OTP and option bytes). The erase operation is either secure or non-secure.

**Page erase**

To erase a page, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the PER bit and select the page to erase (PNB) with the associated bank (BKER) in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR).
4. Set the STRT bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR).
5. Wait for the BSY bit to be cleared in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR).

**Bank 1 or bank 2 mass erase**

To perform a bank mass erase, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 or MER2 bit (depending on the bank) in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR). Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the STRT bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR).
5. Wait for the BSY bit to be cleared in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

6. The MER1 or MER2 bits can be cleared if no more bank erase is requested.

**Mass erase**

To perform a mass erase, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

2. Check and clear all non-secure error programming flags due to a previous programming. If not, the PGSERR bit is set.

3. Set the MER1 bit and MER2 bits in the **FLASH non-secure control register (FLASH_NSCR)** or **FLASH secure control register (FLASH_SECCR)**.

4. Set the STRT bit in the **FLASH non-secure control register (FLASH_NSCR)** or **FLASH secure control register (FLASH_SECCR)**.

5. Wait for the BSY bit to be cleared in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

6. The MER1 and MER2 bit can be cleared if no more mass erase is requested.

**Note:** The internal oscillator HSI16 (16 MHz) is enabled automatically when the STRT bit is set, and disabled automatically when the STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

To erase a page, a bank or to perform a mass erase, the software must have sufficient privilege (see Table 64 and Table 65).

**7.3.7 Flash main memory programming sequences**

The Flash memory is programmed 137 bits at a time (128-bit data + 9 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets the PROGERR flag in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

It is only possible to program quad-word (4 x 32-bit data).

- Any attempt to write byte or half-word sets the SIZERR flag in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

- Any attempt to write a quad-word that is not aligned with a quad-word address sets the PGAERR flag in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.
Flash programming

The Flash memory programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the BSY bit in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR).
2. Check that the write buffer is empty by checking the WDW bit in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR).
3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
4. Set the PG bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR).
5. Perform the data write operation at the desired Flash memory address, or in the OTP area. Only a quad-word can be programmed and OTP can be only programmed in non-secure access:
   - Write a first word in an address aligned on a quad-word address. The WDW bits in the FLASH non-secure status register (FLASH_NSSR) and FLASH secure status register (FLASH_SECSR) are set to indicate that more data can be written in the write buffer.
   - Write the second, third and fourth word in the same quad-word.
6. The BSY bit gets set. WDW is reset automatically.
7. Wait until the BSY bit is cleared in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR). The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.
8. If the EOP flag is set in the FLASH non-secure status register (FLASH_NSSR) or FLASH secure status register (FLASH_SECSR) (meaning that the programming operation has succeeded and the EOPIE bit is set), it must be cleared by software.
9. Clear the PG bit in the FLASH non-secure control register (FLASH_NSCR) or FLASH secure control register (FLASH_SECCR) if there is no more programming request.

Note: When the Flash memory interface received a good sequence (a quad-word), programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

No option bytes modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected. Refer to Section 7.7: Summary of Flash memory and Flash memory registers access control.

If the user needs to program only one word, the quad-word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the quad-word to program.
Flash burst programming (8 quad-words)

The Flash memory burst programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the BSY bit in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

2. Check that the write buffer is empty by checking the WDW bit in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**.

3. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.

4. Set the BWR and PG bits in the **FLASH non-secure control register (FLASH_NSCR)** or **FLASH secure control register (FLASH_SECCR)**.

5. Perform the data write operation at the desired Flash memory address, or in the OTP area. Only 8 quad-words can be programmed:
   - Write a first 32-bit word in an address aligned on a 8*quad-word address (multiple of 0x80). The WDW bits in the **FLASH non-secure status register (FLASH_NSSR)** and **FLASH secure status register (FLASH_SECSR)** are set to indicate that more data can be written in the write buffer.
   - Write the 31 other 32-bit words consecutively.

6. The BSY bit gets set. WDW is reset automatically.

7. Wait until the BSY bit is cleared in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)**. The software must make sure that BSY is set or WDW is cleared before waiting for BSY to get cleared.

8. If the EOP flag is set in the **FLASH non-secure status register (FLASH_NSSR)** or **FLASH secure status register (FLASH_SECSR)** (meaning that the programming operation has succeeded and the EOPIE bit is set), it has to be cleared by software.

9. Clear the BWR and PG bits in the **FLASH non-secure control register (FLASH_NSCR)** or **FLASH secure control register (FLASH_SECCR)** if there is no more programming request.

*Note:* When the Flash memory interface received a good sequence, programming is automatically launched and the BSY bits are set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

No option bytes modification nor erase request is allowed when the WDW bit is set.

Programming is possible only if the privileged and security attributes are respected. Refer to Section 7.7: Summary of Flash memory and Flash memory registers access control.

### 7.3.8 Flash memory endurance

Each Flash memory page can be written and erased 10 000 times. In addition, up to 256 Kbytes (32 pages) per bank feature an increased endurance of 100 kcycles, that can be used for data storage that usually needs more intensive cycling capability than code storage. Any Flash page can be chosen to be cycled more than 10 000 times (up to 100 000 times). It is the application responsibility to limit the size of the Flash area cycled more than 10 000 times to 256 Kbytes per bank.
7.3.9 Flash memory errors flags

Flash programming errors

Several kind of errors can be detected during secure and non-secure operations. In case of error, the Flash memory operation (programming or erasing) is aborted.

The secure errors flags are only set during a secure operation and non-secure flags are only set during a non-secure operation.

- **PROGERR**: secure/non-secure programming error
  It is set when the word to program is pointing to an address:
  - not previously erased
  - already fully programmed to 0
  - already partially programmed (contains 0 and 1) and the new value to program is not full zero
  - for OTP programming, when the address is already partially programmed (contains 0 and 1)

- **SIZERR**: secure/non-secure size programming error
  Only 32-bit data can be written. SIZERR flag is set if a byte or a half-word is written.

- **PGAERR**: secure/non-secure alignment programming error
  It is set when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address.
  For burst programming, it is set when the first word to be programmed is not aligned on a 8 *quad-word address or if the following word writes are not done at consecutive 32-bit addresses.

- **PGSERR**: programming sequence error
  PGSERR is set if one of the following conditions occurs during a erase or program operation:
  - A data is written when PG is cleared.
  - A program operation is requested during erase: PG is set while MER1 or MER2 or PER is set.
  - In the erase sequence, PG is set while STRT is already set.
  - In the erase sequence, if STRT is set while MER1 and MER2 and PER are cleared.
  - If page and mass erase are requested at the same time, STRT and PER are set while MER1 or MER2 is set.
  - If an operation is started while the write buffer is waiting for the next data, STRT or OPTSTRT is set while WDW is already set.
  - If STRT and OPTSTRT are set at the same time.
  - A non-secure PGSERR is set if the non secure STRT bit is set by a secure access.
  - A secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR or PGSERR is already set due to a previous programming error.
  - A non-secure PGSERR is set if PROGERR, SIZERR, PGAERR, WRPERR, PGSERR or OPTWERR is already set due to a previous programming error.

- **WRPERR**: write protection error
  - Refer to *Table 59* to *Table 62* for all the conditions of WRPERR flag setting.
• **OPTWERR**: option bytes write error

OPTWERR is set if when user option bytes are modified with an invalid configuration. It is set when attempting:

– to program an invalid secure watermark-based area. Refer to Table 50
– to set or clear the TZEN option bit when RDP is not at correct level (refer to Rules for modifying specific option bytes)
– to clear the BOOT_LOCK option bit when RDP is not at correct level (refer to Rules for modifying specific option bytes)
– to modify SWAP_BANK option bit while BOOT_LOCK and TZEN are set
– to modify SECBOOTADD0 option bit while BOOT_LOCK is set
– to modify DUALBANK option bit while BOOT_LOCK and TZEN are set
– to modify SECWM1Rx (resp. SECWM2Rx) while HDP1_ACCDIS (resp. HDP2_ACCDIS) is set
– to modify the option bytes, except the SWAP_BANK option bit, when RDP is set to two
– to regress from RDP level 0.5 to RDP level 0
– to modify OEM1KEYRx while RDP level is 0.5 or 1 and OEM1LOCK bit is set
– to modify OEM2KEYRx while RDP level is 1 and OEM2LOCK bit is set
– to regress from RDP level 1 to RDP level 0 while OEM1LOCK bit is set and a wrong OEM1KEY is shifted through JTAG or SWD
– to regress from RDP level 1 to RDP level 0.5 while OEM2LOCK bit is set and a wrong OEM2KEY is shifted through JTAG or SWD
– to modify WRPxyR while its UNLOCK bit is cleared
– to set the UNLOCK bit in the WRPxyR when RDP is not at correct level (refer to Rules for modifying specific option bytes)

If an error occurs during a secure or non-secure program or erase operation, one of the following programming error flags is set:

• non-secure programming error flags: PROGERR, SIZERR, PGAERR, PSGERR, OPTWRERR or WRPERR is set in the *FLASH non-secure status register (FLASH_NSSR)*.

If the non-secure error interrupt enable bit ERRIE is set in the *FLASH non-secure control register (FLASH_NSCR)*, an interrupt is generated and the operation error flag OPERR is set in the FLASH_NSSR register.

• Secure programming error flags: PROGERR, SIZERR, PGAERR, PSGERR or WRPERR is set in the *FLASH secure status register (FLASH_SECSR)*.

If the secure error interrupt enable bit ERRIE is set in the *FLASH secure control register (FLASH_SECCR)*, an interrupt is generated and the operation error flag OPERR is set in the FLASH_SECSR register.

**Note:** If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.

Any programming error flushes the write buffer.
7.3.10 **Read-while-write (RWW)**

The Flash memory is divided into two banks allowing read-while-write operations. This feature allows a read operation to be performed from one bank while erase or program operation is performed to the other bank.

*Note:* Write-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

**Read from bank 1 while page erasing in bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa).

**Read from bank 1 while mass erasing bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa).

**Read from bank 1 while programming bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2 (and vice versa).

*Note:* Due to the Cortex-M33 unified C-Bus, user software must ensure to not stall C-Bus with multiple consecutive writes. It is recommended to wait for the BSY flag to be cleared before programming the next quad-word.

7.3.11 **Power-down during Flash programming or erase operation**

The contents of the Flash memory currently being accessed are not guaranteed if a power-down occurs during a Flash memory program or erase operation.

7.3.12 **Reset during Flash programming or erase operation**

The contents of the Flash memory currently being accessed are not guaranteed if a reset occurs during a Flash memory program or erase operation. The status of the Flash memory can be recovered from the *FLASH operation status register (FLASH_OPSR)* when a system reset occurs during a Flash memory program or erase operation.

It is the software responsibility to check the status of the Flash memory and to take corrective actions. This must be done after each system reset before any other programming or erase operation is performed.

The table below describes the corrective action to be taken according to the status provided in the CODE_OP field of the *FLASH operation status register (FLASH_OPSR)*.

<table>
<thead>
<tr>
<th>CODE_OP</th>
<th>Operation interrupted</th>
<th>Address</th>
<th>Bank</th>
<th>System Flash</th>
<th>Corrective action</th>
</tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: For single and burst write, it is mandatory to perform a page erase because the current Flash memory locations may no longer be writable. Consequently, the remaining page content must be saved before page erase and restored afterwards.

For OTP write, it is not possible to perform a page erase. The OTP quad-word is lost.

For burst write, ADDR_OP gives the first address of burst. User must restart the same burst operation.

For page erase, ADDR_OP gives the first address of erased page.
7.4 FLASH option bytes

7.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode (refer to Section 7.4.2: Option-byte programming). The user option bytes are accessible through the Flash memory registers interface.

The table below describes the organization of all user option bytes available in the Flash memory interface registers.

Table 48. User option-byte organization mapping

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  | Register map |

7.4.2 Option-byte programming

After reset, the options related to the operation bits OPTSTRT and OBL_LAUNCH in the FLASH_NSCR register, are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the FLASH non-secure control register (FLASH_NSCR) must be cleared.

The following sequence is used to unlock this register:

1. Unlock the FLASH_NSCR register with the LOCK clearing sequence (refer to Unlock the secure/non-secure Flash control registers).
2. Write OPTKEY1 = 0x08192A3B in the FLASH_OPTKEYR register.
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If the LOCK bit in FLASH_NSCR is set by software, OPTLOCK is automatically set too.

Option bytes modification sequence

To modify the user options value, follow the procedure below:

1. Check that no Flash memory operation is on going by checking the BSY bit in the FLASH_NSSR register.
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers.
4. Set the options start bit OPTSTRT in the FLASH_NSCR register.
5. Wait for the BSY bit to be cleared.
6. Set the OBL_LAUNCH option bit to start option bytes loading.

Note: If the OPTWERR or PGSERR error bit is set, the old option byte values are kept.

Option byte loading

After the BSY bit is cleared, all new options are updated into the Flash memory but they are not applied to the system. They affect the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- when OBL_LAUNCH bit is set in the FLASH non-secure control register (FLASH_NSCR)
- after a power reset (BOR reset or exit from Standby/Shutdown modes)

On system reset rising, internal option registers are copied into option registers. These registers are also used to modify the option bytes. If these registers are not modified by user, they reflect the options state of the system.

Rules for modifying specific option bytes

Some of the option byte field must respect specific rules before being updated with new values. These option bytes, as well as the associated constraints, are described below:

- TZEN option bit
  - TZEN can only be set on RDP level 0.
  - Deactivation of TZEN is only possible when RDP is changing from level 1 to level 0.
• **BOOT_LOCK** option bit
  – **BOOT_LOCK** has only effect when TZEN is set.
  – **BOOT_LOCK** can be set without any constraint.
  – Deactivation of **BOOT_LOCK** is only possible when RDP is level 0.

• **SWAP_BANK** option bit
  – It cannot be modified when **BOOT_LOCK** and TZEN option bits are set.

• **SECBOOTADD0** option bytes
  – It cannot be modified when **BOOT_LOCK** option bit is set.

• **DUALBANK** option bit
  – It cannot be modified when **BOOT_LOCK** and TZEN option bits are set.

• **SECWMxRy** option bits
  – It is not possible to modify secure (SECWMx_PSTRT[6:0] and SECWMx_PEND[6:0] option bits), and HDP (HDPx_PEND[6:0] and HDPxEN option bits) area in bank x when the HDPx_ACCDIS bit is set.

• **RDP** option bits
  – Refer to *Device life cycle managed by readout protection (RDP) transitions*.

• **WRPxyR** option bits
  – These bits cannot be modified when their UNLOCK bit is cleared.

• **UNLOCK** option bits
  – These bits can be set only when regressing from RDP level 1 to level 0.

If the user options modification tries to set or modify one of the listed option bytes without following their associated rules, the option bytes modification is discarded and the OPTWERR error flag is set.

### 7.5 FLASH TrustZone security and privilege protections

#### 7.5.1 TrustZone security protection

The global TrustZone system security is activated by setting the TZEN option bit in the FLASH_OPTR register.

When TrustZone is active (TZEN = 1), the following additional security features are available:

• Secure watermark-based user options bytes defining secure and HDP areas
• Secure or non-secure block-based areas can be configured on-the-fly after reset. This is a volatile secure area.
• An additional RDP protection: RDP level 0.5
• Erase or program operation can be performed in secure or non-secure mode with associated configuration bit.

When the TrustZone is disabled (TZEN = 0), the above features are deactivated and all secure registers are RAZ/WI.
Activate TrustZone security

When the TrustZone is activated (TZEN is modified from 0 to 1), the secure watermark-based user options bytes are set to default secure state: all Flash memory is secure, and no HDP area, as shown in the table below.

<table>
<thead>
<tr>
<th>Secure watermark option bytes values after OBL when TZEN is activated (from 0 to 1)</th>
<th>Security attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECWMx_PSTRT = 0 and SECWMx_PEND = 0x7F</td>
<td>All Flash memory secure</td>
</tr>
<tr>
<td>HDPxEN = 0 and HDPx_PEND = 0</td>
<td>No secure HDP area</td>
</tr>
</tbody>
</table>

Illegal access generation

A non-secure access to a secure Flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in the TZIC_IER2 register.

A non-secure access to a secure Flash register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in the TZIC_IER2 register.

Deactivate TrustZone security

Deactivation of TZEN (from 1 to 0) is only possible when the RDP is changing from level 1 to level 0.

When the TrustZone is deactivated (TZEN is modified from 1 to 0) after option bytes loading, the following security features are deactivated:

- Watermark-based secure area (refer to Section 7.5.2)
- Block-based secure area (refer to Section 7.5.4)
- RDP level 0.5 (refer to Section 7.6.2: Readout protection (RDP))
- Secure interrupts (refer to Section 7.8: FLASH interrupts)
- All secure registers are RAZ/WI

7.5.2 Watermark-based secure Flash memory area protection

When TrustZone security is active (TZEN = 1), a part of the Flash memory can be protected against non-secure read and write accesses. Up to two different non-volatile secure areas can be defined by option bytes and can be read or written by a secure access only: one area per bank can be selected with a page granularity.

The secure areas are defined by a start-page offset and end-page offset using the SECWMx_PSTRT and SECWMx_PEND (x=1,2 for area 1 and area 2) option bytes. These offsets are defined in the secure watermark registers address registers FLASH secure watermark1 register 1 (FLASH_SECWM1R1) and FLASH secure watermark2 register 1 (FLASH_SECWM2R1).

The SECWMx_PSTRT and SECWMx_PEND option bytes can only be modified by secure firmware when the HDPx_ACCDIS bit is reset. If the HDPx_ACCDIS bit is set, the SECWMx_PSTRT and SECWMx_PEND cannot be modified until next system reset.
Caution: Switching a Flash memory area from secure to no-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to non-secure attribute whenever is needed. It is also recommended to flush the instruction cache.

### 7.5.3 Secure hide protection (HDP)

The secure HDP area is part of the Flash memory watermark-based secure area. Access to the hide protection area can be denied by setting the HDPx_ACCDIS bit in the `FLASH secure HDP control register (FLASH_SECHDPCR)`.

When the HDPx_ACCDIS bit is set, instruction fetch, data read, write and erase operations on this hide protection area are denied. For example, software code in the secure Flash hide protected area can be executed only once and deny any further access to this area until next system reset. The HDPx_ACCDIS bit can be only cleared by a system reset.

**Note:** It is the software responsibility to take any appropriate action to protect the HDP code before resetting the HDPxEN bit such as erasing the HDP area and flushing the instruction cache.

One non-volatile secure hide protection (HDP) area per bank can be defined with a page granularity.

The secure HDP area is enabled by the HDPxEN (x = 1,2 for area 1 and area 2). When the HDPxEN bit is reset, there is no HDP area. The HDPxEN bit can be set or reset on the fly by the secure firmware if the HDPx_ACCDIS bit is reset. If the HDPx_ACCDIS bit is set, the HDPxEN bit and secure watermark configuration cannot be modified until next system reset.

The secure HDP area size is defined by the end-page offset using the HDPx_PEND option bytes while the start-page offset is already defined by SECWMx_PSTRT option bytes. These offsets are defined in the secure watermark registers address registers: `FLASH secure watermark1 register 1 (FLASH_SECWM1R1)`, `FLASH secure watermark1 register 2 (FLASH_SECWM1R2)`, `FLASH secure watermark2 register 1 (FLASH_SECWM2R1)` and `FLASH secure watermark2 register 2 (FLASH_SECWM2R2)`.

---

Table 50. Secure watermark-based area

<table>
<thead>
<tr>
<th>Secure watermark option bytes values (x = 1,2)</th>
<th>Secure watermark protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECWMx_PSTRT &gt; SECWMx_PEND</td>
<td>No secure area</td>
</tr>
<tr>
<td>SECWMx_PSTRT = SECWMx_PEND</td>
<td>One page defined by SECWMx_PSTRT is secure watermark-based protected</td>
</tr>
<tr>
<td>SECWMx_PSTRT &lt; SECWMx_PEND</td>
<td>The area between SECWMx_PSTRT and SECWMx_PEND is secure watermark-based protected.</td>
</tr>
</tbody>
</table>
For example, to protect by HDP from the address 0x0C00 4000 (included) to the address 0x0C00 5FFF (included):

- If the banks are not swapped, the option bytes registers must be programmed with:
  - SECWM1_PSTRT = 0x2
  - HDP1_PEND = 0x3
- If the two banks are swapped, the protection must apply to bank 2 and the option bytes registers must be programmed with:
  - SECWM2_PSTRT = 0x2
  - HDP2_PEND = 0x3

**Note:** For more details on the bank swapping mechanism, refer to Section 7.5.8.

If an invalid secure HDP area is defined as described in the table below, the OPTWERR flag error is set and option bytes modification is discarded.

### Table 51. Secure hide protection

<table>
<thead>
<tr>
<th>HDPxEN = 0</th>
<th>-</th>
<th>HDPxEN = 1</th>
<th>SECWMx_PSTRT ≤ HDPx_PEND ≤ SECWMx_PEND</th>
<th>Others</th>
<th>Hide protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>No secure HDP area</td>
<td>-</td>
<td>The area between SECWMx_PSTRT and HDPx_PEND is secure HDP protected.</td>
<td>Invalid secure area. Hide protection area is defined outside the secure area.</td>
<td></td>
</tr>
</tbody>
</table>

The table below summarizes the possible secure and HDP protection area configurations.

### Table 52. Secure and HDP protections

<table>
<thead>
<tr>
<th>HDPxEN</th>
<th>Option bytes</th>
<th>Protections area</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>SECWMx_PSTRT &gt; SECWMx_PEND</td>
<td>No secure area</td>
</tr>
</tbody>
</table>
| 0      | SECWMx_PSTRT ≤ SECWMx_PEND | No secure HDP area
|        | - If SECWMx_PSTRT = SECWMx_PEND, one page defined by SECWMx_PSTRT is secure protected. |
| 1      | SECWMx_PSTRT ≤ HDPx_PEND ≤ SECWMx_PEND | The area between SECWMx_PSTRT and HDPx_PEND is secure HDP protected.
|        | - If SECWMx_PSTRT = HDPx_PEND, one page defined by HDPx_PEND is secure HDP protected. |
| Others | Invalid secure area
|        | HDP area is defined outside the secure area. |

### 7.5.4 Block-based secure Flash memory area protection

Any page can be programmed on the fly as secure or non-secure using the block-based configuration registers. FLASH_SECBB1Rx (resp. FLASH_SECBB2Rx) registers are used to configure the security attribute for pages in bank 1 (resp. bank 2).
When the page security attribute, bit i in SECyBBRx, is set, the security attribute is the same as the secure watermark-based area. The secure page is only accessible by a secure access.

If the SECyBBi bit is set or reset for a page already included in a secure watermark-based area, the page keeps the watermark-based protection security attributes.

To modify a block-based page security attribution, the following actions are recommended:
- Check that no Flash memory operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in SECyBBRx.

Caution: Switching a page or memory block from secure to non-secure does not erase the content of the associated block. User secure software must perform the following needed operations before switching a block to non-secure attribute:
- Erase page content,
- Invalidate the instruction cache.

Note: For SECyBBRx bit i access control, refer to Table 66: SECyBBRx registers access when TrustZone is active (TZEN = 1).

7.5.5 Flash security attribute state

The Flash memory is secure when at least one secure area is defined either by watermark-based option bytes or block-based security registers.

It is possible to override the Flash security state using the INV bit in the FLASH_SECCR register.

The FLASHEN and FLASHSMEN bits security attributes in RCC follow the Flash memory security attribute. It is possible to override the Flash memory security attribute in RCC using the INV bit in the FLASH_SECCR register. A secure firmware setting this INV bit allows a non-secure firmware to disable the Flash memory clock when the Flash memory is in power down or when the MCU enters low-power modes.

<table>
<thead>
<tr>
<th>Secure area</th>
<th>INV bit</th>
<th>Flash security state</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>0</td>
<td>Non-secure</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Secure</td>
</tr>
<tr>
<td>Yes</td>
<td>0</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Non-secure</td>
</tr>
</tbody>
</table>

7.5.6 Block-based privileged Flash memory area protection

Any page can be programmed on the fly as privileged or unprivileged using the block-based configuration registers. FLASH_PRIVBB1Rx (resp. FLASH_PRIVBB2Rx) registers are used to configure the privilege attribute for pages in bank 1 (resp. bank 2).

When the page privilege attribute, bit i in PRIVyBBRx, is set, the page is only accessible by a privileged access. An unprivileged page is accessible by a privileged or unprivileged access.
To modify a block-based privilege attribution, the following actions are recommended:

- Check that no Flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute bit i in PRIVyBBRx.

Caution: Switching a page or memory block from privileged to unprivileged does not erase the content of the associated block.

Note: For PRIVyBBRx bit i access control, refer to Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1) and Table 68: PRIVyBBRx registers access when TrustZone is disabled (TZEN = 0).

7.5.7 Flash memory registers privileged and unprivileged modes

The Flash memory registers can be read and written by privileged and unprivileged accesses depending on the SPRIV and NSPRIV bits in FLASH privilege configuration register (FLASH_PRIVCFGR), with the following rules:

- When the SPRIV (resp. NSPRIV) bit is reset, all secure (resp. non-secure) Flash memory registers can be read and written by both privileged or unprivileged access.
- When the SPRIV (resp. NSPRIV) bit is set, all secure (resp. non-secure) Flash memory registers can be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

Table 63: Flash registers access summarizes the Flash memory registers access control.

7.5.8 Flash memory bank attributes in case of bank swap

The SWAP_BANK option bit modifies the address of each bank in the memory map. When SWAP_BANK is reset, the Flash memory bank 1 is at the lower address range. When SWAP_BANK is set, the Flash memory bank 1 is at the higher address range.

Flash memory bank attributes follow their bank so there is no need to modify the following registers when swapping banks:

- FLASH secure watermark y register x FLASH_SECWMyRx
- FLASH write protection x area y FLASH_WRPxyR (refer to Section 7.6.1)
- FLASH secure block based bank y register x FLASH_SECyBBRx
- FLASH privilege block based bank y register x FLASH_PRIVyBBRx
- PDREQx bits in the FLASH access control register (FLASH_ACR)
- PDx bits in the FLASH non-secure status register (FLASH_NSSR)

Note: The BK_ECC bit in the FLASH ECC register (FLASH_ECCR) always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.

The BK_OP bit in the FLASH operation status register (FLASH_OPSR) always refers to bank 1 (resp. bank 2) when it is low (resp. high), whatever SWAP_BANK value.
The figures below show how security attributes and protections behave in case of bank swap.

Figure 20. Flash memory security attributes and protections in case of no bank swap (SWAP_BANK = 0)

Figure 21. Flash memory security attributes and protections in case of bank swap (SWAP_BANK = 1)

7.6 FLASH memory protection

The Flash memory interface implements the following protection mechanisms:

- write protection (WRP)
- readout protection (RDP)
- additional secure protections when TrustZone is active (refer to Section 7.5)
  - up to two secure watermark-based non-volatile areas
  - up to two secure hide protection areas
  - secure block-based volatile areas with page granularity
- privileged block-based volatile areas with page granularity (refer to Section 7.5.6)
7.6.1 Write protection (WRP)

The user area in Flash memory can be protected against unwanted write operations. Two write-protected (WRP) areas can be defined in each bank, with page granularity.

Each area is defined by a start page offset and an end page offset related to the physical Flash bank base address. These offsets are defined in the WRP address registers: FLASH WRP1 area A address register (FLASH_WRP1AR), FLASH WRP1 area B address register (FLASH_WRP1BR), FLASH WPR2 area A address register (FLASH_WRP2AR) and FLASH WPR2 area B address register (FLASH_WRP2BR).

The bank “x” WRP “y” area (x = 1,2 and y = A,B) is defined as follows:

- from the address: bank “x” base address + [WRPxy_PSTRT x 0x2000] (included)
- to the address: bank “x” base address + [(WRPxy_PEND+1) x 0x2000] (excluded)

For example, to protect by WRP from the address 0x0806 2000 (included) to the address 0x0807 3FFF (included):

- If the banks are not swapped, FLASH_WRP1AR register must be programmed with:
  - WRP1A_PSTRT = 0x31
  - WRP1A_PEND = 0x39
  WRP1B_PSTRT and WRP1B_PEND in FLASH_WRP1BR can be used instead (area “B” in bank 1).

- If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  - WRP2A_PSTRT = 0x31
  - WRP2A_PEND = 0x39
  WRP2B_PSTRT and WRP2B_PEND in FLASH_WRP2BR can be used instead (area “B in bank 2).

Note: For more details on the bank swapping mechanism, refer to Section 7.5.8: Flash memory bank attributes in case of bank swap.

When WRP is active, protected Flash memory pages cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted, the secure or non-secure write protection error flag (WRPERR) is set in the FLASH_NSSR or FLASH_SECSR register. This flag is also set for any write access to the following:

- system Flash memory
- OTP area

Note: When the memory readout protection level 1 is selected (RDP level = 1), it is not possible to program or erase the Flash memory (secure or non-secure) if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or system Flash memory, even if WRP is not activated.

When the memory readout protection level 0.5 is selected (RDP level = 0.5), it is not possible to program or erase the Flash secure memory if the CPU debug features are connected (JTAG or single wire), even if WRP is not activated.

Note: To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in the Flash control register.
Write protection lock

Each WRP area can be independently locked by writing 0 to the UNLOCK bit in the FLASH WRP1 area A address register (FLASH_WRP1AR), FLASH WRP1 area B address register (FLASH_WRP1BR), FLASH WPR2 area A address register (FLASH_WRP2AR) or FLASH WPR2 area B address register (FLASH_WRP2BR). Once a WRP area is locked, it is not possible to modify its settings. In order to unlock a WRP area, a regression to RDP level 0 must be launched.

In order to make the WRP area immutable and act as a ROM, the following actions are needed:

- If RDP level is 0, 0.5 or 1, provision a OEM1KEY in order to prevent a regression to RDP level 0 for users not knowing the key.
- If RDP level is 2, either provision a OEM1KEY (refer to first bullet) or do not provision a OEM2KEY (preventing regression from level 2 to level 1).

For more information on RDP regressions, refer to Device life cycle managed by readout protection (RDP) transitions.

</tr>
</tbody>
</table>
Readout protection (RDP)

The readout protection protects the Flash main memory, the option bytes, the backup registers, the backup RAM and the SRAMs.

Readout protection levels when TrustZone is disabled

There are three levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2). The Flash memory is protected according to the RDP option byte value shown in the table below.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>Readout protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>Level 0</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

- Level 0: no protection
  Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.

- Level 1: readout protection
  When the readout protection level 1 is set:
  - **User mode**: code executing in user mode (boot Flash) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
  - **Debug, boot RAM and bootloader modes**: in debug mode or when the microcontroller boots from RAM or system memory, the Flash main memory, the backup registers, the backup RAM and the SRAM2 are totally inaccessible; any read or write access to the Flash main memory generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.

- Level 2: no debug
  When the readout protection level 2 is set:
  - The protection level 1 is guaranteed.
  - All debug features are disabled:
    - if OEM2 key has not been provided, JTAG and SWD are definitively disabled.
    - if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTHDEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
  - The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
  - Only boot from main Flash memory is possible; all operations are allowed on the Flash main memory. Read, erase and program accesses to the Flash memory and SRAMs from user code are allowed.
Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to OEM2 RDP lock mechanism).

Note: The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

</tbody>
</table>

1. When the protection level 2 is active, the debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. Option bytes are only accessible through the Flash registers interface and OPTSTRT bit.
4. The Flash main memory is erased when the RDP option byte changes from level 1 to level 0.
5. SWAP_BANK option bit can be modified.
6. OTP can only be written once.
7. The backup registers are erased when RDP changes from level 1 to level 0.
8. All SRAMs are erased when RDP changes from level 1 to level 0.
9. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0.
Readout protection levels when TrustZone is enabled

There are four levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2). The Flash memory is protected according to the RDP option byte value shown in the table below.

- Level 0: no protection
  Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.
  - **RSS mode:** when booting from RSS, the debug access is disabled while executing RSS code.

- Level 0.5: non-secure debug only
  All read and write operations (if no write protection is set) from/to the non-secure Flash memory are possible. The debug access to secure area is prohibited. Debug access to non-secure area remains possible.
  - **User mode:** code executing in user mode (**boot Flash**) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
  - **Non-secure debug mode:** non-secure debug is possible when the CPU is in non-secure state. The secure Flash memory, the secure backup registers and SRAMs area are inaccessible; the non-secure Flash memory, the non-secure backup registers and the non-secure SRAMs area remain accessible for debug purpose.
  - **RSS mode:** when booting from RSS, the debug access is disabled while executing RSS code.
  - **Boot RAM mode:** boot from SRAM is not possible.

- Level 1: readout protection
  When the readout protection level 1 is set:
  - **User mode:** code executing in user mode (**boot Flash**) can access the Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
  - **Non-secure debug mode:** non-secure debug is possible when the CPU is in non-secure state. However, an intrusion is detected in case of debug access: the Flash main memory, the backup registers, the backup RAM and the SRAM2 are totally inaccessible; any read or write access to the Flash main memory generates a bus fault.

<table>
<thead>
<tr>
<th>RDP byte value</th>

<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>
error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.

- **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.
- **Boot RAM mode**: boot from SRAM is not possible.

- **Level 2: no debug**
  When the readout protection level 2 is set:
  - The protection level 1 is guaranteed.
  - All debug features are disabled
    . if OEM2 key has not been provided, JTAG and SWD are definitively disabled.
    . if OEM2 key has been provided under a lower RDP protection, JTAG and SWD remain enabled under reset only to interface with DBGMCU_SR, DBGMCU_DBG_AUTH_HOST and DBGMCU_DBG_AUTH_DEVICE registers to obtain device identification and provide OEM2 key to request RDP regression.
  - The boot from SRAM (boot RAM mode) and the boot from system memory (boot loader mode) are no longer available.
  - Boot from RSS is possible.
  - When booting from main Flash or RSS, all operations are allowed on the Flash main memory. Read, erase and program accesses to Flash memory and SRAMs from user code are allowed.
  - Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation unless an OEM2 key has been provisioned (refer to OEM2 RDP lock mechanism).

  **Note:** The debug feature is also disabled under reset.
  STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set. Regress parts to RDP level 1 before returning them for analysis (refer to OEM2 RDP lock mechanism).

</table>

<sup>(1)</sup> Refer to OEM2 RDP lock mechanism.
Device life cycle managed by readout protection (RDP) transitions

It is easy to move from level 0 or level 0.5 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 0.5 or from level 1. Once in level 2, it is no longer possible to modify the readout protection level unless an OEM2 key is provisioned (refer to OEM2 RDP lock mechanism).

When the RDP is reprogrammed to the value 0xAA to move from level 1 to level 0, a mass erase of the Flash main memory and all SRAMs is performed. The backup registers, the OTFDEC keys, ICACHE, DCACHE, and PKA SRAM are also erased. The OTP area is not erased.
At RDP level 0.5, it is not possible to request RDP level 0. Instead, a RDP increase to level 1 followed by a RDP regression to level 0 is required.

When the RDP is programmed to the value 0x55 to move from level 1 to level 0.5, a partial mass erase of the Flash main memory is performed. Only non-secure watermark-based areas are erased (even if it is defined as secure by block-based). The backup registers, the OTFDEC keys, ICACHE, DCACHE, PKA SRAM, and all SRAMs are mass erased. The OTP area is not erased. The RDP level 0.5 and partial non-secure erase are only available when TrustZone is active.

Note: **Full mass erase is performed only when level 1 is active and level 0 requested. When the protection level is increased (0 to 0.5, 0 to 1, 0.5 to 1, 1 to 2, 0 to 2 or 0.5 to 2), there is no mass erase.**

To validate the readout protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in FLASH non-secure control register (FLASH_NSCR).

Before launching a RDP regression, the software must invalidate the ICACHE and wait for the BUSYF bit to get cleared.

**Figure 22. RDP level transition scheme when TrustZone is disabled (TZEN = 0)**

- **Level 2**
  - RDP = 0xCC
  - RDP increase + option bytes modification

- **Level 1**
  - RDP ≠ 0xAA and RDP ≠ 0xCC
  - RDP regression (full mass erase) – can be done by debug interface or by bootloader. Regression can be blocked by OEM1 key.

- **Level 0**
  - RDP = 0xAA
  - RDP unchanged + option bytes modification

- **OEM1**
  - Write RDP = 0xAA
  - Mass erase

- **OEM2**
  - Write RDP ≠ 0xAA and RDP ≠ 0xCC
OEM1/OEM2 lock activation

Two 64-bit keys (OEM1KEY and OEM2KEY) can be defined in order to lock the RDP regression. Each 64-bit key is coded on two registers `FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)` (resp. `FLASH OEM2 key register 1 (FLASH_OEM2KEYR1)`), `FLASH OEM1 key register 2 (FLASH_OEM1KEYR2)` (resp. `FLASH OEM2 key register 2 (FLASH_OEM2KEYR2)`). OEM1KEY and OEM2KEY cannot be read through these registers. They are read as zero.

**OEM1KEY** can be modified:
- in readout protection level 0
- in readout protection level 0.5 or 1 if OEM1LOCK = 0 in `FLASH non-secure status register (FLASH_NSSR)`

**OEM2KEY** can be modified:
- in readout protection level 0 or 0.5
- in readout protection level 1 if OEM2LOCK = 0 in `FLASH non-secure status register (FLASH_NSSR)`

When attempting to modify the `FLASH OEM1 key register 1 (FLASH_OEM1KEYR1)`, `FLASH OEM1 key register 2 (FLASH_OEM1KEYR2)` or `FLASH OEM2 key register 1 (FLASH_OEM2KEYR1)`, `FLASH OEM2 key register 2 (FLASH_OEM2KEYR2)` without following these rules, the user option modification is not done and the OPTWERR bit is set.
In order to activate OEM1 lock mechanism, the following steps are needed:

- Check that the OEM1LOCK bit is not set or that the readout protection is at level 0.
- Write a 64-bit key in FLASH OEM1 key register 1 (FLASH_OEM1KEYR1) and FLASH OEM1 key register 2 (FLASH_OEM1KEYR2).
- Launch option modification by setting the OPTSTRT bit in the FLASH non-secure control register (FLASH_NSCR).
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
- Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.
- Check that OEM1LOCK is set.

In order to activate OEM2 lock mechanism, the following steps are needed:

- Check that the OEM2LOCK bit is not set or that the readout protection is at level 0 or 0.5.
- Write a 64-bit key in FLASH OEM2 key register 1 (FLASH_OEM2KEYR1) and FLASH OEM2 key register 2 (FLASH_OEM2KEYR2).
- Launch option modification by setting the OPTSTRT bit in the FLASH non-secure control register (FLASH_NSCR).
- Wait for the BSY bit to be cleared and check that OPTWERR is not set.
- Set the OBL_LAUNCH option bit to start option bytes loading or perform a power-on reset.
- Check that OEM2LOCK is set.

**Note:** The OEM1KEY and OEM2KEY must not contain only 1 or only 0.

**OEM1 RDP lock mechanism**

The OEM1 RDP lock mechanism is active when the OEM1LOCK bit is set. It blocks the RDP level 1 to RDP level 0 regression.

In order to regress from RDP level 1 to RDP level 0, the following unlock sequence must be applied:

- Shift OEM1KEY[31:0] then OEM1KEY[63:32] through JTAG or SWD in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM1KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM1KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 1 to RDP level 0 without following this sequence sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM1LOCK =0), the regression from RDP level 1 to RDP level 0 is always granted.

**OEM2 RDP lock mechanism**

The OEM2 RDP lock mechanism is active when the OEM2LOCK bit is set. It allows the following actions:

- Block RDP level 1 to RDP level 0.5 regression.
- Authorize RDP level 2 to RDP level 1 regression.
In order to regress from RDP level 1 to RDP level 0.5, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM2KEY value, the RDP regression can be launched by setting the OPTSTRT bit.
- If the key does not match the OEM2KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

In order to regress from RDP level 2 to RDP level 1, the following unlock sequence must be applied:

- Shift OEM2KEY[31:0] then OEM2KEY[63:32] through JTAG or SWD under reset in the DBGMCU_DBG_AUTH_HOST register.
- If this key matches the OEM2KEY value:
  - the RDP regression is launched by hardware (it is not possible to execute instructions when the key is matching).
  - apply a power-on reset (cycle V_DD power supply OFF and ON).
- If the key does not match the OEM2KEY value, the RDP regression and any access to the Flash memory are blocked until a next power-on reset.

Attempting to regress from RDP level 2 to RDP level 1 without following these sequences, leaves option bytes unchanged.

Attempting to regress from RDP level 1 to RDP level 0.5 without following these sequences, sets the OPTWERR option bit and the option bytes remain unchanged.

When the lock mechanism is not activated (OEM2LOCK =0), the following happens:

- The regression from RDP level 1 to RDP level 0.5 is always granted.
- The regression from RDP level 2 to RDP level 1 is never granted. When attempting to modify the options bytes, the protection error flag OPTWERR is set in the FLASH_NSSR register and an interrupt can be generated.
### 7.7 Summary of Flash memory and Flash memory registers access control

The tables below summarize all the Flash memory and registers accesses status versus RDP level, WRP and HDP protections.

Table 59. Flash memory access versus RDP level when TrustZone is active (TZEN = 1)

<table>
<thead>
<tr>

7.9 FLASH registers

7.9.1 FLASH access control register (FLASH_ACR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x00
Reset value: 0x0000 0000
Access: no wait state when no Flash memory read is ongoing; word, half-word and byte access

<table>
<thead>
<tr>
<th>Interrupt vector</th>

</tbody>
</table>

1. Secure EOP (resp. non-secure EOP) is set only if secure EOPIE (resp. non-secure EOPIE) is set.
2. Secure OPERR (resp. non-secure OPERR) is set only if secure ERRIE (resp. non-secure ERRIE) is set.
Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **SLEEP_PD**: Flash memory power-down mode during Sleep mode
This bit determines whether the Flash memory is in power-down mode or Idle mode when
the device is in Sleep mode.
0: Flash in Idle mode during Sleep mode
1: Flash in power-down mode during Sleep mode

**Caution:** The Flash must not be put in power-down while a program or an erase operation is
ongoing.

Bit 13  **PDREQ2**: Bank 2 power-down mode request
This bit is write-protected with FLASH_PDKEY2R. This bit requests bank 2 to enter power-
down mode. When bank 2 enters power-down mode, this bit is cleared by hardware and the
PDKEY2R is locked.
0: No request for bank 2 to enter power-down mode
1: Bank 2 requested to enter power-down mode

Bit 12  **PDREQ1**: Bank 1 power-down mode request
This bit is write-protected with FLASH_PDKEY1R. This bit requests bank 1 to enter power-
down mode. When bank 1 enters power-down mode, this bit is cleared by hardware and the
PDKEY1R is locked.
0: No request for bank 1 to enter power-down mode
1: Bank 1 requested to enter power-down mode

Bit 11  **LPM**: Low-power read mode
This bit puts the Flash memory in low-power read mode.
0: Flash not in low-power read mode
1: Flash in low-power read mode

Bits 10:9  Reserved, must be kept at reset value.

Bit 8  **PRFTEN**: Prefetch enable
This bit enables the prefetch buffer in the embedded Flash memory.
0: Prefetch disabled
1: Prefetch enabled

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **LATENCY[3:0]**: Latency
These bits represent the ratio between the HCLK (AHB clock) period and the Flash memory
access time.
0000: Zero wait state
0001: One wait state
0010: Two wait states
...
1111: Fifteen wait states
7.9.2 FLASH non-secure key register (FLASH_NSKEYR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x08
Reset value: 0x0000 0000
Access: one wait state; word access

<table>
<thead>
<tr>
<th>NSKEY[31:16]</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 NSKEY[31:0]: Flash memory non-secure key

The following values must be written consecutively to unlock the FLASH_NSCR register, allowing the Flash memory non-secure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB

7.9.3 FLASH secure key register (FLASH_SECKEYR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x0C
Reset value: 0x0000 0000
Access: one wait state; word access

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:0 SECKEY[31:0]: Flash memory secure key

The following values must be written consecutively to unlock the FLASH_SECCR register, allowing the Flash memory secure programming/erasing operations:
KEY1: 0x4567 0123
KEY2: 0xCDEF 89AB
7.9.4  **FLASH option key register (FLASH_OPTKEYR)**

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x10
Reset value: 0x0000 0000
Access: one wait state; word access

<table>
<thead>
<tr>
<th>OPTKEY[31:16]</th>

</tbody>
</table>

Bits 31:0 **OPTKEY[31:0]**: Option byte key
- The following values must be written consecutively to unlock the FLASH_OPTR register allowing option byte programming/erasing operations:
  - KEY1: 0x0819 2A3B
  - KEY2: 0x4C5D 6E7F

7.9.5  **FLASH bank 1 power-down key register (FLASH_PDCALL1R)**

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x18
Reset value: 0x0000 0000
Access: no wait state; word access

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:0 **PDKEY[31:0]**: Bank 1 power-down key
- The following values must be written consecutively to unlock the PDREQ1 bit in FLASH_ACR:
  - PDKEY1_1: 0x0415 2637
  - PDKEY1_2: 0xFAFB FCFD
7.9.6  **FLASH bank 2 power-down key register (FLASH_PDKEY2R)**

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x1C
Reset value: 0x0000 0000
Access: no wait state; word access

<table>
<thead>
<tr>
<th>Address offset: 0x1C</th>

</tbody>
</table>

Bits 31:0 **PDKEY2[31:0]**: Bank 2 power-down key
The following values must be written consecutively to unlock the PDREQ2 bit in FLASH_ACR:
PDKEY2_1: 0x4051 6273
PDKEY2_2: 0xAFBF CFDF

7.9.7  **FLASH non-secure status register (FLASH_NSSR)**

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x20
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

<table>

</tr>
</tbody>
</table>
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **PD2**: Bank 2 in power-down mode
This bit indicates that the Flash memory bank 2 is in power-down state. It is reset when bank 2 is in normal mode or being awakened.

Bit 20  **PD1**: Bank 1 in power-down mode
This bit indicates that the Flash memory bank 1 is in power-down state. It is reset when bank 1 is in normal mode or being awakened.

Bit 19  **OEM2LOCK**: OEM2 lock
This bit indicates that the OEM2 RDP key read during the OBL is not virgin. When set, the OEM2 RDP lock mechanism is active.

Bit 18  **OEM1LOCK**: OEM1 lock
This bit indicates that the OEM1 RDP key read during the OBL is not virgin. When set, the OEM1 RDP lock mechanism is active.

Bit 17  **WDW**: Non-secure wait data to write
This bit indicates that the Flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the Flash memory.

Bit 16  **BSY**: Non-secure busy
This indicates that a Flash memory secure or non-secure operation is in progress. This bit is set at the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **OPTWERR**: Option write error
This bit is set by hardware when the options bytes are written with an invalid configuration. It is cleared by writing 1.
Refer to **Section 7.3.9: Flash memory errors flags** for full conditions of error flag setting.

Bits 12:8  Reserved, must be kept at reset value.

Bit 7  **PGSERR**: Non-secure programming sequence error
This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1.
Refer to **Section 7.3.9: Flash memory errors flags** for full conditions of error flag setting.

Bit 6  **SIZERR**: Non-secure size error
This bit is set by hardware when the size of the access is a byte or half-word during a non-secure program sequence. Only quad-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5  **PGAERR**: Non-secure programming alignment error
This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address. This bit is cleared by writing 1.

Bit 4  **WRPERR**: Non-secure write protection error
This bit is set by hardware when a non-secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the Flash memory. This bit is cleared by writing 1.
Refer to **Section 7.3.9: Flash memory errors flags** for full conditions of error flag setting.
Bit 3  **PROGERR**: Non-secure programming error  
This bit is set by hardware when a non-secure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **OPERR**: Non-secure operation error  
This bit is set by hardware when a Flash memory non-secure operation (program/erase) completes unsuccessfullly. This bit is set only if non-secure error interrupts are enabled (NSERRIE = 1). This bit is cleared by writing 1.

Bit 0  **EOP**: Non-secure end of operation  
This bit is set by hardware when one or more Flash memory non-secure operation (program/erase) has been completed successfully. This bit is set only if the non-secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_NSCR). This bit is cleared by writing 1.

### 7.9.8 FLASH secure status register (FLASH_SECSR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x24

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

</table>

Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **WDW**: Secure wait data to write  
This bit indicates that the Flash memory write buffer has been written by a secure or non-secure operation. It is set when the first data is stored in the buffer and cleared when the write is performed in the Flash memory.

Bit 16  **BSY**: Secure busy  
This bit indicates that a Flash memory secure or non-secure operation is in progress. This is set on the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **PGSERR**: Secure programming sequence error  
This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1.

Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.
Bit 6 **SIZERR**: Secure size error
This bit is set by hardware when the size of the access is a byte or half-word during a secure program sequence. Only quad-word programming is allowed by means of successive word accesses. This bit is cleared by writing 1.

Bit 5 **PGAERR**: Secure programming alignment error
This bit is set by hardware when the first word to be programmed is not aligned with a quad-word address, or the second, third or forth word does not belong to the same quad-word address. This bit is cleared by writing 1.

Bit 4 **WRPERR**: Secure write protection error
This bit is set by hardware when a secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the Flash memory. This bit is cleared by writing 1.
Refer to *Section 7.3.9: Flash memory errors flags* for full conditions of error flag setting.

Bit 3 **PROGERR**: Secure programming error
This bit is set by hardware when a secure quad-word address to be programmed contains a value different from all 1 before programming, except if the data to write is all 0. This bit is cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Secure operation error
This bit is set by hardware when a Flash memory secure operation (program/erase) completes unsuccessfully. This bit is set only if secure error interrupts are enabled (SECERRIE = 1). This bit is cleared by writing 1.

Bit 0 **EOP**: Secure end of operation
This bit is set by hardware when one or more Flash memory secure operation (program/erase) has been completed successfully. This bit is set only if the secure end of operation interrupts are enabled (EOPIE = 1 in FLASH_SECCR). This bit is cleared by writing 1.
7.9.9 **FLASH non-secure control register (FLASH_NSCR)**

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access is stalled until the BSY bits are reset.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x28

Reset value: 0xC000 0000

Access: no wait state when no Flash memory operation is ongoing; word, half-word and byte access

<table>

</tbody>
</table>
Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **OPTSTRT**: Options modification start
This bit triggers an options operation when set. It can not be written if OPTLOCK bit is set. This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_NSSR.

Bit 16 **STRT**: Non-secure start
This bit triggers a non-secure erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, the PGSERR bit in FLASH_NSSR is set (this condition is forbidden).
This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_NSSR.

Bit 15 **MER2**: Non-secure bank 2 mass erase
This bit triggers the bank 2 non-secure mass erase (all bank 2 user pages) when set.

Bit 14 **BWR**: Non-secure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Non-secure bank selection for page erase
0: Bank 1 selected for non-secure page erase
1: Bank 2 selected for non-secure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Non-secure page number selection
These bits select the page to erase.
0000000: page 0
0000000: page 1
...
1111111: page 127

Bit 2 **MER1**: Non-secure bank 1 mass erase
This bit triggers the bank 1 non-secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Non-secure page erase
0: Non-secure page erase disabled
1: Non-secure page erase enabled

Bit 0 **PG**: Non-secure programming
0: Non-secure Flash programming disabled
1: Non-secure Flash programming enabled
### 7.9.10 FLASH secure control register (FLASH_SECCR)

This register can only be written when the BSY or OBL_LAUNCH are reset. Otherwise, the write access stalls until the BSY bits are reset.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x2C

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is ongoing; word, half-word and byte access

</table>

**Bit 31 LOCK:** Secure lock
- This bit is set only. When set, the FLASH_SECCR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_SECKEYR register.
- In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

**Bit 30 Reserved, must be kept at reset value.**

**Bit 29 INV:** Flash memory security state invert
- This bit inverts the Flash memory security state.

**Bits 28:26 Reserved, must be kept at reset value.**

**Bit 25 ERRIE:** Secure error interrupt enable
- This bit enables the interrupt generation when the OPERR bit in the FLASH_SECSR is set to 1.
  - 0: Secure OPERR error interrupt disabled
  - 1: Secure OPERR error interrupt enabled

**Bit 24 EOPIE:** Secure End of operation interrupt enable
- This bit enables the interrupt generation when the EOP bit in the FLASH_SECSR is set to 1.
  - 0: Secure EOP Interrupt disabled
  - 1: Secure EOP Interrupt enabled

**Bits 23:17 Reserved, must be kept at reset value.**

**Bit 16 STRT:** Secure start
- This bit triggers a secure erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, the PGSERR in the FLASH_SECSR is set (this condition is forbidden).
- This bit is set only by software and is cleared when the BSY bit is cleared in FLASH_SECSR.

**Bit 15 MER2:** Secure bank 2 mass erase
- This bit triggers the bank 2 secure mass erase (all bank 2 user pages) when set.
Bit 14 **BWR**: Secure burst write programming mode
When set, this bit selects the burst write programming mode.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKER**: Secure bank selection for page erase
0: Bank 1 selected for secure page erase
1: Bank 2 selected for secure page erase

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **PNB[6:0]**: Secure page number selection
These bits select the page to erase:
00000000: page 0
00000001: page 1
...
11111111: page 127

Bit 2 **MER1**: Secure bank 1 mass erase
This bit triggers the bank 1 secure mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Secure page erase
0: Secure page erase disabled
1: Secure page erase enabled

Bit 0 **PG**: Secure programming
0: Secure Flash programming disabled
1: Secure Flash programming enabled

### 7.9.11 FLASH ECC register (FLASH_ECCR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x30
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>

</tr>
<tr>
<td>r  r  r  r  r  r  r  r  r  r  r  r  r  r  r  r</td>
</tr>
</tbody>
</table>
Bit 31  **ECCD**: ECC detection
This bit is set by hardware when two ECC errors have been detected (only if ECCC and ECCD were previously cleared). When this bit is set, a NMI is generated. This bit is cleared by writing 1.

Bit 30  **ECCC**: ECC correction
This bit is set by hardware when one ECC error has been detected and corrected (only if ECCC and ECCD were previously cleared). An interrupt is generated if ECCIE is set. This bit is cleared by writing 1.

Bits 29:25  Reserved, must be kept at reset value.

Bit 24  **ECCIE**: ECC correction interrupt enable
This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is set.
0: ECCC interrupt disabled
1: ECCC interrupt enabled.

Bit 23  Reserved, must be kept at reset value.

Bit 22  **SYSF_ECC**: System Flash memory ECC fail
This bit indicates that the ECC error correction or double ECC error detection is located in the system Flash memory.

Bit 21  **BK_ECC**: ECC fail bank
This bit indicates which bank is concerned by the ECC error correction or by the double ECC error detection.
0: Bank 1
1: Bank 2

Bit 20  Reserved, must be kept at reset value.

Bits 19:0  **ADDR_ECC[19:0]**: ECC fail address
This field indicates which address is concerned by the ECC error correction or by the double ECC error detection. The address is given by bank from address 0x0 0000 to 0xF FFF0.

### 7.9.12  **FLASH operation status register (FLASH_OPSR)**

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x34
Reset value: 0x0000 0000
(0x0000 0000 after system reset and 0x0000 0000 after power-on reset)
Access: no wait state; word, half-word and byte access

### 7.9.13 FLASH option register (FLASH_OPTR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

**Address offset:** 0x40

**Reset value:** 0xXXXX XXXX

(Registers bits 0 to 31 are loaded with values from the Flash memory at OBL)

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

Bit 31  **TZEN**: Global TrustZone security enable
0: Global TrustZone security disabled
1: Global TrustZone security enabled

Bit 30  **IO\_VDDIO2\_HSLV**: High-speed IO at low V\_DDIO2 voltage configuration bit
This bit can be set only with V\_DDIO2 below 2.5 V.
0: High-speed IO at low V\_DDIO2 voltage feature disabled (V\_DDIO2 can exceed 2.5 V)
1: High-speed IO at low V\_DDIO2 voltage feature enabled (V\_DDIO2 remains below 2.5 V)

Bit 29  **IO\_VDD\_HSLV**: High-speed IO at low V\_DD voltage configuration bit
This bit can be set only with V\_DD below 2.5 V
0: High-speed IO at low V\_DD voltage feature disabled (V\_DD can exceed 2.5 V)
1: High-speed IO at low V\_DD voltage feature enabled (V\_DD remains below 2.5 V)

Bit 28  **PA15\_PUPEN**: PA15 pull-up enable
0: USB power delivery dead-battery enabled/TDI pull-up deactivated
1: USB power delivery dead-battery disabled/TDI pull-up activated

Bit 27  **nBOOT0**: nBOOT0 option bit
0: nBOOT0 = 0
1: nBOOT0 = 1

Bit 26  **nSWBOOT0**: Software BOOT0
0: BOOT0 taken from the option bit nBOOT0
1: BOOT0 taken from PH3/BOOT0 pin

Bit 25  **SRAM2\_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs

Bit 24  **SRAM2\_ECC**: SRAM2 ECC detection and correction enable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 23  **SRAM3\_ECC**: SRAM3 ECC detection and correction enable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled

Bit 22  **BKPRAM\_ECC**: Backup RAM ECC detection and correction enable
0: Backup RAM ECC check enabled
1: Backup RAM ECC check disabled

Bit 21  **DUALBANK**: Dual-bank on 1-Mbyte and 512-Kbyte Flash memory devices
0: Single bank Flash with contiguous address in bank 1
1: Dual-bank Flash with contiguous addresses

Bit 20  **SWAP\_BANK**: Swap banks
0: Bank 1 and bank 2 addresses not swapped
1: Bank 1 and bank 2 addresses swapped

Bit 19  **WWDG\_SW**: Window watchdog selection
0: Hardware window watchdog selected
1: Software window watchdog selected

Bit 18  **IWDG\_STDBY**: Independent watchdog counter freeze in Standby mode
0: Independent watchdog counter frozen in Standby mode
1: Independent watchdog counter running in Standby mode
Bit 17  **IWDG_STOP**: Independent watchdog counter freeze in Stop mode  
0: Independent watchdog counter frozen in Stop mode  
1: Independent watchdog counter running in Stop mode

Bit 16  **IWDG_SW**: Independent watchdog selection  
0: Hardware independent watchdog selected  
1: Software independent watchdog selected

Bit 15  **SRAM1345_RST**: SRAM1, SRAM3 and SRAM4 erase upon system reset  
0: SRAM1, SRAM3 and SRAM4 erased when a system reset occurs  
1: SRAM1, SRAM3 and SRAM4 not erased when a system reset occurs

Bit 14  **nRST_SHDW**: Reset generation in Shutdown mode  
0: Reset generated when entering the Shutdown mode  
1: No reset generated when entering the Shutdown mode

Bit 13  **nRST_STDBY**: Reset generation in Standby mode  
0: Reset generated when entering the Standby mode  
1: No reset generated when entering the Standby mode

Bit 12  **nRST_STOP**: Reset generation in Stop mode  
0: Reset generated when entering the Stop mode  
1: No reset generated when entering the Stop mode

Bit 11  Reserved, must be kept at reset value.

Bits 10:8  **BORLEV[2:0]**: BOR reset level  
These bits contain the VDD supply level threshold that activates/releases the reset.  
000: BOR level 0 (reset level threshold around 1.7 V)  
001: BOR level 1 (reset level threshold around 2.0 V)  
010: BOR level 2 (reset level threshold around 2.2 V)  
011: BOR level 3 (reset level threshold around 2.5 V)  
100: BOR level 4 (reset level threshold around 2.8 V)

Bits 7:0  **RDP[7:0]**: Readout protection level  
0xAA: Level 0 (readout protection not active)  
0x55: Level 0.5 (readout protection not active, only non-secure debug access is possible). Only available when TrustZone is active (TZEN=1)  
0xCC: Level 2 (chip readout protection active)  
Others: Level 1 (memories readout protection active)

*Note:* Refer to Section 7.6.2: Readout protection (RDP) for more details.
### 7.9.14 FLASH non-secure boot address 0 register (FLASH_NSBOOTADD0R)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x44
Reset value: 0xXXXX XXXF
(The option bytes are loaded with values from the Flash memory at reset release)
Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

#### NSBOOTADD0[24:9]

Bits 31:7 **NSBOOTADD0[24:0]**: Non-secure boot base address 0
The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the BOOT0 pin or nSWBOOT0 state.
Examples:
NSBOOTADD0[24:0] = 0x01000000: Boot from non-secure Flash memory (0x0800 0000)
NSBOOTADD0[24:0] = 0x017F2000: Boot from system memory bootloader (0x0BF9 0000)
NSBOOTADD0[24:0] = 0x04000000: Boot from non-secure SRAM1 on S-Bus (0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.
7.9.15  FLASH non-secure boot address 1 register  
(FLASH_NSBOOTADD1R)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against unprivileged access when NSPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x48  
Reset value: 0xXXXX XXXF  
(The option bytes are loaded with values from the Flash memory at reset release)  
Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

Bits 31:7  **NSBOOTADD1[24:0]**: Non-secure boot address 1  
The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. These bits correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the BOOT0 pin or nSWBOOT0 state.  
Examples:  
NSBOOTADD1[24:0] = 0x0100000: Boot from non-secure Flash memory (0x0800 0000)  
NSBOOTADD1[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)  
NSBOOTADD1[24:0] = 0x0400000: Boot from non-secure SRAM1 on S-Bus (0x2000 0000)  

Bits 6:0  Reserved, must be kept at reset value.
7.9.16  **FLASH secure boot address 0 register (FLASH_SECBOOTADD0R)**

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x4C
Reset value: 0xXXXX XXXX
(The option bytes are loaded with values from the Flash memory at reset release)
Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

- **SECBOOTADD0[24:9]**
- **SECBOOTADD0[8:0]**

Bits 31:7  **SECBOOTADD0[24:0]**: Secure boot base address 0
The secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes. This bits correspond to address [31:7] The SECBOOTADD0 option bytes are selected following the BOOT0 pin or nSWBOOT0 state.
Examples:
- SECBOOTADD0[24:0] = 0x018 0000: Boot from secure Flash memory (0x0C00 0000)
- SECBOOTADD0[24:0] = 0x01F F000: Boot from RSS (0x0FF8 0000)
- SECBOOTADD0[24:0] = 0x060 0000: Boot from secure SRAM1 on S-Bus (0x3000 0000)

Bits 6:1  Reserved, must be kept at reset value.

Bit 0  **BOOT_LOCK**: Boot lock
When set, the boot is always forced to base address value programmed in SECBOOTADD0[24:0] option bytes whatever the boot selection option. When set, this bit can only be cleared when RDP is at Level 0.
7.9.17 FLASH secure watermark1 register 1 (FLASH_SECWM1R1)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x50

Reset value: 0xFFFF FFFX

(Recently bits are loaded with values from the Flash memory at OBL. Reserved bits are read as 1.)

Access: no wait state when no option bytes modification is ongoing; word, half-word and byte access.

```

Bits 31:0 SEC2BBi: page secure/non-secure attribution ($i = 31$ to 0)
Bits 31:0 **SEC2BBi**: page secure/non-secure attribution \((i = 31 \text{ to } 0)\)
Each bit is used to set one page security attribution in bank 2.
0: Page \((32 \times (x - 1) + i)\) in bank 2 not block-based secure
1: Page \((32 \times (x - 1) + i)\) in bank 2 block-based secure

7.9.31 **FLASH secure HDP control register (FLASH_SECHDPCR)**
This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.
Address offset: 0xC0
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HDP2_ACCDIS**: HDP2 area access disable
When set, this bit is only cleared by a system reset.
0: Access to HDP2 area granted
1: Access to HDP2 area denied (SECWM2Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)

Bit 0 **HDP1_ACCDIS**: HDP1 area access disable
When set, this bit is only cleared by a system reset.
0: Access to HDP1 area granted
1: Access to HDP1 area denied (SECWM1Ry option bytes modification blocked - refer to *Rules for modifying specific option bytes*)
### 7.9.32  FLASH privilege configuration register (FLASH_PRIVCFGR)

This register can be read by both privileged and unprivileged access. NSPRIV is a non-secure bit. SPRIV is a secure bit.

**Address offset:** 0xC4.

**Reset value:** 0x0000 0000

**Access:** no wait state; word, half-word and byte access

**Bits 31:2** Reserved, must be kept at reset value.

- **Bit 1  NSPRIV:** Privileged protection for non-secure registers
  - This bit can be read by both privileged or unprivileged, secure and non-secure access.
  - 0: Non-secure Flash registers can be read and written by privileged or unprivileged access.
  - 1: Non-secure Flash registers can be read and written by privileged access only.
  - The NSPRIV bit can be written by a secure or non-secure privileged access. A secure or non-secure unprivileged write access on NSPRIV bit is ignored.

- **Bit 0  SPRIV:** Privileged protection for secure registers
  - This bit can be accessed only when TrustZone is enabled (TZEN = 1). This bit can be read by both privileged or unprivileged, secure and non-secure access.
  - 0: Secure Flash registers can be read and written by privileged or unprivileged access.
  - 1: Secure Flash registers can be read and written by privileged access only.
  - The SPRIV bit can be written only by a secure privileged access. A non-secure write access on SPRIV bit is ignored. A secure unprivileged write access on SPRIV bit is ignored.
7.9.33 FLASH privilege block based bank 1 register x (FLASH_PRIVBB1Rx)

This register is privileged. It can be read written only by a privileged access. This register can be protected against non-secure access (refer to Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1)).

Address offset: 0xD0 + 4 *(x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

Bits 31:0 PRIV1BBi: page privileged/unprivileged attribution (i = 31 to 0)

Each bit is used to set one page privilege attribution in bank 1.

0: Page (32 * (x - 1) + i) in bank 1 accessible by unprivileged access
1: Page (32 * (x - 1) + i) in bank 1 only accessible by privileged access
7.9.34 FLASH privilege block based bank 2 register x (FLASH_PRIVBB2Rx)

This register is privilege. It can be read written only by a privileged access. This register can be protected against non-secure access (refer to Table 67: PRIVyBBRx registers access when TrustZone is active (TZEN = 1)).

Address offset: 0xF0 + 4 *(x - 1), (x = 1 to 4)
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

Refer to [Section 2.3](#) for the register boundary addresses.
8 Instruction cache (ICACHE)

8.1 Introduction

The instruction cache (ICACHE) is introduced on C-AHB code bus of Cortex-M33 processor to improve performance when fetching instruction and data from both internal and external memories.

Some specific features like dual master port, hit-under-miss and critical-word-first refill policy, allow close to zero wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are described below:

- **Bus interface**
  - one 32-bit AHB slave port, the execution port (input from Cortex-M33 C-AHB code interface)
  - two AHB master ports: one 128-bit master1 and one 32-bit master2 ports (outputs to Fast and Slow buses of main AHB bus matrix, respectively)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)

- **Cache access**
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, ICACHE assigns fast traffic (addressing FLASH and SRAM memories) to the AHB master1 port, and slow traffic (addressing external memories sitting on OCTOSPI and FMC interfaces) to AHB master2 port, thus preventing processor stalls on lines refills from external memories. This allows ISR (interrupt service routine) fetching on internal FLASH memory to take place in parallel with a cache line refill from external memory.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile

- **Memory address remap**
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the internal Code region, for execution)

- **Replacement and refill**
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls
– Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)

• Performance counters
  ICACHE implements two performance counters:
  – Hit monitor counter (32-bit)
  – Miss monitor counter (16-bit)

• Error management
  – Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt

• TrustZone security support

• Maintenance operation
  – Cache invalidate: full cache invalidation, fast command, non interruptible

### 8.3 ICACHE implementation

### 8.4 ICACHE functional description

The purpose of the instruction cache is to cache instruction fetches or instruction memories loads, coming from the processor. As such ICACHE only manages read transactions and does not manage write transactions.

For error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.
8.4.1 ICACHE block diagram

Figure 24. ICACHE block diagram

8.4.2 ICACHE reset and clocks

ICACHE is clocked on Cortex-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:
- ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, ICACHE is bypassed, except the remapping mechanism that is still functional: the slave input requests (remapped or not) are just forwarded to the master port(s).
8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after ICACHE reset is released
- when cache is disabled, by setting the EN bit low in the ICACHE_CR register (by software)
- when executing ICACHE invalidate command, by setting the CACHEINV bit high in the ICACHE_CR register (by software)

When a cacheable transaction is received at input execution port, its AHB address (HADDR_in) is split into the following fields (see table below for definition of B and W):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The table below gives a summary of ICACHE main parameters for TAG memory dimensioning and Figure 25 shows the functional view of TAG and data memories, for a n-way set associative ICACHE.

8.4.4 Direct mapped ICACHE (1-way cache)

Default configuration (at reset) is 2-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure ICACHE as direct mapped by writing WAYSEL = 0 (only possible when cache is disabled, EN=0 in ICACHE_CR).

The table below gives a summary of ICACHE main parameters for TAG memory in case the direct mapped cache operating mode is selected.

**Table 73. TAG memory dimensioning parameters for direct mapped cache mode**

<td>19-bit</td>
</tr>
</tbody>
</table>
All cache operations (such as read, refill, remapping, invalidation) remain the same in direct mapped configuration; the only difference is the absence of a replacement algorithm in case of line eviction (as explained in Section 8.4.8), since only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

In order to activate the ICACHE functioning, the EN bit must be set in the ICACHE_CR register.

When ICACHE is disabled, it is bypassed and all transactions are copied from slave port to master ports in the same clock cycle.

It is recommended to initialize or to modify the main memory content (the region to be later cached) with ICACHE disabled, and to enable ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

In order to insure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when hardware reset signal is released, when ICACHE_CR.CACHEINV is set or when ICACHE_CR.EN is cleared. During the procedure, ICACHE_SR.BUSYF is set, and once finished, ICACHE_SR.BUSYF is cleared and ICACHE_SR.BSYENDF is set (raising the ICACHE interrupt if enabled on such a busy end condition).

Software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF still at 1) is treated as non cacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether ICACHE is enabled or not, if input transaction address falls into memory regions defined and enabled in ICACHE_CRRx (see Figure 26).

ICACHE is by default disabled at boot.

8.4.6 Cacheable and non-cacheable traffic

ICACHE is developed for Cortex-M33 core. It is placed on C-AHB bus, and thus caches the Code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

In order to make some other memory regions cacheable, ICACHE supports a memory region remapping feature. It allows the definition of up to four external memory regions, which addresses have an alias in the Code region. Addressing these external memory regions through their Code alias address allows the memory request to be routed to the C-AHB bus and to be managed by ICACHE.

Typically, any external memory space physically mapped at an address somewhere in range [0x6000 0000:0x9FFF FFFF] can be aliased with an address in range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the Code region, ICACHE implements the address remapping functionality first. If aliased, it is the remapped address which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.
The remapping functionality is available also for non-cacheable traffic and when cache is disabled.

Further details on address remapping are provided in Section 8.4.7.

An incoming memory request to ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in Table 74. This AHB attribute depends on the MPU programming for the addressed region.

### Table 74. ICACHE cacheability for AHB transaction

<table>
<thead>
<tr>
<th>AHB Lookup attribute</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Cacheable</td>
</tr>
<tr>
<td>0</td>
<td>Non cacheable</td>
</tr>
</tbody>
</table>

In case of non cacheable access, ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port, except the transaction address which may be modified due to the address remapping feature (see Section 8.4.7).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In case of cacheable access, the ICACHE behaves as explained in Section 8.4.8.

Cacheable memory regions are defined and programmed by the user in the memory protection unit (MPU), that is responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

The table below summarizes product memories programmable configurations.

### Table 75. Configurations of product memories

</tbody>
</table>

### 8.4.7 Address remapping

ICACHE allows an alias address to be defined in Code region for up to four external memory regions.

The address remapping is applied on the Code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx register (x = 0 to 3, number of remapped regions). This programming can be done only when ICACHE is disabled.
Each region x can be individually enabled with the REN bit in ICACHE_CRRx. Once enabled, the remap operation occurs even if ICACHE is disabled or if the transaction is not cacheable.

Remap regions can have different size: each region size can be programmed in the RSIZE field of its ICACHE_CRRx register. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum region size of 2 Mbytes and a maximum region size of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given Code sub-region base address, and the modification of this address into its (remapped) external physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code sub-region base address programmed in the BASEADDR field of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = log2(region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region)

- If region x is enabled, the master port output AHB address (HADDR_out) is then composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs.

The figure below describes the matching and the output address generation.

![Figure 26. ICACHE remapping address mechanism](MSv48194V2)

The table below summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending on RSIZE.

<table>
<thead>
<tr>
<th>Region size (Mbytes)</th>
<th>Base address size (MSBs)</th>
<th>Remap address (MSBs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>10</td>
</tr>
<tr>
<td>8</td>
<td>6</td>
<td>9</td>
</tr>
<tr>
<td>16</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>7</td>
</tr>
</tbody>
</table>
Care must be taken while programming BASEADDR and REMAPADDR fields in ICACHE_CRRx: if programmed value is bigger than expected (in terms of number of MSBs, see Table 76), the unnecessary extra LSBs are ignored.

Typical remapping example: a 128-Mbyte FMC region (NOR/SRAM) physically located in the external address range \([0x6800\ 0000:0x6FFF\ FFFF]\), remapped in Code section range \([0x1000\ 0000:0x17FF\ FFFF]\):
- REMAPADDR\([31:21]\) = 0x340
- BASEADDR\([28:21]\) = 0x80
- HADDR_in\([31:27]\) is compared to 000:BASEADDR\([28:27]\), and HADDR_in/BASEADDR\([26:21]\) are ignored for the comparison.

If the comparison matches:
- HADDR_out\([31:27]\) gets REMAPADDR\([31:27]\) (in place of HADDR_in\([31:27]\))
- HADDR_out\([26:0]\) gets HADDR_in\([26:0]\)

The software can program the kind of AHB burst that is generated by ICACHE master ports on bus matrix (for cache line refill), by setting the HBURST bit in ICACHE_CRRx with:
- WRAP for remapped external memories accessed through OCTOSPI interface that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through FMC interface that does not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming SAU (secure attribution unit) and MPU (memory protection unit) attributes for both the external regions and their aliased Code sub-regions.

### 8.4.8 Cacheable accesses

When ICACHE receives a cacheable transaction from Cortex-M33, ICACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.
There are then three alternatives:

- Address is present inside the TAG memory, cache line is valid: **cache hit**, the data is read from cache and provided to the processor in the same cycle.

- Address is not present in the TAG memory: **cache miss**, the data is read from main memory and provided to the processor, and a cache line refill is performed. The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

In case no address remap occurs, the burst generated on ICACHE master bus is \( WRAP_w \) (\( w \) being the cache line width, in words); if an address remap occurs, the kind of burst depends on the HBURST bit programmed in the corresponding ICACHE_CRRx register.

The AHB transaction attributes are also propagated to main AHB bus matrix on the master port selected for the line refill.

- Address is not present in TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache hit** (hit-under-miss feature).

This happens during cache line refill, ICACHE is capable of providing the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from main memory).

In case of cache refill (due to cache miss), ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data, the line pointed by the index of the input address.

- In n-way set associative mode, one line among 2 can be used (the line pointed by the address index, in each of the 2 ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written, is already valid, the targeted cache line must be invalidated first; this is true whatever the direct map or n-way set associative cache mode.

### 8.4.9 Dual master cache

ICACHE can implement a dual port AHB master on main AHB bus matrix: master1 and master2 ports. This is used to split the traffic going to different destination memories.

The non-remapped traffic goes systematically to master1 port. The re-mapped traffic to external memories must be routed on master2 port by programming the MSTSEL bit of ICACHE_CRRx (on a region basis).

Typically, code can be fetched as follows:

- internal FLASH memory and internal SRAM on master1 port (Fast bus)
- external FLASH/RAM (through OCTOSPI/FMC interfaces) on master2 port (Slow bus)

For systems not implementing external memories, it is also possible to decouple the traffic to the internal FLASH memory from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual master feature allows the processor to have an alternative path in case of fetching from different memories.
8.4.10 ICACHE security
ICACHE implements a v8-M TrustZone as defined by Arm.
ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance
The software can invalidate the whole content of the ICACHE by programming the CACHEINV bit in the ICACHE_CR register.

When CACHEINV is set, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). The CACHEINV bit of ICACHE_CR is also automatically cleared.

Once the invalidate operation is finished, ICACHE automatically clears the BUSYF flag and sets the BSYENDF flag in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised.

Then, the (empty) cache is available again.

8.4.12 ICACHE performance monitoring
ICACHE provides two monitors for performance analysis: a 32-bit hit monitor and a 16-bit miss monitor.

- The hit monitor counts the AHB-transactions at the input of ICACHE (execution port) that do not generate a transaction on ICACHE output (master1 or master2 port). It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see Section 8.4.8).

- The miss monitor counts the AHB-transactions at the input of the ICACHE (execution port) that generate a transaction on ICACHE output (master1 or master2 port). It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through the HITMEN bit in ICACHE_CR.
- Reset the hit monitor by setting the HITMRST bit in ICACHE_CR.
- Enable/stop the miss monitor through the MISSMEN bit in ICACHE_CR.
- Reset the miss monitor by setting the MISSMRST bit in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

8.4.13 ICACHE boot
ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.
Code remapping at boot is not needed for Cortex-M33 since it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.
Once boot is finished, ICACHE can be enabled (software setting the EN bit to 1 in ICACHE_CR).

### 8.5 ICACHE low-power modes

At product level, using ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints, may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see Figure 25). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves fetch performance; even if for most codes execution, it is a little less efficient than with a n-way set associative cache mode.

### 8.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), ICACHE generates an error by setting the ERRF flag in ICACHE_SR. In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

Both interrupts use the same ICACHE interrupt vector.

<table>
<thead>
<tr>
<th>Interrupt vector</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICACHE</td>
<td>Functional error</td>
<td>ERRF flag in ICACHE_SR</td>

<td>BSYENDF flag in ICACHE_SR</td>
<td>BSYENDIE bit in ICACHE_IER</td>
<td>Set CBSYENDF bit to 1 in ICACHE_FCR</td>
</tr>
</tbody>
</table>

ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master1 or master2 port back to the execution port.

9 Data cache (DCACHE)

9.1 Introduction

The data cache (DCACHE) is introduced on S-AHB system bus of Cortex-M33 processor to improve the performance of data traffic to/from external memories. Some specific features like hit-under-miss and critical-word-first refill policy allow optimum performance on external memories data accesses.

9.2 DCACHE main features

The main features of DCACHE are described below:

- **Bus interface**
  - one 32-bit AHB slave port, the system port (input from Cortex-M33 S-AHB system interface)
  - one 32-bit AHB master port (output to main AHB bus matrix)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for DCACHE registers access)

- **Cache access**
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimized cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative
  - Supports both write-back and write-through policies (selectable with AHB bufferable attribute)
  - Read and write-back always allocate
  - Write-through always non-allocate (write-around)
  - Supports byte, half-word and word writes

- **Replacement and refill**
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy for read transactions, minimizing processor stalls
  - Possibility to configure burst type of all AHB memory transactions: INCRw or WRAPw (size w aligned on cache line size)

- **Performance counters**
  DCACHE implements four performance counters:
  - Two hit monitor counters (32-bit): number of read hits, number of write hits
  - Two miss monitor counters (16-bit): number of read misses, number of write misses
• Error management
  – Possibility to detect error for master port request initiated by DCACHE itself
    (a cache line written back into main memory, because of an eviction or a clean
    operation), to flag this error, and optionally to raise an interrupt

• TrustZone security support

• Maintenance operations
  – Cache invalidate: full cache invalidation, fast command, non interruptible
  – Cache invalidate range: invalidates cache lines (reset valid bit = 0) whose address
    belongs to defined range, background task, interruptible
  – Cache clean range: cleans cache lines (if dirty bit = 1, write back line, then clear
    dirty bit) whose address belongs to defined range, background task, interruptible
  – Cache clean and invalidate range: cleans and invalidates cache lines
    (if dirty bit = 1, write back line, then clear valid bit) whose address belongs to
    defined range, background task, interruptible

9.3 DCACHE implementation

DCACHE1 is placed on Cortex-M33 S-AHB bus and caches only the external RAM memory
region (OCTOSPI and FMC), in address range [0x6000 0000:0x9FFF FFFF] of the
memory map.

Indeed, by placing a bus matrix demultiplexing node in front of DCACHE1, S-AHB bus
memory requests addressing SRAM region or peripherals region (respectively in ranges
[0x2000 0000:0x3FFF FFFF] and [0x4000 0000:0x5FFF FFFF]) are routed directly to the
main AHB bus matrix and DCACHE1 is bypassed.

9.4 DCACHE functional description

The purpose of the data cache is to cache external memories data loads and stores coming
from the processor. These accesses include the instruction fetches that may occur at
an external memory address. As such DCACHE manages both read and write transactions.
9.4.1 DCACHE block diagram

Figure 27. DCACHE block diagram

9.4.2 DCACHE reset and clocks

DCACHE is clocked on the Cortex-M33 S-AHB bus clock.

When the DCACHE reset signal is released, a cache invalidate procedure is automatically launched, making DCACHE busy (DCACHE_SR = 0x0000 0001).

When this procedure is finished:

- DCACHE is invalidated: “cold cache”, with all cache line valid, dirty and privilege bits = 0 (DCACHE must be filled up)
- DCACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- DCACHE is disabled: the EN bit in DCACHE_CR holds its reset state (= 0).

Note: When disabled, DCACHE is bypassed: the slave input requests are just forwarded to the master port.
9.4.3 DCACHE TAG memory

The DCACHE TAG memory contains:

- address tags, that indicate which data are contained in the cache data memories
- validity bits
- dirty bits
- privilege bits

There is one valid bit, one dirty bit and one privilege bit per cache line (per way).

The valid bit enables/disables access to data cache line: if the line is not valid, the data access (read or write) is performed in main memory.

Valid bit is set when cache line is written (refilled by either a read miss or a write-back miss).

Valid bits are reset in any of the below cases:

- after DCACHE reset is released
- when cache is disabled, by setting the EN bit low in DCACHE_CR register (by software)
- when executing one of the DCACHE invalidate commands, setting by software the CACHEINV bit high or CACHECMD = 0b010 or 0b011 in DCACHE_CR register (see Section 9.4.8).

The dirty bit indicates that the cache line has up-to-date values with respect to main memory content (in other words, cache has last right value, main memory is not up to date).

Dirty bit is set when cache line is written by a slave port write transaction (only in case of an access with write-back attribute).

Dirty bits are reset in any of the below cases:

- after DCACHE reset is released
- when a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data and dirty bit = 1)
- when cache invalidation is performed
- when executing one of the DCACHE clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b001 or 0b011 in DCACHE_CR register (see Section 9.4.8).

The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AHB privileged attribute at input slave port, for the first access to this line (it is written only during the line refill, on read miss or write-back miss). The privilege bit holds same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

Privilege bits are reset when cache is invalidated and after DCACHE reset is released.

When a cacheable transaction is received at input slave port, its AHB address (HADDR_in) is split into the following fields (see the table below for B and W values):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the DCACHE.
The table below gives DCACHE main parameters for TAG memory dimensioning. Figure 28 shows the functional view of TAG and data memories, for a n-way set associative DCACHE.

**Figure 28. DCACHE TAG and data memories functional view**

9.4.4 DCACHE enable

In order to activate the DCACHE functioning, the EN bit must be set in DCACHE_CR register.

When DCACHE is disabled, it is bypassed and all transactions are copied from slave port to master port in the same clock cycle, and no comparison is performed with TAG address.
DCACHE is by default disabled at boot.

### 9.4.5 Cacheable and non-cacheable traffic

DCACHE is developed for Cortex-M33 core and caches the memory regions addressed by the AHB bus connected to it.

In addition, the AHB bus traffic to the memory regions can be cacheable or non-cacheable. An incoming memory request to DCACHE is defined as cacheable according to its AHB transaction memory lookup attribute.

In case of write transaction, the DCACHE write policy is defined as write-through or write-back according to its AHB transaction memory bufferable attribute (see the table below).

These AHB attributes depend on the memory protection unit (MPU) programming for the addressed region.

<table>
<thead>
<tr>

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Read: cacheable</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Write: (cacheable) write-back</td>
</tr>
</tbody>
</table>

In case of non cacheable access, DCACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In case of cacheable access, DCACHE behaves as explained in Section 9.4.6.

Cacheable memory regions are defined and programmed by the user in the MPU, responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

### 9.4.6 Cacheable accesses

When DCACHE receives a cacheable transaction from Cortex-M33, on its slave port, DCACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.
For **read transaction**, there are then three alternatives:

- Address is present inside the TAG memory, cache line is valid: **cache read hit**, the data is read from cache and provided to the processor in the same cycle.
- Address is not present in the TAG memory: **cache read miss**, the data is read from main memory and provided to the processor, and a cache line refill is performed. The critical-word-first refill policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory). The kind of burst generated on DCACHE master bus depends on the HBURST bit programmed in DCACHE_CR register: either INCRw or WRAPw (w being the cache line width, in words).
- The AHB transaction attributes are also propagated from the slave input (missing) request to the master output refill request.
- Address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache read hit** as well (hit-under-miss feature).

Whatever the line refill is due to a read or write (missing) transaction, DCACHE is capable of providing the requested read data as soon as the data is available at its master interface, thus avoiding a miss (with data fetch from main memory).

For **write-back transaction** (write transaction, with write-back bufferable attribute), there are three alternatives as well:

- Address is present inside the TAG memory, cache line is valid: **cache write-back hit**, the data is written in cache.
- Address is not present in the TAG memory (or cache line is not valid): **cache write-back miss**.
  
  First, a line allocation is performed by reading the entire cache line data from main memory. The kind of burst generated on DCACHE master bus for this line refill depends on the HBURST bit programmed in DCACHE_CR register: either INCRw or WRAPw (w being the cache line width, in words), and the AHB transaction attributes are propagated from the slave port initial request.
  
  Once the refilled line is written in DCACHE, the initial data provided on slave port is written in this DCACHE line (it overwrites the data part of the cache line that was refilled just before).
- Address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache write-back hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, DCACHE is capable of writing incoming data directly inside the refilled line, thus avoiding a miss (with refill from main memory).

For **write-through transaction** (write transaction, with write-through bufferable attribute), only two alternatives exist:

- Address is present inside the TAG memory, cache line is valid: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- Address is not present in the TAG memory (or cache line is not valid): **cache write-through miss**, the data incoming at slave port is written only in main memory (unlike the write-back miss, there is no line allocation and data written in cache).

In case of cache refill (due to cache miss), DCACHE selects which cache line is written with the refill data: as a 2-way set associative cache, one line among 2 can be used (the line
pointed by the address index, in each of the 2 ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:
- if the dirty tag of this line equals 0 (clean data), the line is simply invalidated.
- if it equals 1 (dirty data), the line must be written back in the main memory.

In such a case, DCACHE generates a burst write transaction on its master port, with burst type set to INCRw (w being the cache line width, in words), and with AHB memory transaction attribute signals set as below:
  - data (not instruction)
  - privileged = TAG privilege bit
  - write-back (even if it does not care)
  - normal memory
  - cacheable
  - allocate (even if it does not care)
  - non shareable

These AHB attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted by DCACHE) because the evicting transaction has no relation with the initial missing transaction. Note this AHB attributes setting is fixed, excepted the privileged bit that is copied from the TAG privilege bit of the evicted line.

### 9.4.7 DCACHE security

DCACHE implements a v8-M TrustZone as defined by Arm.

DCACHE configuration registers are protected at system level.

### 9.4.8 DCACHE maintenance

DCACHE features several maintenance operations that the software can programmed in DCACHE_CR control register:
- **Full invalidate**: invalidates the whole cache, non interruptible task.

  The software can invalidate the whole content of DCACHE by programming the CACHEINV bit in DCACHE_CR register.

  When CACHEINV is set, the DCACHE control logic sets the BUSYF flag in DCACHE_SR status register, and performs the operation of cache invalidation, resetting each TAG valid bit to 0 (one valid bit per cache line). Each dirty and privilege bits are also reset during cache invalidation to prevent unknown values at next cache line validation. The CACHEINV bit of DCACHE_CR is automatically cleared.

  Once the full invalidate operation is finished, DCACHE automatically clears the BUSYF flag and sets the BSYENDF flag in DCACHE_SR register.

  If enabled on this flag condition (BSYENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised. Then, the (empty) cache is available again.

  This full invalidate operation is not interruptible, meaning that cache does not treat any cacheable request while BUSYF flag is set. However, non-cacheable traffic is treated
(since the request address is not compared to TAG ones), DCACHE being bypassed in the same clock cycle (same behavior as when DCACHE is disabled).

- **Invalid range**: invalidates a certain range of addresses in the cache, back-ground task (interruptible).

  The software can invalidate a given data region in DCACHE by programming DCACHE.CR register with bits STARTCMD = 1 and CACHECMD = 0b010, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  DCACHE control logic then parses the whole TAG memory. If the read line address (TAG Address + Line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), the corresponding cache line is invalidated (line TAG bits cleared, i.e. Valid bit = Dirty bit = Privilege bit = 0).

  When STARTCMD is set, the DCACHE control logic sets the BUSYCMDF flag in DCACHE_SR and launches the invalidate range operation. The STARTCMD bit of DCACHE_CR is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), DCACHE automatically clears the BUSYCMDF flag in DCACHE_SR register.

  If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

  During this invalidate range operation, DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the invalidation process. In other words, the TAG memory is accessed for invalidate range operation only if not already accessed by an external cache request. This implies that invalidate range execution is usually not performed in one go, but can be interrupted.

- **Clean range**: cleans a certain range of addresses in the cache, back-ground task (interruptible).

  Cleaning a cache line means making sure that main memory content is up-to-date with the data which might have been modified in cache. So the clean operation consists in performing the write-back in main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

  The software can clean a given data region in DCACHE by programming DCACHE.CR register with bits STARTCMD = 1, and CACHECMD = 0b001, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  DCACHE control logic then parses the whole TAG memory. If the read line address (TAG Address + Line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR) and the
corresponding line is dirty, this line is cleaned, meaning the whole cache line is written-
back in memory through the DCACHE master port and its TAG dirty bit is cleared.

When STARTCMD is set, the DCACHE control logic sets the BUSYCMDF flag in
DCACHE_SR and launches the clean range operation. The STARTCMD bit of
DCACHE_CR is also automatically cleared.

Once the operation is finished (all TAG memory parsed), DCACHE automatically clears
the BUSYCMDF flag and sets the CMDENDF flag in DCACHE_SR register.

If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE
interrupt is raised.

During this clean range operation, DCACHE is interruptible, meaning it can accept new
incoming requests that take higher priority than the cleaning process. In other words,
the TAG memory is accessed for clean range operation only if not already accessed by
an external cache request. This implies that clean range execution is usually not
performed in one go, but can be interrupted.

It is under the software responsibility that no bus initiator attempts to change the
content of the region being cleaned until clean range is completed. For that, the
software should take advantage of BUSYCMDF flag in DCACHE_SR and polls this flag
to prevent any spurious access to the area being cleaned. Alternatively it can also rely
on the command end flag (CMDENDF) or on the DCACHE interrupt to detect the end
of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates a certain range of addresses in
the cache, back-ground task (interruptible).

Same as clean range, with an additional reset of its TAG valid bit when a cache line is
cleaned.

The software can launch this clean and invalidate range operation, by programming
DCACHE_CR register with bits STARTCMD = 1, and CACHECMD = 0b011, after the
address range was programmed into DCACHE_CMDRSADDRR (range start address)
and DCACHE_CMDREADDRR (range end address).

It sets and clears the same flags, and potentially the same interrupt as invalidate range
or clean range operations.

9.4.9 DCACHE performance monitoring

DCACHE provides four monitors for performance analysis: two 32-bit hit monitors and two
16-bits miss monitors.

- The read-hit and the write-hit monitors count the AHB transactions at the input of
DCACHE (slave port) that do not generate a transaction on DCACHE output (master
port).

It also takes into account all accesses whose address is present in the TAG memory or
in the refill buffer (due to a previous miss, and whose data is coming, or is soon to
come, from cache master port) (see Section 9.4.6).

- The read-miss and the write-miss monitors count the AHB transactions at the input of
DCACHE (slave port) that generate a transaction on DCACHE output (master port)

It also takes into account all accesses whose address is not present neither in the TAG
memory, nor in the refill buffer.

Upon reaching their maximum values, monitors do not wrap over.
The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through the R(W)HITMEN bit in DCACHE_CR.
- Reset the read (write) hit monitor, by setting the R(W)HITMRST bit in DCACHE_CR.
- Enable/stop the read (write) miss monitor, through the R(W)MISSMEN bit in DCACHE_CR.
- Reset the read (write) miss monitor, by setting the R(W)MISSMRST bit in DCACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

9.4.10 DCACHE boot

DCACHE is disabled (EN = 0 in DCACHE_CR) at boot.

Once boot is finished, DCACHE can be enabled (software setting the EN bit to 1 in DCACHE_CR).

9.5 DCACHE low-power modes

At product level, using DCACHE reduces the power consumption by loading/storing data from/to the internal DCACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even much higher, since the cached main memories are external.

9.6 DCACHE error management and interrupts

A transaction initiated on the DCACHE master port may return an error (a write attempt into a read-only memory, for instance). If the master port request was propagated from a slave port request, the error is propagated back to the slave port. If ever the master port request is initiated by DCACHE itself (a cache line is written back into the main memory because of an eviction or a clean operation), DCACHE receives this functional error and flags it internally by setting the ERRF flag in DCACHE_SR.

In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in DCACHE_IER).

Another case of potential interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, DCACHE sets the BSYENDF flag in DCACHE_SR.

An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in DCACHE_IER).

Last case is at the end of invalidate and/or clean range operations: when the command busy state is finished, DCACHE sets the CMDENDF flag in DCACHE_SR.

An interrupt is also generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in DCACHE_IER).

All DCACHE interrupts use the same DCACHE interrupt vector.
DCACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master port back to the S-AHB slave port.

Bit 11 **STARTCMD**: starts maintenance command (maintenance operation defined in CACHECMD).
   Can be set by software, only when \( \text{EN} = 1 \), \( \text{BUSYCMDF} = 0 \), \( \text{BUSYF} = 0 \) and
   \( \text{CACHECMD} = 0b001, 0b010 \) or \( 0b011 \).
   Cleared by hardware when the BUSYCMDF flag is set (during cache maintenance
   operation). Writing 0 has no effect.
   0: command operation (cache maintenance) finished
   1: start maintenance command (cache maintenance)

Bits 10:8 **CACHECMD[2:0]**: cache command maintenance operation (cleans and/or invalidates
   an address range)
   Can be set and cleared by software, only when no maintenance command is ongoing
   (BUSYCMDF = 0).
   000: no operation
   001: clean range
   010: invalidate range
   011: clean and invalidate range
   others: reserved

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CACHEINV**: full cache invalidation
   Can be set by software, only when \( \text{EN} = 1 \).
   Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation).
   Writing 0 has no effect.
   0: no effect
   1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
   0: cache disabled
   1: cache enabled
### DCACHE status register (DCACHE_SR)

</table>
Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **CCMDENDF**: clear command end flag
Set by software.
0: no effect
1: clears CMDENDF flag in DCACHE_SR

Bit 3  Reserved, must be kept at reset value.

Bit 2  **CERRF**: clear cache error flag
Set by software.
0: no effect
1: clears ERRF flag in DCACHE_SR

Bit 1  **CBSYENDF**: clear full invalidate busy end flag
Set by software.
0: no effect
1: clears BSYENDF flag in DCACHE_SR

Bit 0  Reserved, must be kept at reset value.

### 9.7.5  DCACHE read-hit monitor register (DCACHE_RHMONR)

10  Power control (PWR)

10.1  Introduction

The power controller manages all device power supplies and power modes transitions.

10.2  PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain ($V_{CORE}$)
  - $V_{DD}$ domain
  - Backup domain
  - Analog domain ($V_{DDA}$)
  - Supply for the SMPS power stage (available on SMPS packages)
  - $V_{DDIO2}$ domain on port PG[15:2]
  - $V_{DDUSB}$ for USB transceiver
- System supply voltage regulation
  - SMPS step-down converter
  - Linear voltage regulator (LDO)
- Power supply supervision
  - BOR monitor
  - PVD monitor
  - PVM monitor ($V_{DDA}$, $V_{DDUSB}$, $V_{DDIO2}$)
  - Out of functional range temperature monitor
  - Out of functional range Backup domain voltage monitor
- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes
- $V_{BAT}$ battery charging
- TrustZone security and privileged protection
10.3 PWR pins and internal signals

### 10.4 PWR power supplies and supply domains

#### Figure 29. Power supply overview
10.4.1 External power supplies

The devices require a 1.71 V to 3.6 V V\textsubscript{DD} operating voltage supply. Several independent supplies can be provided for specific peripherals. Those supplies must not be provided without a valid operating supply on the VDD pin:

- \( V_{DD} = 1.71 \text{ V to } 3.6 \text{ V} \) (functionality guaranteed down to V\textsubscript{BOR} minimum value)
  
  \( V_{DD} \) is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through the VDD pins.

- \( V_{DDA} = 1.58 \text{ V (COMPs) / 1.6 \text{ V (DACs, OPAMPs) / 1.62 \text{ V (ADCs) / 1.8 \text{ V (VREFBUF) to } 3.6 \text{ V}}) \}

  \( V_{DDA} \) is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The \( V_{DDA} \) voltage level is independent from the \( V_{DD} \) voltage and must be connected to VDD or VSS (preferably to VDD) when these peripherals are not used.

- \( V_{DDSMSPS} = 1.71 \text{ V to } 3.6 \text{ V} \)
  
  \( V_{DDSMSPS} \) is the external power supply for the SMPS step-down converter. It is provided externally through VDDSMSPS supply pin, and must be connected to the same supply as VDD pin.

- \( V_{LXSMSPS} \) is the switched SMPS step-down converter output.

*Note:* The SMPS power supply pins are available only on a specific package with SMPS step-down converter option.

- \( V_{DDUSB} = 3.0 \text{ V to } 3.6 \text{ V} \)
  
  \( V_{DDUSB} \) is the external independent power supply for USB transceivers. The \( V_{DDUSB} \) voltage level is independent from the \( V_{DD} \) voltage and must preferably be connected to VDD when the USB is not used.

- \( V_{DDI02} = 1.08 \text{ V to } 3.6 \text{ V} \)
  
  \( V_{DDI02} \) is the external power supply for 14 I/Os (port G[15:2]). The \( V_{DDI02} \) voltage level is independent from the \( V_{DD} \) voltage and must preferably be connected to \( V_{DD} \) when PG[15:2] are not used.

- \( V_{BAT} = 1.65 \text{ V to } 3.6 \text{ V} \) (functionality guaranteed down to V\textsubscript{BOR\_VBAT} minimum value, refer to the product datasheet)

  \( V_{BAT} \) is the power supply when \( V_{DD} \) is not present (through power switch) for RTC, TAMP, external clock 32 kHz oscillator, backup registers and optionally backup SRAM.

- \( V_{REF\_-, VREF\_+} \)

  \( V_{REF\_+} \) is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  \( V_{REF\_+} \) can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports four output voltages, that are configured with VRS bit in the VREFBUF\_CSR register:

  - \( V_{REF\_+} \) around 1.5 V. This requires \( V_{DDA} \geq 1.8 \text{ V} \).
  - \( V_{REF\_+} \) around 1.8 V. This requires \( V_{DDA} \geq 2.1 \text{ V} \).
  - \( V_{REF\_+} \) around 2.048 V. This requires \( V_{DDA} \geq 2.4 \text{ V} \).
  - \( V_{REF\_+} \) around 2.5 V. This requires \( V_{DDA} \geq 2.8 \text{ V} \).

  \( V_{REF\_-} \) and \( V_{REF\_+} \) pins are not available on all packages. When not available, they are bonded to VSSA and VDDA, respectively.
When the VREF+ is double-bonded with VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled. $V_{REF-}$ must always be equal to $V_{SSA}$.

### 10.4.2 Internal regulators

The devices embed two regulators: one LDO and one SMPS in parallel to provide the $V_{CORE}$ supply for digital peripherals, SRAMs (except BKPSRAM) and embedded Flash memory. The SMPS generates this voltage on VDD11 (two pins) with a total external capacitor of 4.7 μF typical and requires an external coil of 2.2 μH typical.

The LDO generates this voltage on VCAP (one or two pins depending on packages) with a total of external capacitor of 4.7 μF typical.

Both regulators can provide four different voltages (voltage scaling) and can operate in Stop mode.

It is possible to switch from SMPS to LDO and from LDO to SMPS on the fly.

### 10.4.3 Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When $V_{DD}$ is below 1 V, other power supplies ($V_{DDA}$, $V_{DDIO2}$, $V_{DDUSB}$) must remain below $V_{DD} + 300$ mV.
- When $V_{DD}$ is above 1 V, all power supplies are independent.

During the power-down phase, $V_{DD}$ can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling capacitors to be discharged with different time constants during the power-down transient phase.

### 10.4.4 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The $V_{DDA}$ supply voltage can be different from $V_{DD}$. The presence of $V_{DDA}$ must be checked before enabling any of the analog peripherals supplied by $V_{DDA}$ (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

After reset, the analog features supplied by $V_{DDA}$ are logically and electrically isolated and therefore are not available. The isolation must be removed before using the analog peripherals, by setting the ASV bit in the PWR_SVMCR register, once the $V_{DDA}$ supply is present.

The $V_{DDA}$ supply can be monitored by the analog voltage monitors (AVM), and compared with two thresholds (1.6 V for AVM1 or 1.8 V for AVM2), refer to Section 10.6.3: Peripheral voltage monitoring (PVM) for more details.

When a single supply is used, $V_{DDA}$ can be externally connected to $V_{DD}$ through the external filtering circuit in order to ensure a noise-free $V_{DDA}$ reference voltage.
ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+, a separate reference voltage lower than VDDA. VREF+ is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

VREF+ can be provided either by an external reference or by an internal buffered voltage reference (VREFBUF). The internal voltage reference can output a configurable voltage: 1.5 V, 1.8 V, 2.048 V or 2.4 V. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet and to Section 32: Voltage reference buffer (VREFBUF) for further information.

10.4.5 Independent I/O supply rail

Some I/Os from port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the VDDIO2 pin. The VDDIO2 voltage level is completely independent from VDD or VDDA. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by VDDIO2 are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IO2SV bit in the PWR_SVMCR register, once the VDDIO2 supply is present.

The VDDIO2 supply is monitored by the IO2 voltage monitoring (IO2VM) and compared with the internal reference voltage (3/4 * VREFINT, around 0.9 V), refer to Section 10.6.3: Peripheral voltage monitoring (PVM) for more details.

10.4.6 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. VDDUSB range is from 3.0 V to 3.6 V and is completely independent from VDD or VDDA.

After reset, the USB features supplied by VDDUSB are logically and electrically isolated and therefore are not available. The isolation must be removed before using the USB OTG peripheral, by setting the USV bit in the PWR_SVMCR register, once the VDDUSB supply is present.

The VDDUSB supply is monitored by the USB voltage monitoring (UVM) and compared with the internal reference voltage (VREFINT, around 1.2 V), refer to Section 10.6.3: Peripheral voltage monitoring (PVM) for more details.

10.4.7 Battery Backup domain

To retain the content of the backup registers and supply the RTC function when VDD is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The VBAT pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The backup SRAM is optionally powered by VBAT pin when the BREN bit is set in the PWR Backup domain control register 1 (PWR_BDCR1). The switch to the VBAT supply is controlled by the power-down reset embedded in the Reset block.
Warning: During \( t_{\text{RSTTEMPO}} \) (temporization at \( V_{\text{DD}} \) startup) or after a PDR has been detected, the power switch between \( V_{\text{BAT}} \) and \( V_{\text{DD}} \) remains connected to \( V_{\text{BAT}} \). During the startup phase, if \( V_{\text{DD}} \) is established in less than \( t_{\text{RSTTEMPO}} \) (refer to the datasheet for the value of \( t_{\text{RSTTEMPO}} \)) and \( V_{\text{DD}} > V_{\text{BAT}} + 0.6 \text{ V} \), a current may be injected into \( V_{\text{BAT}} \) through an internal diode connected between \( V_{\text{DD}} \) and the power switch (\( V_{\text{BAT}} \)).

If the power supply/battery connected to the \( V_{\text{BAT}} \) pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the \( V_{\text{BAT}} \) pin.

If no external battery is used in the application, it is recommended to connect \( V_{\text{BAT}} \) externally to \( V_{\text{DD}} \) with a 100 nF external ceramic decoupling capacitor.

When the Backup domain is supplied by \( V_{\text{DD}} \) (analog switch connected to \( V_{\text{DD}} \)), the following pins are available:

- PC13, PC14 and PC15, that can be configured by RTC or LSE (refer to Section 47.3: RTC functional description)
- PE3, PE4, PE5, PE6, PC13, PA0, PA1, PC5 when they are configured by TAMP peripheral as tamper pins

Note: Due to the fact that the analog switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed must be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (for example to drive a LED).

**Backup domain access**

After a system reset, the Backup domain (RCC Backup domain control register \( \text{RCC}_{\text{BDCR}}, \text{RTC} \) registers, \( \text{TAMP} \) registers, backup registers and backup SRAM) is protected against possible unwanted write accesses. To enable access to the Backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the \( \text{RCC}_{\text{AHB3 peripheral clock enable register}} \) (\( \text{RCC}_{\text{AHB3ENR}} \)).
2. Set the DBP bit in the \( \text{PWR disable Backup domain register} \) (\( \text{PWR}_{\text{DBPR}} \)) to enable access to the Backup domain.

**\( V_{\text{BAT}} \) battery charging**

When \( V_{\text{DD}} \) is present, It is possible to charge the external battery on \( V_{\text{BAT}} \) through an internal resistance.

The \( V_{\text{BAT}} \) charging is done either through a 5 k\( \Omega \) resistor or through a 1.5 k\( \Omega \) resistor depending on the \( \text{VBRS} \) bit value in the \( \text{PWR}_{\text{BDCR2}} \) register.

The battery charging is enabled by setting \( \text{VBE} \) bit in the \( \text{PWR}_{\text{BDCR2}} \) register. It is automatically disabled in \( V_{\text{BAT}} \) mode.
10.5  PWR system supply voltage regulation

10.5.1  SMPS and LDO embedded regulators

The devices embed two internal regulators, that can be selected when the application runs, depending on the application requirements:

- a SMPS step-down converter
- a linear voltage regulator (LDO)

The SMPS allows the power consumption to be reduced but some applications can be perturbed by the noise generated by the SMPS, requiring the application to switch to LDO.

The LDO and the SMPS regulators have two modes: Main regulator mode (used when performance is needed), and Low-power regulator mode. LDO or SMPS can be used in all voltage scaling ranges, and in all Stop modes.

10.5.2  LDO and SMPS versus reset, voltage scaling, and low-power modes

After reset, the regulator is the LDO, in range 4. Switching to SMPS provides lower consumption in particular at high $V_{DD}$ voltage. It is possible to switch from LDO to SMPS, or from SMPS to LDO in any range, by configuring the REGSEL bit.

When exiting the Stop or Standby mode, the regulator is the same than when entering low-power modes. The voltage range is the range 4.

10.5.3  LDO and SMPS step down converter fast startup

After POR reset, the LDO and SMPS regulators starts in high-power mode and in slow-startup mode. This slow-startup feature is selected to limit the inrush current after power-on reset. This increases the wakeup time when exiting Stop or Standby mode.

However, it is possible to configure a faster startup on the fly and it is applied for next startup either after a system reset or wakeup from low-power mode except Shutdown and $V_{BAT}$ modes. The fast startup is selected by setting the FSTEN bit in the PWR_CR3 register.

10.5.4  Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique that consists in increasing or decreasing the voltage used for the digital peripherals ($V_{CORE}$), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase $V_{CORE}$ is known as overvolting. It allows the device to improve its performance.

Dynamic voltage scaling to decrease $V_{CORE}$ is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

The regulator operates in the following ranges:

- Range 1: high performance
  It provides a typical output voltage at 1.2 V. It is used when the system clock frequency is up to 160 MHz.
- Range 2: medium-high performance
  It provides a typical output voltage at 1.1 V. It is used when the system clock frequency
is up to 110 MHz.

- **Range 3: medium-low power range**
  It provides a typical output voltage at 1.0 V. The system clock frequency can be up to 55 MHz.

- **Range 4: low power range**
  It provides a typical output voltage at 0.9 V. The system clock frequency can be up to 25 MHz.

Voltage scaling is selected through the VOS[1:0] bits in the PWR_VOSR register. The EPOD (embedded power distribution) booster must be enabled and ready before increasing the system clock frequency above 55 MHz in range 1 and range 2.

The sequence to switch the voltage scaling from range “L” (lower power) to range “P” (higher performance) with L > P is the following:

1. If target SYSCLK > 55 MHz:
   a) Configure the PLL1MBOOST[3:0] in the RCC_PLL1CFGR to generate a booster clock frequency between 4 and 16 MHz.
   b) Switch on the PLL1 oscillator clock source.
   c) Select the PLL1 clock source (PLL1SRC[1:0] in the RCC_PLL1CFGR).
2. Program the VOS[1:0] bits to range P in the PWR_VOSR register.
3. Wait until the VOSRDY flag is set in the PWR_VOSR register.
4. If target SYSCLK > 55 MHz:
   a) Set BOOSTEN in the PWR_VOSR register. This step can be done together with VOS programming.
   b) Wait until the BOOSTRDY flag is set in the PWR_VOSR register.
5. Adjust number of wait states according new frequency target in range “P” (LATENCY bits in the FLASH_ACR and WSC bits in the RAMCFG_MxCR).
6. Configure and enable the PLL if needed.
7. Configure and switch to new system frequency.

The sequence to switch the voltage scaling from range “P” (higher performance) to range “L” (lower power) with L > P is:

1. Reduce the system frequency to a value lower than range “L” maximum frequency.
2. Adjust number of wait states according new frequency target (LATENCY bits in the FLASH_ACR and WSC bits in the RAMCFG_MxCR).
3. If new SYSCLK ≤ 55 MHz, clear BOOSTEN in the PWR_VOSR register if it was set.
4. Program the VOS bits to range “L” in the PWR_VOSR register. This step can be done together with BOOSTEN clearing.

### 10.6 PWR power supply supervision

#### 10.6.1 Brownout reset (BOR)

The device has an integrated Brownout reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.
Five BOR thresholds can be selected through option bytes. BOR0 provides the always enabled power-on/power-down functionality, independent from any other higher BOR level selection.

During power-on, the BOR keeps the device under reset until the supply voltage \( V_{DD} \) reaches the specified \( V_{BORx} \) threshold. When \( V_{DD} \) drops below the selected threshold, a device reset is generated. When \( V_{DD} \) is above the \( V_{BORx} \) upper limit, the device reset is released and the system can start.

For more details on the Brownout reset thresholds, refer to the electrical characteristics section in the datasheet.

During Stop1, Stop 2, Stop 3 and Standby modes, it is possible to set the BOR in ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in \textit{PWR control register 1 (PWR\_CR1)}.

![Figure 30. Brownout reset waveform](MS31444V5)

1. The reset temporization \( t_{RSTTEMPO} \) is present only for the BOR lowest threshold \( (V_{BOR0}) \).

### 10.6.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the \( V_{DD} \) power supply by comparing it to a threshold selected by the PVDLS[2:0] bits in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)}. The PVD is enabled by setting the PVDE bit.

A PVDO flag is available in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)} to indicate if \( V_{DD} \) is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers (refer to \textit{Table 99: PWR interrupt requests}).

The rising/falling edge sensitivity of the EXTI Line must be configured according to PVD output behavior. For example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when \( V_{DD} \) drops below the PVD threshold. As an example, the service routine can perform emergency shutdown tasks.

The PVD can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVD is not functional in Stop 3 mode.

During Stop1, Stop 2 and Stop 3 modes, it is possible to set the PVD in ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in PWR\_CR1.
10.6.3 Peripheral voltage monitoring (PVM)

Only $V_{DD}$ is monitored by default, as it is the only supply required for all system-related functions. The other supplies ($V_{DDA}$, $V_{DDIO2}$ and $V_{DDUSB}$) can be independent from $V_{DD}$ and can be monitored with four peripheral voltage monitoring (PVM):

- The UVM monitors the USB supply $V_{DDUSB}$. $V_{DDUSBRDY}$ indicates if the $V_{DDUSB}$ independent power supply is higher or lower than the $V_{UVM}$ threshold.
- The IO2VM monitors the $PG[15:2]$ supply $V_{DDIO2}$. $V_{DDIO2RDY}$ indicates if the $V_{DDIO2}$ independent power supply is higher or lower than the $V_{IO2VM}$ threshold.
- The AVM1 monitors the analog supply $V_{DDA}$. $V_{DDA1RDY}$ indicates if the $V_{DDA}$ independent power supply is higher or lower than the $V_{AVM1}$ threshold.
- The AVM2 monitors the analog supply $V_{DDA}$. $V_{DDA2RDY}$ indicates if the $V_{DDA}$ independent power supply is higher or lower than the $V_{AVM2}$ threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the PVM threshold and/or when it rises above the PVM threshold, depending on EXTI line rising/falling edge configuration. Refer to Table 99: PWR interrupt requests.

Each PVM can remain active in Stop 0, Stop 1, Stop 2 modes, and the PVM interrupt can wake up from the Stop mode. The PVM is not functional in Stop 3 mode.

</tbody>
</table>
The independent supplies (\(V_{DDA}\), \(V_{DDIO2}\) and \(V_{DDUSB}\)) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies:

- If these supplies are shorted externally to \(V_{DD}\), the application assumes they are available without enabling any peripheral voltage monitoring.
- If these supplies are independent from \(V_{DD}\), the peripheral voltage monitoring (PVM) can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB OTG peripheral:

1. If \(V_{DDUSB}\) is independent from \(V_{DD}\):
   a) Enable the UVM by setting UVEN bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)}.
   b) Wait for the UVM wakeup time.
   c) Wait until VDDUSBRDY bit is set in the \textit{PWR supply voltage monitoring status register (PWR\_SVMSR)}.
   d) Disable the UVM for consumption saving (optional).
2. Set the USV bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)} to remove the \(V_{DDUSB}\) power isolation.

The following sequence must be done before using any I/O from PG[15:2]:

1. If \(V_{DDIO2}\) is independent from \(V_{DD}\):
   a) Enable the IO2VM by setting IO2VM bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)}.
   b) Wait for the IO2CVM wakeup time.
   c) Wait until VDDIO2RDY bit is set in the \textit{PWR supply voltage monitoring status register (PWR\_SVMSR)}.
   d) Disable the IO2VM for consumption saving (optional).
2. Set the IO2SV bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)} to remove the \(V_{DDIO2}\) power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If \(V_{DDA}\) is independent from \(V_{DD}\):
   a) Enable the AVM1 or AVM2 by setting AVM1EN or AVM2EN bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)}.
   b) Wait for the AVM wakeup time.
   c) Wait until VDDA1RDY or VDDA2RDY bit is set in the \textit{PWR supply voltage monitoring status register (PWR\_SVMSR)}.
   d) Disable the AVM for consumption saving (optional).
2. Set the ASV bit in the \textit{PWR supply voltage monitoring control register (PWR\_SVMCR)} to remove the \(V_{DDA}\) power isolation.

### 10.6.4 Backup domain voltage and temperature monitoring

When the Backup domain voltage and temperature monitoring is enabled (MONEN = 1 in the PWR\_DBPR register), the Backup domain voltage and the temperature are monitored.
If the Backup domain voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E = 1 in the TAMP.CR1 register), a tamper event is generated when the Backup domain voltage is above the functional range. In case the Backup domain voltage is below the functional range, a Brownout reset is generated, erasing all device including Backup domain.

Note: The Backup domain voltage is $V_{DD}$ when present, $V_{BAT}$ otherwise.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E = 1 in the TAMP.CR1 register), a tamper event is generated when the temperature is above or below the functional range.

### 10.7 PWR power management

#### 10.7.1 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features these low-power modes:

- **Sleep mode:**
  
  CPU clock off, all peripherals including Cortex-M33 core such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to Section 10.7.5: Sleep mode.

- **Stop 0, Stop 1, Stop 2, Stop 3 modes:**
  
  Stop mode achieves the lowest power consumption while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are disabled. The LSE or LSI is still running.
  
  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).
  
  Some peripherals are autonomous and can operate in Stop mode by requesting their kernel clock and their bus (APB or AHB) when needed, in order to transfer data with DMA (GPDMA1 or LPDMA1 depending on peripherals and power mode).
  
  In Stop 2 and Stop 3 modes, most of the core domain is put in a lower leakage mode. Stop 0 and Stop 1 offers the largest number of active peripherals and wakeup sources, a smaller wakeup time but a higher consumption than Stop 2.
  
  In Stop 0 mode, the regulator remains in main regulator mode, allowing a very fast wakeup time but with much higher consumption.
  
  Stop 3 is the lowest power mode with full retention, but the functional peripherals and sources of wakeup are reduced to the same ones than in Standby mode.
  
  The system clock when exiting from Stop mode can be either MSIS up to 24 MHz or HSI16, depending on software configuration.
  
  Refer to Section 10.7.6: Stop 0 mode, Section 10.7.7: Stop 1 mode, Section 10.7.8: Stop 2 mode and Section 10.7.9: Stop 3 mode.

- **Standby mode:**
  
  The Standby mode is used to achieve the lowest power consumption with BOR. The
internal regulator is switched off so that the core domain is powered off. The PLL, the MSI (MSIS and MSIK) RC, the HSI16 RC and the HSE crystal oscillators are also switched off.

The RTC can remain active (Standby mode with RTC, Standby mode without RTC). The Brownout reset (BOR) always remains active in Standby mode. The state of each I/O during Standby mode can be selected by software: I/O with internal pull-up, internal pull-down or floating.

After entering Standby mode, SRAMs and register contents are lost except for registers and backup SRAM in the Backup domain and Standby circuitry. Optionally, the full SRAM2 or 8 Kbytes or 56 Kbytes can be retained in Standby mode, supplied by the low-power regulator (standby with RAM2 retention mode).

The BORL (Brownout reset detector low) can be configured in ultra-low-power mode to further reduce power consumption during standby mode.

The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), a RTC event occurs (alarm, periodic wakeup, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.

The system clock after wakeup is MSIS at 4 MHz.

Refer to Section 10.7.10: Standby mode.

• Shutdown mode:

The Shutdown mode allows the lowest power consumption. The internal regulator is switched off so that the core domain is powered off. The PLL, the HSI16, the MSI (MSIS and MSIK), the LSI and the HSE oscillators are also switched off.

The RTC can remain active (Shutdown mode with RTC, Shutdown mode without RTC). The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

SRAMs and register contents are lost except for registers in the Backup domain.

The device exits Shutdown mode when an external reset (NRST pin), a WKUP pin event (configurable rising or falling edge), or a RTC event occurs (alarm, periodic wakeup, timestamp), or a tamper detection.

The system clock after wakeup is MSIS at 4 MHz.

Refer to Section 10.7.11: Shutdown mode.
The table below shows the power modes overview.

**Peripheral Run Sleep**

**Stop 0/1 Stop 2 Stop 3 Standby Shutdown**

**Wake up capability**

**1. Y = yes (enable). O = optional (disable by default, can be enabled by software). - = not available.**

**2. The Flash memory can be configured in power-down mode. By default, it is not in power-down mode.**

**3. The SRAMs can be powered on or off independently.**

**4. The SRAM clock can be gated on or off independently.**

**5. ECC error interrupt or NMI wakes up from Stop mode.**

**6. 8 Kbytes, 56 Kbytes or full SRAM2 content can be preserved.**
In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks and configuring voltage scaling to lower-power ranges.
- Gating the clocks to the APB and AHB peripherals when they are unused.
- Powering off unused RAMs

When a SRAM has been powered off, it can be powered on again by following the procedure:

1. Reset SRAMxPD in PWR_CR1.
2. Wait for 1.6 µs.
3. Set SRAMxEN in RCC_AHBxENR.

**Debug mode**

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop 1, Stop 2, Stop 3, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 65.2.5: Debug and low-power modes.*
10.7.2 Low-power background autonomous mode (LPBAM)

The devices support a low-power background autonomous mode (LPBAM), that allows peripherals to be functional and autonomous in Stop 0, Stop 1 and Stop 2 modes (without any software running).

Stop 0 and Stop 1 modes

In Stop 0 and Stop 1 modes, the autonomous peripherals are ADC4, DAC1, LPTIMx (x = 1 to 4), USARTx (x = 1 to 5), LPUART1, SPIx (x = 1 to 3), I2Cx (x = 1 to 4), MDF1, ADF1, GPDMA1 and LPDMA1:

- ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3 and ADF1 are autonomous only with LPDMA1 and SRAM4.
- LPTIM2, USARTx (x = 1 to 5), SPI1, SPI2, I2C1, I2C2, I2C4 and MDF1 are autonomous only with GPDMA1 and SRAM1 to SRAM4.

Stop 2 mode

In Stop 2 mode, the autonomous peripherals are ADC4, DAC1, LPTIM1, LPTIM3, LPUART1, SPI3, I2C3, ADF1 and LPDMA1. In this mode, the SRAM4 can be accessed by the LPDMA1.

LPBAM features

Those autonomous peripherals support the following features:

- Functionality in Stop mode thanks to its own independent clock (named kernel clock) request capability: the peripheral kernel clock is automatically switched on when requested by a peripheral, and automatically switched off when no peripheral requests it.
- DMA transfers supported in Stop mode thanks to the system clock request capability: the system clock (MSIS or HSI16) automatically switched on when requested by a peripheral, and automatically switched off when no peripheral requests it. When the system clock is requested by an autonomous peripheral, the system clock is woken up and distributed to all peripherals enabled in the RCC. This allows the DMA to access the enabled SRAM, and any enabled peripheral register (for instance GPIO or LPGPIO registers).
- Automatic start of the peripheral thanks to the hardware synchronous or asynchronous triggers (such as I/Os edge detection and low-power timer event)
- Wakeup from Stop mode with peripheral interrupt

The GPDMA1 and LPDMA1 are fully functional and the linked-list is updated in Stop mode, allowing the different DMA transfers to be linked without any CPU wakeup. This can be used to chain different peripherals transfers, or to write peripherals registers in order to change their configuration while remaining in Stop mode.

The DMA transfers from memory to memory can be started by hardware synchronous or asynchronous triggers, and the DMA transfers between peripherals and memories can also be gated by those triggers.
Here below some use-cases that can be done while remaining in Stop mode:

- ADC or DAC conversion triggered by a low-power timer (or any other trigger)
  - Wakeup from Stop mode on analog watchdog if the ADC conversion result is out of the programmed thresholds
  - Wakeup from Stop mode on DMA buffer event
- Audio digital filter data transfer into SRAM
  - Wakeup from Stop on sound activity detection
- I2C slave reception or transmission, SPI reception, UART/LPUART reception
  - Wakeup at the end of peripheral transfer or on DMA buffer event
- I2C master transfer, SPI transmission, UART/LPUART transmission, triggered by a low-power trigger (or any other trigger)
  - Example: Sensor periodic read
  - Wakeup at the end of peripheral transfer or on DMA buffer event
- Bridges between peripherals
  - Example: ADC converted data transferred by communication peripherals
- Data transfer from/to GPIO/LPGPIO to/from SRAM for:
  - Controlling external components
  - Implementing data transmission and reception protocols
- Data transfer from a SRAM to another one

10.7.3 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to Section 11: Reset and clock control (RCC).

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers. This bit must be set for the peripherals requesting clocks in Stop mode for LPBAM.

Disabling the peripherals autonomous clock in Stop 2 mode can be performed automatically by resetting the corresponding bit in the RCC_AHB3AMENR and RCC_APB3AMENR registers.
10.7.4 Low-power modes

Entering into a low-power mode

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex-M33 system control register is set on Return from ISR.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Caution: The peripherals with autonomous mode feature are able to generate an AHB or APB clock request, depending on their internal events. If a clock request is present when WFI or WFE is executed, the low-power mode entry is delayed until the clock request is released.

Exiting a low-power mode

The way the MCU exits the Sleep or Stop mode depends on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - an NVIC IRQ interrupt:
    - When SEVONPEND = 0 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with high enough priority wake up and interrupt the MCU.
    - When SEVONPEND = 1 in the Cortex-M33 system control register
      By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. All NVIC interrupts wake up the MCU, even the disabled ones. Only enabled NVIC interrupts with high enough priority wake up and interrupt the MCU.
  - an event:
    Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Stop 3, Standby or Shutdown mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see Figure 621: RTC block diagram).

After waking up from Standby or Shutdown mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).
Caution: When the device is in Stop mode, a peripheral interrupt powers on an internal oscillator. The corresponding NVIC interrupt channel must be enabled to allow the interrupt to exit the device from Stop mode. It is not allowed to disable a peripheral interrupt by disabling only the NVIC channel while keeping the peripheral interrupt enable, as the device could remain in Stop mode with clock ON.

The peripherals with autonomous mode feature are able to generate an AHB or APB clock request when the device is in Stop mode, depending on their internal events. The software must ensure that either DMA transfer or interrupt is served, by configuring properly and in a consistent way the RCC, the autonomous peripherals, the DMA channels and NVIC. Note that when an autonomous peripheral requests the bus clock in Stop mode, the AHB and APB clocks are distributed to all enabled peripherals (limited to SmartRun domain peripherals in Stop 2 mode). Consequently, enabled peripherals, even without autonomous mode capability, are temporarily clocked and can also generate an interrupt during this time. These peripherals interrupts wake up the device from Stop mode.

10.7.5 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The MCU enters the Sleep mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting the Sleep mode

The MCU exits the Sleep mode as described in *Exiting a low-power mode* (see the table below for details on how to exit the Sleep mode).

<table>
<thead>
<tr>
<th>Sleep mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry | WFI (wait for interrupt) or WFE (wait for event) while:  
| | -- SLEEPDEEP = 0  
| | -- No interrupt (for WFI) or event (for WFE) pending  
| | Refer to the Cortex-M33 system control register.  
| | On return from ISR while:  
| | -- SLEEPDEEP = 0 and  
| | -- SLEEPONEXIT = 1  
| | -- No interrupt pending  
| | Refer to the Cortex-M33 system control register.  

Table 90. Sleep mode
10.7.6 Stop 0 mode

The Stop 0 mode is based on the Cortex-M33 Deepsleep mod combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. In Stop 0 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

Some peripherals with the LPBAM capability can switch on HSI16 or MSIS or MSIK for transferring data (see Section 10.7.2 for details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 0 mode.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 0 mode

The MCU enters the Stop 0 mode as described in Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 91 for details on how to enter the Stop 0 mode).

If the Flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset (see Section 52.4: IWDG functional description).
- The real-time clock (RTC) is configured by the RTCEN bit in the RCC Backup domain control register (RCC_BDCR).
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BCDR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BCDR.
Several peripherals can be autonomous in Stop 0 mode and can add consumption if they are enabled (see Section 10.7.2 for more details).

The OPAMPs, the COMPs, the PVM and the PVD can be used in Stop 0 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

**Exiting the Stop 0 mode**

The MCU exits the Stop 0 mode as described in Exiting a low-power mode (see Table 91 for details on how to exit Stop 0 mode).

When exiting Stop 0 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the bit STOPWUCK is set in **RCC clock configuration register 1 (RCC_CFGR1)**. The MSIS oscillator is selected as system clock if STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSIS selection allows a wakeup at higher frequency (up to 24 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wakeup from Stop capability. All peripheral clocks must be enabled to allow a wakeup from Stop interrupt (see Peripheral clock gating).

When exiting the Stop 0 mode, the MCU is in Run mode, range 4.

### Table 91. Stop 0 mode

<table>
<thead>
<tr>
<th>Stop 0 mode</th>
<th>Description</th>
</tr>

<td>- SLEEPONEXIT = 1</td>
</tr>
<tr>
<td></td>
<td>- No interrupt pending</td>
</tr>
<tr>
<td></td>
<td>- LPMS = 000 in PWR_CR1</td>
</tr>
</tbody>
</table>

**Note:** To enter Stop 0 mode, all EXTI line pending bits (in the **EXTI rising edge pending register (EXTI_RPR2)**), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and the program execution continues.
If WFI or Return from ISR was used for entry:
- any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see Table 153: STM32U575/585 vector table).
- any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request (the peripheral vector must be enabled in the NVIC).

If WFE was used for entry and SEVONPEND = 0:
- any EXTI line configured in event mode (see Section 17.3: EXTI functional description).

If WFE was used for entry and SEVONPEND = 1:
- any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability (see Table 153: STM32U575/585 vector table).
- any EXTI line configured in event mode (see Section 17.3: EXTI functional description).
- any peripheral interrupt occurring when the AHB/APB clocks are present due to an autonomous peripheral clock request.

Note: All peripheral clocks must be enabled to allow this peripheral to generate a wakeup from Stop interrupt ([PERIPH]EN, [PERIPH]SMEN and [PERIPH]AMEN bits must be set in the RCC, and a functional independent clock must be selected).

Wakeup latency
Longest wakeup time between: MSIS or HSI16 wakeup time and Flash wakeup time from Stop 0 mode.

Table 91. Stop 0 mode (continued)
10.7.7 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the regulator is in low-power mode (see the table below for details on how to enter and exit Stop 1 mode).

10.7.8 Stop 2 mode

The Stop 2 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 2 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled.

Some peripherals with the LPBAM capability can switch on HSI16 or MSIS or MSIK for transferring data (see Section 10.7.2 for more details).

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduced consumption.

The BOR is always available in Stop 2 mode. The ULPMEN bit in the PWR.CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode.

I/O states in Stop 2 mode

In the Stop 2 mode, all I/O pins keep the same state as in the Run mode.

Entering Stop 2 mode

The MCU enters the Stop 2 mode as described in Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 93 for details on how to enter the Stop 2 mode).

If the Flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see Section 52.4: IWDG functional description).
- The real-time clock (RTC) is configured by the RTCEN bit in the RCC Backup domain control register (RCC_BDCR).
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

Several peripherals can be autonomous in Stop 2 mode and can add consumption if they are enabled (see Section 10.7.2 for more details).

The OPAMPs, the COMPs, the PVM and the PVD can be used in Stop 2 mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x = 1, 4), the DAC1 (two channels), the temperature sensor and the VREFBUF can consume power during the Stop 2 mode, unless they are disabled before entering this mode.

All the peripherals that cannot be enabled in Stop 2 mode must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring the RCC registers.
Exiting Stop 2 mode

The MCU exits the Stop 2 mode as defined in *Exiting a low-power mode* (see Table 93 for details on how to exit Stop 2 mode).

When exiting Stop 2 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the bit STOPWUCK is set in *RCC clock configuration register 1* (*RCC_CFGR1*). MSIS is selected as system clock if STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSI selection allows a wakeup at higher frequency (up to 24 MHz).

Several peripherals are autonomous in Stop mode, and can generate interrupts with wakeup from Stop capability. All peripheral clocks must be enabled to allow a wakeup from Stop interrupt (see *Peripheral clock gating*).

When exiting the Stop 2 mode, the MCU is in Run mode, range 4.

<table>
<thead>
<tr>
<th>Stop 2 mode</th>

</tr>
<tr>
<td></td>
<td>– LPMS = 010 in PWR_CR1</td>
</tr>
</tbody>
</table>

**Note:** To enter Stop 2 mode, all EXTI line pending bits (in *EXTI rising edge pending register (EXTI_RPR2)*), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.
10.7.9 Stop 3 mode

The Stop 3 mode is based on the Cortex-M33 Deepsleep mode combined with peripheral clock gating. In Stop 3 mode, all clocks in the core domain are stopped. The PLL, MSIS, MSIK, HSI16 and HSE oscillators are disabled. All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduce consumption.

The BOR is always available in Stop 3 mode. The ULPMEN bit in the PWR_CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode.

All other peripherals must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by configuring RCC registers.

I/O states in Stop 3 mode

In the Stop 3 mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.
Some I/Os (listed in Section 13.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Stop 3 mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Stop 3 mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

**Entering Stop 3 mode**

The MCU enters the Stop 3 mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 System Control register is set (see Table 94 for details on how to enter the Stop 3 mode).

If the Flash memory programming is ongoing, the Stop 3 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 3 mode entry is delayed until the APB access is finished.

In Stop 3 mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see Section 44.3: IWDG functional description).
- The real-time clock (RTC) is configured by the RTCEN bit in the RCC Backup domain control register (RCC_BDCR).
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPREDIV bits in RCC_BDCR.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in RCC_BDCR.

**Exiting Stop 3 mode**

The MCU exits the Stop 3 mode as described in *Exiting a low-power mode* (see Table 94 for details on how to exit Stop 3 mode).

When exiting Stop 3 mode by issuing an interrupt or a wakeup event, HSI16 is selected as system clock if the STOPWUCK bit is set in RCC clock configuration register 1 (RCC_CFRG1). MSIS is selected as system clock if STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSIS selection allows a wakeup at higher frequency (up to 24 MHz).

When exiting the Stop 3 mode, the MCU is in Run mode, range 4.
The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off. The SRAMs and register contents are lost except for registers in the Backup domain and Standby circuitry (see Figure 29: Power supply overview). SRAM2 content can be partially or fully preserved depending on RRSB1 and RRSB2 bits configuration in PWR_CR1. In this case, the low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The ULPMEN bit in the PWR_CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode.

Wakeup latency: Longest wakeup time between: MSIS or HSI16 wake up time and regulator wake up time from low-power mode + Flash wake up time from Stop 3 mode.

### 10.7.10 Standby mode

The lowest power mode in which the BOR is active is the Standby mode. It is based on the Cortex-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the Backup domain and Standby circuitry (see Figure 29: Power supply overview). SRAM2 content can be partially or fully preserved depending on RRSB1 and RRSB2 bits configuration in PWR_CR1. In this case, the low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The ULPMEN bit in the PWR_CR1 register must be configured to 1 to reach the lowest power consumption by forcing the BOR in ultra-low-power mode.

### I/O states in Standby mode

In the Standby mode, the I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers), or with a pull-down (see PWR_PDCRx registers), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O.

Some I/Os (listed in Section 13.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during
Standby mode setting their respective bit to 1 in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, x = 1 to 8) and the eight RTC tampers pins are available.

**Entering Standby mode**

The MCU enters the Standby mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 95 for details on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 52.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in *RCC Backup domain control register (RCC_BDCR)*.
- The internal RC oscillator LSI clock or LSI clock divided by 128, is configured by the LSION and LSIPRE bits in *RCC_BDCR*.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in *RCC_BDCR*.

**Exiting Standby mode**

The MCU exits the Standby mode as described in *Exiting a low-power mode*. The SBF status flag in the *PWR status register (PWR_SR)* indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for *PWR control register 3 (PWR_CR3)* (see Table 95 for more details on how to exit Standby mode).

When exiting Standby mode, I/Os that were configured with pull-up or pull-down during Standby through PWR_PUCRx or PWR_PDCRx, keep this configuration upon exiting Standby mode until the APC bit in PWR_CR3 is cleared. Once APC is cleared, the I/Os are either configured to their reset values or to the pull-up/pull-down state according to the GPIOx_PUPDR registers. The content of the PWR_PUCRx or PWR_PDCRx registers is not lost and can be re-used for a sub-sequent entering into Standby mode.

Some I/Os (listed in *Section 13.3.1: General-purpose I/O (GPIO)*) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so is configured at this reset value, as well when exiting Standby mode.

For I/Os, with a pull-up or pull-down pre-defined after reset (some JTAG/SW I/Os) or with the GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up are applied until APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.
The lowest power consumption is reached in Shutdown mode. It is based on the Deepsleep mode with the voltage regulator disabled. The core domain is consequently powered off. The PLL, HSI16, MSIS, MSIK and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the Backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, I/Os are by default in floating state. If the APC bit in the PWR_APCR register is set, the I/Os can be configured either with a pull-up (see PWR_PUCRx registers \((x=A,B,C,D,E,F,G,H)\)), or with a pull-down (see PWR_PDCRx registers \((x=A,B,C,D,E,F,G,H)\)), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register is set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same I/O. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in \(\text{Section 13.3.1: General-purpose I/O (GPIO)}\)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting to 1 their respective bit in the PWR_PUCRx or PWR_PDCRx registers, or to be configured to floating state if the bit is kept at 0.

The RTC outputs on PC13 and PB2 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. The 24 wakeup pins multiplexed on eight events (WKUPx, \(x = 1 \text{ to } 8\)) and the eight RTC tampers pins are available.
Entering Shutdown mode

The MCU enters the Shutdown mode as described in *Entering into a low-power mode*, when the SLEEPDEEP bit in the Cortex-M33 system control register is set (see Table 96 for details on how to enter Shutdown mode).

In Shutdown mode, the following features can be selected by programming individual control bits:

- The real-time clock (RTC) is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR). Caution: in case of VDD power-down, the RTC content is lost.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

**Caution:** The Shutdown mode cannot be entered if the BREN bit is set in the PWR Backup domain control register 1 (PWR_BDCR1). If BREN = 1, the Standby mode is entered instead of Shutdown mode.

Exiting Shutdown mode

The MCU exits the Shutdown mode as described in *Exiting a low-power mode*. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the Backup domain) are reset after a wakeup from Shutdown (see Table 96 for more details on how to exit Shutdown mode).

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR_PUCRx or PWR_PDCRx lose their configuration and are configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in Section 13.3.1: General-purpose I/O (GPIO)).

</table>
10.7.12 Power modes output pins

In order to help the debug, three signals are available as device pins alternate functions:

- **CSLEEP**
  When set, CSLEEP indicates that the CPU is in Sleep mode: WFI or WFE has been executed.
  When cleared, CSLEEP indicates that the CPU is in Run mode.

- **CDSTOP**
  When set, CDSTOP indicates that the CPU domain (CD) is in CStop mode, meaning that the following conditions are filled:
  - WFI or WFE has been executed with CPU SLEEPDEEP = 1.
  - No AHB/APB clock is running in the CPU domain.
  When cleared, CDSTOP indicates that the CPU domain is not in CStop mode: AHB/APB clocks run in the CPU domain.

- **SRDSTOP**
  When set, SRDSTOP indicates that the SmartRun domain (SRD) is in DStop mode, meaning that the following conditions are filled:
  - WFI or WFE has been executed with CPU SLEEPDEEP = 1.
  - No AHB/APB clock is running in the SRD domain.
  When cleared, SRDSTOP indicates that the SmartRun domain is not in DStop mode: AHB/APB clocks run in the SRD domain.

*Note:* The AHB/APB clocks run after WFI or WFE has been executed if an autonomous peripheral requests its bus clock in Stop mode. The peripherals bus clock request can delay or prevent the device to enter low-power modes (refer to Section 10.7.2: Low-power background autonomous mode (LPBAM) and Section 10.7.4: Low-power modes).

The table below explains the MCU power mode depending on these signals states.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. CSLEEP, CDSTOP and SRDSTOP are generated in core domain, consequently they are not driven in Standby and Shutdown modes.

---

The AHB/APB clocks run after WFI or WFE has been executed if an autonomous peripheral requests its bus clock in Stop mode. The peripherals bus clock request can delay or prevent the device to enter low-power modes (refer to Section 10.7.2: Low-power background autonomous mode (LPBAM) and Section 10.7.4: Low-power modes).
10.8 PWR security and privileged protection

10.8.1 PWR security protection

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, some PWR register fields can be secured against non-secure access.

The PWR TrustZone security allows the following features to be secured through the PWR_SECCFGR register:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- \( V_{BAT} \) mode
- I/Os pull-up/pull-down configuration

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling (VOS) configuration and the regulator booster (BOOSTEN) are secure.
- A GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode is secure.
- The UCPD1 is secure in the GTZC: the PWR_UCPDR register is secure.

Table 98 gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR. As soon as at least one function is configured to be secure, the PWR clock control is also secure in the RCC.

A non-secure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a non-secure write access.
- The secured bits are read as 0 (RAZ) with a non-secure read access.

A non-secure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a non-secure read access.

When the TrustZone security is disabled (TZEN = 0), PWR_SECCFGR is RAZ/WI and all other registers are non-secure.

</tr>
</tbody>
</table>
10.8.2 PWR privileged protection

By default, after a reset, all PWR registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR that can be written with privileged access only. PWR_PRIVCFGR can be read by secure and non secure, privileged and unprivileged accesses.

The SPRIV bit in PWR_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in Table 98: PWR Security configuration summary).

When the SPRIV bit is set in PWR_PRIVCFGR:
- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit of PWR_PRIVCFGR can be written with privileged access only, secure or non-secure. This bit configures the privileged access of all PWR securable functions that are configured as non-secure (defined by PWR_SECCFGR, GTZC, RCC or GPIO as shown in Table 98: PWR Security configuration summary (continued)).
When the NSPRIV bit is set in PWR_PRIVCFGR:

- The PWR securable bits that are configured as non-secure, can be written only with privileged access.
- The PWR securable bits that are configured as non-secure, can be read only with privileged access except PWR_PRIVCFGR that can be read by privileged or unprivileged accesses.
- The VOSRDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_SMVR, PWR_BDSR and PWR_WUSR, can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

</table>

1. The PWR_S3WU interrupt is generated only when the device is in Stop 3 mode (not applicable in Run, Sleep, Stop 0, Stop 1 and Stop 2 modes). The PWR_S3WU interrupt is not generated for internal wakeup sources (WUSELx = 11).

2. Only an interrupt can wake up from Stop 3 mode (not possible with an event).
10.10 PWR registers

10.10.1 PWR control register 1 (PWR_CR1)

This register is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGFR.

This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x00

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SRAM4PD**: SRAM4 power down

This bit is used to reduce the consumption by powering off the SRAM4.

0: SRAM4 powered on
1: SRAM4 powered off

Bit 10 **SRAM3PD**: SRAM3 power down

This bit is used to reduce the consumption by powering off the SRAM3.

0: SRAM3 powered on
1: SRAM3 powered off

Bit 9 **SRAM2PD**: SRAM2 power down

This bit is used to reduce the consumption by powering off the SRAM2.

0: SRAM2 powered on
1: SRAM2 powered off

Bit 8 **SRAM1PD**: SRAM1 power down

This bit is used to reduce the consumption by powering off the SRAM1.

0: SRAM1 powered on
1: SRAM1 powered off

Bit 7 **ULPMEN**: BOR ultra-low power mode

This bit is used to reduce the consumption by configuring the BOR in discontinuous mode.

0: BOR operating in continuous (normal) mode in Stop 1, Stop 2, Stop 3 and Standby modes and when the regulator is in range 4 (Run, Sleep or Stop 0 mode)
1: BOR operating in discontinuous (ultra-low power) mode in Stop 1, Stop 2, Stop 3 and Standby modes, and when the regulator is in range 4 (Run, Sleep or Stop 0 mode)

**Caution:** This bit must be set to reach the lowest power consumption in the low-power modes.
Bit 6 **RRSB2**: SRAM2 page 2 retention in Stop 3 and Standby modes
This bit is used to keep the SRAM2 page 2 content in Stop 3 and Standby modes. The SRAM2 page 2 corresponds to the last 56 Kbytes of the SRAM2 (from SRAM2 base address + 0x2000 to SRAM2 base address + 0xFFF).

- 0: SRAM2 page2 content not retained in Stop3 and Standby modes
- 1: SRAM2 page2 content retained in Stop 3 and Standby modes

*Note:* This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bit 5 **RRSB1**: SRAM2 page 1 retention in Stop 3 and Standby modes
This bit is used to keep the SRAM2 page 1 content in Stop 3 and Standby modes. The SRAM2 page 1 corresponds to the first 8 Kbytes of the SRAM2 (from SRAM2 base address to SRAM2 base address + 0x1FFF).

- 0: SRAM2 page1 content not retained in Stop 3 and Standby modes
- 1: SRAM2 page1 content retained in Stop 3 and Standby modes

*Note:* This bit has no effect in Shutdown mode.
The backup SRAM is also retained when this bit is set.

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:0 **LPMS[2:0]**: Low-power mode selection
These bits select the low-power mode entered when the CPU enters the Deepsleep mode.

- 000: Stop 0 mode
- 001: Stop 1 mode
- 010: Stop 2 mode
- 011: Stop 3 mode
- 10x: Standby mode (Standby mode also entered if LPMS = 11X in PWR_CR1 with BREN = 1 in PWR_BDCR1)
- 11x: Shutdown mode if BREN = 0 in PWR_BDCR1

10.10.2 **PWR control register 2 (PWR_CR2)**
This register is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when LPMSEC = 0 and NSPRIV = 1.

0: SRAM3 page 6 content retained in Stop modes  
1: SRAM3 page 6 content lost in Stop modes

Bit 20  **SRAM3PDS5**: SRAM3 page 5 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)  
0: SRAM3 page 5 content retained in Stop modes  
1: SRAM3 page 5 content lost in Stop modes

Bit 19  **SRAM3PDS4**: SRAM3 page 4 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)  
0: SRAM3 page 4 content retained in Stop modes  
1: SRAM3 page 4 content lost in Stop modes

Bit 18  **SRAM3PDS3**: SRAM3 page 3 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)  
0: SRAM3 page 3 content retained in Stop modes  
1: SRAM3 page 3 content lost in Stop modes

Bit 17  **SRAM3PDS2**: SRAM3 page 2 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)  
0: SRAM3 page 2 content retained in Stop modes  
1: SRAM3 page 2 content lost in Stop modes

Bit 16  **SRAM3PDS1**: SRAM3 page 1 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)  
0: SRAM3 page 1 content retained in Stop modes  
1: SRAM3 page 1 content lost in Stop modes

Bit 15  Reserved, must be kept at reset value.

Bit 14  **FLASHFWU**: Flash memory fast wakeup from Stop 0 and Stop 1 modes  
This bit is used to obtain the best trade-off between low-power consumption and wakeup time when exiting the Stop 0 or Stop 1 modes.  
When this bit is set, the Flash memory remains in normal mode in Stop 0 and Stop 1 modes, which offers a faster startup time with higher consumption.  
0: Flash memory enters low-power mode in Stop 0 and Stop 1 modes (lower-power consumption).  
1: Flash memory remains in normal mode in Stop 0 and Stop 1 modes (faster wakeup time).

Bit 13  **SRAM4FWU**: SRAM4 fast wakeup from Stop 0, Stop 1 and Stop 2 modes  
This bit is used to obtain the best trade-off between low-power consumption and wakeup time. SRAM4 wakeup time increases the wakeup time when exiting Stop 0, 1 and 2 modes, and also increases the LPDMA access time to SRAM4 during Stop modes.  
0: SRAM4 enters low-power mode in Stop 0, 1 and 2 modes (source biasing for lower-power consumption).  
1: SRAM4 remains in normal mode in Stop 0, 1 and 2 modes (higher consumption but no SRAM4 wakeup time).
Bit 12 **PKARAMPDS**: PKA SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: PKA SRAM content retained in Stop modes
- 1: PKA SRAM content lost in Stop modes

Bit 11 **PRAMPDS**: FMAC, FDCAN and USB peripherals SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: FMAC, FDCAN and USB peripherals SRAM content retained in Stop modes
- 1: FMAC, FDCAN and USB peripherals SRAM content lost in Stop modes

Bit 10 **DMA2DRAMPDS**: DMA2D SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: DMA2D SRAM content retained in Stop modes
- 1: DMA2D SRAM content lost in Stop modes

Bit 9 **DC1RAMPDS**: DCACHE1 SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: DCACHE1 SRAM content retained in Stop modes
- 1: DCACHE1 SRAM content lost in Stop modes

Bit 8 **ICRAMPDS**: ICACHE SRAM power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: ICACHE SRAM content retained in Stop modes
- 1: ICACHE SRAM content lost in Stop modes

Bit 7 Reserved, must be kept at reset value.

Bit 6 **SRAM4PDS**: SRAM4 power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: SRAM4 content retained in Stop modes
- 1: SRAM4 content lost in Stop modes

Bit 5 **SRAM2PDS2**: SRAM2 page 2 (56 Kbytes) power-down in Stop modes (Stop 0, 1, 2)
- 0: SRAM2 page 2 content retained in Stop modes
- 1: SRAM2 page 2 content lost in Stop modes

*Note: The SRAM2 page 2 retention in Stop 3 is controlled by RRSB2 bit in PWR.CR1.*

Bit 4 **SRAM2PDS1**: SRAM2 page 1 (8 Kbytes) power-down in Stop modes (Stop 0, 1, 2)
- 0: SRAM2 page 1 content retained in Stop modes
- 1: SRAM2 page 1 content lost in Stop modes

*Note: The SRAM2 page 1 retention in Stop 3 is controlled by RRSB1 bit in PWR.CR1.*

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SRAM1PDS3**: SRAM1 page 3 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: SRAM1 page 3 content retained in Stop modes
- 1: SRAM1 page 3 content lost in Stop modes

Bit 1 **SRAM1PDS2**: SRAM1 page 2 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: SRAM1 page 2 content retained in Stop modes
- 1: SRAM1 page 2 content lost in Stop modes

Bit 0 **SRAM1PDS1**: SRAM1 page 1 (64 Kbytes) power-down in Stop modes (Stop 0, 1, 2, 3)
- 0: SRAM1 page 1 content retained in Stop modes
- 1: SRAM1 page 1 content lost in Stop modes
10.10.3 **PWR control register 3 (PWR_CR3)**

This register is protected against non-secure access when VDMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x08

Power-on reset value: 0x0000 0000

Exit from Standby modes: not affected

System reset: not affected, except REGSEL that is cleared to 0

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSTEN**: Fast soft start

- 0: LDO/SMPS fast startup disabled (limited inrush current)
- 1: LDO/SMPS fast startup enabled

Bit 1 **REGSEL**: Regulator selection

- 0: LDO selected
- 1: SMPS selected

*Note: REGSEL is reserved and must be kept at reset value in packages without SMPS.*

Bit 0 Reserved, must be kept at reset value.
10.10.4 PWR voltage scaling register (PWR_VOSR)

Some register fields are protected against non-secure access depending on RCC_SECCFGR.

These fields can be protected against unprivileged access depending on PWR_PRIVCFGR.

Address offset: 0x0C

Reset value: 0x0000 8000

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 BOOSTEN: EPOD booster enable

This bit is protected against non-secure access when SYSCLKSEC = 1 in RCC_SECCFGR.
It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.
This bit must be set in range 1 and range 2 before increasing the system clock frequency above 55 MHz.
This bit is reset when going into Stop modes (0, 1, 2, 3).
0: Booster disabled
1: Booster enabled

Bits 17:16 VOS[1:0]: Voltage scaling range selection

This field is protected against non-secure access when SYSCLKSEC = 1 in RCC_SECCFGR. It is protected against unprivileged access when SYSCLKSEC = 1 in RCC_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SYSCLKSEC = 0 and NSPRIV = 1.
00: Range 4 (lowest power)
01: Range 3
10: Range 2
11: Range 1 (highest frequency)

Bit 15 VOSRDY: Ready bit for VCORE voltage scaling output selection
0: Not ready, voltage level < VOS selected level
1: Ready, voltage level ≥ VOS selected level

Bit 14 BOOSTRDY: EPOD booster ready
This bit is set to 1 by hardware when the power booster startup time is reached. The system clock frequency can be switched higher than 55 MHz only after this bit is set.
0: Power booster not ready
1: Power booster ready

Bits 13:0 Reserved, must be kept at reset value.
10.10.5 PWR supply voltage monitoring control register (PWR_SVMCR)

This register is protected against non-secure access when VDMSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when VDMSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when VDMSEC = 0 and NSPRIV = 1.

Address offset: 0x10
Reset value: 0x0000 0000

</table>

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ASV**: VDDA independent analog supply valid

This bit is used to validate the VDDA supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the analog peripherals. If VDDA is not always present in the application, the VDDA voltage monitor can be used to determine whether this supply is ready or not.

0: VDDA not present: logical and electrical isolation is applied to ignore this supply.
1: VDDA valid

Bit 29 **IO2SV**: VDDIO2 independent I/Os supply valid

This bit is used to validate the VDDIO2 supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PG[15:2]. If VDDIO2 is not always present in the application, the VDDIO2 voltage monitor can be used to determine whether this supply is ready or not.

0: VDDIO2 not present: logical and electrical isolation is applied to ignore this supply.
1: VDDIO2 valid

Bit 28 **USV**: VDDUSB independent USB supply valid

This bit is used to validate the VDDUSB supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB OTG peripheral. If VDDUSB is not always present in the application, the VDDUSB voltage monitor can be used to determine whether this supply is ready or not.

0: VDDUSB not present: logical and electrical isolation is applied to ignore this supply.
1: VDDUSB valid

Bit 27 **AVM2EN**: VDDA independent analog supply voltage monitor 2 enable (1.8 V threshold)

0: VDDA voltage monitor 2 disabled
1: VDDA voltage monitor 2 enabled

Bit 26 **AVM1EN**: VDDA independent analog supply voltage monitor 1 enable (1.6 V threshold)

0: VDDA voltage monitor 1 disabled
1: VDDA voltage monitor 1 enabled
Bit 25 **IO2VMEN**: $V_{DDIO2}$ independent I/Os voltage monitor enable
- 0: $V_{DDIO2}$ voltage monitor disabled
- 1: $V_{DDIO2}$ voltage monitor enabled

Bit 24 **UVMEN**: $V_{DDUSB}$ independent USB voltage monitor enable
- 0: $V_{DDUSB}$ voltage monitor disabled
- 1: $V_{DDUSB}$ voltage monitor enabled

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:5 **PVDLS[2:0]**: Programmable voltage detector (PVD) level selection
These bits select the voltage threshold detected by the PVD:
- 000: $V_{PVDD0}$ around 2.0 V
- 001: $V_{PVDD1}$ around 2.2 V
- 010: $V_{PVDD2}$ around 2.4 V
- 011: $V_{PVDD3}$ around 2.5 V
- 100: $V_{PVDD4}$ around 2.6 V
- 101: $V_{PVDD5}$ around 2.8 V
- 110: $V_{PVDD6}$ around 2.9 V
- 111: External input analog voltage $PVD_{IN}$ (compared internally to $V_{REFINT}$)

Bit 4 **PVDE**: Programmable voltage detector enable
- 0: PVD disabled
- 1: PVD enabled

Bits 3:0 Reserved, must be kept at reset value.

### 10.10.6 PWR wakeup control register 1 (PWR_WUCR1)

Each register bit WUPEnx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in PWR_SECCFGR.

Each bit WUPEnx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x14

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

ST
Bits 31:8  Reserved, must be kept at reset value.

Bit 7  **WUPP8**: Wakeup pin WKUP8 polarity
       This bit must be configured when WUPEN8 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 6  **WUPP7**: Wakeup pin WKUP7 polarity
       This bit must be configured when WUPEN7 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 5  **WUPP6**: Wakeup pin WKUP6 polarity
       This bit must be configured when WUPEN6 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 4  **WUPP5**: Wakeup pin WKUP5 polarity
       This bit must be configured when WUPEN5 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 3  **WUPP4**: Wakeup pin WKUP4 polarity
       This bit must be configured when WUPEN4 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 2  **WUPP3**: Wakeup pin WKUP3 polarity
       This bit must be configured when WUPEN3 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 1  **WUPP2**: Wakeup pin WKUP2 polarity
       This bit must be configured when WUPEN2 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)

Bit 0  **WUPP1**: Wakeup pin WKUP1 polarity.
       This bit must be configured when WUPEN1 = 0.
       0: Detection on high level (rising edge)
       1: Detection on low level (falling edge)
10.10.8 **PWR wakeup control register 3 (PWR_WUCR3)**

Each register field WUSELx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in PWR_SECCFGR.

Each field WUSELx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Bits 31:1 Reserved, must be kept at reset value.

Bit 0  **DBP**: Disable Backup domain write protection

In reset state, all registers and SRAM in Backup domain are protected against parasitic write access. This bit must be set to enable the write access to these registers.

0: Write access to Backup domain disabled

1: Write access to Backup domain enabled

10.10.12  **PWR USB Type-C and Power Delivery register (PWR_UCPDR)**

This register is protected against non-secure access when UCPD1SEC = 1 in TZSC_SECCFGR.

This register is protected against unprivileged access when UCPD1SEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when UCPD1SEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x2C

Reset value: 0x0000 0000

(reset value not affected by exit from Standby modes)

</table>

Bits 31:2 Reserved, must be kept at reset value.
**Bit 1** **UCPD_STBY**: UCPD Stop 3 and Standby modes

When set, this bit is used to memorize the UCPD configuration in Stop 3 and Standby modes. This bit must be written to 1 just before entering Stop 3 or Standby mode when using UCPD. It must be written to 0 after exiting Stop 3 or Standby mode and before writing any UCPD registers.

**Bit 0** **UCPD_DBDIS**: UCPD dead battery disable

After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to handover control to the UCPD (the UCPD must be initialized before doing the disable).

- 0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins
- 1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins

### 10.10.13 PWR security configuration register (PWR_SECCFGR)

This register can be written only when the access is secure. It can be read by secure or non-secure access.

This register is write-protected against unprivileged write access when SPRIV = 1 in PWR_PRIVCFGR.

Address offset: 0x30

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

**Bit 15** **APCSEC**: Pull-up/pull-down secure protection

- 0: PWR_APCR can be read and written with secure or non-secure access.
- 1: PWR_APCR can be read and written only with secure access.

**Bit 14** **VBSEC**: Backup domain secure protection

- 0: PWR_BDCR1, PWR_BDCR2 and PWR_DBPR can be read and written with secure or non-secure access.
- 1: PWR_BDCR1, PWR_BDCR2 and PWR_DBPR can be read and written only with secure access.

**Bit 13** **VDMSEC**: Voltage detection and monitoring secure protection

- 0: PWR_SVMCR and PWR_CR3 can be read and written with secure or non-secure access.
- 1: PWR_SVMCR and PWR_CR3 can be read and written only with secure access.
**Bit 12** **LPMSEC**: Low-power modes secure protection
- 0: PWR_CR1, PWR_CR2 and CSSF in the PWR_SR can be read and written with secure or non-secure access.
- 1: PWR_CR1, PWR_CR2, and CSSF in the PWR_SR can be read and written only with secure access.

**Bits 11-8** Reserved, must be kept at reset value.

**Bit 7** **WUP8SEC**: WUP8 secure protection
- 0: Bits related to the WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP8 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 6** **WUP7SEC**: WUP7 secure protection
- 0: Bits related to the WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP7 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 5** **WUP6SEC**: WUP6 secure protection
- 0: Bits related to the WKUP6 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP6 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 4** **WUP5SEC**: WUP5 secure protection
- 0: Bits related to the WKUP5 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP5 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 3** **WUP4SEC**: WUP4 secure protection
- 0: Bits related to the WKUP4 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP4 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 2** **WUP3SEC**: WUP3 secure protection
- 0: Bits related to the WKUP3 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP3 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 1** **WUP2SEC**: WUP2 secure protection
- 0: Bits related to the WKUP2 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP2 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.

**Bit 0** **WUP1SEC**: WUP1 secure protection
- 0: Bits related to the WKUP1 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written with secure or non-secure access.
- 1: Bits related to the WKUP1 pin in PWR_WUCR1, PWR_WUCR2, PWR_WUCR3 and PWR_WUSCR can be read and written only with secure access.
10.10.14 PWR privilege control register (PWR_PRIVCFGR)

This register can be written only when the access is privileged. It can be read by privileged or unprivileged access.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: PWR non-secure functions privilege configuration

This bit is set and reset by software. It can be written only by privileged access, secure or non-secure.

0: Read and write to PWR non-secure functions can be done by privileged or unprivileged access.

1: Read and write to PWR non-secure functions can be done by privileged access only.

Bit 0 **SPRIV**: PWR secure functions privilege configuration

This bit is set and reset by software. It can be written only by a secure privileged access.

0: Read and write to PWR secure functions can be done by privileged or unprivileged access.

1: Read and write to PWR secure functions can be done by privileged access only.

10.10.15 PWR status register (PWR_SR)

Some register fields are protected against non-secure access depending on PWR_SECCFGR.

Some register fields are protected against unprivileged access depending on PWR_PRIVCFGR.

Address offset: 0x38

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.
Bit 2  **SBF**: Standby flag  
This bit is set by hardware when the device enters the Standby mode, and is cleared by 
writing 1 to the CSSF bit, or by a power-on reset. It is not cleared by the system reset.  
0: The device did not enter Standby mode.  
1: The device entered Standby mode.

Bit 1  **STOPF**: Stop flag  
This bit is set by hardware when the device enters a Stop mode, and is cleared by software 
by writing 1 to the CSSF bit.  
0: The device did not enter any Stop mode.  
1: The device entered a Stop mode.

Bit 0  **CSSF**: Clear Stop and Standby flags  
This bit is protected against non-secure access when LPMSEC = 1 in PWR_SECCFGR.  
This bit is protected against unprivileged access when LPMSEC = 1 and SPRIV = 1 in 
PWR_PRIVCFG, or when LPMSEC = 0 and NSPRIV = 1.  
Writing 1 to this bit clears the STOPF and SBF flags.

### 10.10.16 PWR supply voltage monitoring status register (PWR_SVMSR)

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **VDDA2RDY**: VDDA ready versus 1.8 V voltage monitor  
0: VDDA is below the threshold of the VDDA voltage monitor 2 (around 1.8 V).  
1: VDDA is equal or above the threshold of the VDDA voltage monitor 2 (around 1.8 V).

Bit 26  **VDDA1RDY**: VDDA ready versus 1.6V voltage monitor  
0: VDDA is below the threshold of the VDDA voltage monitor 1 (around 1.6 V).  
1: VDDA is equal or above the threshold of the VDDA voltage monitor 1 (around 1.6 V).

Bit 25  **VDDIO2RDY**: VDDIO2 ready  
0: VDDIO2 is below the threshold of the VDDIO2 voltage monitor.  
1: VDDIO2 is equal or above the threshold of the VDDIO2 voltage monitor.

Bit 24  **VDDUSBRDY**: VDDUSB ready  
0: VDDUSB is below the threshold of the VDDUSB voltage monitor.  
1: VDDUSB is equal or above the threshold of the VDDUSB voltage monitor.
10.10.17 PWR Backup domain status register (PWR_BDSR)

Access: 14 AHB clock cycles added compared to a standard AHB access
Address offset: 0x40
Backup domain reset value: 0x0000 0000
Power-on reset: not affected
Exit from Standby modes: not affected
System reset: not affected

| Bit 31:4 | Reserved, must be kept at reset value. |
| Bit 30  | TEMPH: Temperature level monitoring versus high threshold |
|         | 0: Temperature < high threshold |
|         | 1: Temperature ≥ high threshold |
| Bit 29  | TEMPL: Temperature level monitoring versus low threshold |
|         | 0: Temperature > low threshold |
|         | 1: Temperature ≤ low threshold |
Bit 1 **VBATH**: Backup domain voltage level monitoring versus high threshold
0: Backup domain voltage level < high threshold
1: Backup domain voltage level ≥ high threshold

Bit 0  Reserved, must be kept at reset value.

10.10.18 **PWR wakeup status register (PWR_WUSR)**

Access: 14 AHB clock cycles added compared to a standard AHB access
Address offset: 0x44

</tbody>
</table>

Bits 31:8  Reserved, must be kept at reset value.

Bit 7 **WUF8**: Wakeup flag 8
This bit is set when a wakeup event is detected on WKUP8 pin. This bit is cleared by writing 1 in the CWUF8 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN8 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 6 **WUF7**: Wakeup flag 7
This bit is set when a wakeup event is detected on WKUP7 pin. This bit is cleared by writing 1 in the CWUF7 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN7 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 5 **WUF6**: Wakeup flag 6
This bit is set when a wakeup event is detected on WKUP6 pin. This bit is cleared by writing 1 in the CWUF6 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN6 = 0.
If WUSEL = 11, this bit is cleared by hardware when all internal wakeup source are cleared.

Bit 4 **WUF5**: Wakeup flag 5
This bit is set when a wakeup event is detected on WKUP5 pin. This bit is cleared by writing 1 in the CWUF5 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN5 = 0.

Bit 3 **WUF4**: Wakeup flag 4
This bit is set when a wakeup event is detected on WKUP4 pin. This bit is cleared by writing 1 in the CWUF4 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN4 = 0.

Bit 2 **WUF3**: Wakeup flag 3
This bit is set when a wakeup event is detected on WKUP3 pin. This bit is cleared by writing 1 in the CWUF3 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN3 = 0.
Bit 1 **WUF2**: Wakeup flag 2

This bit is set when a wakeup event is detected on WKUP2 pin. This bit is cleared by writing 1 in the CWUF2 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN2 = 0.

Bit 0 **WUF1**: Wakeup flag 1

This bit is set when a wakeup event is detected on WKUP1 pin. This bit is cleared by writing 1 in the CWUF1 bit of PWR_WUSCR when WUSEL ≠ 11, or by hardware when WUPEN1 = 0.

### 10.10.19 PWR wakeup status clear register (PWR_WUSCR)

Each register bit CWUFx (x = 1 to 8) is protected against non-secure access when WUPxSEC = 1 in PWR_SECCFG.

Each bit CWUFx is protected against unprivileged access when WUPxSEC = 1 in PWR_SECCFG and SPRIV = 1 in PWR_PRIVCFG, or when WUPxSEC = 0 and NSPRIV = 1.

Bits 31:8: Reserved, must be kept at reset value.

- **Bit 7 CWUF8**: Wakeup flag 8
  - Writing 1 to this bit clears the WUF8 flag in PWR_WUSR.

- **Bit 6 CWUF7**: Wakeup flag 7
  - Writing 1 to this bit clears the WUF7 flag in PWR_WUSR.

- **Bit 5 CWUF6**: Wakeup flag 6
  - Writing 1 to this bit clears the WUF6 flag in PWR_WUSR.

- **Bit 4 CWUF5**: Wakeup flag 5
  - Writing 1 to this bit clears the WUF5 flag in PWR_WUSR.

- **Bit 3 CWUF4**: Wakeup flag 4
  - Writing 1 to this bit clears the WUF4 flag in PWR_WUSR.

- **Bit 2 CWUF3**: Wakeup flag 3
  - Writing 1 to this bit clears the WUF3 flag in PWR_WUSR.

- **Bit 1 CWUF2**: Wakeup flag 2
  - Writing 1 to this bit clears the WUF2 flag in PWR_WUSR.

- **Bit 0 CWUF1**: Wakeup flag 1
  - Writing 1 to this bit clears the WUF1 flag in PWR_WUSR.
10.10.20 PWR apply pull configuration register (PWR_APCR)

This register is protected against non-secure access when APCSEC = 1 in PWR_SECCFGR.

This register is protected against unprivileged access when APCSEC = 1 and SPRIV = 1 in PWR_PRIVCFGR, or when APCSEC = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x4C

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in PWR_PUCRx and PWR_PDCRx are applied. When this bit is cleared, PWR_PUCRx and PWR_PDCRx are not applied to the I/Os.

10.10.21 PWR port A pull-up control register (PWR_PUCRA)

Each register bit PUy is protected against non-secure access when SECy = 1 in GPIOA_SECCFGR.

Each register bit PUy is protected against unprivileged access when SECy = 1 in GPIOA_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

10.10.33 PWR port G pull-up control register (PWR_PUCRG)

Each register bit PUy is protected against non-secure access when SECy = 1 in GPIOG_SECCFGR.

Each register bit PUy is protected against unprivileged access when SECy = 1 in GPIOG_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x80

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

10.10.34 PWR port G pull-down control register (PWR_PDCRG)

Each register bit PDy is protected against non-secure access when SECy = 1 in GPIOG_SECCFGR.

Each register bit PDy is protected against unprivileged access when SECy = 1 in GPIOG_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x84

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PDy**: Port G pull-down bit y (y = 15 to 0)

When set, each bit activates the pull-down on PGy when the APC bit is set in PWR_APCR. The pull-down is not activated if the corresponding PDy bit is also set.
### 10.10.35 PWR port H pull-up control register (PWR_PUCRH)

Each register bit PUy is protected against non-secure access when SECy = 1 in GPIOH_SECCFGR.

Each register bit PUy is protected against unprivileged access when SECy = 1 in GPIOH_SECCFGR and SPRIV = 1 in PWR_PRVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x88

Reset value: 0x0000 0000

(reset value not affected by exit Standby mode)

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  PUy: Port H pull-up bit y (y = 15 to 0)

When set, each bit activates the pull-up on PHy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.

### 10.10.36 PWR port H pull-down control register (PWR_PDCRH)

Each register bit PDy is protected against non-secure access when SECy = 1 in GPIOH_SECCFGR.

Each register bit PDy is protected against unprivileged access when SECy = 1 in GPIOH_SECCFGR and SPRIV = 1 in PWR_PRVCFGR, or when SECy = 0 and NSPRIV = 1.

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PDy**: Port H pull-down bit y (y = 15 to 0)
When set, each bit activates the pull-down on PHy when the APC bit is set in PWR_APCR.

### 10.10.37 PWR port I pull-up control register (PWR_PUCRI)

Each register bit PUy is protected against non-secure access when SECy = 1 in GPIOI_SECCFGR.

Each register bit PUy is protected against unprivileged access when SECy=1 in GPIOI_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x90

Reset value: 0x0000 0000
(reset value not affected by exit Standby mode)

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **PUy**: Port I pull-up bit y (y = 7 to 0)
When set, each bit activates the pull-up on PIy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDy bit is also set.
10.10.38 PWR port I pull-down control register (PWR_PDCRI)

Each register bit PDy is protected against non-secure access when SECy = 1 in GPIOI_SECCFGR.

Each register bit PDy is protected against unprivileged access when SECy = 1 in GPIOI_SECCFGR and SPRIV = 1 in PWR_PRIVCFGFR, or when SECy = 0 and NSPRIV = 1.

Access: 14 AHB clock cycles added compared to a standard AHB access

Address offset: 0x94

Reset value: 0x0000 0000

Bits 31:8: Reserved, must be kept at reset value.

Bits 7:0: PDy: Port I pull-down bit y (y = 7 to 0)

When set, each bit activates the pull-down on PIy when the APC bit is set in PWR_APCR.

Refer to Section 2.3 for the register boundary addresses.
11  Reset and clock control (RCC)

11.1  Introduction

The reset and clock control (RCC) manages the different kind of reset, and generates all clocks for the bus and peripherals.

11.2  RCC pins and internal signals

The table below lists the RCC inputs and output signals connected to package pins or balls.

Table 101. RCC input/output signals connected to package pins or balls

11.3  RCC reset functional description

There are three types of reset:
- a system reset
- a power reset
- a Backup domain reset

11.3.1  Power reset

A power reset is generated when one of the following events occurs:
- a Brownout reset (BOR)
- when exiting Standby mode
- when exiting Shutdown mode

A BOR sets all registers to their reset values except the ones in the Backup domain.

When exiting Standby mode, all registers in the core domain are set to their reset value. Registers outside the core domain (RTC, TAMP, WKUP, IWDG, and Standby/Shutdown mode control) are not impacted.

When exiting Shutdown mode, a Brownout reset is generated, resetting all registers except those in the Backup domain.
11.3.2 System reset

A system reset sets all registers to their reset values except the reset flags in RCC control/status register (RCC_CSR) and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:

- a low level on the NRST pin (external reset)
- a window watchdog event (WWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset) (see Software reset)
- a low-power mode security reset (see Low-power mode security reset)
- an option-byte loader reset (see Option byte loader reset)
- a Brownout reset

The reset source can be identified by checking the reset flags in RCC control/status register (RCC_CSR).

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected via the boot option bytes.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case on an internal reset, the internal pull-up R_{PU} is deactivated in order to save the power consumption through the pull-up resistor.

**Figure 32. Simplified diagram of the reset circuit**

![Simplified diagram of the reset circuit](image)

Software reset

The SYSRESETREQ bit in Cortex-M33 application interrupt and reset control register must be set to force a software reset on the device.
Low-power mode security reset

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- Entering Standby mode: this type of reset is enabled by resetting nRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Entering Stop mode: this type of reset is enabled by resetting nRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.
- Entering Shutdown mode: this type of reset is enabled by resetting nRST_SHDW bit in user option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the user option bytes, refer to Section 7.4.1: Option bytes description.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit is set in the FLASH_NSCR register. This bit is used to launch the option byte loading by software.

11.3.3 Backup domain reset

The Backup domain has two specific resets.

A Backup domain reset is generated when one of the following events occurs:

- a software reset, triggered by setting the BDRST bit in the RCC Backup domain control register (RCC_BDCR)
- a V_DD or V_BAT power on, if both supplies have previously been powered off

A Backup domain reset affects the LSE oscillator, the RTC, the backup registers, the backup SRAM, the SRAM2, all secrets protected by tamper (refer to Table 523: TAMP interconnection) and the RCC_BDCR register.

11.4 RCC clocks functional description

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI16: high-speed internal 16 MHz RC oscillator clock
- MSIS: multi-speed internal RC oscillator clock
- HSE: high-speed external crystal or clock, from 4 to 50 MHz
- PLL1 clock

The MSIS is used as system clock source after startup from reset, configured at 4 MHz.
The devices have the following additional clock sources:

- MSIK: multi-speed internal RC oscillator clock used for peripherals kernel clocks
- LSI: 32 kHz/250 Hz low-speed internal RC that drives the independent watchdog and optionally the RTC used for auto-wake-up from Stop and Standby modes
- LSE: 32.768 kHz low-speed external crystal or clock that optionally drives the real-time clock (rtc_ck)
- HSI48: internal 48 MHz RC that potentially drives the OTG_FS, the SDMMC and the RNG
- SHSI: secure high-speed internal 48 MHz RC that drives the SAES
- PLL2 and PLL3 clocks

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB and APB domains is 160 MHz.

All the peripheral clocks are derived from their bus clock (HCLK, PCLK1, PCLK2 or PCLK3) except the following ones that receive an independent kernel clock. This kernel clock can be selected by software between several sources thanks to RCC_CCIPRx registers (x = 1, 2, 3):

OTG_FS, SDMMCx (x = 1, 2), RNG, ADCx (x = 1, 4), DAC1, U(S)ARTx (x = 1 to 5), LPUART1, I2Cx (x = 1 to 4), SPIx (x = 1 to 3), OCTOSPIx (x = 1, 2), SAIx (x = 1, 2), MDF1, ADF1, FDCAN1, LPTIMx (x = 1 to 4), (S)AES.

In addition, the RTC kernel clock is selected by software in RCC_BDCR. The IWDG clock is always the LSI 32 kHz clock.

The RCC feeds the Cortex system timer (SysTick) external clock with the AHB clock (HCLK) divided by eight, or LSE or LSI. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex-M33 free-running clock.
11.4.1 HSE clock

The high-speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

**Figure 34. HSE/ LSE clock sources**

<tr>
<td>Crystal/ceramic resonators</td>
<td><img src="image2.png" alt="Crystal/ceramic Diagram" /></td>
</tr>
</tbody>
</table>
External crystal/ceramic resonator (HSE crystal)

The 4 to 50 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in Figure 34. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the **RCC clock control register (RCC_CR)** indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the **RCC clock interrupt enable register (RCC_CIER)**.

The HSE crystal can be switched on and off using the HSEON bit in the **RCC clock control register (RCC_CR)**.

**External source (HSE bypass)**

In this mode, an external clock source must be provided. It can have a frequency of up to 50 MHz. This mode is selected by setting the HSEBYP and HSEON bits in the **RCC clock control register (RCC_CR)**. The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) must drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO (see Figure 34).

11.4.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator. However, even with calibration, the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wakeup from Stop modes (Stop 0, Stop 1, Stop 2 or Stop 3). Refer to **Section 11.8.6: RCC clock configuration register 1 (RCC_CFGR1)**. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to **Section 11.4.11: Clock security system (CSS)**.

Calibration

The RC oscillator frequencies may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at $T_A = 25^\circ C$.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the **RCC internal clock sources calibration register 3 (RCC_ICSCR3)**.

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. The HSI16 frequency can be trimmed in the application using the HSITRIM[6:0] in the **RCC internal clock sources calibration register 3 (RCC_ICSCR3)**.

For more details on how to measure the HSI16 frequency variation, refer to **Section 11.4.19: Internal/external clock measurement with TIM15/TIM16/TIM17**.

The HSIRDY flag in the **RCC clock control register (RCC_CR)** indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.
The HSI16 RC can be switched on and off using the HSION bit in the *RCC clock control register (RCC_CR)*.

The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 11.4.11: Clock security system (CSS).

### 11.4.3 MSI (MSIS and MSIK) clocks

The MSI is made of four internal RC oscillators: MSIRC0 at 48 MHz, MSIRC1 at 4 MHz, MSIRC2 at 3.072 MHz and MSIRC3 at 400 kHz. Each oscillator feeds a prescaler providing a division by 1, 2, 3 or 4. Two output clocks are generated from these divided oscillators: MSIS, that can be selected as system clock, and MSIK, that can be selected by some peripherals as kernel clock.

**Figure 35. MSI block diagram**

MSIS and MSIK frequency range can be adjusted by software, by using respectively the MSISRANGE[3:0] and MSIKRANGE[3:0] fields in the *RCC internal clock sources calibration*.
Reset and clock control (RCC) RM0456

register 1 (RCC_ICSCR1), with MSIRGSEL = 1. Sixteen frequency ranges are available, generated from the four internal RCs, as shown in the table below.

</tbody>
</table>

The MSIS clock is used as system clock after restart from Reset, wakeup from Standby and Shutdown low-power modes. After restart from Reset or when exiting Shutdown mode, the MSIS and MSIK frequencies are set to their default value 4 MHz. The frequency range at wakeup from Standby mode can be adjusted by software, using respectively the MSISSRANGE\[3:0\] and MSIKSRANGE\[3:0\] fields with MSIRGSEL=0. Refer to Section 11.8.50: RCC control/status register (RCC_CSR).

The MSIS clock can be selected as system clock after a wakeup from Stop mode (Stop 0, Stop 1, Stop 2 or Stop 3) depending on STOPWUCK in the RCC clock control register (RCC_CR). It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 11.4.11: Clock security system (CSS).

The MSI oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when used in PLL-mode with the LSE, the MSI provides a very accurate clock source that can be used by the OTG_FS peripheral, and feeds the PLL.

The MSISRDY and MSIKRDY flags in the RCC clock control register (RCC_CR) indicate whether the MSIS and MSIK RC are stable or not. At startup, the MSIS and MSIK RC output clocks are not released until their respective bit is set by hardware. The MSIS and MSIK RC can be switched on and off by using the MSISON and MSIKON bits in the RCC clock control register (RCC_CR).

### Hardware auto calibration with LSE (PLL-mode)

When a 32.768 kHz external oscillator is present in the application, it is possible to configure either the MSIS or the MSIK in a PLL-mode. This mode is enabled:

- for MSIS by setting the MSIPLLEN bit with MSIPLLSEL = 1 in the RCC clock control register (RCC_CR)
- for MSIK by setting the MSIPLLEN bit with MSIPLLSEL = 0

In case MSIS and MSIK ranges are generated from the same MSIRC source, the PLL-mode is applied on both MSIS and MSIK. When configured in PLL-mode, the MSIS or MSIK automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSIK in PLL-mode can be used for the OTG_FS device, avoiding the need of an external high-speed crystal.

### MSI PLL-mode stabilization time

When MSIPLLEN = 1, the final accuracy after enabling the MSI (by writing MSISON = 1 or MSIKON = 1 or following a peripheral clock request in Stop mode) is reached after a stabilization time \(t_{\text{STAB}}(\text{MSI})\) when MSIPLLAST = 0. This stabilization time is needed even if the LSE is kept enable. Refer to datasheet for \(t_{\text{STAB}}(\text{MSI})\) value.
If MSIPPLEN = 1 with MSIPLLFAST =1 , the MSI oscillator is kept powered on when a request to switch it off is received (either by writing MSISON = 0 and MSIKON =0 , or because no peripheral requests this clock in Stop mode). In this case the MSI PLL-mode accuracy is kept when the MSI is switched on again, providing that the \( t_{\text{STAB}}(\text{MSI}) \) stabilization time is reached before switching off the MSI. This mode can be used for autonomous peripherals requiring accuracy in Stop mode, with an extra consumption as the oscillator remains powered on, but gated off when disabled.

### Software calibration

The MSIRCx (\( x = 0 \) to 3) oscillators frequency may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for \( 1 \% \) accuracy at an ambient temperature, \( T_A = 25 \, ^\circ\text{C} \). After reset, the factory calibration value is loaded in the MSICALx\([4:0] \) bits (\( x = 0 \) to 3) in the `RCC internal clock sources calibration register 1 (RCC_ICSCCR1)`

If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. The MSIRCx frequency can be trimmed in the application by using the MSITRIMx\([4:0] \) bits (\( x = 0 \) to 3) in the RCC_ICSCR register.

**Note:**
The final accuracy after applying the calibration value is reached after a stabilization time. This stabilization time is needed after reset of exiting Standby or Shutdown mode. It is also needed when switching from PLL-mode to normal mode.

The hardware auto calibration with LSE must not be used in conjunction with software calibration.

For more details on how to measure the MSI frequency variation, refer to Section 11.4.19: *Internal/external clock measurement with TIM15/TIM16/TIM17*.

### 11.4.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG) as well as SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency that is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral, refer to Section 12: *Clock recovery system (CRS)*.

The HSI48RDY flag in the `RCC_CR` register indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the `RCC_CR` register.

### 11.4.5 SHSI clock

The SHSI is an internal securable RC oscillator dedicated to clock the SAES. The SHSIRDY flag in the `RCC clock control register (RCC_CR)` indicates if the SHSI RC is stable or not. At startup, the SHSI RC output clock is not released until this bit is set by hardware.

The SHSI RC can be switched on and off using the SHSION bit in the `RCC_CR` register.
11.4.6 PLL

The RCC features three PLLs:
- a main PLL, PLL1, that is generally used to provide clocks to the CPU and to some peripherals
- two dedicated PLL2 and PLL3, that are used to generate the kernel clock for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:
- Input frequency range: 4 to 16 MHz
- Capability to work either in integer or Fractional mode
- 13-bit sigma-delta ($\Sigma\Delta$) modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm
- The $\Sigma\Delta$ modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
- Each PLL offers three outputs with post-dividers.

The PLLs are controlled via the registers RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLxCFGR and RCC_CR ($x = 1,2,3$).

The frequency of the reference clock provided to the PLLs (refx_ck) must range from 4 to 16 MHz. The user application must program properly the PLLxM ($x = 1,2,3$) dividers in the RCC PLL1 configuration register (RCC_PLL1CFGR), RCC PLL2 configuration register (RCC_PLL2CFGR) and RCC PLL3 configuration register (RCC_PLL3CFGR) in order to match this condition. In addition, PLLxRGE must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

To reduce the power consumption, it is recommended to configure the VCOx output to the lowest frequency.

**Figure 36. PLL block diagram**

PLLxN loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operates in integer mode when the value of SH_REGx is set to 0 (PLLxFRACN shadow register). The SH_REGx is updated with the PLLxFRACN value when the
PLLxFRACEN bit goes from 0 to 1. The ΣΔ modulator is designed to minimize the jitter impact while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON to 1 in the **RCC clock control register (RCC_CR)**. The PLLxRDY bits indicate that the PLL is ready (meaning locked).

**Note:** Before enabling the PLLs, make sure that the reference frequency (refx_ck) provided to the PLL is stable. PLLxM or PLLxSRC must not be changed when the PLLx is ON.

The hardware prevents writing PLL1ON to 0 if the PLL1 is currently used to deliver the system clock.

The following PLL parameters cannot be changed once the PLL is enabled: PLLxN, PLLxRGE, PLLxP, PLLxQ, PLLxR, PLLxPEN, PLLxQEN and PLLxREN.

To insure an optimal behavior of the PLL when one of the post-divider (PLLxP, PLLxQ or PLLxR) is not used, the application must set the enable bit (PLLxPEN, PLLxQEN, PLLxREN) as well as the corresponding post-divider bits (PLLxP, PLLxQ or PLLxR) to 0. If the above rules are not respected, the PLL output frequency is not guaranteed.

### Output frequency computation

When the PLL is configured in integer mode (SH_REG = 0), the VCO frequency (F\textsubscript{VCO}) is given by the following expression (x = 1, 2, 3):

$$F_{\text{VCO}} = F_{\text{refx}_x\_ck} \times \text{PLLxN}$$

$$F_{\text{pll}_x\_y\_ck} = (F_{\text{VCO}}/(\text{PLLx}_{xy} + 1)) \text{ with } y = P, Q \text{ or } R$$

When the PLL is configured in fractional mode (SH_REG ≠ 0), the PLLxN divider must be initialized before enabling the PLLs. However, it is possible to change the value of PLLxFRACN on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

$$F_{\text{VCO}} = F_{\text{refx}_x\_ck} \times \left(\text{PLLxN} + \frac{\text{PLLxFRACN}}{2^{(13)}}\right)$$

The PLLs are disabled by hardware when:

- the system enters Stop or Standby mode
- an HSE failure occurs, when HSE or PLL (clocked by HSE) are used as system clock.
PLL initialization phase

Here below the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLLs registers according to the required frequency.
   - For integer mode, set PLLxFRACEN to 0 in the RCC PLL1 configuration register (RCC_PLL1CFGR), RCC PLL2 configuration register (RCC_PLL2CFGR) and RCC PLL3 configuration register (RCC_PLL3CFGR).
   - For fractional mode, set PLLxFRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to 1.

2. Once the PLLxON bit is set to 1, the application must wait until PLLxRDY bit is set to 1. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be set back to 0 as long as PLLxRDY = 0.

3. Once the PLLxRDY bit is set to 1, the PLLx is ready to be used.

4. If the application intends to tune the PLLx frequency on-the-fly (possible only in fractional mode), then:
   a) PLLxFRACEN must be set to 0. When PLLxFRACEN = 0, the ΣΔ modulator still operates with the value latched into SH_REG.
   b) A new value must be uploaded into PLLxFRACR (FracValue(n).
   c) PLLxFRACEN must be set to 1 to latch the content of PLLxFRACR into its shadow register.
Figure 37. PLL initialization flow

Note: When the PLLxRDY goes to 1, it means that the difference between the PLLx output frequency and the target value is lower than ± 2 %.

11.4.7 LSE clock

The LSE crystal is a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in RCC Backup domain control register (RCC_BDCR). If the LSE is used by other peripherals of functions than RTC and TAMP, the LSESYSEN bit must be also be set in the RCC Backup domain control register (RCC_BDCR) (refer to Section : LSE when used by peripherals other than RTC/TAMP, and RCC functions).
The crystal oscillator driving strength is configured using the LSEDRV[1:0] bits, according to crystal specification, to obtain the best compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive must be programmed before enabling the LSE.

The LSERDY flag in the **RCC Backup domain control register (RCC_BDCR)** indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the **RCC clock interrupt enable register (RCC_CIER)**.

**External source (LSE bypass)**

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits in the **RCC Backup domain control register (RCC_BDCR)**. The external clock signal (square, sinus or triangle) with ~50% duty cycle, must drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO (see **Figure 34**).

**LSE when used by peripherals other than RTC/TAMP, and RCC functions**

By default, when enabled, the LSE is sent only to RTC and TAMP (assuming that RTCSEL = 01).

If the LSE is needed for other peripherals (such as peripheral clock or trigger source), or if the LSE is used by a RCC function (such as LSCO, MCO, MSI PLL mode), the sequence below must be done:

1. Set the LSEON in RCC_BDCR and wait the LSE clock ready bit (LSERDY = 1 in RCC_BDCR).
2. Set the LSESYSSEN bit in RCC_BDCR.
3. Wait the LSESYS clock is ready (LSESYSRDY = 1 in RCC_BDCR).

The LSE consumption is increased when LSESYSSEN = 1.

**11.4.8 LSI clock**

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby modes for the independent watchdog (IWDG) and RTC. The clock frequency is either 32 kHz or 250 Hz depending on the LSIPREDIV bit in **RCC Backup domain control register (RCC_BDCR)**. Setting LSIPREDIV allows a lower consumption (refer to the electrical characteristics section of the datasheet for more details).

When the IWDG is enabled or when the RTC or TAMP is clocked by the LSI, the LSIPREDIV cannot be changed anymore.

The LSI RC can be switched on and off using the LSION bit in the **RCC Backup domain control register (RCC_BDCR)**.

The LSIRDY flag in the **RCC Backup domain control register (RCC_BDCR)** indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the **RCC clock interrupt enable register (RCC_CIER)**.
11.4.9 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- MSIS oscillator
- HSI16 oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 160 MHz. After a system reset, the MSIS oscillator, at 4 MHz, is selected as system clock. When a clock source is used directly through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the RCC clock control register (RCC_CR) indicate which clocks are ready and which clock is currently used as a system clock.

The table below gives the different bus frequencies depending on the product voltage range.

</tbody>
</table>

1. Max frequency can vary depending on peripherals connected to PLL outputs.
11.4.11  Clock security system (CSS)

The CSS can be activated by software. In this case, the clock detector is enabled after the HSE oscillator wakeup time, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled. A clock failure event is sent to some timers break input and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI). This allows the MCU to perform rescue operations. The CSSI is linked to the Cortex-M33 NMI (non-maskable interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSSI occurs and a NMI is automatically generated. The NMI is executed indefinitely unless the CSSI pending bit is cleared. As a consequence, in the NMI ISR, the user must clear the CSSI by setting the CSSC bit in the RCC clock interrupt clear register (RCC_CICR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSIS or the HSI16 oscillator depending on the STOPWUCK configuration in the RCC clock control register (RCC_CR), and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

11.4.12  Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in the RCC Backup domain control register (RCC_BDCR). This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes including VBAT. It works also under system reset (excluding power-on reset).

The clock security system on LSE detects when the LSE disappears or in case of over frequency. In addition, the glitches on LSE can be filtered by setting LSEGFON. LSEGFON must be written when the LSE is disabled (LSEON = 0 and LSERDY = 0).

If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC but no hardware action is made to the registers. If the MSI was in PLL-mode, this mode is disabled.

The CSS on LSE detection event is connected to the internal tamper 3 of the TAMP peripheral. The internal tamper 3 must be enabled (ITAMP3E = 1 in TAMP_CR1 register) and the associated interrupt enabled (ITAMP3IE in TAMP_IER) in order to wake up from the low-power modes. This erases also the TAMP backup registers and backup SRAM unless the ITAMP3NOER = 1 in the TAMP_CR3 (see Section 55: Tamper and backup registers (TAMP) for more details).

In case of CSS on LSE detection event (LSECSSD = 1 in the RCC_BDCR), the software must then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

Refer to datasheet for CSS on LSE electrical characteristics.
11.4.13 ADC and DAC clocks

The ADC and DAC kernel clock source is selected thanks to ADCDACSEL[2:0] in the RCC peripherals independent clock configuration register 3 (RCC_CCIPR3). The ADC clock ratio must be around 50 %. For this reason, the AHB clock, when selected as ADC clock, must not be divided with HPRE prescaler. If pll2_r_ck is selected as ADC clock, the PLL2R division factor must be even (division by 2 or 4 for example).

If the application requires that the ADC or DAC is precisely triggered by a TIMx timer without any uncertainty, the HCLK must be selected as ADC and DAC kernel clock source. The other clock sources are asynchronous to TIMx timers therefore an uncertainty of the trigger instant is added by the resynchronization between the two clock domains. The LPTIMx timers are also asynchronous.

The DAC requires an additional low-power clock (LSI or LSE) to operate in sample and hold mode, available in Stop mode. This clock is selected with DAC1SEL in the RCC_CCIPR3.

11.4.14 RTC and TAMP clock

The RTCCLK clock source is used by RTC and TAMP, and can be either the HSE / 32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the RCC Backup domain control register (RCC_BDCR). This selection cannot be modified without resetting the Backup domain. The system must always be configured so as to get a PCLK frequency greater than or equal to the RTCCLK frequency for a proper operation of the RTC. The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to Section 55: Tamper and backup registers (TAMP) for more details).

The LSE and the LSI clocks are in the Backup domain, whereas the HSE clock is not. Consequently:

- If LSE or LSI is selected as RTC and TAMP clock, these peripherals continue to work even if the VDD supply is switched off, provided the VBAT supply is maintained.
- If the HSE clock divided by a prescaler is used as the RTC or TAMP clock, the RTC state is not guaranteed if the VDD supply is powered off or if the internal voltage regulator is powered off (removing power from the core domain). Depending on the TAMP configuration, this one can remain functional if used in a mode that does not need any kernel clock.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

If the LSE is needed only for the RTC or TAMP, LSESYSEN must be kept at reset value to get the lowest consumption.

11.4.15 Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:

- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (∗2) the APB domain frequency.
11.4.16 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

11.4.17 OCTOSPI clock

The OCTOSPIx kernel clock, selected by OCTOSPIxSEL[1:0], can be up to 200 MHz when pll1_q_ck is used.

11.4.18 Clock-out capability

- MCO
  The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of the following clock signals can be selected as MCO clock.
  - LSI
  - LSE
  - SYSCLK
  - HSI16
  - HSI48
  - HSE
  - PLLCLK
  - MSI
  - MSIS
  The selection is controlled by the MCOS[3:0] bits in the RCC clock control register (RCC_CR). The selected clock can be divided with the MCOPRE[2:0] field in the RCC clock control register (RCC_CR).

- LSCO
  Another output (LSCO) allows one of the low-speed clocks below to be output onto the external LSCO pin:
  - LSI
  - LSE
  This output remains available in all Stop modes, Standby and Shutdown modes. This output is not available in VBAT mode. The selection is controlled by the LSCOSEL bit and enabled with the LSCOEN in the RCC Backup domain control register (RCC_BDCR).

The MCO clock output requires the corresponding alternate function selected on the MCO pin. The LSCO pin must be left in default reset state.

11.4.19 Internal/external clock measurement with TIM15/TIM16/TIM17

The frequency of all on-board clock sources can be indirectly measured by mean of the TIM15, TIM16 or TIM17 channel 1 input capture and LPTIM1 or LPTIM2 channel 2 input capture.
HSI16 and MSI calibration using LSE

The primary purpose of connecting the LSE to the channel 1 input capture of TIM15, TIM16 and TIM17, and to the channel 2 input capture of LPTIM2, is to be able to precisely measure the HSI16 and MSI system clocks (for this, either HSI16 or MSIS must be used as system clock source). The number of HSI16 (MSIS respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm), the internal clock frequency can be determined with the same resolution, and the source can be trimmed to compensate the manufacturing, process, temperature and/or voltage related frequency deviations.

The four oscillators of MSI and HSI16 oscillator have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (such as the HSI16/LSE ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

Note: When the LSE is available, the MSI can be automatically trimmed by LSE using the PLL-mode.

HSI16 and MSI calibration using HSE

If the HSE is available, it can be used as system clock and the timer input capture must be connected either to MSI (divided by 1024 or by 4) or to HSI/256. The timers 16 and 17 channel 1 input capture, as well as the LPTIM2 input capture 2, are connected to the divided oscillator only when TIMICSEL[2:0] is different from 0xx in the RCC peripherals independent clock configuration register 1 (RCC_CCIPR1).

Considering that the timers counter is 16-bit, and that the ratio between HSE and the input capture signal must be the highest possible, a division by 1024 must be selected when the MSIRC0, MSIRC1 or MSIRC2 is measured, and a division by 4 when the MSIRC4 is measured.

LSI calibration

The calibration of the LSI follows the same principle, but changing the reference clock. The LSI clock must be connected to the channel 1 input capture of the TIM16 or TIM17, or to the channel 2 input capture of the LPTIM1. Then defining the HSE as system clock source, the number of its clock counts between consecutive edges of the LSI signal, provides a measure of the internal low-speed clock period.

The basic concept consists in providing a relative measurement (such as the HSE/LSI ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

11.4.20 Peripherals clock gating and autonomous mode

Peripherals clock gating in Run mode

Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENR registers.

When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.
The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, the clock is active after 2 cycles of the peripheral bus clock.

**Caution:** Just after enabling the clock for a peripheral, the software must wait for these 2 clock cycles before accessing the peripheral registers.

**Peripherals clock gating in Sleep and Stop modes**

When a peripheral is enabled, its clock can be automatically gated off when the device is in Sleep mode, by clearing the peripheral SMEN bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers. Both EN and SMEN bit of the peripheral must be set to keep the clock on in Sleep mode.

The SMEN bit of the peripheral is also used to allow peripheral clocking in Stop 0 and Stop 1 modes, upon peripheral request.

When the clock is requested by a peripheral, this clock is distributed to all enabled peripherals. Therefore the SMEN bit must be cleared before entering Stop mode, if the peripheral is not used in Stop mode.

**Caution:** The SMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wakeup interrupt is generated through the EXTI.

**Peripherals clock gating and autonomous mode in Stop 0/1/2 modes**

Some peripherals support autonomous mode (refer to Table 105: Autonomous peripherals). These peripherals are able to generate a kernel clock request and an AHB/APB bus clock request when they need, in order to operate and update their status register even in Stop mode. Depending on the peripheral configuration, either a DMA request or an interrupt can be associated to the peripheral event.

Upon an AHB or APB bus clock request from an autonomous peripheral, either MSI or HSI16 oscillator is woken up, depending on the oscillator selected by STOPWUCK in the RCC clock configuration register 1 (RCC_CFGR1).

If the autonomous peripheral is configured with DMA requests enabled, a data transfer is performed thanks to the AHB/APB clock. The bus clocks as well as the oscillator (HSI16 or MSI) are automatically switched off as soon as the transfer is finished, if no other peripheral requests it. The device automatically goes back in Stop mode.

If the autonomous peripheral is configured with interrupt enabled, the interrupt wakes up the device into Run mode.

The autonomous peripherals mapped on AHB3 or APB3 belong to the SmartRun domain and are autonomous in Stop 0, Stop 1 and Stop 2 with the LPDMA1 and SRAM4.

The autonomous peripherals mapped on AHB1, AHB2, APB1 and APB2, belong to the CPU domain and are autonomous in Stop 0 and Stop 1 only with the GPDMA1 and SRAM1, SRAM2, SRAM3 or SRAM4.
The table below shows the list of peripherals with autonomous mode capability.

</table>

1. Enabled if both xxEN and xxSMEN bits of the peripheral are set (xx = instance name)
2. SRAM4 belongs to SmartRun domain (SRD) but can be addressed by GPDMA 1 in Stop 0 and Stop 1 modes.
3. Enabled if all xxEN, xxSMEN and xxAMEN bits of the peripheral are set (xx = instance name)

For peripherals in CPU domain, the autonomous mode is enabled in Stop 0 and Stop 1 modes if both xxEN and xxSMEN bits of the peripheral are set.

For peripherals in SmartRun domain, the autonomous mode is enabled in Stop 0, Stop 1 and Stop 2 modes if both xxEN and xxSMEN bits of the peripheral are set, plus the xxAMEN bit of the peripheral in the **RCC SmartRun domain peripheral autonomous mode register (RCC_SRDAMR)**.

If an autonomous peripheral requests its kernel clock in Stop 0, Stop 1 or Stop 2 mode, the internal oscillator (HSI16 or MSI) is woken up if it was off, and the kernel clock is propagated only to the peripheral requesting it. When the peripheral releases its kernel clock request, the HSI16 or MSI is switched off if no other peripheral requests it.

If an autonomous peripheral belonging to CPU domain requests its bus clock (AHB1, AHB2, APB1 or APB2 clock) in Stop 0 or Stop 1 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the system clock is propagated to all peripherals configured with both xxEN and xxSMEN bits set.

If an autonomous peripheral belonging to SmartRun domain requests its bus clock (AHB3 or APB3 clock) in Stop 0, Stop 1 or Stop 2 mode, the internal oscillator (HSI16 or MSI depending on STOPWUCK value in RCC_CFGR1) is woken up if it was off, and the HCLK3/PCLK3 clocks are propagated to all peripherals of the SmartRun domain configured with xxEN, xxSMEN and xxAMEN set.
Caution: The AMEN bit of the peripheral must be set to allow the generation of an interrupt capable to wake up the device from Stop mode. This is not necessary when the peripheral wakeup interrupt is generated through the EXTI.

Note: MSIK or HSI16 can be forced to remain ON in Stop 0, Stop 1 or Stop 2 mode, by configuring MSIKERON or HSISKERON is the RCC_CR. In this case, the oscillator is propagated only to the kernel clock of the enabled autonomous peripherals with this oscillator selected as kernel clock. This allows the peripheral baudrates or conversion rates increase, as there is no need to wait for the oscillator wakeup time when the peripheral requests its kernel clock.

The LSE or LSI selected as peripheral kernel clock remains always ON in Stop modes.

The AHB3 and APB3 clocks can be forced to remain ON by setting the SRDRUN bit in the PWR_CR2 register. This allows the LPDMA1 latency to be improved as there is no need to wait for the oscillator wakeup time when the peripheral requests its bus clock.

11.5 RCC security and privilege functional description

11.5.1 RCC TrustZone security protection modes

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTCR register, the RCC is able to secure RCC configuration and status bits from being modified by non-secure accesses.

This is configured through the RCC secure configuration register (RCC_SECCFGR) to prevent non-secure access to read or modify the following features:

• HSE, HSE-CSS, HSI, MSI, LSI, LSE, LSE-CSS, LSCO, HSI48 configuration and status bits
• PLL1, PLL2, PLL3, AHB and APB prescalers configuration and status bits
• system clock (SYSCLK) and ICLK source clock selection and status bits
• MCO clock output configuration and STOPWUCK and STOPKERWUCK bit
• Remove reset flag RMVF configuration

If SPRIV is set in the RCC privilege configuration register (RCC_PRIVCFGR), the RCC_SECCFGR register can be written only by secure and privileged access. If SPRIV is cleared in RCC_PRIVCFGR, RCC_SECCFGR can be written only by secure access, privileged or unprivileged.

RCC_SECCFGR can be read by secure, non-secure, privileged and unprivileged access.

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits, are also secure in the RCC_AHBxENR, RCC_APBxENR, RCC_AHBxSMEN, RCC_APBxSMEN, RCC_SRDAMEN, RCC_CCIPR1, RCC_CCIPR2, RCC_CCIPR3 and RCC_BDCR registers.

The SHSI configuration and status bits are secured when the SAES is configured as secure.

A peripheral is secure when:

• For securable peripherals by TZSC (TrustZone security controller), the SEC security bit corresponding to this peripheral is set in the GTZC TZSC secure configuration registers.
• For TrustZone-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.
Table 106 summarizes the RCC secured bits following the security configuration bit in the RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and non-secure bits:

- **Secured bits**: read and write operations are only allowed by a secure access. Non-secure read returns 0 and write accesses are ignored. No illegal access event is generated.
- **Non-secure bits**: no restriction. Read and write operations are allowed by both secure and non-secure accesses.
- **A non-secure write access to RCC_SECCFGR is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the GTZC TZIC registers. RCC_SECCFGR can be read by secure or non-secure access.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers are non-secure. RCC_SECCFGR write accesses are ignored.

</table>
11.5.2 RCC privilege protection modes

By default, after reset, all RCC registers can be read or written with both privileged and unprivileged access except RCC privilege configuration register (RCC_PRIVCFGR) that can be written with privileged access only. RCC_PRIVCFGR can be read by secure and non-secure, privileged and unprivileged access.

The SPRIV bit in RCC_PRIVCFGR can be written with secure privileged access only. This bit configures the privileged access of all RCC secure functions (as defined by RCC secure configuration register (RCC_SECCFGR) or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the SPRIV bit is set in RCC_PRIVCFGR:
- Writing the RCC secure bits is possible only with privileged access, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged access except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit in RCC_PRIVCFGR can be written with privileged access only, secure or non-secure. This bit configures the privileged access of all RCC non-secure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone-aware peripherals).

When the NSPRIV bit is set in RCC_PRIVCFGR:
- Writing the RCC non-secure bits is possible only with privileged access.
- The RCC non-secure bits can be read only with privileged access except RCC_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).
11.6 RCC low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep mode stops the CPU clock. The memory interface clocks (Flash memory, caches and all SRAM interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop modes (Stop 0, Stop 1, Stop 2, Stop 3) stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI and HSE oscillators. However, HSI16 or MSI can be switched ON if the peripheral requests it for autonomous mode purpose, or to generate a wakeup interrupt (see Section 11.4.20: Peripherals clock gating and autonomous mode for more details). LSI and LSE remain active in Stop modes.
- Standby and Shutdown modes stop all the clocks in the core domain and disable the PLLs, HSI16, HSI48, SHSI, MSI and HSE oscillators.

The CPU Deepsleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

When exiting Stop modes (Stop 0, Stop 1, Stop 2 or Stop 3), the system clock is either MSIS or HSI16, depending on the software configuration of STOPWUCK in the RCC clock configuration register 1 (RCC_CFGR1). The frequency (range and user trim) of the MSIS and MSIK oscillators is the one configured before entering Stop mode, except if above 24 MHz. In this case, the MSIS or MSIK range is the 24 MHz range. The user trim of HSI16 is kept. If MSI is in PLL-mode before entering Stop mode with MSIPLLFAST = 0, the PLL-mode stabilization time must be waited for after wakeup even if the LSE was kept ON during the Stop mode. The PLL-mode accuracy is kept after wakeup from Stop 0, Stop 1 or Stop 2 mode without stabilization time if MSIPLLFAST = 1. The MSIPLLFAST bit has no effect when exiting Stop 3 mode.

The other internal oscillator can be automatically woken up in addition to the one used by the system clock, in order to avoid waiting for the other oscillator wakeup time when the device is back in Run mode. This is done thanks to STOPKERWUCK in RCC_CFGR1.

When leaving the Standby and Shutdown modes, the system clock is MSIS. The MSIS and MSIK frequency at wakeup from Standby mode is configured with MSISSRANGE and MSIKSRANGE in RCC_CSR, from 1 to 4 MHz. The MSI frequency at wakeup from Shutdown mode is 4 MHz. The user trim is lost.

If a Flash memory programming operation is ongoing, Stop, Standby or Shutdown mode entry is delayed until the Flash memory interface access is finished. If an access to the APB domain is ongoing, Stop, Standby or Shutdown mode entry is delayed until the APB access is finished. If an autonomous peripheral generates a system clock request, Stop, Standby or Shutdown mode entry is delayed until the system clock request is released.
### 11.7 RCC interrupts

The table below summarizes the interrupt sources and the way to control them.

<table>

</tbody>
</table>

1. The RCC secure interrupt vector is used only when TrustZone is enabled.
2. The SAESSEC bit is in the GTZC peripheral.
3. The LSE CSS failure event (LSECSSSD) is connected to TAMP internal tamper 3. In order to get the interrupt associated to this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. The ITAMP3F, ITAMP3E, ITAMP3IE and CITAMP3F bits are in the TAMP peripheral.
4. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSSON = 1).
11.8 RCC registers

11.8.1 RCC clock control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 0035

HSEBYP and HSEEXT are cleared upon power-on reset. They are not affected upon other types of reset.

Access: no wait state; word, half-word and byte access

<table>

</tbody>
</table>
Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable the main PLL.
Cleared by hardware when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the PLL1 clock is used as the system clock.
0: PLL1 OFF
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: HSE external clock bypass mode
Set and reset by software to select the external clock mode in bypass mode. External clock mode must be configured with HSEON bit to be used by the device. This bit can be written only if the HSE oscillator is disabled. This bit is active only if the HSE bypass mode is enabled.
0: external HSE clock analog mode
1: external HSE clock digital mode (through I/O Schmitt trigger)

Bit 19 **CSSON**: Clock security system enable
Set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.
0: clock security system OFF (clock detector OFF)
1: clock security system ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE crystal oscillator bypass
Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE crystal oscillator not bypassed
1: HSE crystal oscillator bypassed with external clock

Bit 17 **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE oscillator not ready
1: HSE oscillator ready

*Note: Once the HSEON bit is cleared, HSERDY goes low after six HSE clock cycles.*

Bit 16 **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE oscillator when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator OFF
1: HSE oscillator ON

Bit 15 **SHSIRDY**: SHSI clock ready flag
Set by hardware to indicate that the SHSI oscillator is stable. This bit is set only when SHSI is enabled by software by setting SHSION.
0: SHSI oscillator not ready
1: SHSI oscillator ready

*Note: Once the SHSION bit is cleared, SHSIRDY goes low after six SHSI clock cycles.*
Bit 14 **SHSION**: SHSI clock enable
Set and cleared by software.
Cleared by hardware to stop the SHSI when entering in Stop, Standby or Shutdown modes.
0: SHSI oscillator OFF
1: SHSI oscillator ON

Bit 13 **HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that HSI48 oscillator is stable. This bit is set only when HSI48 is enabled by software by setting HSI48ON.
0: HSI48 oscillator not ready
1: HSI48 oscillator ready

Bit 12 **HSI48ON**: HSI48 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI48 when entering in Stop, Standby or Shutdown modes.
0: HSI48 oscillator OFF
1: HSI48 oscillator ON

Bit 11 Reserved, must be kept at reset value.

Bit 10 **HSIRDY**: HSI16 clock ready flag
Set by hardware to indicate that HSI16 oscillator is stable. This bit is set only when HSI16 is enabled by software by setting HSION.
0: HSI16 oscillator not ready
1: HSI16 oscillator ready

*Note: Once the HSION bit is cleared, HSIRDY goes low after six HSI16 clock cycles.*

Bit 9 **HSIKERON**: HSI16 enable for some peripheral kernels
Set and cleared by software to force HSI16 ON even in Stop modes. Keeping the HSI16 ON in Stop mode allows the communication speed not to be reduced by the HSI16 startup time.
This bit has no effect on HSION value.
Refer to [Peripherals clock gating and autonomous mode](#) for more details.
The HSIKERON must be configured at 0 before entering Stop 3 mode.
0: No effect on HSI16 oscillator
1: HSI16 oscillator forced ON even in Stop mode

Bit 8 **HSION**: HSI16 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby or Shutdown mode.
Set by hardware to force the HSI16 oscillator ON when STOPWUCK = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.
This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.
0: HSI16 oscillator OFF
1: HSI16 oscillator ON

Bit 7 **MSIPLLFAST**: MSI PLL mode fast startup
Set and reset by software to enable/disable the fast PLL mode start-up of the MSI clock source. This bit is used only if PLL mode is selected (MSIPLLEN = 1).

*Caution:* The fast start-up feature is not active the first time the PLL mode is selected. The fast start-up is active when the MSI in PLL mode returns from switch off.
0: MSI PLL normal start-up
1: MSI PLL fast start-up
Bit 6 **MSIPLLSEL**: MSI clock with PLL mode selection

Set and cleared by software to select which MSI output clock uses the PLL mode. This bit can be written only when the MSI PLL mode is disabled (MSIPLLEN = 0).

0: PLL mode applied to MSIK (MSI kernel) clock output
1: PLL mode applied to MSIS (MSI system) clock output

*Note: If the MSI kernel clock output uses the same oscillator source than the MSI system clock output, then the PLL mode is applied to both clock outputs.*

Bit 5 **MSIKRDY**: MSIK clock ready flag

Set by hardware to indicate that the MSIK is stable. This bit is set only when MSI kernel oscillator is enabled by software by setting MSIKON.

0: MSIK (MSI kernel) oscillator not ready
1: MSIK (MSI kernel) oscillator ready

*Note: Once the MSIKON bit is cleared, MSIKRDY goes low after six MSIK oscillator clock cycles.*

Bit 4 **MSikon**: MSIK clock enable

Set and cleared by software.

Cleared by hardware to stop the MSIK when entering Stop, Standby or Shutdown mode.
Set by hardware to force the MSIK oscillator ON when exiting Standby or Shutdown mode.
Set by hardware to force the MSIK oscillator ON when STOPWUCK = 0 or STOPKERWUCK = 0 when exiting Stop modes or in case of a failure of the HSE oscillator.

0: MSIK (MSI kernel) oscillator disabled
1: MSIK (MSI kernel) oscillator enabled

Bit 3 **MSIPLLEN**: MSI clock PLL-mode enable

Set and cleared by software to enable/disable the PLL part of the MSI clock source. MSIPLLEN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). A hardware protection prevents from enabling MSIPLLEN if LSE is not ready.

This bit is cleared by hardware when LSE is disabled (LSEON = 0) or when the CSS on LSE detects a LSE failure (see RCC_CSR).

0: MSI PLL-mode OFF
1: MSI PLL-mode ON

Bit 2 **MSISRDY**: MSIS clock ready flag

Set by hardware to indicate that the MSIS oscillator is stable. This bit is set only when MSIS is enabled by software by setting MSISON.

0: MSIS (MSI system) oscillator not ready
1: MSIS (MSI system) oscillator ready

*Note: Once the MSISON bit is cleared, MSISRDY goes low after six MSIS clock cycles.*

Bit 1 **MSIkerON**: MSI enable for some peripheral kernels

Set and cleared by software to force MSI ON even in Stop modes. Keeping the MSI ON in Stop mode allows the communication speed not to be reduced by the MSI startup time. This bit has no effect on MSISON and MSIKON values (see *Peripherals clock gating and autonomous mode* for more details).

The MSIKERON must be configured at 0 before entering Stop 3 mode.

0: No effect on MSI oscillator
1: MSI oscillator forced ON even in Stop mode
Bit 0  **MSISON:** MSIS clock enable
Set and cleared by software.
Cleared by hardware to stop the MSIS oscillator when entering Stop, Standby or Shutdown mode.
Set by hardware to force the MSIS oscillator ON when exiting Standby or Shutdown mode.
Set by hardware to force the MSIS oscillator ON when STOPWUCK = 0 when exiting Stop modes or in case of a failure of the HSE oscillator.
Set by hardware when used directly or indirectly as system clock.
0: MSIS (MSI system) oscillator OFF
1: MSIS (MSI system) oscillator ON

### 11.8.2 RCC internal clock sources calibration register 1 (RCC_ICSCR1)

Address offset: 0x008

Reset value: 0x440X XXXX

X is factory-programmed.

</tbody>
</table>
Bits 31:28 **MSISRANGE[3:0]**: MSIS clock ranges

These bits are configured by software to choose the frequency range of MSIS oscillator when MSIRGSEL is set. 16 frequency ranges are available:

- 0000: range 0 around 48 MHz
- 0001: range 1 around 24 MHz
- 0010: range 2 around 16 MHz
- 0011: range 3 around 12 MHz
- 0100: range 4 around 4 MHz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.33 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- 1001: range 9 around 1.536 MHz
- 1010: range 10 around 1.024 MHz
- 1011: range 11 around 768 kHz
- 1100: range 12 around 400 kHz
- 1101: range 13 around 200 kHz
- 1110: range 14 around 133 kHz
- 1111: range 15 around 100 kHz

**Note:** MSISRANGE can be modified when MSIS is OFF (MSISON = 0) or when MSIS is ready (MSISRDY = 1). MSISRANGE must NOT be modified when MSIS is ON and NOT ready (MSISON = 1 and MSISRDY = 0).

MSISRANGE is kept when the device wakes up from Stop mode, except when the MSIS range is above 24 MHz. In this case MSISRANGE is changed by hardware into range 2 (24 MHz).

Bits 27:24 **MSIKRANGE[3:0]**: MSIK clock ranges

These bits are configured by software to choose the frequency range of MSIK oscillator when MSIRGSEL is set. 16 frequency ranges are available:

- 0000: range 0 around 48 MHz
- 0001: range 1 around 24 MHz
- 0010: range 2 around 16 MHz
- 0011: range 3 around 12 MHz
- 0100: range 4 around 4 MHz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.33 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- 1001: range 9 around 1.536 MHz
- 1010: range 10 around 1.024 MHz
- 1011: range 11 around 768 kHz
- 1100: range 12 around 400 kHz
- 1101: range 13 around 200 kHz
- 1110: range 14 around 133 kHz
- 1111: range 15 around 100 kHz

**Note:** MSIKRANGE can be modified when MSIK is OFF (MSISON = 0) or when MSIK is ready (MSIKRDY = 1). MSIKRANGE must NOT be modified when MSIK is ON and NOT ready (MSIKON = 1 and MSIKRDY = 0).

MSIKRANGE is kept when the device wakes up from Stop mode, except when the MSIK range is above 24 MHz. In this case MSIKRANGE is changed by hardware into range 2 (24 MHz).
Bit 23 **MSIRGSEL**: MSI clock range selection
   Set by software to select the MSIS and MSIK clocks range with MSISRANGE[3:0] and MSIKRANGE[3:0]. Write 0 has no effect.
   After exiting Standby or Shutdown mode, or after a reset, this bit is at 0 and the MSIS and MSIK ranges are provided by MSISSRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR.
   0: MSIS/MSIK ranges provided by MSISSRANGE[3:0] and MSIKSRANGE[3:0] in RCC_CSR
   1: MSIS/MSIK ranges provided by MSISRANGE[3:0] and MSIKRANGE[3:0] in RCC_ICSCR

Bit 22 **MSIBIAS**: MSI bias mode selection
   Set by software to select the MSI bias mode. By default, the MSI bias is in continuous mode in order to maintain the output clocks accuracy. Setting this bit reduces the MSI consumption under range 4 but decrease its accuracy.
   0: MSI bias continuous mode (clock accuracy fast settling time)
   1: MSI bias sampling mode (ultra-low-power mode)

Bits 21:20 Reserved, must be kept at reset value.

Bits 19:15 **MSICAL0[4:0]**: MSIRC0 clock calibration for MSI ranges 0 to 3
   These bits are initialized at startup with the factory-programmed MSIRC0 calibration trim value for ranges 0 to 3. When MSITRIM0 is written, MSICAL0 is updated with the sum of MSITRIM0[4:0] and the factory-programmed calibration trim value MSIRC0[4:0].

Bits 14:10 **MSICAL1[4:0]**: MSIRC1 clock calibration for MSI ranges 4 to 7
   These bits are initialized at startup with the factory-programmed MSIRC1 calibration trim value for ranges 4 to 7. When MSITRIM1 is written, MSICAL1 is updated with the sum of MSITRIM1[4:0] and the factory calibration trim value MSIRC1[4:0].
   **Caution:** There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 9:5 **MSICAL2[4:0]**: MSIRC2 clock calibration for MSI ranges 8 to 11
   These bits are initialized at startup with the factory-programmed MSIRC2 calibration trim value for ranges 8 to 11. When MSITRIM2 is written, MSICAL2 is updated with the sum of MSITRIM2[4:0] and the factory calibration trim value MSIRC2[4:0].
   **Caution:** There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

Bits 4:0 **MSICAL3[4:0]**: MSIRC3 clock calibration for MSI ranges 12 to 15
   These bits are initialized at startup with the factory-programmed MSIRC3 calibration trim value for ranges 12 to 15. When MSITRIM3 is written, MSICAL3 is updated with the sum of MSITRIM3[4:0] and the factory calibration trim value MSIRC2[4:0].
   **Caution:** There is no hardware protection to limit a potential overflow due to the addition of MSITRIM bitfield and factory program bitfield for this calibration value. Control must be managed by software at user level.

- **MSITRIM0[4:1]**
  - **MSITRIM1[4:0]**
  - **MSITRIM2[4:0]**
  - **MSITRIM3[4:0]**

**Note:** The hardware auto calibration with LSE must not be used in conjunction with software calibration.

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:15 **MSITRIM0[4:0]**: MSI clock trimming for ranges 0 to 3  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC0[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 14:10 **MSITRIM1[4:0]**: MSI clock trimming for ranges 4 to 7  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC1[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 9:5 **MSITRIM2[4:0]**: MSI clock trimming for ranges 8 to 11  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC2[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.

Bits 4:0 **MSITRIM3[4:0]**: MSI clock trimming for ranges 12 to 15  
These bits provide an additional user-programmable trimming value that is added to the factory-programmed calibration trim value MSIRC3[4:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the MSI.
11.8.4 RCC internal clock sources calibration register 3 (RCC_ICSCR3)

Address offset: 0x010
Reset value: 0x0010 0XXX
X is factory-programmed.
Access: no wait state; word, half-word and byte access

<table>

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 HSITRIM[4:0]: HSI clock trimming
These bits provide an additional user-programmable trimming value that is added to the HSICAL[11:0] bits. It can be programmed to adjust to voltage and temperature variations that influence the frequency of the HSI.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 HSICAL[11:0]: HSI clock calibration
These bits are initialized at startup with the factory-programmed HSI calibration trim value. When HSITRIM is written, HSICAL is updated with the sum of HSITRIM and the factory trim value.

11.8.5 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x014
Reset value: 0x0000 0XXX
X is factory-programmed.
Access: no wait state; word, half-word and byte access

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 HSI48CAL[8:0]: HSI48 clock calibration
These bits are initialized at startup with the factory-programmed HSI48 calibration trim value.
### 11.8.6 RCC clock configuration register 1 (RCC CfGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2; word, half-word and byte access

1 or 2 wait states are inserted only if the access occurs during clock source switch.

<td>31:30 MCOPRE[2:0]</td>
<td>Microcontroller clock output prescaler</td>
</tr>
<tr>
<td>27:6</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

- **Bit 31:** Reserved, must be kept at reset value.
- **Bits 30:28** **MCOPRE[2:0]:** Microcontroller clock output prescaler
  - Set and cleared by software.
  - It is highly recommended to change this prescaler before MCO output is enabled.
  - 000: MCO divided by 1
  - 001: MCO divided by 2
  - 010: MCO divided by 4
  - 011: MCO divided by 8
  - 100: MCO divided by 16
  - Others: not allowed

- **Bits 27:24** **MCOSEL[3:0]:** Microcontroller clock output
  - Set and cleared by software.
  - 0000: MCO output disabled, no clock on MCO
  - 0001: SYSCLK system clock selected
  - 0010: MSIS clock selected
  - 0011: HSI16 clock selected
  - 0100: HSE clock selected
  - 0101: Main PLL clock pll1_r_ck selected
  - 0110: LSI clock selected
  - 0111: LSE clock selected
  - 1000: Internal HSI48 clock selected
  - 1001: MSIK clock selected
  - Others: reserved

  *Note:* This clock output may have some truncated cycles at startup or during MCO clock source switching.

- **Bits 23:6:** Reserved, must be kept at reset value.
Bit 5 STOPKERWUCK: wakeup from Stop kernel clock automatic enable selection
Set and cleared by software to enable automatically another oscillator when exiting Stop mode. This oscillator can be used as independent kernel clock by peripherals.
0: MSIK oscillator automatically enabled when exiting Stop mode
1: HSI16 oscillator automatically enabled when exiting Stop mode

Bit 4 STOPWUCK: wakeup from Stop and CSS backup clock selection
Set and cleared by software to select the system clock used when exiting Stop mode. The selected clock is also used as emergency clock for the clock security system on HSE.
Warning: STOPWUCK must not be modified when the CSS is enabled by HSECSSON bit in RCC_CR and the system clock is HSE (SW = 10) or a switch on HSE is requested (SW = 10).
0: MSIS oscillator selected as wakeup from stop clock and CSS backup clock
1: HSI16 oscillator selected as wakeup from stop clock and CSS backup clock

Bits 3:2 SWS[1:0]: system clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
00: MSIS oscillator used as system clock
01: HSI16 oscillator used as system clock
10: HSE used as system clock
11: PLL pll1_r_ck used as system clock

Bits 1:0 SW[1:0]: system clock switch
Set and cleared by software to select system clock source (SYSCLK).
Configured by hardware to force MSIS oscillator selection when exiting Standby or Shutdown mode. Configured by hardware to force MSIS or HSI16 oscillator selection when exiting Stop mode or in case of HSE oscillator failure, depending on STOPWUCK value.
00: MSIS selected as system clock
01: HSI16 selected as system clock
10: HSE selected as system clock
11: PLL pll1_r_ck selected as system clock

11.8.7 RCC clock configuration register 2 (RCC_CFGR2)
Address offset: 0x020
Reset value: 0x0000 0000
Access: word, half-word and byte access
1 or 2 wait states are inserted only if the access occurs during clock source switch.
From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

Bits 31:21 Reserved, must be kept at reset value.
Bit 20  **APB2DIS**: APB2 clock disable
This bit can be set in order to further reduce power consumption, when none of the APB2 peripherals are used and when their clocks are disabled in RCC_APB2ENR. When this bit is set, all the APB2 peripherals clocks are off.
0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: APB2 clock disabled

Bit 19  **APB1DIS**: APB1 clock disable
This bit can be set in order to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used and when their clocks are disabled in RCC_APB1ENR. When this bit is set, all the APB1 peripherals clocks are off, except for IWDG.
0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: APB1 clock disabled

Bit 18  **AHB2DIS2**: AHB2_2 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR2 are used and when their clocks are disabled in RCC_AHB2ENR2. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2ENR2 are off.
0: AHB2_2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB2_2 clock disabled

Bit 17  **AHB2DIS1**: AHB2_1 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB2 peripherals from RCC_AHB2ENR1 (except SRAM2 and SRAM3) are used and when their clocks are disabled in RCC_AHB2ENR1. When this bit is set, all the AHB2 peripherals clocks from RCC_AHB2ENR1 are off, except for SRAM2 and SRAM3.
0: AHB2_1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB2_1 clock disabled

Bit 16  **AHB1DIS**: AHB1 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB1 peripherals (except those listed hereafter) are used and when their clocks are disabled in RCC_AHB1ENR. When this bit is set, all the AHB1 peripherals clocks are off, except for FLASH, BKPSRAM, ICACHE, DCACHE1 and SRAM1.
0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB1 clock disabled

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8  **PPRE2[2:0]**: APB2 prescaler
Set and cleared by software to control the division factor of the APB2 clock (PCLK2).
0xx: PCLK2 not divided
100: PCLK2 divided by 2
101: PCLK2 divided by 4
110: PCLK2 divided by 8
111: PCLK2 divided by 16

Bit 7 Reserved, must be kept at reset value.
Bits 6:4 **PPRE1[2:0]**: APB1 prescaler  
Set and cleared by software to control the division factor of the APB1 clock (PCLK1).  
0xx: PCLK1 not divided  
100: PCLK1 divided by 2  
101: PCLK1 divided by 4  
110: PCLK1 divided by 8  
111: PCLK1 divided by 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler  
Set and cleared by software to control the division factor of the AHB clock (HCLK).  
**Caution:** Depending on the device voltage range, the software must set these bits correctly to ensure that the system frequency does not exceed the maximum allowed frequency (for more details, refer to Table 103: Bus maximum frequency). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value is taken into account.  
0xxx: SYSCLK not divided  
1000: SYSCLK divided by 2  
1001: SYSCLK divided by 4  
1010: SYSCLK divided by 8  
1011: SYSCLK divided by 16  
1100: SYSCLK divided by 64  
1101: SYSCLK divided by 128  
1110: SYSCLK divided by 256  
1111: SYSCLK divided by 512

11.8.8 RCC clock configuration register 3 (RCC_CFGR3)

Address offset: 0x024  
Reset value: 0x0000 0000  
Access: word, half-word and byte access  
From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **APB3DIS**: APB3 clock disable  
This bit can be set in order to further reduce power consumption, when none of the APB3 peripherals from RCC_APB3ENR are used and when their clocks are disabled in RCC_APB3ENR. When this bit is set, all the APB3 peripherals clocks are off.  
0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits  
1: APB3 clock disabled
Bit 16 **AHB3DIS**: AHB3 clock disable
This bit can be set in order to further reduce power consumption, when none of the AHB3 peripherals (except SRAM4) are used and when their clocks are disabled in RCC_AHB3ENR. When this bit is set, all the AHB3 peripherals clocks are off, except for SRAM4.
0: AHB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits
1: AHB3 clock disabled

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE3[2:0]**: APB3 prescaler
Set and cleared by software to control the division factor of the APB3 clock (PCLK3).
0xx: HCLK not divided
100: HCLK divided by 2
101: HCLK divided by 4
110: HCLK divided by 8
111: HCLK divided by 16

Bits 3:0 Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **PLL1REN**: PLL1 DIVR divider output enable
Set and reset by software to enable the pll1_r_ck output of the PLL1.
To save power, PLL1RENPLL2REN and PLL1R bits must be set to 0 when the pll1_r_ck is not used.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0: pll1_r_ck output disabled
1: pll1_r_ck output enabled
Bit 17 **PLL1QEN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the pll1_q_ck output of the PLL1.
To save power, PLL1QEN and PLL1Q bits must be set to 0 when the pll1_q_ck is not used.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0: pll1_q_ck output disabled
1: pll1_q_ck output enabled

Bit 16 **PLL1PEN**: PLL1 DIVP divider output enable
Set and reset by software to enable the pll1_p_ck output of the PLL1.
To save power, PLL1PEN and PLL1P bits must be set to 0 when the pll1_p_ck is not used.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0: pll1_p_ck output disabled
1: pll1_p_ck output enabled

Bits 15:12 **PLL1MBOOST[3:0]**: Prescaler for EPOD booster input clock
Set and cleared by software to configure the prescaler of the PLL1, used for the EPOD booster. The EPOD booster input frequency is PLL1 input clock frequency/PLL1MBOOST.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0) and EPOD Boost mode is disabled (see Section 10: Power control (PWR)).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 4
0011: division by 6
0100: division by 8
0101: division by 10
0110: division by 12
0111: division by 14
1000: division by 16
others: reserved

Bits 11:8 **PLL1M[3:0]**: Prescaler for PLL1
Set and cleared by software to configure the prescaler of the PLL1. The VCO1 input frequency is PLL1 input clock frequency/PLL1M.
This bit can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000: division by 1 (bypass)
0001: division by 2
0010: division by 3
...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL1FRACEN**: PLL1 fractional latch enable
Set and reset by software to latch the content of PLL1FRACN into the ΣΔ modulator.
In order to latch the PLL1FRACN value into the ΣΔ modulator, PLL1FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL1FRACN into the modulator (see PLL initialization phase for details).

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL1.
This bit must be written before enabling the PLL1.
00-01-10: PLL1 input (ref1_ck) clock range frequency between 4 and 8 MHz
11: PLL1 input (ref1_ck) clock range frequency between 8 and 16 MHz
11.8.10 RCC PLL2 configuration register (RCC_PLL2CFGR)

Address offset: 0x02C
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 PLL2REN: PLL2 DIVR divider output enable
Set and reset by software to enable the pll2_r_ck output of the PLL2.
To save power, PLL2REN and PLL2R bits must be set to 0 when the pll2_r_ck is not used.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0: pll2_r_ck output disabled
1: pll2_r_ck output enabled

Bit 17 PLL2QEN: PLL2 DIVQ divider output enable
Set and reset by software to enable the pll2_q_ck output of the PLL2.
To save power, PLL2QEN and PLL2Q bits must be set to 0 when the pll2_q_ck is not used.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0: pll2_q_ck output disabled
1: pll2_q_ck output enabled

Bit 16 PLL2PEN: PLL2 DIVP divider output enable
Set and reset by software to enable the pll2_p_ck output of the PLL2.
To save power, PLL2PEN and PLL2P bits must be set to 0 when the pll2_p_ck is not used.
This bit can be written only when the PLL2 is disabled (PLL2ON = 0 and PLL2RDY = 0).
0: pll2_p_ck output disabled
1: pll2_p_ck output enabled

Bits 15:12 Reserved, must be kept at reset value.
11.8.11 RCC PLL3 configuration register (RCC_PLL3CFGR)

...
1111: division by 16

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of PLL3FRACN into the ΣΔ modulator. In order to latch the PLL3FRACN value into the ΣΔ modulator, PLL3FRACEN must be set to 0, then set to 1: the transition 0 to 1 transfers the content of PLL3FRACN into the modulator (see PLL initialization phase for details).

Bits 3:2 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3. This bit must be written before enabling the PLL3.
00-01-10: PLL3 input (ref3_ck) clock range frequency between 4 and 8 MHz
11: PLL3 input (ref3_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL3SRC[1:0]**: PLL3 entry clock source
Set and cleared by software to select PLL3 clock source. These bits can be written only when the PLL3 is disabled.
In order to save power, when no PLL3 is used, the value of PLL3SRC must be 00.
00: No clock sent to PLL3
01: MSIS clock selected as PLL3 clock entry
10: HSI16 clock selected as PLL3 clock entry
11: HSE clock selected as PLL3 clock entry

Bit 31  Reserved, must be kept at reset value.

Bits 30:24 **PLL1R[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the pll1_r_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_r_ck = vco1_ck
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: pll1_r_ck = vco1_ck / 3
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23  Reserved, must be kept at reset value.

Bits 22:16 **PLL1Q[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the pll1_q_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).
0000000: pll1_q_ck = vco1_ck
0000001: pll1_q_ck = vco1_ck / 2 (default after reset)
0000010: pll1_q_ck = vco1_ck / 3
0000011: pll1_q_ck = vco1_ck / 4
...
1111111: pll1_q_ck = vco1_ck / 128

Bits 15:9 **PLL1P[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the pll1_p_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = 0 and PLL1RDY = 0).

Note that odd division factors are not allowed.

0000000: Not allowed
0000001: pll1_p_ck = vco1_ck / 2 (default after reset)
0000010: Not allowed
0000011: pll1_p_ck = vco1_ck / 4
...

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 PLL1FRACN[12:0]: Fractional part of the multiplication factor for PLL1 VCO
Set and reset by software to control the fractional part of the multiplication factor of the VCO.
These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.
VCO output frequency = \( \text{F}_{\text{ref1 cling}} \times \left( \text{PLL1N} + \left( \text{PLL1FRACN} / 2^{13} \right) \right) \), with:
- PLL1N must be between 4 and 512.
- PLL1FRACN can be between 0 and 2^{13} - 1.
- The input frequency \( \text{F}_{\text{ref1 cling}} \) must be between 4 and 16 MHz.
To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:
- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into PLL1FRACN.
- Set the bit PLL1FRACEN to 1.

Bits 2:0 Reserved, must be kept at reset value.

</table>

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SHSIRDYF**: SHSI ready interrupt flag
Set by hardware when the SHSI clock becomes stable and SHSIRDYIE is set.
Cleared by software setting the SHSIRDYC bit.
0: No clock ready interrupt caused by the SHSI oscillator
1: Clock ready interrupt caused by the SHSI oscillator
Bit 11  **MSIKRDYF**: MSIK ready interrupt flag
Set by hardware when the MSIK clock becomes stable and MSIKRDYIE is set.
Cleared by software setting the MSIKRDYC bit.
0: No clock ready interrupt caused by the MSIK oscillator
1: Clock ready interrupt caused by the MSIK oscillator

Bit 10  **CSSF**: Clock security system interrupt flag
Set by hardware when a failure is detected in the HSE oscillator.
Cleared by software setting the CSSC bit.
0: No clock security interrupt caused by HSE clock failure
1: Clock security interrupt caused by HSE clock failure

Bit 9  Reserved, must be kept at reset value.

Bit 8  **PLL3RDYF**: PLL3 ready interrupt flag
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
Cleared by software setting the PLL3RDYC bit.
0: No clock ready interrupt caused by PLL3 lock
1: Clock ready interrupt caused by PLL3 lock

Bit 7  **PLL2RDYF**: PLL2 ready interrupt flag
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
Cleared by software setting the PLL2RDYC bit.
0: No clock ready interrupt caused by PLL2 lock
1: Clock ready interrupt caused by PLL2 lock

Bit 6  **PLL1RDYF**: PLL1 ready interrupt flag
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
Cleared by software setting the PLL1RDYC bit.
0: No clock ready interrupt caused by PLL1 lock
1: Clock ready interrupt caused by PLL1 lock

Bit 5  **HSI48RDYF**: HSI48 ready interrupt flag
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
Cleared by software setting the HSI48RDYC bit.
0: No clock ready interrupt caused by the HSI48 oscillator
1: Clock ready interrupt caused by the HSI48 oscillator

Bit 4  **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
Cleared by software setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3  **HSIRDYF**: HSI16 ready interrupt flag
Set by hardware when the HSI16 clock becomes stable and HSIRDYIE is set in a response to setting the HSION (see RCC_CR). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator
Bit 2 **MSISRDYF**: MSIS ready interrupt flag
Set by hardware when the MSIS clock becomes stable and MSISRDYIE is set.
Cleared by software setting the MSISRDYC bit.
0: No clock ready interrupt caused by the MSIS oscillator
1: Clock ready interrupt caused by the MSIS oscillator

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
Cleared by software setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
Cleared by software setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator

### 11.8.20 RCC clock interrupt clear register (RCC_CICR)

Address offset: 0x058
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SHSIRDYC**: SHSI oscillator ready interrupt clear
Writing this bit to 1 clears the SHSIRDYF flag. Writing 0 has no effect.

Bit 11 **MSIKRDYC**: MSIK oscillator ready interrupt clear
Writing this bit to 1 clears the MSIKRDYF flag. Writing 0 has no effect.

Bit 10 **CSSC**: Clock security system interrupt clear
Writing this bit to 1 clears the CSSF flag. Writing 0 has no effect.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Writing this bit to 1 clears the PLL3RDYF flag. Writing 0 has no effect.

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Writing this bit to 1 clears the PLL2RDYF flag. Writing 0 has no effect.

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Writing this bit to 1 clears the PLL1RDYF flag. Writing 0 has no effect.
Bit 5  **HSI48RDYC**: HSI48 ready interrupt clear  
   Writing this bit to 1 clears the HSI48RDYF flag. Writing 0 has no effect.

Bit 4  **HSERDYC**: HSE ready interrupt clear  
   Writing this bit to 1 clears the HSERDYF flag. Writing 0 has no effect.

Bit 3  **HSIRDYC**: HSI16 ready interrupt clear  
   Writing this bit to 1 clears the HSIRDYF flag. Writing 0 has no effect.

Bit 2  **MSISRDYC**: MSIS ready interrupt clear  
   Writing this bit to 1 clears the MSISRDYF flag. Writing 0 has no effect.

Bit 1  **LSERDYC**: LSE ready interrupt clear  
   Writing this bit to 1 clears the LSERDYF flag. Writing 0 has no effect.

Bit 0  **LSIRDYC**: LSI ready interrupt clear  
   Writing this bit to 1 clears the LSIRDYF flag. Writing 0 has no effect.

Bits 31:19  Reserved, must be kept at reset value.

Bit 18  **DMA2DRST**: DMA2D reset  
   Set and cleared by software.  
   0: No effect  
   1: Reset DMA2D

Bit 17  **RAMCFGRST**: RAMCFG reset  
   Set and cleared by software.  
   0: No effect  
   1: Reset RAMCFG

Bit 16  **TSCRST**: TSC reset  
   Set and cleared by software.  
   0: No effect  
   1: Reset TSC
Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCRST**: CRC reset
- Set and cleared by software.
- 0: No effect
- 1: Reset CRC

Bits 11:4 Reserved, must be kept at reset value.

Bit 3 **MDF1RST**: MDF1 reset
- Set and cleared by software.
- 0: No effect
- 1: Reset MDF1

Bit 2 **FMACRST**: FMAC reset
- Set and cleared by software.
- 0: No effect
- 1: Reset FMAC

Bit 1 **CORDICRST**: CORDIC reset
- Set and cleared by software.
- 0: No effect
- 1: Reset CORDIC

Bit 0 **GPDMA1RST**: GPDMA1 reset
- Set and cleared by software.
- 0: No effect
- 1: Reset GPDMA1

Set and cleared by software.  
0: DMA2D clock disabled  
1: DMA2D clock enabled
Bit 17 **RAMCFGEN**: RAMCFG clock enable
Set and cleared by software.
0: RAMCFG clock disabled
1: RAMCFG clock enabled

Bit 16 **TSCEN**: Touch sensing controller clock enable
Set and cleared by software.
0: TSC clock disabled
1: TSC clock enabled

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCEN**: CRC clock enable
Set and cleared by software.
0: CRC clock disabled
1: CRC clock enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHEN**: FLASH clock enable
Set and cleared by software. This bit can be disabled only when the Flash memory is in power down mode.
0: FLASH clock disabled
1: FLASH clock enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **MDF1EN**: MDF1 clock enable
Set and reset by software.
0: MDF1 clock disabled
1: MDF1 clock enabled

Bit 2 **FMACEN**: FMAC clock enable
Set and reset by software.
0: FMAC clock disabled
1: FMAC clock enabled

Bit 1 **CORDICEN**: CORDIC clock enable
Set and cleared by software.
0: CORDIC clock disabled
1: CORDIC clock enabled

Bit 0 **GPDMA1EN**: GPDMA1 clock enable
Set and cleared by software.
0: GPDMA1 clock disabled
1: GPDMA1 clock enabled
### 11.8.30 RCC AHB2 peripheral clock enable register 1 (RCC_AHB2ENR1)

Address offset: 0x08C  
Reset value: 0xC000 0000  
Access: no wait state, word, half-word and byte access

**Note:** When the peripheral clock is not active, the peripheral registers read or write access is not supported.

1: CRS clock enabled

Bit 23 Reserved, must be kept at reset value.

Bit 22 I2C2EN: I2C2 clock enable
Set and cleared by software.
0: I2C2 clock disabled
1: I2C2 clock enabled
Bit 21  **I2C1EN**: I2C1 clock enable
   Set and cleared by software.
   0: I2C1 clock disabled
   1: I2C1 clock enabled

Bit 20  **UART5EN**: UART5 clock enable
   Set and cleared by software.
   0: UART5 clock disabled
   1: UART5 clock enabled

Bit 19  **UART4EN**: UART4 clock enable
   Set and cleared by software.
   0: UART4 clock disabled
   1: UART4 clock enabled

Bit 18  **USART3EN**: USART3 clock enable
   Set and cleared by software.
   0: USART3 clock disabled
   1: USART3 clock enabled

Bit 17  **USART2EN**: USART2 clock enable
   Set and cleared by software.
   0: USART2 clock disabled
   1: USART2 clock enabled

Bits 16:15 Reserved, must be kept at reset value.

Bit 14  **SPI2EN**: SPI2 clock enable
   Set and cleared by software.
   0: SPI2 clock disabled
   1: SPI2 clock enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11  **WWDGEN**: WWDG clock enable
   Set by software to enable the window watchdog clock. Reset by hardware system reset.
   This bit can also be set by hardware if the WWDG_SW option bit is reset.
   0: WWDG clock disabled
   1: WWDG clock enabled

Bits 10:6 Reserved, must be kept at reset value.

Bit 5   **TIM7EN**: TIM7 clock enable
   Set and cleared by software.
   0: TIM7 clock disabled
   1: TIM7 clock enabled

Bit 4   **TIM6EN**: TIM6 clock enable
   Set and cleared by software.
   0: TIM6 clock disabled
   1: TIM6 clock enabled

Bit 3   **TIM5EN**: TIM5 clock enable
   Set and cleared by software.
   0: TIM5 clock disabled
   1: TIM5 clock enabled
Bit 2 **TIM4EN**: TIM4 clock enable
Set and cleared by software.
0: TIM4 clock disabled
1: TIM4 clock enabled

Bit 1 **TIM3EN**: TIM3 clock enable
Set and cleared by software.
0: TIM3 clock disabled
1: TIM3 clock enabled

Bit 0 **TIM2EN**: TIM2 clock enable
Set and cleared by software.
0: TIM2 clock disabled
1: TIM2 clock enabled

### 11.8.34 RCC APB1 peripheral clock enable register 2 (RCC_APB1ENR2)

Address offset: 0x0A0
Reset value: 0x0000 0000
Access: no wait state; word, half-word and byte access

*Note: When the peripheral clock is not active, the peripheral registers read or write access is not supported.*

Bit 28 **BKPSRAMSMEN**: BKPSRAM clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: BKPSRAM clocks disabled by the clock gating during Sleep and Stop modes
   1: BKPSRAM clocks enabled by the clock gating during Sleep and Stop modes

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **GTZC1SMEN**: GTZC1 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: GTZC1 clocks disabled by the clock gating during Sleep and Stop modes
   1: GTZC1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **DMA2DSMEN**: DMA2D clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: DMA2D clocks disabled by the clock gating during Sleep and Stop modes
   1: DMA2D clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **RAMCFGSMEN**: RAMCFG clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: RAMCFG clocks disabled by the clock gating during Sleep and Stop modes
   1: RAMCFG clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **TSCSMEN**: TSC clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: TSC clocks disabled by the clock gating during Sleep and Stop modes
   1: TSC clocks enabled by the clock gating during Sleep and Stop modes

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCSMEN**: CRC clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: CRC clocks disabled by the clock gating during Sleep and Stop modes
   1: CRC clocks enabled by the clock gating during Sleep and Stop modes

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHSMEN**: FLASH clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: FLASH clocks disabled by the clock gating during Sleep and Stop modes
   1: FLASH clocks enabled by the clock gating during Sleep and Stop modes

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **MDF1SMEN**: MDF1 clocks enable during Sleep and Stop modes.
   Set and cleared by software.
   0: MDF1 clocks disabled by the clock gating during Sleep and Stop modes
   1: MDF1 clocks enabled by the clock gating during Sleep and Stop modes

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 2 **FMACSMEN**: FMAC clocks enable during Sleep and Stop modes.
   Set and cleared by software.
   0: FMAC clocks disabled by the clock gating during Sleep and Stop modes
   1: FMAC clocks enabled by the clock gating during Sleep and Stop modes
11.8.38 RCC AHB2 peripheral clocks enable in Sleep and Stop modes register 1 (RCC_AHB2SMENR1)

Address offset: 0x0B4
Reset value: 0xFFFF FFFF
Access: no wait state; word, half-word and byte access
This register only configures the clock gating, not the clock source itself.
When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to Section 11.4.20: Peripherals clock gating and autonomous mode).

Bit 14 **OTGSMEN**: OTG_FS clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OTG_FS clocks disabled by the clock gating during Sleep and Stop modes
1: OTG_FS clocks enabled by the clock gating during Sleep and Stop modes

Bit 13 Reserved, must be kept at reset value.

Bit 12 **DCMI_PSSISMEM**: DCMI and PSSI clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DCMI and PSSI clocks disabled by the clock gating during Sleep and Stop modes
1: DCMI and PSSI clocks enabled by the clock gating during Sleep and Stop modes

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ADC1SMEN**: ADC1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: ADC1 clocks disabled by the clock gating during Sleep and Stop modes
1: ADC1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 9 Reserved, must be kept at reset value.

Bit 8 **GPIOISMEN**: IO port I clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port I clocks disabled by the clock gating during Sleep and Stop modes
1: IO port I clocks enabled by the clock gating during Sleep and Stop modes

Bit 7 **GPIOHSMEN**: IO port H clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port H clocks disabled by the clock gating during Sleep and Stop modes
1: IO port H clocks enabled by the clock gating during Sleep and Stop modes

Bit 6 **GPIOGSMEN**: IO port G clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port G clocks disabled by the clock gating during Sleep and Stop modes
1: IO port G clocks enabled by the clock gating during Sleep and Stop modes

Bit 5 **GPIOFSMEN**: IO port F clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port F clocks disabled by the clock gating during Sleep and Stop modes
1: IO port F clocks enabled by the clock gating during Sleep and Stop modes

Bit 4 **GPIOESMEN**: IO port E clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port E clocks disabled by the clock gating during Sleep and Stop modes
1: IO port E clocks enabled by the clock gating during Sleep and Stop modes

Bit 3 **GPIODSMEN**: IO port D clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port D clocks disabled by the clock gating during Sleep and Stop modes
1: IO port D clocks enabled by the clock gating during Sleep and Stop modes

Bit 2 **GPIOCSMEN**: IO port C clocks enable during Sleep and Stop modes
Set and cleared by software.
0: IO port C clocks disabled by the clock gating during Sleep and Stop modes
1: IO port C clocks enabled by the clock gating during Sleep and Stop modes
11.8.39 RCC AHB2 peripheral clocks enable in Sleep and Stop modes register 2 (RCC_AHB2SMENR2)

Address offset: 0x0B8

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to Section 11.4.20: Peripherals clock gating and autonomous mode).

(RCC_AHB3SMENR)

Address offset: 0x0BC

Reset value: 0xFFFF FFFF

Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to Section 11.4.20: Peripherals clock gating and autonomous mode).

Notes:
- **DAC1SMEN**: DAC1 clock enable during Sleep and Stop modes
  - Set and cleared by software.
  - 0: DAC1 clock disabled by the clock gating during Sleep and Stop modes
  - 1: DAC1 clock enabled by the clock gating during Sleep and Stop modes
  - Note: This bit must be set to allow the peripheral to wake up from Stop modes.

- **ADC4SMEN**: ADC4 clock enable during Sleep and Stop modes
  - Set and cleared by software.
  - 0: ADC4 clock disabled by the clock gating during Sleep and Stop modes
  - 1: ADC4 clock enabled by the clock gating during Sleep and Stop modes
  - Note: This bit must be set to allow the peripheral to wake up from Stop modes.

- **Bit 4:3** Reserved, must be kept at reset value.

- **Bit 2** **PWRSMEN**: PWR clock enable during Sleep and Stop modes
  - Set and cleared by software.
  - 0: PWR clock disabled by the clock gating during Sleep and Stop modes
  - 1: PWR clock enabled by the clock gating during Sleep and Stop modes

- **Bit 1** Reserved, must be kept at reset value.

- **Bit 0** **LPGPIO1SMEN**: LPGPIO1 enable during Sleep and Stop modes
  - Set and cleared by software.
  - 0: LPGPIO1 clock disabled by the clock gating during Sleep and Stop modes
  - 1: LPGPIO1 clock enabled by the clock gating during Sleep and Stop modes

- **CRSSMEN**, **IC2SMEN**, **IC1SMEN**, **U4SMEN**, **U3SMEN**, **U2SMEN**, **U1SMEN**, **SP2SMEN**, **SP1SMEN**, **VWDSMEN**, **TIM7SMEN**, **TIM6SMEN**, **TIM5SMEN**, **TIM4SMEN**, **TIM3SMEN**, **TIM2SMEN**, **TIM1SMEN**, **TIM0SMEN**

Notes:
- Bits 31:25 Reserved, must be kept at reset value.
Bit 24  **CRSSMEN**: CRS clock enable during Sleep and Stop modes  
Set and cleared by software.  
0: CRS clocks disabled by the clock gating during Sleep and Stop modes  
1: CRS clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 23  Reserved, must be kept at reset value.

Bit 22  **I2C2SMEN**: I2C2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: I2C2 clocks disabled by the clock gating during Sleep and Stop modes  
1: I2C2 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 21  **I2C1SMEN**: I2C1 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: I2C1 clocks disabled by the clock gating during Sleep and Stop modes  
1: I2C1 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 20  **UART5SMEN**: UART5 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: UART5 clocks disabled by the clock gating during Sleep and Stop modes  
1: UART5 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 19  **UART4SMEN**: UART4 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: UART4 clocks disabled by the clock gating during Sleep and Stop modes  
1: UART4 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 18  **USART3SMEN**: USART3 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: USART3 clocks disabled by the clock gating during Sleep and Stop modes  
1: USART3 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 17  **USART2SMEN**: USART2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: USART2 clocks disabled by the clock gating during Sleep and Stop modes  
1: USART2 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 16:15  Reserved, must be kept at reset value.

Bit 14  **SPI2SMEN**: SPI2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: SPI2 clocks disabled by the clock gating during Sleep and Stop modes  
1: SPI2 clocks enabled by the clock gating during Sleep and Stop modes  

Note: This bit must be set to allow the peripheral to wake up from Stop modes.

Bits 13:12  Reserved, must be kept at reset value.
Bit 11 **WWDGSMEN**: Window watchdog clocks enable during Sleep and Stop modes
Set and cleared by software. This bit is forced to 1 by hardware when the hardware WWDG option is activated.
0: Window watchdog clocks disabled by the clock gating during Sleep and Stop modes
1: Window watchdog clocks enabled by the clock gating during Sleep and Stop modes

Bits 10:6 Reserved, must be kept at reset value.

Bit 5 **TIM7SMEN**: TIM7 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM7 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM7 clocks enabled by the clock gating during Sleep and Stop modes

Bit 4 **TIM6SMEN**: TIM6 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM6 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM6 clocks enabled by the clock gating during Sleep and Stop modes

Bit 3 **TIM5SMEN**: TIM5 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM5 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM5 clocks enabled by the clock gating during Sleep and Stop modes

Bit 2 **TIM4SMEN**: TIM4 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM4 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM4 clocks enabled by the clock gating during Sleep and Stop modes

Bit 1 **TIM3SMEN**: TIM3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM3 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM3 clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 **TIM2SMEN**: TIM2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM2 clocks disabled by the clock gating during Sleep and Stop modes
1: TIM2 clocks enabled by the clock gating during Sleep and Stop modes
11.8.42 RCC APB1 peripheral clocks enable in Sleep and Stop modes register 2 (RCC_APB1SMENR2)

Address offset: 0x0C8
Reset value: 0xFFFF FFFF
Access: no wait state; word, half-word and byte access

This register only configures the clock gating, not the clock source itself.

When a bit is set in Stop mode, the corresponding peripheral clock is enabled only when a peripheral (this one or another) requests AHB or APB clock (refer to Section 11.4.20: Peripherals clock gating and autonomous mode).

Bit 31 **SRAM4AMEN**: SRAM4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: SRAM4 autonomous mode disabled during Stop 0,1,2 mode
1: SRAM4 autonomous mode enabled during Stop 0,1,2 mode

Bit 30 **Reserved**, must be kept at reset value.

Bit 29 **ADF1AMEN**: ADF1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: ADF1 autonomous mode disabled during Stop 0,1,2 mode
1: ADF1 autonomous mode enabled during Stop 0,1,2 mode

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 28 **LPDMA1AMEN**: LPDMA1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPDMA1 autonomous mode disabled during Stop 0,1,2 mode
1: LPDMA1 autonomous mode enabled during Stop 0,1,2 mode

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 27 **DAC1AMEN**: DAC1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: DAC1 autonomous mode disabled during Stop 0,1,2 mode
1: DAC1 autonomous mode enabled during Stop 0,1,2 mode

*Note*: This bit must be set to allow the peripheral to wake up from Stop modes.

Bit 26 **LPGPIO1AMEN**: LPGPIO1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPGPIO1 autonomous mode disabled during Stop 0,1,2 mode
1: LPGPIO1 autonomous mode enabled during Stop 0,1,2 mode
Bit 25 **ADC4AMEN**: ADC4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: ADC4 autonomous mode disabled during Stop 0,1,2 mode
1: ADC4 autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

Bits 24:22 Reserved, must be kept at reset value.

Bit 21 **RTCAPBAMEN**: RTC and TAMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: RTC and TAMP autonomous mode disabled during Stop 0,1,2 mode
1: RTC and TAMP autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

Bit 20 **VREFAMEN**: VREFBUF autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: VREFBUF autonomous mode disabled during Stop 0,1,2 mode
1: VREFBUF autonomous mode enabled during Stop 0,1,2 mode

Bits 19:16 Reserved, must be kept at reset value.

Bit 15 **COMPAMEN**: COMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: COMP autonomous mode disabled during Stop 0,1,2 mode
1: COMP autonomous mode enabled during Stop 0,1,2 mode

Bit 14 **OPAMPAMEN**: OPAMP autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: OPAMP autonomous mode disabled during Stop 0,1,2 mode
1: OPAMP autonomous mode enabled during Stop 0,1,2 mode

Bit 13 **LPTIM4AMEN**: LPTIM4 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM4 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM4 autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

Bit 12 **LPTIM3AMEN**: LPTIM3 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM3 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM3 autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

Bit 11 **LPTIM1AMEN**: LPTIM1 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: LPTIM1 autonomous mode disabled during Stop 0,1,2 mode
1: LPTIM1 autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **I2C3AMEN**: I2C3 autonomous mode enable in Stop 0,1,2 mode
Set and cleared by software.
0: I2C3 autonomous mode disabled during Stop 0,1,2 mode
1: I2C3 autonomous mode enabled during Stop 0,1,2 mode

*Note: This bit must be set to allow the peripheral to wake up from Stop modes.*
11.8.46 RCC peripherals independent clock configuration register 1 (RCC_CCIPR1)

Address offset: 0x0E0
Reset value: 0x0000 0000
Access: no wait states; word, half-word and byte access

Bit 31:29 TIMICSEL[2:0]: Clocks sources for TIM16,TIM17 and LPTIM2 internal input capture
When the TIMICSEL2 bit is set, the TIM16, TIM17 and LPTIM2 internal input capture can be connected either to HSI/256, MSI/4 or MSI/1024. Depending on TIMICSEL[1:0] value, MSI is either MSIK or MSIS.
When TIMICSEL2 is cleared, the HSI, MSIK and MSIS clock sources cannot be selected as TIM16, TIM17 or LPTIM2 internal input capture.
0xx: HSI, MSIK and MSIS dividers disabled
100: HSI/256, MSIS/1024 and MSIS/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
101: HSI/256, MSIS/1024 and MSIK/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
110: HSI/256, MSIK/1024 and MSIS/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture
111: HSI/256, MSIK/1024 and MSIK/4 generated and can be selected by TIM16, TIM17 and LPTIM2 as internal input capture

Note: The clock division must be disabled (TIMICSEL configured to 0xx) before selecting or changing a clock sources division.

Bit 28 Reserved, must be kept at reset value.
Bits 27:26 **ICLKSEL[1:0]**: intermediate clock source selection
These bits are used to select the clock source used by OTG_FS and SDMMC.
- 00: HSI48 clock selected
- 01: PLL2 "Q" (pll2_q_ck) selected
- 10: PLL1 "Q" (pll1_q_ck) selected
- 11: MSIK clock selected

Bits 25:24 **FDCAN1SEL[1:0]**: FDCAN1 kernel clock source selection
These bits are used to select the FDCAN1 kernel clock source.
- 00: HSE clock selected
- 01: PLL1"Q" (pll1_q_ck) selected
- 10: PLL2 "P" (pll2_p_ck) selected
- 11: reserved

Bits 23:22 **SYSTICKSEL[1:0]**: SysTick clock source selection
These bits are used to select the SysTick clock source.
- 00: HCLK/8 selected
- 01: LSI selected
- 10: LSE selected
- 11: reserved

*Note:* When LSE or LSI is selected, the AHB frequency must be at least four times higher than the LSI or LSE frequency. In addition, a jitter up to one HCLK cycle is introduced, due to the LSE or LSI sampling with HCLK in the SysTick circuitry.

Bits 21:20 **SPI1SEL[1:0]**: SPI1 kernel clock source selection
These bits are used to select the SPI1 kernel clock source.
- 00: PCLK2 selected
- 01: SYSCLK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The SPI1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 19:18 **LPTIM2SEL[1:0]**: Low-power timer 2 kernel clock source selection
These bits are used to select the LPTIM2 kernel clock source.
- 00: PCLK1 selected
- 01: LSI selected
- 10: HSI16 selected
- 11: LSE selected

*Note:* The LPTIM2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is LSI, LSE or HSI16 if HSikeron = 1.

Bits 17:16 **SPI2SEL[1:0]**: SPI2 kernel clock source selection
These bits are used to select the SPI2 kernel clock source.
- 00: PCLK1 selected
- 01: SYSCLK selected
- 10: HSI16 selected
- 11: MSIK selected

*Note:* The SPI2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.
Bits 15:14  **I2C4SEL[1:0]**: I2C4 kernel clock source selection
   These bits are used to select the I2C4 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: MSIK selected
   **Note:** The I2C4 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 13:12  **I2C2SEL[1:0]**: I2C2 kernel clock source selection
   These bits are used to select the I2C2 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: MSIK selected
   **Note:** The I2C2 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 11:10  **I2C1SEL[1:0]**: I2C1 kernel clock source selection
   These bits are used to select the I2C1 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: MSIK selected
   **Note:** The I2C1 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or MSIK.

Bits 9:8  **UART5SEL[1:0]**: UART5 kernel clock source selection
   These bits are used to select the UART5 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: LSE selected
   **Note:** The UART5 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 7:6  **UART4SEL[1:0]**: UART4 kernel clock source selection
   This bits are used to select the UART4 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: LSE selected
   **Note:** The UART4 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.

Bits 5:4  **USART3SEL[1:0]**: USART3 kernel clock source selection
   This bits are used to select the USART3 kernel clock source.
   00: PCLK1 selected
   01: SYSCLK selected
   10: HSI16 selected
   11: LSE selected
   **Note:** The USART3 is functional in Stop 0 and Stop 1 mode only when the kernel clock is HSI16 or LSE.
11.8.47 RCC peripherals independent clock configuration register 2 (RCC_CCIPR2)

Address offset: 0x0E4

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

|------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|

|------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 OCTOSPISEL[1:0]: OCTOSPI1 and OCTOSPI2 kernel clock source selection
These bits are used to select the OCTOSPI1 and OCTOSPI2 kernel clock source.
00: SYSCLK selected
01: MSIIK selected
10: PLL1 “Q” (pll1_q_ck) selected, can be up to 200 MHz
11: PLL2 “Q” (pll2_q_ck) selected, can be up to 200 MHz

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 SDMMCSEL: SDMMC1 and SDMMC2 kernel clock source selection
This bit is used to select the SDMMC kernel clock source. It is recommended to change this bit only after reset and before enabling the SDMMC.
0: ICLK clock selected
1: PLL1 “P” (pll1_p_ck) selected, in case higher than 48 MHz is needed (for SDR50 mode)
Bits 13:12 **RNGSEL[1:0]**: RNGSEL kernel clock source selection

These bits are used to select the RNG kernel clock source.

00: HSI48 selected
01: HSI48 / 2 selected, can be used in range 4
10: HSI16 selected
11: reserved

Bit 11 **SAESSEL**: SAES kernel clock source selection

This bit is used to select the SAES kernel clock source.

0: SHSI selected
1: SHSI / 2 selected, can be used in range 4

Bits 10:8 **SAI2SEL[2:0]**: SAI2 kernel clock source selection

These bits are used to select the SAI2 kernel clock source.

000: PLL2 "P" (pll2_p_ck) selected
001: PLL3 "P" (pll3_p_ck) selected
010: PLL1 "P" (pll1_p_ck) selected
011: input pin AUDIOCLK selected
100: HSI16 clock selected
others: reserved

*Note: If the selected clock is the external clock and this clock is stopped, a switch to another clock is impossible.*

Bits 7:5 **SAI1SEL[2:0]**: SAI1 kernel clock source selection

These bits are used to select the SAI1 kernel clock source.

000: PLL2 "P" (pll2_p_ck) selected
001: PLL3 "P" (pll3_p_ck) selected
010: PLL1 "P" (pll1_p_ck) selected
011: input pin AUDIOCLK selected
100: HSI16 clock selected
others: reserved

*Note: If the selected clock is the external clock and this clock is stopped, a switch to another clock is impossible.*

Bits 4:3 Reserved, must be kept at reset value.

Bits 2:0 **MDF1SEL[2:0]**: MDF1 kernel clock source selection

These bits are used to select the MDF1 kernel clock source.

000: HCLK selected
001: PLL1 "P" (pll1_p_ck) selected
010: PLL3 "Q" (pll3_q_ck) selected
011: input pin AUDIOCLK selected
100: MSIK clock selected
others: reserved
11.8.48 RCC peripherals independent clock configuration register 3 (RCC_CCIPR3)

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **ADF1SEL[2:0]**: ADF1 kernel clock source selection

These bits are used to select the ADF1 kernel clock source.

000: HCLK selected
001: PLL1 "P" (pll1_p_ck) selected
010: PLL3 "Q" (pll3_q_ck) selected
011: input pin AUDIOCLK selected
100: MSIK clock selected
others: reserved

**Note:** The ADF1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is AUDIOCLK or MSIK.

Bit 15 **DAC1SEL**: DAC1 sample and hold clock source selection

This bit is used to select the DAC1 sample and hold clock source.

0: LSE selected
1: LSI selected

Bits 14:12 **ADCDACSEL[2:0]**: ADC1, ADC4 and DAC1 kernel clock source selection

These bits are used to select the ADC1, ADC4 and DAC1 kernel clock source.

000: HCLK clock selected
001: SYSCLK selected
010: PLL2 "R" (pll2_r_ck) selected
011: HSE clock selected
100: HSI16 clock selected
101: MSIK clock selected
others: reserved

**Note:** The ADC1, ADC4 and DAC1 are functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK (only ADC4 and DAC1 are functional in Stop 2 mode).
Bits 11:10 **LPTIM1SEL[1:0]**: LPTIM1 kernel clock source selection
These bits are used to select the LPTIM1 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI16 selected
11: LSE selected

*Note:* The LPTIM1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIKERON = 1 or MSIK with MSIKERON = 1.

Bits 9:8 **LPTIM34SEL[1:0]**: LPTIM3 and LPTIM4 kernel clock source selection
These bits are used to select the LPTIM3 and LPTIM4 kernel clock source.
00: MSIK clock selected
01: LSI selected
10: HSI selected
11: LSE selected

*Note:* The LPTIM3 and LPTIM4 are functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is LSI, LSE, HSI16 with HSIKERON = 1 or MSIK with MSIKERON = 1.

Bits 7:6 **I2C3SEL[1:0]**: I2C3 kernel clock source selection
These bits are used to select the I2C3 kernel clock source.
00: PCLK3 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

*Note:* The I2C3 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **SPI3SEL[1:0]**: SPI3 kernel clock source selection
These bits are used to select the SPI3 kernel clock source.
00: PCLK3 selected
01: SYSCLK selected
10: HSI16 selected
11: MSIK selected

*Note:* The SPI3 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16 or MSIK.

Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection
These bits are used to select the LPUART1 kernel clock source.
000: PCLK3 selected
001: SYSCLK selected
010: HSI16 selected
011: LSE selected
100: MSIK selected
others: reserved

*Note:* The LPUART1 is functional in Stop 0, Stop 1 and Stop 2 modes only when the kernel clock is HSI16, LSE or MSIK.
### 11.8.49 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x00F0

Backup domain reset value: 0x0000 0000

Reset by Backup domain reset except LSCOSEL, LSCOEN and BDRST that are reset only by Backup domain power-on reset.

Access: 0 ≤ wait state ≤ 3; word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

**Note:** The bits of this register are outside of the core domain. As a result, after reset, these bits are write-protected and the DBP bit in the PWR Backup domain control register 1 (PWR_BDCR1) must be set before these can be modified (see Section 10: Power control (PWR) for further information). These bits (except LSCOSEL, LSCOEN and BDRST) are only reset after a Backup domain reset (see Section 11.3.3: Backup domain reset). Any internal or external reset does not have any effect on these bits.

Bits 31:29 Reserved, must be kept at reset value.

**Bit 28 LSIPREDIV:** Low-speed clock divider configuration

Set and cleared by software to enable the LSI division. This bit can be written only when the LSI is disabled (LSION = 0 and LSIRDY = 0). If the LSI was previously enabled, it is necessary to wait for at least 60 μs after clearing LSION bit (synchronization time for LSI to be really disabled), before writing LSIPREDIV. The LSIPREDIV cannot be changed if the LSI is used by the IWDG or by the RTC.

0: LSI not divided
1: LSI divided by 128

**Bit 27 LSIRDY:** LSI oscillator ready

Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles. This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.

0: LSI oscillator not ready
1: LSI oscillator ready

**Bit 26 LSION:** LSI oscillator enable

Set and cleared by software. The LSI oscillator is disabled 60 μs maximum after the LSION bit is cleared.

0: LSI oscillator OFF
1: LSI oscillator ON
Bit 25 **LSCOSEL**: Low-speed clock output selection
Set and cleared by software.
0: LSI clock selected
1: LSE clock selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
Set and cleared by software.
0: LSCO disabled
1: LSCO enabled

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset
Set and cleared by software.
0: Reset not activated
1: Reset the entire Backup domain

Bit 15 **RTCEN**: RTC and TAMP clock enable
Set and cleared by software.
0: RTC and TAMP clock disabled
1: RTC and TAMP clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSEGFON**: LSE clock glitch filter enable
Set and cleared by hardware to enable the LSE glitch filter. This bit can be written only when the LSE is disabled (LSEON = 0 and LSERDY = 0)
0: LSE glitch filter disabled
1: LSE glitch filter enabled

Bit 11 **LSEYSYRDY**: LSE system clock (LSESYS) ready
Set and cleared by hardware to indicate when the LSE system clock is stable. When the LSESYSEN bit is set, the LSEYSYRDY flag is set after two LSE clock cycles. The LSE clock must be already enabled and stable (LSEON and LSERDY are set). When the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.
0: LSESYS clock not ready
1: LSESYS clock ready

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC and TAMP clock source selection
Set by software to select the clock source for the RTC and TAMP. Once the RTC and TAMP clock source has been selected, it cannot be changed anymore unless the Backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.
00: No clock selected
01: LSE oscillator clock selected
10: LSI oscillator clock selected
11: HSE oscillator clock divided by 32 selected
Bit 7 **LSESYSEN**: LSE system clock (LSESYS) enable

Set by software to enable always the LSE system clock generated by RCC. This clock can be used by any peripheral when its source clock is the LSE or at system level in case of one of the LSCOSEL, MCO, MSI PLL mode or CSS on LSE is needed.

The LSESYS clock can be generated even if LSESYSEN= 0 if the LSE clock is requested by the CSS on LSE, by a peripheral or any other source clock using LSE.

0: LSESYS only enabled when requested by a peripheral or system function
1: LSESYS enabled always generated by the RCC

Bit 6 **LSECSSD**: CSS on LSE failure Detection

Set by hardware to indicate when a failure is detected by the CCS on the external 32 kHz oscillator (LSE).

0: No failure detected on LSE
1: Failure detected on LSE

Bit 5 **LSECSSON**: CSS on LSE enable

Set by software to enable the CSS on LSE. LSECSSON must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected.

Once enabled, this bit cannot be disabled, except after a LSE failure detection (LSECSSD = 1). In that case, the software must disable the LSECSSON bit.

0: CSS on LSE OFF
1: CSS on LSE ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator drive capability

Set by software to modulate the drive capability of the LSE oscillator. This field can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

00: ‘Xtal mode’ lower driving capability
01: ‘Xtal mode’ medium-low driving capability
10: ‘Xtal mode’ medium-high driving capability
11: ‘Xtal mode’ higher driving capability

*Note: The oscillator is in ‘Xtal mode’ when it is not in bypass mode.*

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the external 32 kHz oscillator is disabled (LSEON = 0 and LSERDY = 0).

0: LSE oscillator not bypassed
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after six external low-speed oscillator clock cycles.

0: LSE oscillator not ready
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable

Set and cleared by software.

0: LSE oscillator OFF
1: LSE oscillator ON
11.8.50 RCC control/status register (RCC_CSR)

Address offset: 0x0F4
Reset value: 0x0C00 4400

Reset by system reset, except reset flags by power reset only.
Access: $0 \leq \text{wait state} \leq 3$; word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

</table>

Bit 31 **LPWRRSTF**: Low-power reset flag
- Set by hardware when a reset occurs due to Stop, Standby or Shutdown mode entry, whereas the corresponding nRST_STOP, nRST_STBY or nRST_SHDW option bit is cleared.
- Cleared by writing to the RMVF bit.
  0: No illegal low-power mode reset occurred
  1: Illegal low-power mode reset occurred

Bit 30 **WWDDRSTF**: Window watchdog reset flag
- Set by hardware when a window watchdog reset occurs.
- Cleared by writing to the RMVF bit.
  0: No window watchdog reset occurred
  1: Window watchdog reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag
- Set by hardware when an independent watchdog reset domain occurs.
- Cleared by writing to the RMVF bit.
  0: No independent watchdog reset occurred
  1: Independent watchdog reset occurred

Bit 28 **SFTRSTF**: Software reset flag
- Set by hardware when a software reset occurs.
- Cleared by writing to the RMVF bit.
  0: No software reset occurred
  1: Software reset occurred

Bit 27 **BORRSTF**: BOR flag
- Set by hardware when a BOR occurs.
- Cleared by writing to the RMVF bit.
  0: No BOR occurred
  1: BOR occurred
Bit 26 **PINRSTF**: NRST pin reset flag
- Set by hardware when a reset from the NRST pin occurs.
- Cleared by writing to the RMVF bit.
- 0: No reset from NRST pin occurred
- 1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option byte loader reset flag
- Set by hardware when a reset from the option byte loading occurs.
- Cleared by writing to the RMVF bit.
- 0: No reset from option byte loading occurred
- 1: Reset from option byte loading occurred

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
- Set by software to clear the reset flags.
- 0: No effect
- 1: Clear the reset flags

Bits 22:16 Reserved, must be kept at reset value.

Bits 15:12 **MSISSRANGE[3:0]**: MSIS range after Standby mode
- Set by software to chose the MSIS frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. **MSISSRANGE** can be written only when **MSIRGSEL = 1**.
- 0100: range 4 around 4M Hz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.5 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- Others: reserved

*Note: Changing the MSISSRANGE does not change the current MSIS frequency.*

Bits 11:8 **MSIKSRANGE[3:0]**: MSIK range after Standby mode
- Set by software to chose the MSIK frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a NRST pin or a power-on reset or when exiting Shutdown mode, the range is always 4 MHz. **MSIKSRANGE** can be written only when **MSIRGSEL = 1**.
- 0100: range 4 around 4M Hz (reset value)
- 0101: range 5 around 2 MHz
- 0110: range 6 around 1.5 MHz
- 0111: range 7 around 1 MHz
- 1000: range 8 around 3.072 MHz
- Others: reserved

*Note: Changing the MSIKSRANGE does not change the current MSIK frequency.*

Bits 7:0 Reserved, must be kept at reset value.
11.8.51 **RCC secure configuration register (RCC_SECCFGR)**

Address offset: 0x110  
Reset value: 0x0000 0000  
Access: no wait state; word, half-word and byte access

When the system is secure (TZEN = 1), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A non-secure write access generates an illegal access event and data is not written. This register can be read by secure or non-secure, privilege or unprivileged access.

When the system is not secure (TZEN = 0), this register is read as 0 and the register write is ignored.

550/3040 RM0456 Rev 1
Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: RCC non-secure functions privilege configuration
Set and reset by software. This bit can be written only by privileged access, secure or non-secure.
0: Read and write to RCC non-secure functions can be done by privileged or unprivileged access.
1: Read and write to RCC non-secure functions can be done by privileged access only.

Bit 0 **SPRIV**: RCC secure functions privilege configuration
Set and reset by software. This bit can be written only by a secure privileged access.
0: Read and write to RCC secure functions can be done by privileged or unprivileged access.
1: Read and write to RCC secure functions can be done by privileged access only.

Refer to Section 2.3 for the register boundary addresses.
12 Clock recovery system (CRS)

12.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

12.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

</tbody>
</table>

12.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFRG register, can be the signal from the LSE clock or the USB SOF signal. For a better robustness of the
SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the RC48 clock) is implemented to filter out any glitches. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 12.7.2: CRS configuration register (CRS_CFGR).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

12.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value must be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value must be decremented).
Figure 39. CRS counter behavior

- CRS counter value
- RELOAD
- OUTRANGE (128 x FELIM)
- WARNING LIMIT (3 x FELIM)
- TOLERANCE LIMIT (FELIM)
- Frequency error counter stopped
- Trimming action:
  - CRS event:
    - MSv32122V1
    - ESYNC

Trimming actions:
- 0
- +2
- +1
- 0
- -1
- -2
- 0

CRS events:
- SYNCERR
- SYNCHWARN
- SYNCOK
- SYNCHWARN
- SYNCHMISS

Frequency error counter stopped.
12.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:
- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 * FELIM value
- OUTRANGE (error limit), defined as 128 * FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCWARN status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCERR or SYNCMISS status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

12.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one to reach the expected synchronization on the zero value. The formula is the following:

\[ \text{RELOAD} = \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} - 1 \]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).
**FELIM value**

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

\[ \text{FELIM} = \left( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) \times \text{STEP} \% / 100\% / 2 \]

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} = 48000 \) and to a typical trimming step size of 0.14%.

*Note:* The trimming step size depends upon the product, check the datasheet for accurate setting.

**Caution:** There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

### 12.5 CRS low-power modes

**Table 111. Effect of low-power modes on CRS**

Bit 31 **SYNCPOL**: SYNC polarity selection
- This bit is set and cleared by software to select the input polarity for the SYNC signal source.
- 0: SYNC active on rising edge (default)
- 1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection
- These bits are set and cleared by software to select the SYNC signal source (see **Table 110: CRS internal input/output signals**):
- 00: crs_sync_in_1 selected as SYNC signal source
- 01: crs_sync_in_2 selected as SYNC signal source
- 10: crs_sync_in_3 selected as SYNC signal source
- 11: crs_sync_in_4 selected as SYNC signal source

**Note**: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.
12.7.3 CRS interrupt and status register (CRS_ISR)

**FECAP[15:0]**: Frequency error capture
FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 12.4.4 for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction
FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
0: Upcounting direction, the actual frequency is above the target.
1: Downcounting direction, the actual frequency is below the target.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow
This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No trimming error signalized
1: Trimming error signalized
Bit 9 **SYNCMISS**: SYNC missed
This flag is set by hardware when the frequency error counter reached value FELIM * 128 and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action has to be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No SYNC missed error signalized
1: SYNC missed error signalized

Bit 8 **SYNCERR**: SYNC error
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No SYNC error signalized
1: SYNC error signalized

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag
This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCFE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.
0: No expected SYNC signalized
1: Expected SYNC signalized

Bit 2 **ERRF**: Error flag
This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register.
0: No synchronization or trimming error signalized
1: Synchronization or trimming error signalized

Bit 1 **SYNCWARNF**: SYNC warning flag
This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCPWarnIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCPWarnC bit in the CRS_ICR register.
0: No SYNC warning signalized
1: SYNC warning signalized

Bit 0 **SYNCOKF**: SYNC event OK flag
This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCPKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCPKGC bit in the CRS_ICR register.
0: No SYNC event OK signalized
1: SYNC event OK signalized
12.7.4 **CRS interrupt flag clear register (CRS_ICR)**

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNCS clear flag

Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag

Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNCS warning clear flag

Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNCS event OK clear flag

Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.
### 12.7.5 CRS register map

Refer to *Section 2.3 on page 116* for the register boundary addresses.
13  General-purpose I/Os (GPIO)

13.1  Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR) and a high-speed low-voltage register (GPIOx_HSLVR).

13.2  GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support

13.3  GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability
Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The Table 114 gives the possible port bit configurations.

**Figure 40. Structure of three-volt or five-volt tolerant GPIO (TT or FT)**

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

1. \(GP = \text{general-purpose}, PP = \text{push-pull}, PU = \text{pull-up}, PD = \text{pull-down}, OD = \text{open-drain}, AF = \text{alternate function.}\)

### 13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTD0/TRACESWO in floating state no pull-up/pull-down

PH3/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see Section 13.3.15: Using PH3 as GPIO).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.
13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions**:
  - For the ADC, DAC, OPAMP and COMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, OPAMP and COMP registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.
13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIO port input data register (GPIOx_IDR) \((x = A \text{ to } I)\) and GPIO port output data register (GPIOx_ODR) \((x = A \text{ to } I)\).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH and GPIOx_HSLVR.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH).

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can
thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

13.3.8 **External interrupt/wakeup lines**

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to *Section 21: Extended interrupts and event controller (EXTI)*.

13.3.9 **Input configuration**

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

![Figure 41. Input floating/pull-up/pull-down configurations](MSv63602V1)

[Diagram showing input floating/pull-up/pull-down configurations]
### 13.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

![Figure 42. Output configuration](msv63641v1.png)

### 13.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
The figure below shows the alternate function configuration of the I/O port bit.

**Figure 43. Alternate function configuration**

### 13.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.

Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

**Figure 44. High-impedance analog configuration**

### 13.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.
When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

13.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to Section 54.3: RTC functional description.

13.3.15 Using PH3 as GPIO

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, PH3 switches from the input mode to the analog input mode:
- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.

13.3.16 OPAMPx_VINM dedicated pins

The OPAMPx_VINM dedicated pins are three-volt tolerant and are supplied by VDDA. These pins do not feature a complete TT structure as shown in Figure 40, but a direct connection to OPAMPx. The OPAMPx_VINM dedicated pins are available on specific packages only (refer to the device datasheet for availability of these pins).

13.3.17 TrustZone security

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR. When the TrustZone is active (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a non-secure access. In case of non-secure access, these bits are RAZ/WI. The GPIO clock and reset control bits in the RCC are automatically configured as secure as soon as at least one I/O in the GPIO is secure.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration (see Section 5: Global TrustZone controller (GTZC) for more details):
- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a non-secure I/O pin. If this is not respected, the input data to the secure peripheral is forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through non-secure I/Os.
- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a non-secure peripheral. If this is not respected, the switch remains open. This prevent the redirection of secure data to a non-secure peripheral or I/O through analog path. Refer to Section 3: System security for more details.
- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is non-secure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. Refer to
Section 3: System security for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

The table below gives a summary of the I/O port secured bits following the security configuration bit in the GPIO_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non secure-read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers bits are non-secure. The GPIOx_SECCFGR register is RAZ/WI.

1. GPIOx, x = A to I. For x = A to H, y = 0 to 15. For x = I, y = 0 to 7.

13.3.18 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

13.3.19 High-speed low-voltage mode (HSLV)

Some I/Os have the capability to increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1).
**Caution:** The I/O HSLV configuration bit must not be set if the I/O supply (VDD or VDDIO2) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device. The I/O HSLV bit can be set only when the corresponding option bit is activated (IO_VDD_HSLV or IO_VDDIO2_HSLV depending on the I/O supply, refer to Section 7.4: FLASH option bytes). There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

### 13.3.20 I/O compensation cell

The I/O commutation slew rate (tfall / trise) can be adapted by software depending on Process, Voltage and Temperatures conditions, in order to reduce the I/O noise on power supply. Refer to Section 15: System configuration controller (SYSCFG) for more details.

### 13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

#### 13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I)

Address offset: 0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFFFF FEBF (for port B)

Reset value: 0xFFFF FFFF (for ports C..H)

Reset value: 0x0000 FFFF (for port I)

Bits 31:16 BRy: Port x reset I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 BSy: Port x set I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

*Note:* A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 LCKK: Lock key

- This bit can be read any time. It can only be modified using the lock key write sequence.
- 0: Port configuration lock key not active
- 1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:
  - WR LCKR[16] = 1 + LCKR[15:0]
  - WR LCKR[16] = 0 + LCKR[15:0]
  - WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read
  - RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

*Note:* During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 LCKy: Port x lock I/O pin y (y = 15 to 0)

- These bits are read/write but can only be written when the LCKK bit is 0
- 0: Port configuration not locked
- 1: Port configuration locked

*Note:* The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
13.4.9  GPIO alternate function low register (GPIOx_AFRL) (x = A to I)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:0  **AFSELy[3:0]**: Alternate function selection for port x I/O pin y (y = 7 to 0)

These bits are written by software to configure alternate function I/Os.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy**: Port x reset IO pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Reset the corresponding ODy bit

**Note**: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.
### 13.4.12 GPIO high-speed low-voltage register (GPIOx_HSLVR) (x = A to I)

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HSLV**: Port x high-speed low-voltage configuration (y = 15 to 0)
- These bits are written by software to optimize the I/O speed when the I/O supply is low.
- Each bit is active only if the corresponding IO_VDD_HSLV/IO_VDDIO2_HSLV user option bit is set. It must be used only if the I/O supply voltage is below 2.7 V.
- Setting these bits when the I/O supply (VDD or VDDIO2) is higher than 2.7 V may be destructive.
- 0: I/O speed optimization disabled
- 1: I/O speed optimization enabled

*Note:* Not all I/Os support the HSLV mode. Refer to the I/O structure in the corresponding datasheet for the list of I/Os supporting this feature. Other I/Os HSLV configuration must be kept at reset value.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

### 13.4.13 GPIO secure configuration register (GPIOx_SECCFGR) (x = A to I)

When the system is secure (TZEN = 1), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

Address offset: 0x30
Reset value: 0x0000 FFFF (for ports A to H)
Reset value: 0x0000 00FF (for port I)

14 Low-power general-purpose I/Os (LPGPIO)

14.1 Introduction

The low-power general-purpose input/output (LPGPIO) allows the I/O control in Stop mode (down to Stop 2 mode), using DMA in memory-to-memory transfer mode. LPGPIO is designed to be used in conjunction with the GPIO.

14.2 LPGPIO main features

- 16 I/Os control in low-power modes down to Stop 2 mode.
- Secure clock and reset management
- Output data from output data register (LPGPIO_ODR)
- Input data to input data register (LPGPIO_IDR)
- Bit set and reset register (LPGPIO_BSRR) for bitwise write access to LPGPIO_ODR
- TrustZone security support

14.3 LPGPIO functional description

14.3.1 LPGPIO and GPIO configuration

The LPGPIO can control in input or output up to 16 I/Os thanks to LPGPIO_Py (y = 0 to 15) pins alternate functions. This control is still functional in Stop 2 mode, thanks to DMA transfers. The I/Os with a LPGPIO function must be configured as LPGPIO alternate function in the GPIO port mode register (GPIOx_MODER) (x = A to I). Then the I/O value can be read in the LPGPIO input data register, and the I/O can be driven by the LPGPIO output data register or thanks to LPGPIO_BSRR/LPGPIO_BRR registers.

14.3.2 LPGPIO control registers

Each of the 16 I/Os controlled by the LPGPIO can be configured as input or output thanks to the LPGPIO port mode register (LPGPIO_MODER).

14.3.3 LPGPIO I/O data registers

The LPGPIO includes the following 16-bit data registers:

- LPGPIO port output data register (LPGPIO_ODR) that stores the data to be output (read/write accessible)
- LPGPIO port input data register (LPGPIO_IDR): the data input through the I/O is stored into this input data register (read only)

14.3.4 LPGPIO I/O data bitwise handling

The 32-bit LPGPIO port bit set/reset register (LPGPIO_BSRR) is implemented to allow bitwise set and reset in the output data register (LPGPIO_ODR).
Each LPGPIO_ODR bit has the following control bits in LPGPIO_BSRR:
- \text{LPGPIO_{BSRR}(i)}: when writing 1 to it, this bit sets the LPGPIO_ODR(i) bit.
- \text{LPGPIO_{BSRR}(i + 16)}: when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

\textbf{Note: Writing 0 to these bits has no effect on LPGPIO_ODR corresponding bits.}

If there is an attempt to set and reset bits of the same index, the set action takes the priority.

Writing LPGPIO_BSRR register does not lock the LPGPIO_ODR bits, that can be anyway accessed directly. LPGPIO_BSRR provides a way to perform atomic bitwise handling.

The 16-bit \textit{LPGPIO port bit reset register (LPGPIO_BRR)} allows individual bit reset. It is the same as LPGPIO_BSRR but with minimal pattern preparation:
- \text{LPGPIO_{BRR}(i)}: when writing 1 to it, this bit resets the LPGPIO_ODR(i) bit.

\subsection{Security protection}

The LPGPIO includes a security mechanism, that allows or locks the access to the I/O configuration and data registers. This system is used to protect the I/O against the data corruption or observation.

The security mechanism within the LPGPIO is directly issued from the \textit{GPIO secure configuration register (GPIOx_SECCFGR)} \((x = A \text{ to } I)\). Therefore, no additional configuration is required.

The LPGPIO security means the following:
- When the executed code is secure, all bits can be accessed.
- When the executed code is non-secure, only the bits concerning the non-secure I/Os can be accessed.

A non-secure access to a secure I/O register bit is silent fail:
- A non-secure write to a secure I/O register bit is ignored (WI).
- A non-secure read to a secure I/O register bit returns 0 (RAZ).
- No bus error is generated.

\subsection{Secure clock and reset management}

The LPGPIO clock and reset control bits in the RCC are automatically configured as secured as soon as at least one I/O with LPGPIO alternate function is secure (refer to the corresponding I/Os in GPIO_SECCFGR registers).
14.4 **LPGPIO registers**

This section gives a detailed description of the LPGPIO registers.

The peripheral registers can be written in word, half-word or byte mode.

Bits 31:16 **BRy**: Reset I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns 0.

0: No action on the corresponding ODy bit
1: Resets the corresponding ODy bit

*Note:* If both **BSy** and **BRy** are set, **BSy** has priority.

Bits 15:0 **BSy**: Port x set I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns 0.

0: No action on the corresponding ODy bit
1: Sets the corresponding ODy bit
14.4.5 LPGPIO port bit reset register (LPGPIO_BRR)

Address offset: 0x28
Reset value: 0x0000 0000

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bit 15:0 | BRy: Reset IO pin y (y = 15 to 0) |
| These bits are write-only. A read to these bits returns 0. |
| 0: No action on the corresponding ODy bit |
| 1: Reset the corresponding ODy bit |

Refer to Section 2.3 for the register boundary addresses.
15  System configuration controller (SYSCFG)

15.1 SYSCFG main features

The STM32U575/585 devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Managing robustness feature
- Configuring FPU interrupts
- Enabling/disabling the FMP high-drive mode of some I/Os and voltage booster for I/Os analog switches
- Managing the I/O compensation cell
- Configuring register security access

15.2 SYSCFG functional description

15.2.1 I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the current slew-rate and output impedance in the I/O buffer. Two compensation cells are embedded, one for the I/Os supplied by VDD and one for the I/Os supplied by VDDIO2.

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os. The HSI is used by the compensation cells and must be enabled before enabling the compensation cells in the SYSCFG compensation cell control/status register (SYSCFG_CCCSR).

When enabled, the compensation cell tracking the PVT, and the 8-bit code PCVx and NCVx (x = 1 for I/Os supplied by VDD, x = 2 for I/Os supplied by VDDIO2) are available in SYSCFG_CCVR once the RDYx is set. If the CSx bit is cleared, the I/Ox receives the code from SYSCFG_CCVR, resulting from the compensation cell.

To optimize the trimming, the code can be adjusted through SYSCFG_CCCR. Two sets of bits are available: PCC1/NCC1 for the VDD power rail and PCC2/NCC2 for the VDDIO2 power rail. They can be selected independently through CS1 and CS2 bits in SYSCFG_CCCSR (see Figure 45).

To reduce the power consumption, it is recommended to copy the code from SYSCFG_CCVR to SYSCFG_CCCR. After the result is ready, set the CSx bit and disable the compensation cell.

Note: The compensation cell can be used only when 1.6 V ≤ VDDIOx ≤ 3.6 V.
15.2.2 SYSCFG TrustZone security and privilege

**SYSCFG TrustZone security**

When the TrustZone security is activated, the SYSCFG is able to secure registers from being modified by non-secure accesses.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

A non-secure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SYSCFG illegal access event is enabled in the GTZC.

**Privileged/unprivileged mode**

The SYSCFG registers can be read and written by privileged and unprivileged accesses except the SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR registers, and the FPUSEC bit in the SYSCFG_SECCFGR.

An unprivileged access to a privileged register is RAZ/WI.
The table below shows the register security overview.

</tbody>
</table>

1. TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.
2. Refer to register description for register access.
### 15.3 SYSCFG registers

#### 15.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR)

When the system is secure (TZEN = 1), this register provides write access security and can be written only when the access is secure. It can be globally write-protected, or each bit of this register can be individually write-protected. A non-secure write access is WI and generates an illegal access event. There are no read restrictions.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access, except for FPUSEC that can be written only with privileged access.

Address offset: 0x00

## 15.3.2 SYSCFG configuration register 1 (SYSCFG_CFRG1)

When the system is secure (TZEN = 1), this register can be a mix of secure and non-secure bits depending on ADC security configuration bit in GTZC peripheral and GPIO security bits. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x04

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address</th>
<th>Bit 31:20</th>

</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **PB9_FMP**: Fast-mode Plus driving capability activation on PB9
- This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PB9 when PB9 is not used by I2C peripheral. This can be used to drive a LED for instance.
  - 0: PB9 pin operates in standard mode.
  - 1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed.

Bit 18 **PB8_FMP**: Fast-mode Plus driving capability activation on PB8
- This bit can be read and written only with secure access if PB8 is secure in GPIOB. This bit enables the Fm+ driving mode for PB8 when PB8 is not used by I2C peripheral. This can be used to drive a LED for instance.
  - 0: PB8 pin operates in standard mode.
  - 1: Fm+ mode is enabled on PB8 pin and the speed control is bypassed.

Bit 17 **PB7_FMP**: Fast-mode Plus driving capability activation on PB7
- This bit can be read and written only with secure access if PB7 is secure in GPIOB. This bit enables the Fm+ driving mode for PB7 when PB7 is not used by I2C peripheral. This can be used to drive a LED for instance.
  - 0: PB7 pin operates in standard mode.
  - 1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed.

Bit 16 **PB6_FMP**: Fast-mode Plus driving capability activation on PB6
- This bit can be read and written only with secure access if PB6 is secure in GPIOB. This bit enables the Fm+ driving mode for PB6 when PB6 is not used by I2C peripheral. This can be used to drive a LED for instance.
  - 0: PB6 pin operates in standard mode.
  - 1: Fm+ mode is enabled on PB6 pin, and the speed control is bypassed.

Bits 15:10 Reserved, must be kept at reset value.
Bit 9 **ANASWVDD**: GPIO analog switch control voltage selection
   This bit can be read and written only with secure access if ADC1 or ADC4 is secure in GTZC.
   0: I/O analog switches are supplied by VDDA or booster when booster is ON.
   1: I/O analog switches are supplied by VDD.
   Note: Refer to Table 119: BOOSTEN and ANASWVDD set/reset for bit 9 setting.

Bit 8 **BOOSTEN**: I/O analog switch voltage booster enable
   This bit can be read and written only with secure access if ADC1 or ADC4 is secure in GTZC.
   0: I/O analog switches are supplied by VDDA voltage.
   1: I/O analog switches are supplied by a dedicated voltage booster (supplied by VDD).
   Note: Refer to Table 119: BOOSTEN and ANASWVDD set/reset for bit 8 setting.

Bits 7:0 Reserved, must be kept at reset value.

the table below describes when the bit 8 (BOOSTEN) and the bit 9 (ANASWVDD) must be set or reset depending on the voltage settings.

### Table 119. BOOSTEN and ANASWVDD set/reset

15.3.3 **SYSCFG FPU interrupt mask register (SYSCFG_FPUIMR)**

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the FPUSEC bit in the SYSCFG_SECCFGR register: a non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN =0), there is no access restriction.

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x08

Bit 1 LOCKNSMPU: Non-secure MPU registers lock
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to non-secure MPU_CTRL_NS, MPU_RNR_NS and MPU_RBAR_NS registers.
0: Non-secure MPU registers write enabled
1: Non-secure MPU registers write disabled

Bit 0 LOCKNSVTOR: VTOR_NS register lock
This bit is set by software and cleared only by a system reset.
0: VTOR_NS register write enabled
1: VTOR_NS register write disabled
15.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLOCKR)

This register is used to lock the configuration of PRIS and BFHFNMINS bits in the AIRCR register, SAU, secure MPU and VTOR_S registers.

When the system is secure (TZEN =1), this register can be written only when the access is secure. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), this register is RAZ/WI.

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 LOCKSAU: SAU registers lock**
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers.
0: SAU registers write enabled
1: SAU registers write disabled

**Bit 1 LOCKSMPU: Secure MPU registers lock**
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to secure MPU_CTRL, MPU_RNR and MPU_RBAR registers.
0: Secure MPU registers writes enabled
1: Secure MPU registers writes disabled

**Bit 0 LOCKSVAIRCR: VTOR_S register and AIRCR register bits lock**
This bit is set by software and cleared only by a system reset. When set, this bit disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.
0: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write enabled
1: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write disabled
**15.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2)**

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the CLASSBSEC bit in the SYSCFG_SECCFGR register. When CLASSBSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 ECCL: ECC lock**

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Flash ECC double error signal connection to TIM1/8/15/16/17 break input.

0: ECC double error disconnected from TIM1/8/15/16/17 break input

1: ECC double error connected to TIM1/8/15/16/17 break input

**Bit 2 PVDL: PVD lock enable bit**

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 break input, as well as the PVDE and PVDLS[2:0] in the PWR register.

0: PVD interrupt disconnected from TIM1/8/15/16/17 break input. PVDE and PVDLS[2:0] bits can be programmed by the application.

1: PVD interrupt connected to TIM1/8/15/16/17 break input. PVDE and PVDLS[2:0] bits are read only.

**Bit 1 SPL: SRAM ECC lock bit**

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM ECC double error signal connection to TIM1/8/15/16/17 break inputs.

0: SRAM double error disconnected from TIM1/8/15/16/17 break inputs

1: SRAM double error connected to TIM1/8/15/16/17 break inputs

**Bit 0 CLL: Cortex-M33 LOCKUP (hardfault) output enable**

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex-M33 LOCKUP (hardfault) output to TIM1/8/15/16/17 break input.

0: Cortex-M33 LOCKUP output disconnected from TIM1/8/15/16/17 break inputs

1: Cortex-M33 LOCKUP output connected to TIM1/8/15/16/17 break inputs
15.3.7 SYSCFG memory erase status register (SYSCFG_MESR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE and PKA SRAM erase status
This bit is set by hardware when ICACHE and PKA SRAM erase is completed after potential tamper detection (refer to Section 55: Tamper and backup registers (TAMP) for more details). This bit is cleared by software by writing 1 to it.

0: ICACHE and PKA SRAM erase on going if not yet cleared by software
1: ICACHE and PKA SRAM erase done

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: Device memories erase status
This bit is set by hardware when SRAM2, BKPSRAM, ICACHE, DCACHE1, PKA SRAM erase is completed after power-on reset or tamper detection (refer to Section 55: Tamper and backup registers (TAMP) for more details). This bit is not reset by system reset and is cleared by software by writing 1 to it.

0: memory erase on going if not yet cleared by software
1: Memory erase done
15.3.8 SYSCFG compensation cell control/status register (SYSCFG_CCCSR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

</table>
Bit 2 **EN2**: VDDIO2 I/Os compensation cell enable
- This bit enables the compensation cell of the I/Os supplied by VDDIO2.
  - 0: VDDIO2 I/Os compensation cell disabled
  - 1: VDDIO2 I/Os compensation cell enabled

Bit 1 **CS1**: VDD I/Os code selection
- This bit selects the code to be applied for the compensation cell of the I/Os supplied by VDD.
  - 0: VDD I/Os code from the cell (available in the SYSCFG_CCVR)
  - 1: VDD I/Os code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

Bit 0 **EN1**: VDD I/Os compensation cell enable
- This bit enables the compensation cell of the I/Os supplied by VDD.
  - 0: VDD I/Os compensation cell disabled
  - 1: VDD I/Os compensation cell enabled

### 15.3.9 SYSCFG compensation cell value register (SYSCFG_CCVR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x20

Reset value: 0x0000 0000

```

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **PCV2[3:0]**: PMOS compensation value of the I/Os supplied by VDDIO2
- This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is reset.
15.3.10 SYSCFG compensation cell code register (SYSCFG_CCCR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SYSCFGSEC bit in the SYSCFG_SECCFGR register. When SYSCFGSEC bit is set, only secure access is allowed: non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 PCC2[3:0]: PMOS compensation code of the I/Os supplied by VDDIO2
These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS2 bit of the SYSCFG_CCCSR is set.
15.3.11 SYSCFG RSS command register (SYSCFG_RSSCMCMDR)

When the system is secure (TZEN = 1), this register can be read and written only when the APB access is secure. Otherwise it is RAZ/WI.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x2C
Power-on reset value: 0x0000 0000
System reset: not affected

16 Peripherals interconnect matrix

16.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep, Stop 0, Stop 1 and Stop 2 modes.
## 16.2 Connection summary

2. "-" means no interconnect.
16.3 Interconnection details

16.3.1 Master to slave interconnection for timers

From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15)

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in master mode, it can reset, start, stop or clock the counter of another timer configured in slave mode.

A description of the feature is provided in Section 47.4.23: Timer synchronization.

The synchronization modes are detailed in:
- Section 46.3.30 for advanced-control timers TIM1/TIM8
- Section 47.4.22 for general-purpose timers TIM2/TIM3/TIM4/TIM5
- Section 48.4.22 for the general-purpose timer TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/TIM8) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/TIM17. The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3.

The possible master/slave connections are given in:
- Table 426 for advanced-control timers TIM1/TIM8
- Table 450 for general-purpose timers TIM2/TIM3/TIM4/TIM5
- Table 466 for the general-purpose timers TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:
- Table 439: Effect of low-power modes on TIM1/TIM8
- Table 458: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5
- Table 473: Effect of low-power modes on TIM15/TIM16/TIM17
16.3.2 Triggers to ADCs

From EXTI, timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) and LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4) to ADC1

From EXTI, timers (TIM1/TIM2/TIM6/TIM15) and LP timers (LPTIM1/LPTIM3) to ADC4

Purpose

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC12, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity. More details in:

- Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])
- EXTEN[1:0] defined in ADC configuration register (ADC_CFGR1)
- JEXTEN[1:0] defined in ADC injected sequence register (ADC_JSQR)

General-purpose timers (TIM2/TIM3/TIM4/TIM5), basic timer (TIM6), advanced-control timers (TIM1/TIM8) and general-purpose timer (TIM15/TIM16/TIM17) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in Section 46.3.31: ADC synchronization for TIM1/TIM8) in addition to the EXTI on channels 11 and 15.

The ADC4 do not have injected channels. The general-purpose timers (TIM2 and TIM15), basic timers (TIM6), and advanced-control timers (TIM1) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo. Low-power timers (LPTIM1/LPTIM3) can be used to generate the ADC triggering event through the LPTIM channels in addition to EXTI on channel 11 and 15.

Triggering signals

For ADC1, the input triggering signals and the description of the interconnection between ADC1, and timers, are given in:

- adc_ext_trgy: Table 231: External triggers for regular channels
- adc_jext_trgy: Table 232: External triggers for injected channels
- Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])
- Section 29.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)

For ADC4, the input triggering signals list and the description of the interconnection between ADC4 and timers, are given in:

- Table 249: ADC interconnection
- Section 30.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)
- Section 30.4.21: Example timing diagrams (single/continuous modes hardware/software triggers)
Active power mode

This interconnection is active in Run and Sleep modes for all ADCs, and under Stop 0, Stop 1 and Stop 2 for ADC4 assuming that its trigger event line is active as well (such as LPTIM). The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:

- Table 439: Effect of low-power modes on TIM1/TIM8
- Table 458: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5
- Table 473: Effect of low-power modes on TIM15/TIM16/TIM17
- Section 30.5: ADC low-power modes for ADC4
- Table 485: STM32U575/585 LPTIM features
- Table 499: Effect of low-power modes on the LPTIM

16.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC4 to TIM1/TIM3/TIM8

Purpose

The internal analog watchdog output signals coming from ADC1/ADC4, are connected to on-chip timers. ADC1/ADC4 can provide trigger event through analog watchdog signals to advanced-control timers (TIM1/TIM3/TIM8) in order to reset, start, stop or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- Section 46.3.6: External trigger input for TIM1/TIM8
- Table 427 for the internal ADC1/ADC4 sources connected to TIM1/TIM8 (tim_et) input multiplexer
- Table 451 for the internal ADC1 sources connected to TIM3 (tim_et) input multiplexer
- Section 29.4.30 for the ADC1/ADC_AWDy_OUT signal output generation
- Section 30.4.25 for the ADC4/ADC_AWDy_OUT signal output generation

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1 and ADC4 are active in Run and Sleep modes. The ADC4 conversion is functional and autonomous in Stop 0, Stop 1 and Stop 2 modes. This conversion can generate a wakeup interrupt and desired trigger action on timers.

16.3.4 Triggers to DAC

From timer (TIM1/TIM2/TIM4/TIM5/TIM6/TIM7/TIM8/TIM15), Low-power timers (LPTIM1/LPTIM3) and EXTI to DAC (DAC1/DAC2)

Purpose

General-purpose timers (TIM2/TIM4/TIM5/TIM15), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), LP timers (LPTIM1/LPTIM3) outputs channels
Triggering signals

The output (from timer) on the TIMx_TRGO signal and from LP timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:

- Table 262: DAC interconnection
- Section 31.4.8: DAC trigger selection

Active power mode

This interconnect is active in Run, Sleep, Stop 0, Stop 1 and Stop 2 modes.

16.3.5 Triggers on MDF1 or ADF1

From EXTI, ADF1, timers (TIM1/TIM3/TIM4/TIM6/TIM7/TIM8/TIM16) and LP timer (LPTIM1), to MDF1

From EXTI and MDF1 to ADF1

Purpose

General-purpose timers (TIM3/TIM4/TIM16), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), low-power timer (LPTIM1), EXTI (EXTI11/EXTI15) and ADF1 can be used to generate a triggering event on MDF1 module and start an A/C conversion. In addition, EXTI15 and MDF1 can trigger ADF1.

A description is given in:

- Section 35.4.2: MDF pins and internal signals
- Section 35.4.11: Start-up sequence examples

Triggering signals

The mdf_trgi[13:0] trigger inputs are the triggering input signals. The MDF and ADF trigger inputs connections are detailed in:

- Table 289: MDF trigger connections
- Table 310: ADF trigger connections

Active power mode

This interconnection remains active down to Stop 0 and Stop 1 for MDF1, and Stop 0, Stop 1 and Stop 2 for ADF1, assuming the trigger source remains active.

16.3.6 Timer break from MDF1

From MDF1 to advanced-control timer (TIM1/TIM8)

Purpose

The MDF features an out-of-limit detectors (OLD) and a short circuit detector (SCD) functions. When a short-circuit or open-circuit errors (such as over current or over voltage)
is detected an interrupt event or/and a break signal can be generated to TIM1 and TIM8. This behavior is described in:

- *Section 35.4.7: Short-circuit detectors (SCD)*
- *Section 35.4.9: Out-of-limit detector (OLD)*
- *Section 46.3.18: Using the break function*
- *Section 46.3.19: Bidirectional break inputs*

**Triggering signals**

The mdf1_break[0:3] output signals are connected to break1 and break2 inputs signals of TIM1/TIM8. The tables below gives the assignment of break signals:

- *Table 290: MDF break connections*
- *Table 428: Timer break interconnect*
- *Table 429: Timer break2 interconnect*

**Active power mode**

This interconnection is active under Run and Sleep modes. Refer to:

- *Section 35.4.14: Autonomous mode*
- *Table 301: Effect of low-power modes on MDF*

### 16.3.7 Internal clock sources to timers

From HSE, LSE, LSI, MSIK, HSI and MCO to timers (TIM1/TIM8/TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) and LP timers (LPTIM1/LPTIM2/LPTIM3)

**Purpose**

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

External clocks (HSE, LSE), internal clocks (LSI, MSI, HSI) and microcontroller output clock (MCO) can be used as input to timers:

- MSIK/HSI are assigned to advanced-control timers TIM1 and TIM8 as external trigger signals inputs (tim_etr3/ tim_etr4). MSIK/HSI can be selected as counter clock provided by an external clock source in mode2: external trigger input (tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 46.3.7: Clock selection* for TIM1/TIM8
  - *Table 427: Interconnect to the tim_etr input multiplexer* for TIM1/TIM8

- MSIK, HSI and LSI are assigned to general purpose timers TIM2/TIM3/TIM4/TIM5 as external inputs signals. MSIK/HSI/LSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 47.4.5: Clock selection* for TIM2/TIM3/TIM4/TIM5
  - External clock mode1: *Table 446: Interconnect to the tim_ti1 input multiplexer* for TIM5, tim_ti1_in1 (LSI) and tim_ti1_in2(HSI)
  - External clock mode2: *Table 451: Interconnect to the tim_etr input multiplexer*, tim_etr3 (MSIK), tim_etr4 (HSI) and tim_etr5 (MSIS) for TIM2/TIM3/TIM4/TIM5
• LSE, LSI, MSI, and HSI are assigned to general purpose timers TIM15/TIM16/TIM17 as external inputs signals. LSE/LSI/MSI/HSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1 or tim_ti2 signals). Inputs assignment and clock selection description are detailed in:
  – Table 48.4.6: Clock selection for TIM15/TIM16/TIM17. External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
  – Table 46.4: Interconnect to the tim_ti1 input multiplexer, tim_ti1_in1 (LSE-TIM15), tim_ti1_in5 (LSE-TIM16/TIM17), tim_ti1_in6 (LSI- TIM16/TIM17), tim_ti1_in7/8 (MSI-TIM16/TIM17) and tim_ti1_in9 (HSI-TIM16/TIM17)
• Microcontroller output clock (MCO) is connected as external input to general-purpose timers TIM16/TIM17. This allows the calibration of the HSI16/MSI system clocks (with TIM15/TIM16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely measure LSI (with TIM16 and HSI16) or MSI (with TIM17 and HSI16) oscillator frequency. When the low-speed external (LSE) oscillator is used, no additional hardware connections are required. This feature is given in:
  – Section 11.4.19: Internal/external clock measurement with TIM15/TIM16/TIM17
  – Table 464: Interconnect to the tim_ti1 input multiplexer for TIM15/TIM16/TIM17
• LSI and LSE can be selected as input capture 2 to LPTIM1 as described in Table 494: LPTIM1 input capture 2 connection.
• HSI/256 can be selected as input capture 2 to LPTIM2 as described in Table 495: LPTIM2 input capture 2 connection.
• MSI/1024 and MSI/4 can be selected as input capture 2 to LPTIM3 as described in Table 496: LPTIM3 input capture 2 connection.

Triggering signals
lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM CfGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode
This feature is available under Run and Sleep modes.

16.3.8 Triggers to low-power timers
From comparators (COMP1/COMP2), EXTI, TAMPP and RTC alarm to LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4)

Purpose
LPTIM1/LPTIM2/LPTIM3/LPTIM4 counters may be started either by software or after the detection of an active edge on one of the eight trigger inputs (see Section 50.4.7: Trigger multiplexer).

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CfGR2).
Triggering signals

This trigger feature is described in Section 50.4.7: Trigger multiplexer and the following sections. The input selection is described in Table 490: LPTIM1/2/3/4 external trigger connection.

Active power mode

This interconnection remains active down to Stop 2 mode.

16.3.9 Blanking sources to comparators

From timers (TIM1/TIM8/TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) to comparators (COMP1/COMP2)

Purpose

Advanced-control timers (TIM1/TIM8) and general-purpose timers (TIM2/TIM3/TIM4/TIM5/TIM15/TIM16/TIM17) can be used as blanking window input to COMP1/COMP2.

The blanking function is described in Section 33.3.6: Comparator output-blanking function. The blanking sources are given in:

- COMP1 control and status register (COMP1_CSR), BLANKSEL[4:0]
- COMP2 control and status register (COMP2_CSR), BLANKSEL[4:0]

Triggering signals

Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/COMP2.

Active power mode

This feature is available under Run and Sleep modes.

16.3.10 RTC wakeup as inputs to timers

From RTC to timers (TIM5/TIM16/TIM17)

Purpose

RTC wakeup interrupt can be used as input to general-purpose timers (TIM5/TIM16/TIM17) channel 1.

Triggering signals

RTC wakeup signal is connected to tim_ti1_in3 signal as described in Table 446: Interconnect to the tim_ti1 input multiplexer for TIM5.

RTC wakeup signal is connected to tim_ti1_in4 signal as described in Table 464: Interconnect to the tim_ti1 input multiplexer for TIM16/TIM17.

Active power mode

This interconnection is active down to Stop 3. Timers are not active but the count is performed at wakeup.
16.3.11 USB OTG SOF as trigger to timers
From USB OTG SOF to TIM2

Purpose
USB OTG SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2. The USB connection to TIM2 is described in Table 450: TIMx internal trigger connection.

Triggering signals
The tim_itr11 internal signal is generated by USB SOF.

Active power mode
This interconnection is active in Run and Sleep modes.

16.3.12 Comparators as inputs, trigger or break signals to timers
From comparators to timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17)

Purpose
The comparators (COMP1/COMP2) output values can be connected to timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) input captures, TIMx_ETR or timer break signals. The connection to ETR is described in Section 46.3.6: External trigger input.

Comparators (COMP1/COMP2) output values can also generate break input signals for timers (such as TIM1 or TIM8). The sources for break (tim_brk) channel are one of the following:

- external: connected to one of the TIMx_BKIN pin (as per selection done in the AFIO controller) with polarity selection and optional digital filtering
- internal: coming from comparators, tim_brk_cmpx input (refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation).

Triggering signals
The tim_etra and tim_brk signals connected TIM1 and TIM8 (coming from COMP1 and COMP2) are given in:

- tim_etra (Table 427: Interconnect to the tim_etra input multiplexer): external trigger internal input bus
  These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control.
- tim_brk (Table 428: Timer break interconnect and Table 429: Timer break2 interconnect)
  - Section 46.3.6: External trigger input
  - Section 46.3.18: Using the break function
For TIM2/TIM3/TIM4/TIM5, the sources connected to the tim_ti[1..4] input multiplexers coming from comparators and some other peripherals, are given in:
- Table 446: Interconnect to the tim_ti1 input multiplexer
- Table 447: Interconnect to the tim_ti2 input multiplexer
- Table 449: Interconnect to the tim_ti4 input multiplexer
- Table 427: Interconnect to the tim_etr input multiplexer
- Table 452: Interconnect to the tim_ocref_clr input multiplexer
- Section 47.4.22: Timers and external trigger synchronization
- TIMx timer input selection register (TIMx_TISEL)(x = 2 to 5)

For TIM15/TIM16/TIM17, the sources connected to timers coming from comparators and other peripherals are given in:
- Table 465: Interconnect to the tim_ti2 input multiplexer
- Table 467: Timer break interconnect
- Table 469: Interconnect to the ocref_clr input multiplexer
- Section 48.4.15: Using the break function
- Section 48.4.22: External trigger synchronization (TIM15 only)

Active power mode

Run, Sleep and wakeup capability in Stop 0, Stop 1 and Stop 2 modes for trigger sources. Input and break remain active in same low-power modes as timers activity, on Run and Sleep modes.

16.3.13 System errors as break signals to timers

From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17)

Purpose

CSS, CPU lockup, SRAM2/SRAM3 ECC double errors, SRAM1/SRAM4 parity errors, FLASH ECC double-error detection and PVD can generate system errors in the form of timer break toward timers (TIM1/TIM8/TIM15/TIM16/TIM17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

Triggering signals

The possible sources of break are described in:
- Section 46.3.18: Using the break function for TIM1/TIM8
- Section 48.4.15: Using the break function for TIM15/TIM16/TIM17
- Table 430: System break interconnect for TIM1/TIM8
- Table 468: System break interconnect for TIM15/TIM16/TIM17

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:
- Table 439: Effect of low-power modes on TIM1/TIM8
- Table 458: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5
Timers generating IRTIM signal

From timers (TIM16/TIM17) to IRTIM

The general-purpose timer (TIM16/TIM17) output channels TiMx_OC1, are used to generate the waveform of the infrared signal output. This functionality is described in Section 51: Infrared interface (IRTIM).

Triggers for communication peripherals

From LP timers (LPTIM1/LPTIM2/LPTIM3), comparators (COMP1/COMP2), GPDMA1 transfer complete, LPDMA1 transfer complete, EXTI, RTC alarm and RTC wakeup to USART1/USART2/USART3, UART4/UART5, LPUART1 I2C1/I2C2/I2C3/I2C4 and SPI1/SPI2/SPI3

Purpose

LP timer (LPTIM1/LPTIM2/LPTIM3) output channels (lptim1_ch1, lptim1_ch2 and lptim3_ch1), comparator (COMP1/COMP2) output channels (comp1_out and comp2_out), EXTI, RTC alarm and RTC wakeup, can be used as trigger to start a communication on the selected USART, UART, LPUART, I2C or SPI peripheral.

A GPDMA1 transfer complete can trigger both the GPDMA1 regular or linked-list new transfers and communication on selected communication peripheral.

A LPDMA1 transfer complete can trigger both the LPDMA1 new transfers and the communication on selected peripheral.

Triggering signals

The outputs from triggers are directly connected to peripheral trigger inputs.

The selection of input triggers is detailed in:

- Table 552: USART interconnection (USART1/2/3 and UART4/5)
- Table 564: LPUART interconnections (LPUART1)
- Table 532: I2C1, I2C2, I2C4 interconnection and Table 533: I2C3 interconnection

The outputs (from timer) are directly connected to SPI1/SPI2/SPI3 inputs on signals spi_itrx (x = 6, 7). The selection of input triggers on SPI is provided in:

- Table 575: SPI interconnection (SPI1 and SPI2)
- Table 576: SPI interconnection (SPI3)

Active power mode

These interconnections remain active in Run, Sleep and Stop modes if both source and communication line are autonomous under the mode. Refer to:

- Section 57.6: USART in low-power modes
- Section 56.5: I2C low-power modes
- Section 59.6: SPI low-power modes
16.3.16 Triggers to GPDMA/LPDMA

From EXTI, RTC (alarm/wakeup), TAMP (TAMP1/TAMP2/TAMP3), timers (TIM2/TIM15), LP timers (LPTIM1/LPTIM3/LPTIM4), comparators (COMP1/COMP2), LP/GPDMA1 transfer complete (gpdma1_chx_tcf/lpdma1_chx_tcf), ADC1/ADC4 analog watchdog to LPDMA1 and GPDMA1

Purpose

A LP/GPDMA trigger can be assigned to a LP/GPDMA channel x. A programmed LP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- Section 18.3.5: LPDMA triggers and Section 17.3.5: GPDMA triggers
- Section 18.4.12: LPDMA triggered transfer and Section 17.4.12: GPDMA triggered transfer
- LPDMA channel x transfer register 2 (LPDMA_CxTR2) and GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

LPDMA trigger mapping is specified in Table 136: Programmed LPDMA1 trigger, according to LPDMA_CxTR2.TRIGSEL[5:0].

GPDMA trigger mapping is specified in Table 126: Programmed GPDMA1 trigger, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop 0 and Stop 1 for GPDMA, and Stop 0, Stop 1 and Stop 2 for LPDMA.

Refer to:

- Section 18.6: LPDMA in low-power modes
- Section 17.6: GPDMA in low-power modes

16.3.17 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1/ADC4), comparators (COMP1/COMP2) and OPAMP (OPAMP1/OPAM2)

Purpose

The internal reference voltage (VREFINT), the internal temperature sensor (VTS) and VBAT monitoring channel are connected to ADC (ADC1/ADC4) input channels. In addition, the internal digital core voltage (VCORE) is connected to ADC1/ADC4 input channels.

DAC channels (DAC1_OUT/DAC2_OUT) and VREFINT are connected to comparators (COMP1/COMP2).
OPAMP1 and OPAMP2 outputs can be connected to ADC1 or ADC4 input channels through the GPIO. DAC1_OUT1 can be connected to OPAMP1_VINP. DAC1_OUT2 can be connected to OPAMP2_VINP.

Refer to Table 261: DAC internal input/output signals for:
- dac_out1 analog output DAC channel1, output, for on-chip peripherals
- dac_out2 analog output DAC channel2, output, for on-chip peripherals

This is according:
- Section 29.2 and Section 30.2: ADC main features
- Section 29.4.11: Channel selection (SQRx, JSQRx)
- Table 282: Operational amplifier possible connections
- Section 33.3.2: COMP pins and internal signals

Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to:
- Section 30.5: ADC low-power modes
- Section 33.4: COMP low-power modes
- Section 34.4: OPAMP low-power modes

16.3.18 ADC data filtering by the MDF1

From ADC1 to MDF1

Purpose

The MDF1 allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the MDF digital filter configuration register x (MDF_DFLTxCICR) is used to select either data from the ADCs in:
- Section 29.4.4: ADC connectivity
- Table 291: MDF ADC data connections
  - mdf_adcitf1_dat[15:0] to adc1_dat
- Table 230: Interconnection
  - adcx_dat[15:0] (x = 1) to mdf1_adcx_dat[15:0]
- Section 35.5: MDF low-power modes
  - Stop0 and Stop1 modes

Active power mode

This feature remains available down to Sleep mode.

16.3.19 Clock source for the DAC sample and hold mode

LSI/LSE to DAC1/DAC2

Purpose

DAC1/DAC2 can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.
Table 261: DAC internal input/output signals:

dac_hold_ck, Input, DAC low-power clock used in sample and hold mode

Active power mode
This feature remains available down to Stop 2 mode.

16.3.20 Internal tamper sources
From internal peripherals, clocks or monitoring to tamper.

Purpose
In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.

List of tamper sources can be found in Table 523: TAMP interconnection.

Active power mode
This interconnection is active in all power modes if the tamper source is activated.

16.3.21 Output from tamper to RTC

From TAMP to RTC

Purpose
The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to section Section 54.3.3: GPIOs controlled by the RTC and TAMP for more details.

Active power mode
This interconnection remain active on all power modes.

16.3.22 Encryption keys to AES/SAES

From TAMP backup registers, system Flash memory to and in between SAES and AES

Purpose
The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system Flash can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to Section 42.4.9: SAES operation with wrapped keys for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to Section 41.4.13: AES operation with shared keys for more details.
Active power mode

AES and SAES are operating under Run and Sleep modes.
17 General purpose direct memory access controller (GPDMA)

17.1 Introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

17.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during low-power modes (see Section 17.3.2)
  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see Section 17.3.1)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
- Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
- 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see Section 17.3.1))
- Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
- Programmable GPDMA request and trigger selection
- Programmable GPDMA half transfer and transfer complete events generation
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers

- **Debug:**
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- **TrustZone support:**
  - Support for secure and non-secure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sub-levels
  - Secure and non-secure interrupts reporting, resulting from any of the respectively secure and non-secure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a non-secure access

- **Privileged/unprivileged support:**
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

### 17.3 GPDMA implementation

#### 17.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.
17.3.2 GPDMA autonomous mode in low-power modes

The GPDMA autonomous mode and wakeup feature are implemented in the device low-power modes as per the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous mode and wakeup</td>
<td>GPDMA1 in Sleep, Stop 0 and Stop 1 modes</td>
</tr>
</tbody>
</table>

17.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via the REQSEL[6:0] field in the GPDMA channel x transfer register 2 (GPDMA_CxTR2), provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

<table>
<thead>
<tr>
<th>GPDMA_CxTR2.REQSEL[6:0]</th>
<th>Selected GPDMA request</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>adc1_dma</td>
</tr>
<tr>
<td>1</td>
<td>adc4_dma</td>
</tr>
<tr>
<td>2</td>
<td>dac1_ch1_dma</td>
</tr>
<tr>
<td>3</td>
<td>dac1_ch2_dma</td>
</tr>
<tr>
<td>4</td>
<td>tim6_upd_dma</td>
</tr>
<tr>
<td>5</td>
<td>tim7_upd_dma</td>
</tr>
<tr>
<td>6</td>
<td>spi1_rx_dma</td>
</tr>
<tr>
<td>7</td>
<td>spi1_tx_dma</td>
</tr>
<tr>
<td>8</td>
<td>spi2_rx_dma</td>
</tr>
</tbody>
</table>

Table 122. GPDMA1 channels implementation

<table>
<thead>
<tr>
<th>Channel x</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
</table>
| x = 0 to 11 | 2 | 0 | Channel x (x = 0 to 11) is implemented with: 
– a FIFO of 8 bytes, 2 words 
– fixed/contiguously incremented addressing |
| x = 12 to 15 | 4 | 1 | Channel x (x = 12 to 15) is implemented with: 
– a FIFO of 32 bytes, 8 words 
– 2D addressing |

These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM. These channels may also be used for GPDMA transfers, between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

17.3.4  GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then the BREQ bit in GPDMA channel x transfer register 2 (GPDMA_CxTR2) must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

<table>
<thead>

</tbody>
</table>

17.3.5  GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via the TRIGSEL[5:0] field in the GPDMA channel x transfer register 2 (GPDMA_CxTR2), provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

17.4 GPDMA functional description

17.4.1 GPDMA block diagram

*Figure 46. GPDMA block diagram*

17.4.2 GPDMA channel state and direct programming without any linked-list

After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 into the GPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 into the GPDMA_CxCR.EN bit, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then de-asserted by hardware) and that the channel is ready to be reconfigured then enabled again.
The figure below illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 47. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

17.4.3 GPDMA channel suspend and resume

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.
Note that an ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

**Figure 48. GPDMA channel suspend and resume sequence**

Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

### 17.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 to the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR. bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 49. GPDMA channel abort and restart sequence

---

17.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI\(_{n+1}\) of a channel \( x \) is the sum of the following:

- the link base address of the channel \( x \) (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLI\(_n\) of the channel \( x \).

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3 when present, in GPDMA_CxLLR.
In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2 when present) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

**Static linked-list data structure**

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3 when present) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x, x = 0 to 11, six contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see Figure 50) and including the first linked-list register file (LLI0) and the next LLIs (LLI1, LLI2,...) in the memory

- channel x, x = 12 to 15, eight contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see Figure 51) and including the first linked-list register file (LLI0) and the next LLIs (LLI1, LLI2,...) in the memory

**Figure 50. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x**
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see Figure 52).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in Figure 53.
The user must program GPDMA_CxLLR for each LLI_x to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

### 17.4.6 Linked-list item transfer execution

A LLI_x transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{x+1}, as defined by the GPDMA_CxLLR value of the LLI_x.

**Note:** The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI, in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.
17.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 when present
  - the last LLI\textsubscript{N}, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI\textsubscript{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, and GPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI\textsubscript{N-1} transfer

GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3 when present).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI\textsubscript{N} is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- if LLI\textsubscript{N} is pointing to a previous LLI

In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

The figure below depicts the GPDMA channel execution and its registers programming in run-to-completion mode.
Figure 54. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Channel state = Idle
- Initialize DMA channel
- Reconfigure DMA channel
- Enable DMA channel
- Setting TCF = 1
- Disabling DMA channel

Channel state = Active
- Valid user setting?
  - Y: Executing once the data transfer from the register file
  - N: BNDT≠ 0 ?
    - Y: Setting USEF = 1
      - Disabling DMA channel
    - N: Setting DTEF = 1
      - Disabling DMA channel

- No transfer error?
  - Y: LLR ≠ 0 ?
    - Y: Loading next LLI into the register file
      - No transfer error?
        - Y: Setting USEF = 1
          - Disabling DMA channel
        - N: Setting ULEF = 1
          - Disabling DMA channel
      - Valid user setting?
        - Y: Setting TCF = 1
          - Disabling DMA channel
        - N: Setting USEF = 1
          - Disabling DMA channel
  - N: Setting USEF = 1
    - Disabling DMA channel

End
Run-time inserting a LLIₙ via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLIₙ₋₁ (start of the LLIₙ loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLIₙ₋₁:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see Section 17.3.5 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLIₙ in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLIₙ₋₁ of the channel x, the software can pause the primary channel x after its LLIₙ₋₁ data transfer, until it is indeed written the LLIₙ.

The figure below depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

**Caution:** This use case is restricted to an application with a LLIₙ₋₁ data transfer that does not need a trigger. The triggering mode of this LLIₙ₋₁ is used to load the next LLIₙ.
17.4.8  **GPDMA channel state and linked-list programming in link step mode**

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI\_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x = 12 to 15, the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.
– GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
– GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
– GPDMA_CxTR3 for channel x = 12 to 15, defines the source/destination additional address offset between burst transfers.
– GPDMA_CxBR2 for channel x = 12 to 15, defines the source/destination additional address offset between blocks at a 2D/repeated block level.
– GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.

- The current LLI_{n} transfer is completed after the single execution of the current LLI_{n}:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and GPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_{n} (all update bits of GPDMA_CxLLR have a static value, LLI_{n}.LLR.LA = LLI_{n-1}.LLR.LA + constant).

The figure below depicts the GPDMA channel execution mode, and its programming in link step mode.
Figure 56. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Channel state = Idle

- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

Channel state = Active

      - Y: Setting USEF = 1, Disabling DMA channel
      - N: End
Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

**Figure 57. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode**

Run-time replacing a LLI_n with a new LLI_n' in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in the figure below.
Run-time replacing a LLI\textsubscript{n} with a new LLI\textsubscript{n'} in link step mode (in the memory)

The software can build and insert a new LLI\textsubscript{n'} and LLI\textsubscript{n'+1'} in the memory, after GPDMA executed the transfer from the LLI\textsubscript{n-1} and loaded a formerly elaborated LLI\textsubscript{n} from the memory, by overwriting partly the linked-list register file (GPDMA-CxBR1.BNDT[15:0] to be null and GPDMA-CxLLR to point to new LLI\textsubscript{n'}) as shown in the figure below.
Figure 59. Replace with a new \( LLI_n' \) and \( LLI_{n+1}' \) in memory in link step mode (option 1)

LSM = 1 with 1-stage linked-list programming:
- Overwriting the (pre)loaded \( LLI_n \) linked-list register file with a new \( LLI_n' \) and \( LLI_{n+1}' \) in memory and overwrite partly linked-list register file
  
  \( (DMA_{CxBR1.BNDT} = 0 \) and DMA_CxLLR to point to new \( LLI_n') \)

DMA executes \( LLI_{n-1} \) and load \( LLI_n \) then CPU builds \( (LLI_n' \) and \( LLI_{n+1}' \) and overwrite (BR1 and LLR)

- \( LLIn' \) transfer
  - Executing \( LLIn' \) data transfer
  - Loading \( LLIn' \)

- \( LLIn \) transfer
  - Loading \( LLIn \)

- \( LLIn+1' \) transfer
  - Executing \( LLIn+1' \) data transfer
  - Loading \( LLIn+1' \)

Transfer complete interrupt

Build \( LLI_n' \) and \( LLI_{n+1}' \) in memory

Write \( DMA_{CxBR1.BNDT} = 0 \) and DMA_CxLLR to point to new \( LLI_n' \)

Enable DMA channel
Run-time replacing a LLI<sub>n</sub> with a new LLI<sub>n'</sub> in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI<sub>n-1</sub> and loads a formerly elaborated LLI<sub>n</sub> from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new LLI<sub>n'</sub> and a new LLI<sub>n+1'</sub>.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI<sub>n-1</sub> is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new LLI<sub>n'</sub>, as shown in the figure below.

Figure 60. Replace with a new LLI<sub>n'</sub> and LLI<sub>n+1'</sub> in memory in link step mode (option 2)

| LSM = 1 with 1-stage linked-list programming: | Overwriting the (pre)loaded LLI<sub>n</sub> linked-list register file by building new LLI<sub>n'</sub> and LLI<sub>n+1'</sub> in memory while disabling (temporary) channel interrupt at NVIC level, and overwriting DMA_CxBR1.BNDT = 0 and DMA_CxLLR to point to new LLI<sub>n'</sub>,

DMA executes LLI<sub>n-1</sub> and loading LLI<sub>n</sub> while CPU builds (LLI<sub>n'</sub> and LLI<sub>n+1'</sub>), then CPU overwrites (BR1 and LLR)
17.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel

- abort and reconfigure the channel with a LSM update (c.f. Section 17.4.4.)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

The figure below shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.
Figure 61. GPDMA channel execution and linked-list programming

Channel state = Idle
- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

    - Y: Setting USEF = 1
    - N: Disabling DMA channel
  - N: Setting TCF = 1
- End
17.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see Section 17.3.1 for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPHPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a GPDMA burst.

### Table 127. Programmed GPDMA source/destination burst

</tbody>
</table>

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPHPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.
GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by the figure below with a 2D destination buffer.
Programmable address jumps 1) after burst and 2) after block.
Example:
burst: I * words (DBL_1=I-1; DDW_LOG2='b10)
block: J * bursts (BNDT=J*I*4)
LLI: K * blocks (BRC=K-1)
GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:
- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

\[
\text{when } \text{FIFO level} \leq 2^{\text{dma_fifo_size}[x]} - (SBL_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}
\]

where:
- FIFO level is the current filling level of the FIFO, in bytes.
- \(2^{\text{dma_fifo_size}[x]}\) is the half of the FIFO size of the channel \(x\), in bytes (see Section 17.3.1 for the implementation details and dma_fifo_size[x] value).
- \((SBL_1[5:0]+1) \times 2^{\text{SDW_LOG2}[1:0]}\) is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIOR[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

\[
\text{when } \text{FIFO level} \geq (DBL_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}
\]

where:
- FIFO level is the current filling level of the FIFO, in bytes.
- \((DBL_1[5:0]+1) \times 2^{\text{DDW_LOG2}[1:0]}\) is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:
- When half of the FIFO size of the channel \(x\) is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.
• if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

• If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

**Note:** In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[21:0] and DDW_LOG2[1:0] fields (see Table 128).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. **Byte-based source reordering**
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.

2. **Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width**, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. **Byte-based destination re-ordering**:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

**Note:** Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.
The table below lists the possible data handling from the source to the destination.

17.4.11 GPDMA transfer request and arbitration

**GPDMA transfer request**

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see Section 17.3.3). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

1. Data stream is timely ordered starting from the byte with the lowest index (B0).
2. RA = right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3, GPDMA_CxBCR2 or GPDMA_CxLLR). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to-memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in Figure 63, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2
  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
- Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
- Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
- Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

**Figure 63. GPDMA arbitration policy**

---

**GPDMA arbitration and bandwidth**

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as BQ3) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B\text{req0}) is **equal** to the allocated bandwidth to req1 (B\text{req1}).
    \[ B\text{req0} = B\text{req1} = 1/2 \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B\text{P0}) is **3 times less** than the allocated bandwidth to req1 (B\text{P1}).
    \[ B\text{req0} = B\text{P0} = 1/2 \times 1/2 \times (1 - B_{Q3}) = 1/4 \times (1 - B_{Q3}) \]
    \[ B\text{req1} = B\text{P1} = (1/2 + 1) \times 1/3 \times (1 - B_{Q3}) = 3/4 \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B\text{P0}) is **5 times less** than the allocated bandwidth to req1 (B\text{P2}).
    \[ B\text{req0} = B\text{P0} = 1/2 \times 1/3 \times (1 - B_{Q3}) = 1/6 \times (1 - B_{Q3}) \]
    \[ B\text{req1} = B\text{P2} = (1/2 + 1 +1) \times 1/3 \times (1 - B_{Q3}) = 5/6 \times (1 - B_{Q3}) \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
Example 2: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:

- The allocated bandwidth to the set of requests of priority 0 \((B_{P0})\) is
  \[
  B_{P0} = \frac{1}{3} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{9} \times (1 - B_{Q3})
  \]

- The allocated bandwidth to the set of requests of priority 1 \((B_{P1})\) is
  \[
  B_{P1} = \left(\frac{1}{3} + \frac{1}{2}\right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{18} \times (1 - B_{Q3})
  \]

- The allocated bandwidth to the set of requests of priority 2 \((B_{P2})\) is
  \[
  B_{P2} = \left(\frac{1}{3} + \frac{1}{2} + 1\right) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{11}{18} \times (1 - B_{Q3})
  \]

- The allocated bandwidth to any request \(n\) \((B_{n})\) among the N requests of that priority \(P_i\) \((i = 0\) to \(2\)) is
  \[
  B_n = \frac{1}{N} \times B_{Pi}
  \]

- The allocated bandwidth to any request \(n\) of priority \(0i\) \((B_{n, P0})\) is
  \[
  B_{n, P0} = \frac{1}{N} \times \frac{1}{9} \times (1 - B_{Q3})
  \]

- The allocated bandwidth to any request \(n\) of priority \(1i\) \((B_{n, P1})\) is
  \[
  B_{n, P1} = \frac{1}{N} \times \frac{5}{18} \times (1 - B_{Q3})
  \]

- The allocated bandwidth to any request \(n\) of priority \(2i\) \((B_{n, P2})\) is
  \[
  B_{n, P2} = \frac{1}{N} \times \frac{11}{18} \times (1 - B_{Q3})
  \]

In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- \(I\) requests \((I \geq 0)\) assigned to priority 0
  If \(I > 0\), these requests are noted from \(i = 0\) to \(I-1\).
- \(J\) requests \((J \geq 0)\) assigned to priority 1
  If \(J > 0\), these requests are noted from \(j = 0\) to \(J-1\).
- \(K\) requests \((K > 0)\) assigned to priority 2
  These requests are noted from \(k = 0\) to \(K-1\)
- \(L\) requests \((L \geq 0)\) assigned to priority 3
  If \(L > 0\), these requests are noted from \(l = 0\) to \(L-1\).

As \(B_{Q3}\) is the reserved bandwidth to time-sensitive requests, the bandwidth for each request \(L\) with priority 3 is:

- \(B_l = B_{Q3} / L\) for \(L > 0\) (else: \(B_l = 0\))

The bandwidth for each non-time sensitive queue is:

- \(B_{Q0} = \frac{1}{3} \times (1 - B_{Q3})\)
- \(B_{Q1} = \frac{1}{3} \times (1 - B_{Q3})\)
- \(B_{Q2} = \frac{1}{3} \times (1 - B_{Q3})\)

The bandwidth for the set of requests with priority 0 is:

- \(B_{P0} = I / (I + J + K) \times B_{Q0}\)

The bandwidth for each request \(i\) with priority 0 is:

- \(B_i = B_{P0} / I\) for \(L > 0\) (else \(B_{P0} = 0\))

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- \(B_{P1,Q0} = J / (I + J + K) \times B_{Q0}\)
The bandwidth for the set of requests with priority 1 and routed to queue 1 is:
- \( B_{P1,Q1} = \frac{J}{J + K} \cdot B_{Q1} \)

The total bandwidth for the set of requests with priority 1 is:
- \( B_{P1} = B_{P1,Q0} + B_{P1,Q1} \)

The bandwidth for each request \( j \) with priority 1 is:
- \( B_j = \frac{B_{P1}}{J} \) for \( J > 0 \) (else \( B_j = 0 \))

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:
- \( B_{P2,Q0} = \frac{K}{I + J + K} \cdot B_{Q0} \)

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:
- \( B_{P2,Q1} = \frac{K}{J + K} \cdot B_{Q1} \)

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:
- \( B_{P2,Q2} = B_{Q2} \)

The total bandwidth for the set of requests with priority 2 is:
- \( B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2} \)

The bandwidth for each request \( k \) with priority 2 is:
- \( B_k = \frac{B_{P2}}{K} \) (\( K > 0 \) in the general case)

Thus finally the maximum allocated residual bandwidths for any \( i, j, k \) non-time sensitive request are:
- in the general case (when there is at least one request \( k \) with a priority 2 (\( K > 0 \))):
  - \( B_i = \frac{1}{I} * \frac{1}{3} * \frac{I}{(I + J + K)} \cdot (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{I} * \frac{1}{3} * \frac{J}{(I + J + K)} \cdot (1 - B_{Q3}) \)
  - \( B_k = \frac{1}{K} * \frac{1}{3} * \frac{K}{(I + J + K) + K(J + K) + 1} \cdot (1 - B_{Q3}) \)
- in the specific case (when there is no request \( k \) with a priority 2 (\( K = 0 \))):
  - \( B_i = \frac{1}{I} * \frac{1}{2} * \frac{I}{(I + J)} \cdot (1 - B_{Q3}) \)
  - \( B_j = \frac{1}{I} * \frac{1}{2} * \frac{J}{(I + J) + 1} \cdot (1 - B_{Q3}) \)

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

### 17.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see Section 17.3.5 for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel \( x = 12 \) to 15, or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details).
Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next LLIn+1, that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLIn trigger.

Caution: After a first new trigger hitn+1 is memorized, if another trigger hitn+2 is detected and if the hitn triggered transfer is still not completed, hitn+2 is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

17.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer
events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

**Figure 65. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel**

**Note:** With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_N-1 in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).
The figure below illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

**Figure 66. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel**

---

### 17.4.14 GPDMA secure/non-secure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and non-secure worlds at any given time.

Any channel \( x \) is a secure or a non-secure hardware resource, as securely configured by GPDMA_SECCFGR.SEC\( x \).

When a channel \( x \) is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A non-secure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by a non-secure agent.
- A non-secure write access to a register field of this channel has no impact.

When a channel \( x \) is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/non-secure state of each GPDMA channel \( x \).
The GPDMA also generates a security illegal access pulse signal on an illegal non-secure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a non-secure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next non-secure transfer as a non-secure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the non-secure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

### 17.4.15 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

### 17.4.16 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

**Data transfer error**

on a bus access (as a AHB single or a burst) to the source or the destination

- The source or destination target reports an AHB error.
The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).

After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.

After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

**Link transfer error**

on a tentative update of a GPDMA channel register from the programmed LLI in the memory

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxCxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 when present), before the user enables again the same channel for a next transfer.

**User setting error**

on a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1]=1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
– for channel x = 12 to 15: a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
– for channel x = 12 to 15: a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
– a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x = 12 to 15: a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– for channel x = 12 to 15: a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
– a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
– a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
– a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1.BNDT = 0)

17.4.17 GPDMA autonomous mode

To save dynamic power consumption while the GPDMA executes the programmed linked-list transfers, the GPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run or low-power modes, provided that the RCC is programmed with the corresponding GPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the GPDMA autonomous feature vs the device low-power modes, refer to Section 17.3.2.

The user can program and schedule the execution of a given GPDMA transfer at a LLI_{n} level of a GPDMA channel x, with GPDMA_CxTR2 as follows:

- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[5:0], SWREQ and REQSEL[6:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See GPDMA channel x transfer register 2 (GPDMA_CxTR2) for more details.

When used in low-power modes, this functionality enables a CPU wakeup on a specific transfer completion by the enabled the GPDMA transfer complete interrupt (GPDMA_CxCR.TCIE = 1) or/and enables to continue with the autonomous GPDMA for operating another LLI_{n+1} transfer over the same channel.
The output channel \( x \) transfer complete event, \( \text{gpdma}_\text{ch}_x \text{tc} \), can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the GPDMA level (see Section 17.3.5), allowing autonomous and fine GPDMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given GPDMA channel \( x \) asserts its clock request in one of the following conditions:

- if the next transfer to be executed is programmed as conditioned by a trigger (\( \text{GPDMAC}_x\text{TR2.TRIGPOL[1:0]} \) and \( \text{GPDMAC}_x\text{TR2.TRIGM[1:0]} \)), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if \( \text{GPDMAC}_x\text{TR2.SWREQ} = 0 \), only when the hardware request is asserted by the selected peripheral
  - if \( \text{GPDMAC}_x\text{TR2.SWREQ} = 1 \) (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled

The GPDMA channel \( x \) releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The GPDMA channel \( x \) is not immediately ready and requested to execute the next transfer.
- If a channel \( x \) interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the GPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the GPDMA releases its clock request to the RCC.

### 17.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel \( x \) can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

*Note:* In debug mode, \( \text{GPDMAC}_x\text{SR.SUSPF} \) is not altered by a suspension from \( \text{DBG.CH}_x\text{STOP} = 1 \). In this case, \( \text{GPDMAC}_x\text{SR.IDLEF} \) can be checked to know the completion status of the channel suspension.

### 17.6 GPDMA in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. GPDMA interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The content of the GPDMA registers is kept when entering Stop mode. The content of the GPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. GPDMA interrupts can cause the device to exit Stop mode(^{(1)}).</td>
</tr>
<tr>
<td>Standby</td>
<td>The GPDMA is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 17.3.2 to know if any Stop mode is supported.
17.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

<table>

<td>GPDMA_CxSR.TOF</td>
<td>Write 1 to GPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

A GPDMA channel x event may be:
- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xx = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xx).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCE[1:0] as follows:
- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCE[1:0].
- A half transfer event is an half block transfer, or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCE[1:0].
A half-block transfer occurs when half of the source block size bytes (rounded-up integer of \( \text{GPDMACxBR1.BNDT}[15:0] / 2 \)) is transferred to the destination.

A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of \( \text{GPDMACxBR1.BRC}[10:0] + 1 \) / 2) is transferred to the destination.

See **GPDMA channel x transfer register 2 (GPDMA_CxTR2)** for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see **Section 17.4.16**).

A trigger overrun is described in **Trigger hit memorization and trigger overrun flag generation**.

### 17.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

### 17.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

**Address offset:** 0x00

**Reset value:** 0x0000 0000

A write access to this register must be secure. A read access is secure or non-secure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix privileged and unprivileged information. If a channel x is configured as privileged (GPDMA_PRIVCFGR.PRIVx = 1), the SECx bit can be written only by a privileged (and secure) agent.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or non-secure world.
17.8.2 **GPDMA privileged configuration register (GPDMA_PRIVCFGR)**

Address offset: 0x04
Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or non-secure.

This register can mix secure and non-secure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

1: secure
17.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08
Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock at boot time the secure privileged attributes of any GPDMA channel/resource (to lock the setting of GPDMA_CxSECCFGR and GPDMA_CxPRIVCFG for any channel x at boot time).

A read access may be privileged or unprivileged, secure or non-secure.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LOCKx: lock the configuration of GPDMA_SECCFGR.SECx and GPDMA_PRIVCFGPR.PRIx, until a global GPDMA reset (x = 15 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.
0: secure privilege configuration of the channel x is writable.
1: secure privilege configuration of the channel x is not writable.

17.8.4 GPDMA non-secure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C
Reset value: 0x0000 0000

This register is a read register.

This is a non-secure register, containing the masked interrupt status bit MISx for each non-secure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is de-asserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGPR.PRIx. A privileged software can read the full non-secure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and non-secure) channels, other privileged bit fields returning zero.
17.8.5 **GPDMA secure masked interrupt status register (GPDMA_SMISR)**

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is de-asserted by hardware when securely writing 1 to the corresponding GPDMA_CxCFR flag clear bit.

This register does not contain any information about a non-secure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Bits 15:0 MISx: masked interrupt status of the secure channel x (x = 15 to 0)

- 0: no interrupt occurred on the secure channel x
- 1: an interrupt occurred on the secure channel x

Bits 31:16 Reserved, must be kept at reset value.
### 17.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)  
Reset value: 0x0000 0000  
This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVR.PRIVx.  
This register is either secure or non-secure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).  
This register must be written when GPDMA_CxCR.EN = 0.  
This register is read-only when GPDMA_CxCR.EN = 1.  
This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.  
This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

| Bits 31:16 | LBA[31:16] | linked-list base address of GPDMA channel x |
| Bits 15:0  | Reserved   | must be kept at reset value. |

### 17.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C + 0x80 * x (x = 0 to 15)  
Reset value: 0x0000 0000  
This is a write register, secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVR.PRIVx).
17.8.8 **GPDMA channel x status register (GPDMA_CxSR)**

Address offset: 0x60 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or non-secure, depending on the secure state of channel x (GPDMA_SECCFRG.SECx), and privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **FIFOL[7:0]**: monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

*Note:* After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxCB1.BDNT[15:0] and GPDMA_CxCB1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TOF**: trigger overrun flag

0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13  **SUSPF**: completed suspension flag

0: no completed suspension event
1: a completed suspension event occurred

Bit 12  **USEF**: user setting error flag

0: no user setting error event
1: a user setting error event occurred

Bit 11  **ULEF**: update link transfer error flag

0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10  **DETF**: data transfer error flag

0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9  **HTF**: half transfer flag

0: no half transfer event
1: a half transfer event occurred

A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxCB1.BNDT[15:0]/2) has been transferred to the destination.

A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxCB1.BRC[10:0]+1)/2)) has been transferred to the destination.

Bit 8  **TCF**: transfer complete flag

0: no transfer complete event
1: a transfer complete event occurred

A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
### GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGGr.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

Bits 31:24: Reserved, must be kept at reset value.

Bits 23:22: **PRIO[1:0]**: priority level of the channel x GPDMA transfer versus others

- 00: low priority, low weight
- 01: low priority, mid weight
- 10: low priority, high weight
- 11: high priority

*Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.*

Bits 21:18: Reserved, must be kept at reset value.

Bit 17: **LAP**: linked-list allocated port

This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.

- 0: port 0 (AHB) allocated
- 1: port 1 (AHB) allocated

*Note: This bit must be written when EN=0. This bit is read-only when EN=1.*
Bit 16  **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0 if present). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 if present.
1: channel executed once for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 if present. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.

*Note: This bit must be written when EN=0. This bit is read-only when EN=1.*

Bit 15  Reserved, must be kept at reset value.

Bit 14  **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13  **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12  **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11  **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10  **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9   **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8   **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2   **SUSP**: suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel i.e. a channel with an ongoing GPDMA transfer over its master ports.
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 48.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.
17.8.10  **GPDMA channel x transfer register 1 (GPDMA_CxTR1)**

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

**Reset value:** 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.
Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination
   If GPDMA_SECCFGR.SECx = 1 and the access is secure:
   0: GPDMA transfer non-secure
   1: GPDMA transfer secure
   This is a secure register bit. This bit can only be read by a secure software. This bit must be
   written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored
   when GPDMA_SECCFGR.SECx = 0.
   When GPDMA_SECCFGR.SECx is de-asserted, this DSEC bit is also de-asserted by
   hardware (on a secure reconfiguration of the channel as non-secure), and the GPDMA
   transfer to the destination is non-secure.

Bit 30 **DAP**: destination allocated port
   This bit is used to allocate the master port for the destination transfer
   0: port 0 (AHB) allocated
   1: port 1 (AHB) allocated
   *Note:* This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange
   If the destination data size is shorter than a word, this bit is ignored.
   If the destination data size is a word:
   0: no halfword-based exchanged within word
   1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange
   If the destination data size is a byte, this bit is ignored.
   If the destination data size is not a byte:
   0: no byte-based exchange within half-word
   1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63
   The burst length unit is one data named beat within a burst. If DBL_1[5:0] =0 , the burst can
   be named as single. Each data/beat has a width defined by the destination data width
   \( DDW_{\log2}[1:0] \).
   *Note:* If a burst transfer crossed a 1-Byte address boundary on a AHB transfer, the GPDMA
   modifies and shortens the programmed burst into singles or bursts of lower length, to be
   compliant with the AHB protocol.
   If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA
   modifies and shortens the programmed burst into singles or bursts of lower length, to be
   compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration
   between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst
   0: fixed burst
   1: contiguously incremented burst
   The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst
   beat/single transfer, or is incremented by the offset value corresponding to a contiguous data
   after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.
Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes
- 00: byte
- 01: half-word (2 bytes)
- 10: word (4 bytes)
- 11: user setting error reported and no transfer issued

*Note:* Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A destination burst transfer must have an aligned address with its data width (start address `GPDMA_CxDar[2:0]` and address offset `GPDMA_CxTR3.DAO[2:0]`, versus `DDW_LOG2[1:0]`). Otherwise a user setting error is reported and no transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source
- If `GPDMA_SECCFGR.SECx = 1` and the access is secure:
  - 0: GPDMA transfer non-secure
  - 1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when `GPDMA_SECCFGR.SECx = 1`. A secure write is ignored when `GPDMA_SECCFGR.SECx = 0`.

When `GPDMA_SECCFGR.SECx` is de-asserted, this SSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as non-secure), and the GPDMA transfer from the source is non-secure.

Bit 14 **SAP**: source allocated port
- This bit is used to allocate the master port for the source transfer
- If `EN = 0`:
  - 0: port 0 (AHB) allocated
  - 1: port 1 (AHB) allocated

*Note:* This bit must be written when `EN = 0`. This bit is read-only when `EN = 1`.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word
- If the source data width is shorter than a word, this bit is ignored.
- If the source data width is a word:
  - 0: no byte-based exchange within the unaligned half-word of each source word
  - 1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode
- If `DDW_LOG2[1:0] = SDW_LOG2[1:0]`: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.
- Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher that source data width, and the condition PAM_2 is when destination data width is higher than source data width.

**Condition: PAM_1**
- 00: source data is transferred as right aligned, padded with 0s up to the destination data width
- 01: source data is transferred as right aligned, sign extended up to the destination data width
- 1x: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

**Condition: PAM_2**
- 00: source data is transferred as right aligned, left-truncated down to the destination data width
- 01: source data is transferred as left-aligned, right-truncated down to the destination data width

*Note:* 1x: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination
Bit 10  Reserved, must be kept at reset value.

Bits 9:4  **SBL \_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL \_1[5:0] = 0 , the burst can be named as single. Each data/beat has a width defined by the destination data width SDW \_LOG2[1:0].

**Note:** If a burst transfer crossed a 1-Kbyte address boundary on an AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3  **SINC**: source incrementing burst

0: fixed burst
1: contiguously incremented burst

The source address, pointed by GPDMA \_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **SDW \_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

**Note:** Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

A source block size must be a multiple of the source data width (GPDMA \_CxBR1.BNDT[2:0] versus SDW \_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA \_CxSAR[2:0] versus SDW \_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.
### 17.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGx.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVx.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LGPDMA_CxE.EN = 0.

This register is read-only when GPDMA_CxE.EN = 1.

This register must be written when the channel is completed (the hardware de-asserted GPDMA_CxE.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxE.LLR.U2 = 1.

</table>
Bits 31:30 **TCEM[1:0]:** transfer complete event mode  
These bits define the transfer granularity for the transfer complete and half transfer complete events generation.  
00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.  
**Note:** If the initial LLI data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.  
01: channel x = 0 to 11, same as 00; channel x=12 to 15, at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0), the complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.  
**Note:** If the initial LLI data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.  
10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer or a 2D/repeated block transfer for channel x = 12 to 15), if any data transfer.  
**Note:** If the initial LLI data transfer is null/void (i.e. directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI.  
11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2 if present). If the channel transfer is continuous/infinite, no event is generated.  
Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]:** trigger event polarity  
These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].  
00: no trigger (masked trigger event)  
01: trigger on the rising edge  
10: trigger on the falling edge  
11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]:** trigger event input selection  
These bits select the trigger event input of the GPDMA transfer (as per Section 17.3.5), with an active trigger event if TRIGPOL[1:0] ≠ 00.
Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x = 0 to 11, same as 00; channel x=12 to 15, at 2D/repeated block level, the first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_n+1 that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_n+1 is memorized, if another second trigger hit_n+2 is detected and if the hit_n triggered transfer is still not completed, hit_n+2 is lost and not memorized.

A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

**Note:** When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ =0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bits 13:12  Reserved, must be kept at reset value.
Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.
1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 17.3.3).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)
1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

**Note:**

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.
1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per Section 17.3.3.

**Caution:** The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.
17.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFG.SCEx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.
This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:
- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **BNDT[15:0]:** block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):
- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR_Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

*Note:* A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

### 17.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:
- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- if all the update bits GPDMA_CxLLR_Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI.
- if GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

</tbody>
</table>
Bit 27  Reserved, must be kept at reset value.

Bits 26:16  **BRC[10:0]:** Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).
When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):
- If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- If all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- If GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0  **BNDT[15:0]:** block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):
- If GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- If all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- If GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

*Note:* A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

*When configured in packing mode (GPDMA_CxTR1.PAM[1]=1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.*
17.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
Bits 31:0  \textbf{SA}[31:0]: source address

This field is the pointer to the address from which the next data is read. During the channel activity, depending on the source addressing mode (GPDMA\_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA\_CxTR1.SDW\_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

- the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA\_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA\_CxTR1.SBL[5:0] and GPDMA\_CxTR1.SDW\_LOG2[21:0]

- the additional source incremented/decremented offset value as programmed by GPDMA\_CxBR1.SDEC and GPDMA\_CxTR3.SAO[12:0]

- once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15), additional block repeat source incremented/decremented offset value as programmed by GPDMA\_CxBR1.BRSDEC and GPDMA\_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA\_CxLLR.USA = 1.

\textbf{Note:}  A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA\_CxTR1.SDW\_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA\_CxTR3.SAO[12:0] is not applied.
17.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

Bits 31:0 DA[31:0]: destination address

This field is the pointer to the address from which the next data is written. During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[21:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:
- the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]
- the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0]
- once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.
17.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

</tbody>
</table>

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]:** destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

**Note:** A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]:** source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

**Note:** A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.
17.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.
This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

BRDAO[15:0]

Bits 31:16  **BRDAO[15:0]:** Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

*Note:* A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

BRSAO[15:0]

Bits 15:0  **BRSAO[15:0]:** Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

*Note:* A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
**17.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)**

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 27  **UDA:** Update GPDMA_CxDAR register from memory  
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.  
0: no GPDMA_CxDAR update  
1: GPDMA_CxDAR update  

Bits 26:17  Reserved, must be kept at reset value.  

Bit 16  **ULL:** Update GPDMA_CxLLR register from memory  
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.  
0: no GPDMA_CxLLR update  
1: GPDMA_CxLLR update  

Bits 15:2  **LA[15:2]:** pointer (16-bit low-significant address) to the next linked-list data structure  
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file. Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxCTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR).  

*Note:* The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.  

Bits 1:0  Reserved, must be kept at reset value.
17.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory
This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory
This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory
This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer. If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed. GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDM CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory
This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update
Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxCTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR).

*Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.*

Bits 1:0 Reserved, must be kept at reset value.

Refer to Section 2.3 for the register boundary addresses.
18  Low-power direct memory access controller (LPDMA)

18.1  Introduction

The low-power direct memory access (LPDMA) controller is a bus master and system peripheral.

The LPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

18.2  LPDMA main features

- Single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral
- Autonomous data transfers during Sleep and Stop modes
- Transfers arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non-time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 4 concurrent LPDMA channels:
  - Intra-channel LPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel LPDMA transfers chaining via programmable LPDMA input triggers connection to LPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive single transfers
  - Programmable LPDMA request and trigger selection
  - Programmable LPDMA half-transfer and transfer-complete events generation
- Pointer to the next linked-list item and its data structure in memory, with automatic update of the LPDMA linked-list control registers

- Debug:
  - Channel suspend and resume support
  - Channel status reporting and event flags

- TrustZone support
  - Support for secure and non-secure LPDMA transfers, independently at a first channel level, and independently at a source/destination and link sub-levels
  - Secure and non-secure interrupts reporting, resulting from any of the respectively secure and non-secure channels
  - TrustZone-aware AHB slave port, protecting any LPDMA secure resource (register, register field) from a non-secure access

- Privileged/unprivileged support:
  - Support for privileged and unprivileged LPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

### 18.3 LPDMA implementation

#### 18.3.1 LPDMA channels

A given LPDMA channel \( x \) is implemented with the hardware parameters as per the table below.

<table>
<thead>
<tr>
<th>Channel ( x )</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
</table>
| \( x = 0 \) to \( 3 \) | \( \text{dma fifo size}[x] \) \( = 0 \) | Channel \( x \) (\( x = 0 \) to \( 3 \)) is implemented with:
  - no FIFO. Only a single source transfer cell is internally registered.
  - fixed/contiguously incremented addressing |

<table>
<thead>
<tr>
<th>Channel</th>
<th>Hardware parameters</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x = 0 ) to ( 3 )</td>
<td>( \text{dma addressing}[x] ) ( = 0 )</td>
<td></td>
</tr>
</tbody>
</table>

#### 18.3.2 LPDMA autonomous mode in low-power modes

The LPDMA autonomous mode and wakeup feature is implemented in the device low-power modes as per the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Low-power modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomous mode and wakeup</td>
<td>LPDMA1 in Sleep, Stop 0, Stop 1 and Stop 2 modes</td>
</tr>
</tbody>
</table>
18.3.3 LPDMA requests

A LPDMA request from a peripheral can be assigned to a LPDMA channel x, via the REQSEL[4:0] field in the LPDMA channel x transfer register 2 (LPDMA_CxTR2), provided that SWREQ = 0.

The LPDMA requests mapping is specified in the table below.

<table>
<thead>
<tr>
<th>LPDMA_CxTR2.REQSEL[4:0]</th>
<th>Selected LPDMA request</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>lpuart1_rx_dma</td>
</tr>
<tr>
<td>1</td>
<td>lpuart1_tx_dma</td>
</tr>
<tr>
<td>2</td>
<td>spi3_rx_dma</td>
</tr>
<tr>
<td>3</td>
<td>spi3_tx_dma</td>
</tr>
<tr>
<td>4</td>
<td>i2c3_rx_dma</td>

</tr>
<tr>
<td>15</td>
<td>lptim3_ic2_dma</td>
</tr>
<tr>
<td>16</td>
<td>lptim3_ue_dma</td>
</tr>
</tbody>
</table>

18.3.4 LPDMA block requests

Some LPDMA requests must be programmed as a block request, and not as a single request. Then the BREQ bit in LPDMA channel x transfer register 2 (LPDMA_CxTR2) must be set for a correct LPDMA execution of the requested peripheral transfer at the hardware level.

The LPDMA block requests are listed in the table below.

<table>
<thead>
<tr>
<th>LPDMA block requests</th>
</tr>
</thead>
<tbody>
<tr>
<td>lptim1_ue_dma</td>
</tr>
<tr>
<td>lptim3_ue_dma</td>
</tr>
</tbody>
</table>
18.3.5 LPDMA triggers

A LPDMA trigger can be assigned to a LPDMA channel x, via the TRIGSEL[4:0] field in the LPDMA channel x transfer register 2 (LPDMA_CxTR2), provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The LPDMA triggers mapping is specified in the table below.

<table>
<thead>
<tr>
<th>LPDMA_CxTR2.TRIGSEL[4:0]</th>
<th>Selected LPDMA trigger</th>
</tr>
</thead>
<tbody>
<tr>

18.4.2 LPDMA channel state and direct programming without any linked-list

After a LPDMA reset, a LPDMA channel x is in idle state. When the software writes 1 into the LPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (LPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.
After enabling/starting a LPDMA channel transfer by writing 1 into the LPDMA_CxCR.EN bit, a LPDMA channel interrupt on a complete transfer notifies the software that the LPDMA channel is back in idle state (EN is then de-asserted by hardware) and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this LPDMA direct programming without any linked-list (LPDMA_CxLLR = 0).

Figure 68. LPDMA channel direct programming without linked-list (LPDMA_CxLLR = 0)
18.4.3 **LPDMA channel suspend and resume**

The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

   Note that an ongoing LPDMA transfer can be a data transfer (a read-followed-by-write single transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to LPDMA_CxCR.SUSP.

The suspend and resume sequence is illustrated in the figure below.

**Figure 69. LPDMA channel suspend and resume sequence**

**Note:** A suspend and resume sequence does not impact the LPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.
18.4.4 LPDMA channel abort and restart

Alternatively, like for aborting a continuous LPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the LPDMA_CxCR.SUSP bit.
2. The software polls suspended flag LPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to LPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing LPDMA transfer over its master port.
3. The software resets the channel by writing 1 to LPDMA_CxCR.RESET. This causes the reset of the channel internal state, the reset of the LPDMA_CxCR. bit, and the reset of the LPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified LPDMA_CxBR1, LPDMA_CxSAR, and LPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the LPDMA_CxCR.EN bit.

The abort and restart sequence is illustrated in the figure below.

**Figure 70. LPDMA channel abort and restart sequence**
18.4.5 LPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI\(_n+1\) of a channel \(x\) is the sum of the following:
- the link base address of the channel \(x\) (in LPDMA\_CxLBAR)
- the link address offset \((LA[15:2] \text{ field in LPDMA\_CxLLR})\)

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits of the LPDMA\_CxLLR register.

In linked-list mode, each LPDMA linked-list register (LPDMA\_CxTR1, LPDMA\_CxTR2, LPDMA\_CxBR1, LPDMA\_CxSAR, LPDMA\_CxDAR or LPDMA\_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the LPDMA\_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

### Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL) of the LPDMA\_CxLLR register are all asserted, the linked-list data structure in memory is maximal with six contiguous 32-bit locations, including LPDMA\_CxTR1, LPDMA\_CxTR2, LPDMA\_CxBR1, LPDMA\_CxSAR, LPDMA\_CxDAR and LPDMA\_CxLLR (see the figure below) and including the first linked-list register file (LLI\(_0\)) and the next LLIs (LLI\(_1\), LLI\(_2\),...) in the memory.

![Figure 71. Static linked-list data structure (all Uxx = 1) of channel x](image-url)
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register LPDMA_CxLLR is pointing to the updated value of the LPDMA_CxTR2 instead of the LPDMA_CxTR1 which is not to be modified.

Example: if UT1 = UB1 = USA = 0, and if UT2 = UDA = ULL = 1, the next LLI does not contain an updated value for LPDMA_CxTR1, nor LPDMA_CxBR1, nor LPDMA_CxSAR. The next LLI contains an updated value for LPDMA_CxTR2, LPDMA_CxDAR, and LPDMA_CxLLR, as shown in the figure below.

Figure 72. LPDMA dynamic linked-list data structure of an addressing channel x

The user must program LPDMA_CxLLR for each LLI to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by LPDMA_CxLBAR.

18.4.6 Linked-list item transfer execution

A LLI transfer is the sequence of:
1. a data transfer: LPDMA executes the data transfer as described by the LPDMA internal register file (this data transfer can be void/null for LLI0)
2. a conditional link transfer: LPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI1, as defined by the LPDMA_CxLLR value of the LLI0.

Note: The initial data transfer as defined by the internal register file (LLI0) can be null (LPDMA_CxBR1.BNDT[15:0] = 0) provided that the conditional update bit UB1 in LPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI in the memory to be executed).

Depending on the intended LPDMA usage, a LPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, LPDMA_CxCR.LSM = 0) or a LPDMA channel x can be programmed for a single execution of a LLI (link step mode, LPDMA_CxCR.LSM = 1), as described in the next paragraphs.
18.4.7 LPDMA channel state and linked-list programming in run-to-completion mode

When LPDMA_CxCR.LSM = 0, a LPDMA channel x is initially programmed, started by writing 1 to LPDMA_CxCR.EN, and after (possibly) completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI0, internal linked-list register file: LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the LPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when LPDMA_CxLLR[31:0] = 0 and LPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

LPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits LPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits Uxx of LPDMA_CxLLR are null (UT1, UT2, UB1, USA, UDA, ULL).

The channel may never be completed when LPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value
  - or LPDMA_CxLLR.ULL = 0
- if LLI_N is pointing to a previous LLI.

In the typical run-to-completion mode, the allocation of a LPDMA channel, including its fine programming, is done once during the LPDMA initialization. In order to have a reserved data communication link and LPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

*Figure 73* depicts the LPDMA channel execution and its registers programming in run-to-completion mode.
Figure 73. LPDMA channel execution and linked-list programming in run-to-completion mode (LPDMA_CxCR.LSM = 0)

Channel state = Idle
- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

Channel state = Active
- Valid user setting?
  - Y: Executing once the data transfer from the register file
  - N: Setting TCF = 1 Disabling DMA channel
- BNDT ≠ 0?
  - Y: Executing once the data transfer from the register file
  - N: Setting DTEF = 1 Disabling DMA channel
- No transfer error?
  - Y: Setting USEF = 1 Disabling DMA channel
  - N: LLR ≠ 0?
    - Y: Loading next LLI into the register file
    - N: Setting ULEF = 1 Disabling DMA channel
- Valid user setting?
  - Y: Setting USEF = 1 Disabling DMA channel
  - N: Setting TCF = 1 Disabling DMA channel

End
Run-time inserting a LLIₙ via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLIₙ₋₁ (start of the LLIₙ loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the LPDMA_CxTR2 in the data structure of the LLIₙ₋₁:

- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[4:0] (see Section 18.3.5 for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLIₙ in the memory and to generate a transfer complete event lpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLIₙ₋₁ of the channel x, the software can pause the primary channel x after its LLIₙ₋₁ data transfer, until it is indeed written the LLIₙ.

Figure 74 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLIₙ₋₁ data transfer that does not need a trigger. The triggering mode of this LLIₙ₋₁ is used to load the next LLIₙ.
Figure 74. Inserting a LLI<sub>n</sub> with an auxiliary LPDMA channel y

- Executing LLI<sub>n-2</sub> data transfer
- Loading LLI<sub>n-1</sub> (with DMA_CxTR2: TRIGM[1:0] = 10, TRIGPOL[1:0] = 01, TRIGSEL = dma_ch_y_tc, and TCEM[1:0] = 01)
  - Executing LLI<sub>n-1</sub> data transfer
  - Transfer complete interrupt
  - Build new LLI<sub>n</sub>
  - Configure channel Y
- Executing data transfer (Memcopy of new LLI<sub>n</sub>)
- Loading new LLI<sub>n</sub>
- Executing LLI<sub>n</sub> data transfer
- Loading LLI<sub>n+1</sub>
18.4.8 LPDMA channel state and linked-list programming in link step mode

When LPDMA_CxCR.LSM = 1, a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

A LPDMA channel transfer can be programmed at LLI level, started by writing 1 into LPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - LPDMA_CxTR1 defines the source/destination elementary single transfers.
  - LPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]).
  - LPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - LPDMA_CxSAR/LPDMA_CxDAR defines the source/destination transfer start address.
  - LPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.

- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when LPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the LPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either LPDMA_CxLLR.ULL = 1 and LPDMA_CxLLR.LA[15:2] is updated by the same value, or LPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

Figure 75 depicts the LPDMA channel execution mode, and its programming in link step mode.
Figure 75. LPDMA channel execution and linked-list programming in link step mode (LPDMA_CxCR.LSM = 1)

Channel state = Idle
- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

Channel state = Active
- Valid user setting?
- BNDT ≠ 0?
- Executing once the data transfer from the register file
- No transfer error?
- LLR ≠ 0?
- Loading next LLI into the register file
- No transfer error?
- Valid user setting?
- Setting TCF = 1
- Setting USEF = 1
- Setting DTEF = 1
- Setting ULEF = 1
- Disabling DMA channel

End
The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI (all update bits of LPDMA_CxLLR have a static value, LLI_{n-1}.LLR.LA = LLI_{n-1}.LLR.LA + constant).

**Run-time adding a LLI_{n+1} in link step mode**

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until(after LPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_{n} from the memory, as shown in the figure below.

**Figure 76. Building LLI_{n+1}: LPDMA dynamic linked-lists in link step mode**

Run-time replacing a LLI_{n} with a new LLI'_{n}, in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI'_{n}, after LPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_{n} from the memory by overwriting directly the linked-list register file with the new LLI'_{n}, as shown in Figure 77.
Run-time replacing a LLI_{in} with a new LLI_{in'} in link step mode (in the memory)

The software can build and insert a new LLI_{in'} and LLI_{in+1'} in the memory, after LPDMA executed the transfer from the LLI_{in-1} and loaded LLI_{in}, then CPU builds and overwrites LLI_{in} as shown in Figure 78.
Figure 78. Replace with a new LLI\(_{n}^{'}\) and LLI\(_{n+1}^{'}\) in memory in link step mode (option 1)

LSM = 1 with 1-stage linked-list programming:
Overwriting the (pre)loaded LLI\(_{n}\) linked-list register file with a new LLI\(_{n}^{'}\) and LLI\(_{n+1}^{'}\) in memory and overwrite partly linked-list register file

(DMA.CxBR1.BNDT = 0 and DMA.CxLLR to point to new LLI\(_{n}^{'}\))

DMA executes LLI\(_{n}\) and load LLI\(_{n}^{'}\) then CPU builds (LLI\(_{n}^{'}\) and LLI\(_{n+1}^{'}\)) and overwrite (BR1 and LLR)

- **DMA Channel**
  - Executing LLI\(_{n+1}^{'}\) data transfer
  - Loading LLI\(_{n}^{'}\)

- **CPU**
  - Build LLI\(_{n}^{'}\) and LLI\(_{n+1}^{'}\) in memory
  - Write DMA.CxBR1.BNDT = 0
    - Write DMA.CxLLR to point to new LLI\(_{n}^{'}\)
  - Enable DMA channel

- **DMA Channel**
  - Executing LLI\(_{n+1}^{'}\) data transfer
  - Loading LLI\(_{n+1}^{'}\)

- **CPU**
  - Enable DMA channel
  - Transfer complete interrupt
Run-time replacing a LLIn with a new LLIn' in link step mode

Other software implementations exist. Meanwhile LPDMA executes the transfer from the LLIn-1 and loads a formerly elaborated LLIn from the memory (or even earlier), the software can do the following:
1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new LLIn' and a new LLIn+1'.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLIn-1 is then restricted to overwrite LPDMA_CxBR1.BNDT[15:0] to be null and LPDMA_CxLLR to point to new LLIn', as shown in Figure 79.

Figure 79. Replace with a new LLIn' and LLIn+1' in memory in link step mode (option 2)
18.4.9 LPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (LPDMA_CxCR.EN = 0) and update the execution mode (LPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the LPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the LPDMA channel
- abort and reconfigure the channel with a LSM update (see Section 18.4.4)

In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 80 shows the overall and unified LPDMA linked-list programming, whatever is the execution mode.
Figure 80. LPDMA channel execution and linked-list programming

Channel state = Idle
- Initialize DMA channel
- Enable DMA channel
- Reconfigure DMA channel

Channel state = Active
- Valid user setting?
  - Yes: Setting USEF = 1, Disabling DMA channel
  - No: BNDT ≠ 0?
    - Yes: Setting USEF = 1, Disabling DMA channel
    - No: Executing once the data transfer from the register file
      - No transfer error?
        - Yes: Loading next LLI into the register file
        - No: Setting DTEF = 1, Disabling DMA channel
      - LLR ≠ 0?
        - Yes: Setting ULEF = 1, Disabling DMA channel
        - No: Setting USEF = 1, Disabling DMA channel
      - LSM = 1?
        - Yes: Setting TCF = 1, Disabling DMA channel
        - No: Setting USEF = 1, Disabling DMA channel

End
18.4.10 LPDMA direct transfers

There is a single transfer operation mode called the direct mode. Any LPDMA channel is used in direct mode. Any channel is implemented without any FIFO (for every channel x, dma_fifo_size[x] = 0).

LPDMA single

A programmed transfer at the lowest level is called a LPDMA single.

A LPDMA single data width is 1, 2 or 4 bytes, as defined by the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields of LPDMA_CxTR1(respectively for source and destination).

Note: The user must not assign a 8-byte data width (SDW_LOG2[1:0] = 0b11 or DDW_LOG2[1:0] = 0b11) else a user setting is reported and no transfer is issued.

The addressing mode after each data of a LPDMA single is defined by the SINC and DINC bits of LPDMA_CxTR1(respectively for source and destination): either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a LPDMA source/destination single (defined by LPDMA_CxSAR and LPDMA_CxDAR) must be aligned with the respective data width.

The table below lists the main characteristics of a LPDMA single.

The next single address in the table is the next source/destination address, pointed by LPDMA_CxSAR and LPDMA_CxDAR, once the programmed source/destination single is completed.

In direct mode, a LPDMA single is an AHB single transfer.
LPDMA data handling: byte-based padding/truncation, sign extension and left/right alignment

The user can configure some data manipulation between a transferred data from the source and its transfer to the destination. Data handling is controlled by the LPDMA_CxTR1 register:

- If destination data width = source data width (DDW_LOG2[1:0] = SDW_LOG2[1:0]), the source data is copied as is and transferred to the destination.
- Else, depending on PAM:
  - If destination data width > source data width, the source data can be either right-aligned and padded with 0 s, or sign extended up to the destination data width.
  - If destination data width < source data width, the source data can be either right-aligned and left-truncated down to the destination data width, or left-aligned and right-truncated down to the destination data width.

There is no data manipulation between two distinct transferred data from the source, before the generation of the destination transfer.

The table below lists possible data handling from the source to the destination.

1. Data stream is timely ordered starting from the byte with the lowest index a.k.a B0.
2. RA = right aligned. LA = left aligned. RT = right truncated. LT = left truncated.
3. 0P = zero bit padding up to the destination data width.
4. SE = sign bit extended up to the destination data width.
18.4.11 LPDMA transfer request and arbitration

LPDMA transfer request

As defined by LPDMA_CxTR2, a programmed LPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the LPDMA hardware peripheral request is driven by the REQSEL[4:0] field (see Section 18.3.4). The selected hardware request can be one of the following:
  - a hardware request from a peripheral configured in LPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - a hardware request from a peripheral for its control registers update from the memory
  - a hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral LPDMA request via LPDMA_CxTR.REQSEL[4:0] to two different channel if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

LPDMA transfer request for arbitration

For a given channel, a LPDMA requested data transfer from the source address to the destination address is arbitrated versus simultaneous requested LPDMA transfers from other channels, in order to be scheduled over the AHB master port. A LPDMA data transfer is atomic to the LPDMA arbitration: it consists of an AHB read single, immediately followed by an AHB write single. It is granted by the arbiter once for both AHB transfers, based on the channel priority defined by LPDMA_CxCR.PRIO[1:0].

An arbitrated LPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR or LPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the master port.

The re arbitration occurs after each granted single transfer:

- whatever how the requested data transfer is programmed:
  - with a software request for a memory-to-memory transfer (LPDMA_CxTR2.SWREQ = 1)
  - with a hardware request (LPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer
- whatever the hardware request type

When the requested data transfer is programmed with a hardware request from a peripheral (LPDMA_CxTR2.SWREQ = 0), the first memory read of a block is gated by the occurrence of the corresponding and selected hardware request, whatever the peripheral is source or destination of the transfer. This first read request to the memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).
LPDMA arbitration

The LPDMA arbitration is directed from the 4-grade assigned channel priority (LPDMA_CxCR.PRI0[1:0]). The arbitration policy, as illustrated in Figure 81, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels
  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single transfers are round-robin arbitrated.

- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2
  Each requested single transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 81. LPDMA arbitration policy

1. RRA: round-robin arbitration
2. FPA: fixed-priority arbitration

LPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as BQ3) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).
The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive LPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1 (B_{req1}).
    \[ B_{req0} = B_{req1} = \frac{1}{2} \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
    \[ B_{req0} = B_{P0} = \frac{1}{2} \times \frac{1}{2} \times (1 - B_{Q3}) = \frac{1}{4} \times (1 - B_{Q3}) \]
    \[ B_{req1} = B_{P1} = \frac{1}{2} \times (1 + 1) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{3}{4} \times (1 - B_{Q3}) \]
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
    \[ B_{req0} = B_{P0} = \frac{1}{2} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{6} \times (1 - B_{Q3}) \]
    \[ B_{req1} = B_{P2} = \frac{1}{2} \times (1 + 1 + 1) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{6} \times (1 - B_{Q3}) \]

The above computed bandwidth calculation is based on a theoretical input request, always active for any LPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one LPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of LPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    \[ B_{P0} = \frac{1}{3} \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{1}{9} \times (1 - B_{Q3}) \]
  - The allocated bandwidth to the set of requests of priority 1 (B_{P1}) is
    \[ B_{P1} = \frac{1}{3} \times (1 + 1) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{5}{18} \times (1 - B_{Q3}) \]
  - The allocated bandwidth to the set of requests of priority 2 (B_{P2}) is
    \[ B_{P2} = \frac{1}{3} \times (1 + 1 + 1) \times \frac{1}{3} \times (1 - B_{Q3}) = \frac{11}{18} \times (1 - B_{Q3}) \]
  - The allocated bandwidth to any request n (B_{n}) among the N requests of that priority Pi (i = 0 to 2) is
    \[ B_{n} = \frac{1}{N} \times B_{P_i} \]
  - The allocated bandwidth to any request n of priority 0 (B_{n,0}) is
    \[ B_{n,0} = \frac{1}{N} \times \frac{1}{9} \times (1 - B_{Q3}) \]
    \[ B_{n,1} = \frac{1}{N} \times \frac{5}{18} \times (1 - B_{Q3}) \]
    \[ B_{n,2} = \frac{1}{N} \times \frac{11}{18} \times (1 - B_{Q3}) \]

In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.
More generally, assume that the following requests are present:

- \( I \) requests \((I \geq 0)\) assigned to priority 0
  - If \( I > 0 \), these requests are noted from \( i = 0 \) to \( I-1 \).
- \( J \) requests \((J \geq 0)\) assigned to priority 1
  - If \( J > 0 \), these requests are noted from \( j = 0 \) to \( J-1 \).
- \( K \) requests \((K > 0)\) assigned to priority 2
  - These requests are noted from \( k = 0 \) to \( K-1 \).
- \( L \) requests \((L \geq 0)\) assigned to priority 3
  - If \( L > 0 \), these requests are noted from \( l = 0 \) to \( L-1 \).

As \( B_{Q3} \) is the reserved bandwidth to time-sensitive requests, the bandwidth for each request \( L \) with priority 3 is:

- \( B_l = B_{Q3} / L \) for \( L > 0 \) (else: \( B_l = 0 \))

The bandwidth for each non-time sensitive queue is:

- \( B_{Q0} = 1/3 * (1 - B_{Q3}) \)
- \( B_{Q1} = 1/3 * (1 - B_{Q3}) \)
- \( B_{Q2} = 1/3 * (1 - B_{Q3}) \)

The bandwidth for the set of requests with priority 0 is:

- \( B_{P0} = I / (I + J + K) * B_{Q0} \)

The bandwidth for each request \( i \) with priority 0 is:

- \( B_i = B_{P0} / I \) for \( L > 0 \) (else \( B_i = 0 \))

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- \( B_{P1,Q0} = J / (I + J + K) * B_{Q0} \)

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- \( B_{P1,Q1} = J / (J + K) * B_{Q1} \)

The total bandwidth for the set of requests with priority 1 is:

- \( B_{P1} = B_{P1,Q0} + B_{P1,Q1} \)

The bandwidth for each request \( j \) with priority 1 is:

- \( B_j = B_{P1} / J \) for \( J > 0 \) (else \( B_j = 0 \))

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- \( B_{P2,Q0} = K / (I + J + K) * B_{Q0} \)

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- \( B_{P2,Q1} = K / (J + K) * B_{Q1} \)

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- \( B_{P2,Q2} = B_{Q2} \)

The total bandwidth for the set of requests with priority 2 is:

- \( B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2} \)

The bandwidth for each request \( k \) with priority 2 is:

- \( B_k = B_{P2} / K \) (K>0 in the general case)
Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 \((K > 0)\)):
  
  \[
  B_i = \frac{1}{I} \times \frac{1}{3} \times \frac{I}{(I + J + K)} \times (1 - B_{Q3})
  \]
  
  \[
  B_j = \frac{1}{J} \times \frac{1}{3} \times \left[ \frac{J}{(I + J + K)} + \frac{J}{(J + K)} \right] \times (1 - B_{Q3})
  \]
  
  \[
  B_k = \frac{1}{K} \times \frac{1}{3} \times \left[ \frac{K}{(I + J + K)} + \frac{K}{(J + K)} + 1 \right] \times (1 - B_{Q3})
  \]

- in the specific case (when there is no request k with a priority 2 \((K = 0)\)):
  
  \[
  B_i = \frac{1}{I} \times \frac{1}{2} \times \frac{I}{(I + J)} \times (1 - B_{Q3})
  \]
  
  \[
  B_j = \frac{1}{J} \times \frac{1}{2} \times \left[ \frac{J}{(I + J)} + 1 \right] \times (1 - B_{Q3})
  \]

Consequently, the LPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

### 18.4.12 LPDMA triggered transfer

A programmed LPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGSEL[4:0] (see Section 18.3.5 for the trigger selection).

The triggered transfer, as defined by the trigger mode in LPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first single read of a block, or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see the TRIGM[1:0] description in LPDMA channel x transfer register 2 (LPDMA_CxTR2) for more details).

#### Trigger hit memorization and trigger overrun flag generation

The LPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[4:0] are not modified, and the channel is enabled.

Transferring a next LLI\(_{n+1}\) that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI\(_n\) trigger.

**Caution:** After a first new trigger hit\(_{n+1}\) is memorized, if another trigger hit\(_{n+2}\) is detected and if the hit\(_n\) triggered transfer is still not completed, hit\(_{n+2}\) is lost and not memorized. A trigger overrun flag is reported (LPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.
The figure below illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

**Figure 82. Trigger hit, memorization and overrun waveform**

</table>

**Note:** The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

### 18.4.13 LPDMA circular buffering with linked-list programming

**LPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers**

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer events/interrupts generation (LPDMA_CxCR.HTIE = 1 and LPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI0 is configured for the first block transfer. A continuously-executed LLI1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). LPDMA automatically reloads the initially programmed LPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore LPDMA_CxBR1.
The figure below illustrates this programming with a LPDMA channel and a source circular buffer.

**Figure 83. LPDMA circular buffer programming: update of the memory start address**

If circular buffering must be executed after some other transfers over the shared LPDMA channel \( x \), the before-last \( \text{LLI}_{N-1} \) in memory is needed to configure the first block transfer. And the last \( \text{LLI}_N \) restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).
The figure below illustrates this programming with a shared LPDMA channel, and a source circular buffer.

**Figure 84. Shared LPDMA channel with circular buffering: update of the memory start address**

18.4.14 LPDMA secure/non-secure channel

The LPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and non-secure worlds at any given time.

Any channel x is a secure or a non-secure hardware resource, as configured by LPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure agent, the following access control rules are applied:

- A non-secure read access to a register field of this channel is forced to return 0, except for LPDMA_SECCFGR, LPDMA_PRIVCFGRN, LPDMA_RCFGLOCKR that are readable by a non-secure agent.
- A non-secure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or non-secure the LPDMA data transfer from the source (LPDMA_CxTR1.SSEC) and the LPDMA data transfer to the destination (LPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file, is automatically performed with secure transfers via the master port.

LPDMA generates a secure bus dma_sec[3:0], reflecting LPDMA_SECCFGR, to keep the other peripherals informed of the secure/non-secure state of each LPDMA channel x.
LPDMA also generates a security illegal access pulse signal on an illegal non-secure access to a secure LPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a non-secure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next non-secure transfer as a non-secure software is not allowed to do so and must have LPDMA_CxCR.EN = 0 before the non-secure software can reprogram the LPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

18.4.15 LPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via LPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for LPDMA_PRIVCFGR, LPDMA_SECCFGR, that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the LPDMA memory into its register file is automatically performed with privileged (respectively unprivileged) transfers, via the master port.

LPDMA generates a privileged bus, dma_priv[3:0], reflecting LPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each DMA channel x.

Additionally, the LPDMA generates a privileged illegal access pulse signal on an illegal unprivileged access to a privileged LPDMA register. This signal may be used or not, depending on the product (see the system security section for more details).

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have LPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the LPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (LPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.
18.4.16 LPDMA error management

LPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single) to the source or the destination:
- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware). The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the data error (LPDMA_CxSR.DTEF = 1).
- After a LPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a LPDMA data transfer error, the user must issue a channel reset (set LPDMA_CxCR.RESET) to reset the hardware LPDMA channel data path before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a LPDMA channel register from the programmed LLI in the memory:
- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (LPDMA_CxCR.EN cleared by the LPDMA hardware), the channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and the link error (LPDMA_CxSR.ULEF = 1).
- After a LPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (LPDMA_CxLBAR and LPDMA_CxLLR), including the protection attributes.
- After a LPDMA link error, the user must explicitly write the linked-list register file (LPDMA_CxTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a LPDMA transfer with an unauthorized user setting:
- The programmed channel transfer is disabled (LPDMA_CxCR.EN forced and cleared by the LPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (LPDMA_CxSR.IDLEF = 1) and a user setting error (LPDMA_CxSR.USEF = 1).
- After a LPDMA user setting error, the user must perform a debug session, taking care of the LPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI (LPDMA_CxBR1.BNDT[15:0] = 0 and LPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source single transfer (LPDMA_CxBR1.BNDT[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned source start address, being not a multiple of the programmed data width of a source single transfer (LPDMA_CxSAR[2:0] versus LPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination single transfer (LPDMA_CxDAR[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (LPDMA_CxTR1.SDW_LOG2[1:0] = 0b11)
- a programmed double-word destination data width (LPDMA_CxTR1.DDW_LOG2[1:0] = 0b11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (LPDMA_CxLLR.UB1 = 1 and LPDMA_CxBR1.BNDT = 0)

18.4.17 LPDMA autonomous mode

To save dynamic power consumption while LPDMA executes the programmed linked-list transfers, LPDMA hardware automatically manages its own clock gating and generates a clock request output signal to the RCC, whenever the device is in Run, Sleep or Stop mode, provided that the RCC is programmed with the corresponding LPDMA enable control bits.

For more details about the RCC programming, refer to the RCC section of the reference manual.

For mode details about the availability of the LPDMA autonomous feature vs the device low-power modes, refer to Section 18.3.2.

The user can program and schedule the execution of a given LPDMA transfer at a LLI_n level of a LPDMA channel x, with LPDMA_CxTR2 as follows:
- The software controls and conditions the input of a transfer with TRIGM[1:0], TRIGPOL[1:0], TRIGSEL[4:0], SWREQ and REQSEL[4:0] for the input trigger and request.
- The software controls and signals the output of a transfer with TCEM[1:0] for generating or not a transfer complete event, and generating or not an associated half data transfer event).

See LPDMA channel x transfer register 2 (LPDMA_CxTR2) for more details.

The output channel x transfer complete event, lpdma_chx_tc, can be programmed as a selected input trigger for a channel if this event is looped-back and connected at the LPDMA level (see Section 18.3.5), allowing autonomous and fine DMA inter-channel transfer scheduling, without needing a cleared transfer complete flag (TCF).

A given LPDMA channel x asserts its clock request in one of the following conditions:
- if the next transfer to be executed is programmed as conditioned by a trigger (LPDMA_CxTR2.TRIGPOL[1:0] and LPDMA_CxTR2.TRIGM[1:0]), only when the trigger hit occurs.
- if the next transfer to be executed is not conditioned by a trigger:
  - if LPDMA_CxTR2.SWREQ = 0, only when the hardware request is asserted by the selected peripheral
  - if LPDMA_CxTR2.SWREQ = 1 (memory-to-memory, GPIO to/from memory), as soon as the GPDMA is enabled
The LPDMA channel x releases its clock request as soon as all the following conditions are met:

- The transfer to be executed is completed.
- The LPDMA channel x is not immediately ready and requested to execute the next transfer.
- If a channel x interrupt was raised, all the flags of the status register that can cause this interrupt, are cleared by a software agent.

When one channel asserts its clock request, the LPDMA asserts its clock request to the RCC. When none channel asserts its clock request, the LPDMA releases its clock request to the RCC.

18.5 LPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

*Note:* In debug mode, LPDMA_CxSR.SUSPF is not altered by a suspension from DBG_CHx_STOP = 1. In this case, LPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

18.6 LPDMA in low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPDMA interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(^{(1)})</td>
<td>The content of the LPDMA registers is kept when entering Stop mode. The content of the LPDMA registers can be autonomously updated by a next linked-list item from memory, to perform autonomous data transfers. LPDMA interrupts can cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The LPDMA is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 18.3.2 to know which Stop mode is supported.
18.7 LPDMA interrupts

There is one LPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Interrupt enable</th>
<th>Event flag</th>
<th>Event clear method</th>

<tr>
<td></td>
<td>Trigger overrun</td>
<td>LPDMA_CxCR.TOFIE</td>
<td>LPDMA_CxR.TOF</td>
<td>Writes 1 to LPDMA_CxFCR.TOF</td>
</tr>
</tbody>
</table>

A LPDMA channel x event may be:
- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

**Note:** When a channel x transfer complete event occurs, the output signal lpdma.chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:
- the corresponding interrupt event xx is enabled (LPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (LPDMA_CxSR.xx = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into LPDMA_CxFCR.xx).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by LPDMA_CxTR2.TCEM[1:0] as follows:
- A transfer complete event is a block transfer complete or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode LPDMA_CxTR2.TCEM[1:0].
- A half transfer event is a half block transfer. A half-block transfer occurs when half of the source block size bytes (rounded-up integer of LPDMACxBR1.BNDT[15:0] / 2) is transferred to the destination.

See **LPDMA channel x transfer register 2 (LPDMA_CxTR2)** for more details.
A transfer error rises in one of the following situations:

- during a single data transfer from the source or to the destination (DTEF)
- during an update of a LPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a LPDMA channel with an unauthorized setting (USEF)

The user must perform a debug session to correct the LPDMA channel programming versus the USEF root causes list (see Section 18.4.16).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

## 18.8 LPDMA registers

The LPDMA registers must be accessed with an aligned 32-bit word data access.

### 18.8.1 LPDMA secure configuration register (LPDMA_SECCFGR)

Address offset: 0x000

Reset value: 0x0000 0000

A write access is ignored at bit level if the corresponding channel x is locked (LPDMA_RCFGLOCKR.LOCKx = 1).

A write access to this register must be secure and privileged. A read access is secure or non-secure, privileged or unprivileged.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (when LPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or non-secure world.

<td>0: non-secure, 1: secure</td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **SECx**: secure state of channel x (x = 3 to 0)

- 0: non-secure
- 1: secure
18.8.2 LPDMA privileged configuration register (LPDMA_PRIVCFGR)

Address offset: 0x004
Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or non-secure.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register can mix secure and non-secure information. If a channel x is configured as secure (LPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a LPDMA channel (LPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

0: unprivileged
1: privileged
18.8.3 LPDMA configuration lock register (LPDMA_RCFGLOCKR)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attribute in order to individually lock at boot time the secure privileged attributes of any DMA channel/resource (to lock the setting of LPDMA_SECCFGR, LPDMA_PRIVCFGR for any channel x at boot time).

A read access may be privileged or unprivileged, secure or non-secure.

</table>

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **LOCKx**: lock the configuration of LPDMA_SECCFGR.SECx, LPDMA_PRIVCFGR.PRIVx until a global DMA reset (x = 3 to 0)

- This bit is cleared after reset and, once set, it cannot be reset until a global DMA reset.
- 0: secure privilege configuration of the channel x is writable.
- 1: secure privilege configuration of the channel x is not writable.

18.8.4 LPDMA non-secure masked interrupt status register (LPDMA_MISR)

Address offset: 0x00C
Reset value: 0x0000 0000

This register is a read register.

This is a non-secure register, containing the masked interrupt status bit MISx for each non-secure channel x (channel x configured with LPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of LPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of LPDMA_CxCR.

Every bit is de-asserted by hardware when writing 1 to the corresponding flag clear bit in LPDMA_CxFCR.

If a channel x is in secure state (LPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGR.PRIVx. A privileged software can read the full non-secure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and non-secure) channel(s), other privileged bit fields returning zero.
18.8.5 LPDMA secure masked interrupt status register (LPDMA_SMISR)

Address offset: 0x010

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (LPDMA_SECCFGRx.SECx = 1). It is a logical OR of all the LPDMA_CxSR flags, each source flag being enabled by the corresponding LPDMA_CxCR interrupt enable bit.

Every bit is de-asserted by hardware when securely writing 1 to the corresponding LPDMA_CxCFR flag clear bit.

This register does not contain any information about a non-secure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel LPDMA_PRIVCFGx.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 MISx: masked interrupt status of the secure channel x (x = 3 to 0)
- 0: no interrupt occurred on the secure channel x
- 1: an interrupt occurred on the secure channel x
18.8.6  **LPDMA channel x linked-list base address register (LPDMA_CxLBAR)**

Address offset: 0x050 + 0x080 * x (x = 0 to 3)  
Reset value: 0x0000 0000  
This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x LPDMA PRIVR.PRIVx.  
This register is either secure or non-secure depending on the secure state of the channel x (LPDMA_SECCFGR.SECx).  
This register must be written when LPDMA_CxCR.EN = 0.  
This register is read-only when LPDMA_CxCR.EN = 1.  
This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the LPDMA transfers, are conditionally and automatically updated.  
This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit LPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

### LPDMA_CxLBAR

</table>

18.8.7  **LPDMA channel x flag clear register (LPDMA_CxFCR)**

Address offset: 0x05C + 0x080 * x (x = 0 to 3)  
Reset value: 0x0000 0000  
This is a write register, secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx) and privileged or non-privileged, depending on the privileged state of the channel x (LPDMA_PRIVR.PRIVx).

### LPDMA_CxFCR

### 18.8.8  LPDMA channel x status register (LPDMA_CxSR)

Address offset: 0x060 + 0x080 * x (x = 0 to 3)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or non-secure, depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel (LPDMA_PRIVCFGPR.PRIVx).

<td>channel in idle state</td>
</tr>
</tbody>
</table>

This idle flag is de-asserted by hardware when the channel is enabled (LPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).
18.8.9  LPDMA channel x control register (LPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of the channel x (LPDMA_PRIVR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:22  PRIO[1:0]: priority level of the channel x LPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:17  Reserved, must be kept at reset value.

Bit 16  LSM: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI
(LPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0). Then LPDMA_CxBR1.BNDT[15:0] = 0.
1: channel executed once for the current LLI
First the block transfer is executed as defined by the current internal register file until LPDMA_CxBR1.BNDT[15:0] =0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by LPDMA_CxLLR. Then channel execution is completed.

Note: This bit must be written when EN=0. This bit is read-only when EN=1.

Bit 15  Reserved, must be kept at reset value.

Bit 14  TOIE: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13  SUSPIE: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12  USEIE: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled
Bit 11 **ULEIE**: update link transfer error interrupt enable
  0: interrupt disabled
  1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
  0: interrupt disabled
  1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
  0: interrupt disabled
  1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
  0: interrupt disabled
  1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP**: suspend
  Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
  Software must write 1 in order to suspend an active channel (with an ongoing DMA transfer over its master ports).
  The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in Figure 69.
  0: write: resume channel, read: channel not suspended
  1: write: suspend channel, read: channel suspended.

Bit 1 **RESET**: reset
  This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
  The reset is effective when the channel is in steady state, meaning one of the following:
  - active channel in suspended state ($\text{LPDMA}_\text{CxSR}.\text{SUSPF} = 1$ and $\text{LPDMA}_\text{CxSR}.\text{IDLEF} = \text{LPDMA}_\text{CxCR}.\text{EN} = 1$)
  - channel in disabled state ($\text{LPDMA}_\text{CxSR}.\text{IDLEF} = 1$ and $\text{LPDMA}_\text{CxCR}.\text{EN} = 0$).
  After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers ($\text{LPDMA}_\text{CxBR1}$, $\text{LPDMA}_\text{CxSAR}$ and $\text{LPDMA}_\text{CxDAR}$) before enabling again the channel (see the programming sequence in Figure 70).
  0: no channel reset
  1: channel reset

Bit 0 **EN**: enable
  Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:
  this bit is de-asserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, e.g. if $\text{LSM}=1$ at the end of a single execution of the LLI).
  Else, this bit can be asserted by software.
  Writing 0 into this EN bit is ignored.
  0: write: ignored, read: channel disabled
  1: write: enable channel, read: channel enabled
18.8.10 LPDMA channel x transfer register 1 (LPDMA_CxTR1)

Address offset: 0x090 + 0x080 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or non-privileged, depending on the privileged state of the channel x in LPDMA_PRIVR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.
This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted LPDMA_CxCR.EN. A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.UT1 = 1.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>DSEC: security attribute of the LPDMA transfer to the destination</th>
</tr>
</thead>
</table>
| rw | If LPDMA_SECCFGR.SECx = 1 and the access is secure:
0: LPDMA transfer non-secure
1: LPDMA transfer secure
This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when LPDMA_SECCFGR.SECx = 1. A secure write is ignored when LPDMA_SECCFGR.SECx = 0.
When LPDMA_SECCFGR.SECx is de-asserted, this DSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as non-secure), and the LPDMA transfer to the destination is non-secure. |

<table>
<thead>
<tr>
<th>Bit 19</th>
<th>DINC: destination incrementing single</th>
</tr>
</thead>
</table>
| rw | 0: fixed single
1: contiguously incremented single
The destination address, pointed by LPDMA_CxDAR, is kept constant after a single transfer, or is incremented by the offset value corresponding to a contiguous data after a single transfer. |

<table>
<thead>
<tr>
<th>Bit 18</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>Bit 18 Reserved, must be kept at reset value.</td>

<tbody>
<tr>
<td>rw</td>
<td>Bits 30:20 Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit 16</th>
<th>SDW_LOG2[1:0]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>Bits 30:20 Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a single in bytes
- 00: byte
- 01: half-word (2 bytes)
- 10: word (4 bytes)
- 11: user setting error reported and no transfer issued

**Note:** Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.
A destination single transfer must have an aligned address with its data width (start address LPDMA_CxDAR[2:0] versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the LPDMA transfer from the source
- If LPDMA_SECCFG.SECx = 1 and the access is secure:
  - 0: LPDMA transfer non-secure
  - 1: LPDMA transfer secure

  This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when LPDMA_SECCFG.SECx = 1. A secure write is ignored when LPDMA_SECCFG.SECx = 0.

  When LPDMA_SECCFG.SECx is de-asserted, this SSEC bit is also de-asserted by hardware (on a secure reconfiguration of the channel as non-secure), and the LPDMA transfer from the source is non-secure.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **PAM**: padding/alignment mode
- If DDW_LOG2[1:0]=SDW_LOG2[1:0]: if the data width of a single destination transfer is equal to the data width of a single source transfer, this bit is ignored.

  Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher that source data width, and the condition PAM_2 is when destination data width is higher than source data width.

  **Condition: PAM_1**
  - 0: source data is transferred as right aligned, padded with 0s up to the destination data width
  - 1: source data is transferred as right aligned, sign extended up to the destination data width

  **Condition: PAM_2**
  - 0: source data is transferred as left-aligned, left-truncated down to the destination data width
  - 1: source data is transferred as left-aligned, right-truncated down to the destination data width

Bits 10:4 Reserved, must be kept at reset value.
Bit 3  **SINC**: source incrementing single
0: fixed single
1: contiguously incremented single
The source address, pointed by LPDMA_CxSAR, is kept constant after a single transfer or is incremented by the offset value corresponding to a contiguous data after a single transfer.

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **SDW_LOG2[1:0]**: binary logarithm of the source data width of a single in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

**Note**: Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

A source block size must be a multiple of the source data width
(LPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source single transfer must have an aligned address with its data width (start address LPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

### 18.8.11  **LPDMA channel x transfer register 2 (LPDMA_CxTR2)**

Address offset: 0x094 + 0x080 * x (x = 0 to 73)

Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFRG.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory, if LPDMA_CxLLR.UT2 = 1.
Bits 31:30  **TCEM[1:0]:** transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when LPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

**Note:** If the initial LLI0 data transfer is null/void (directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: same as 00

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer), if any data transfer.

**Note:** If the initial LLI0 data transfer is null/void (i.e. directly programmed by the internal register file with LPDMA_CxBR1.BNDT[15:0] =0 ), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address LPDMA_CxLLR.LA[15:2] to zero and clears all the LPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26  Reserved, must be kept at reset value.

Bits 25:24  **TRIGPOL[1:0]:** trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[4:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:21  Reserved, must be kept at reset value.

Bits 20:16  **TRIGSEL[4:0]:** trigger event input selection

These bits select the trigger event input of the LPDMA transfer (as per Section 18.3.5), with an active trigger event if TRIGPOL[1:0] = 00.
Bits 15:14 **TRIGM[1:0]: trigger mode**

These bits define the transfer granularity for its conditioning by the trigger.
If the channel x is enabled (LPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 0b00 or 0b11, these TRIGM[1:0] bits are ignored.
Else, a DMA transfer is conditioned by at least one trigger hit:
00: at block level: the first single read of each block transfer is conditioned by one hit trigger.
01: same as 00
10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.
11: at programmed single level: each programmed single read is conditioned by one hit trigger.
The LPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 0b01 or respectively TRIGPOL[1:0] = 0b10).
The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[4:0] is not modified, and the channel is enabled.
Transferring a next LLI_{n+1} that updates the LPDMA_CxTR2 with a new value for any of TRIGSEL[4:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_{n} trigger.
After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_{n} triggered transfer is still not completed, hit_{n+2} is lost and not memorized, and a trigger overrun flag is reported (LPDMA_CxSR.TOF = 1), an interrupt is generated if enabled (LPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Bits 13:12 Reserved, must be kept at reset value.

**Bit 11 BREQ: block hardware request**

If the channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:
0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a single level.
1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see Section 18.3.4).

**Bit 10 Reserved, must be kept at reset value.**

**Bit 9 SWREQ: software request**

This bit is internally taken into account when LPDMA_CxCR.EN is asserted.
0: no software request. The selected hardware request REQSEL[4:0] is taken into account.
1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[4:0] is ignored.

**Bits 8:5 Reserved, must be kept at reset value.**

**Bits 4:0 **REQUEST[4:0]: DMA hardware request selection**

These bits are ignored if channel x is activated (LPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per Section 18.3.3.

**Caution:** The user must not assign a same input hardware request (same REQUEST[4:0] value) to different active DMA channels (LPDMA_CxCR.EN = 1 and LPDMA_CxTR2.SWREQ = 0 for these channels). DMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.
18.8.12 LPDMA channel x block register 1 (LPDMA_CxBR1)

Address offset: 0x098 + 0x080 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if LPDMA_CxLLR.UB1 = 1, this register is automatically updated by DMA from the next LLI in memory.
- If LPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed values for the field BNDT[15:0].
- If all the update bits LPDMA_CxLLR.Uxx are null and if LPDMA_CxLLR.LA[15:0] # 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI.
- If LPPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

18.8.13 **LPDMA channel x source address register (LPDMA_CxSAR)**

Address offset: 0x09C + 0x080 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFG.R_SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer from the source.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.USA = 1.
18.8.14 LPDMA channel x destination address register (LPDMA_CxDAR)

Address offset: 0x0A0 + 0x080 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFG.RSECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVR.PRIx).

This register configures the destination start address of a transfer.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next single transfer to the destination.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by DMA from the memory if LPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination single (DA[2:0] versus LPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.
18.8.15 LPDMA channel x linked-list address register (LPDMA_CxLLR)

Address offset: 0x0CC + 0x080 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register is secure or non-secure depending on the secure state of channel x (LPDMA_SECCFGR.SECx), and privileged or non-privileged, depending on the privileged state of channel x (LPDMA_PRIVR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when LPDMA_CxCR.EN = 0.

This register is read-only when LPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has de-asserted LPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by LPDMA from the memory if LPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update LPDMA_CxTR1 from memory
This bit controls the update of the LPDMA_CxTR1 register from the memory during the link transfer.
0: no LPDMA_CxTR1 update
1: LPDMA_CxTR1 update

Bit 30 **UT2**: Update LPDMA_CxTR2 from memory
This bit controls the update of the LPDMA_CxTR2 register from the memory during the link transfer.
0: no LPDMA_CxTR2 update
1: LPDMA_CxTR2 update

Bit 29 **UB1**: Update LPDMA_CxBR1 from memory
This bit controls the update of the LPDMA_CxBR1 register from the memory during the link transfer.
0: no LPDMA_CxBR1 update from memory and internally restored to the previous programmed value
1: LPDMA_CxBR1 update

Bit 28 **USA**: Update LPDMA_CxSAR from memory
This bit controls the update of the LPDMA_CxSAR register from the memory during the link transfer.
0: no LPDMA_CxSAR update
1: LPDMA_CxSAR update

Bit 27 **UDA**: Update LPDMA_CxDAR register from memory
This bit is used to control the update of the LPDMA_CxDAR register from the memory during the link transfer.
0: no LPDMA_CxDAR update
1: LPDMA_CxDAR update
Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update LPDMA_CxLLR register from memory

This bit is used to control the update of the LPDMA_CxLLR register from the memory during the link transfer.

0: no LPDMA_CxLLR update
1: LPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:20] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list DMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list DMA internal register file (LDMA_CxCTR1, LPDMA_CxTR2, LPDMA_CxBR1, LPDMA_CxSAR, LPDMA_CxDAR and LPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

### 18.8.16 LPDMA register map

#### Table 141. LPDMA register map and reset values

| Offset  | Register      | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 for the register boundary addresses.
19 Chrom-ART Accelerator controller (DMA2D)

19.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

19.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas expressed in pixels or bytes
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to-memory with pixel format conversion, blending and fixed color foreground, and memory-to-memory with pixel format conversion, blending and fixed color background.
• Area filling with a fixed color
• Copy from an area to another
• Copy with pixel format conversion between source and destination images
• Copy from two sources with independent color format and blending
• Output buffer byte swapping to support refresh of displays through parallel interface
• Abort and suspend of DMA2D operations
• Watermark interrupt on a user programmable destination line
• Interrupt generation on bus error or access conflict
• Interrupt generation on process completion

19.3 DMA2D functional description

19.3.1 DMA2D block diagram
The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:
• Register-to-memory
• Memory-to-memory
• Memory-to-memory with Pixel Format Conversion
• Memory-to-memory with Pixel Format Conversion and Blending
• Memory-to memory with pixel format conversion, blending and fixed color foreground
• Memory-to memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in Figure 85: DMA2D block diagram.
19.3.2 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D_CR) which allows selecting:

The user application can perform the following operations:
- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

19.3.3 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).
They are programmed through a set of control registers:
- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

### 19.3.4 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in *Table 142: Supported color mode in input*.

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>0001</td>
<td>RGB888</td>
</tr>
<tr>
<td>0010</td>
<td>RGB565</td>
</tr>
<tr>
<td>0011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>0100</td>
<td>ARGB4444</td>
</tr>
<tr>
<td>0101</td>

<td>L4</td>
</tr>
<tr>
<td>1001</td>
<td>A8</td>
</tr>
<tr>
<td>1010</td>
<td>A4</td>
</tr>
</tbody>
</table>
The color format are coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format is indirect color mode (L/AL), a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D_FGCOLR for foreground pixels and in the DMA2D_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in Table 143: Data order in memory.

<table>

</tr>
</tbody>
</table>

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers as shown in Table 144: Alpha mode configuration.
The alpha channel can be:

- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 144. Alpha mode configuration

<tr>
<td>11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the incoming alpha value can be inverted setting the AI bit of the DMA2D_FGPFCCR/DMA2D_BGPFCR registers. This applies also to the Alpha value stored in the DMA2D_FGPFCCR/DMA2D_BGPFCR and in the CLUT.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_FGPFCCR/DMA2D_BGPFCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D_FGCOLR/DMA2D_BGCOLR registers.

19.3.5 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading
  
  The following sequence must be followed to load the CLUT:
  
  a) Program the CLUT address into the DMA2D_FGCMAR register (foreground CLUT) or DMA2D_BGCMAR register (background CLUT)
  
  b) Program the CLUT size in the CS[7:0] field of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT).
  
  c) Set the START bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict
occurs, a CLUT access error interrupt is raised assuming CAEIE is set to ‘1’ in DMA2D_CR.

- Manual loading
  
The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format is 24 or 32 bits. It is configured through the CCM bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) as shown in Table 145: Supported CLUT color mode.

<table>
<thead>
<tr>
<th>CCM</th>
<th>CLUT color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>32-bit ARGB8888</td>
</tr>
<tr>
<td>1</td>
<td>24-bit RGB888</td>
</tr>
</tbody>
</table>

The way the CLUT data are organized in the system memory is specified in Table 146: CLUT data order in system memory.

<table>
<thead>
<tr>
<th>CLUT Color Mode</th>

<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
</table>

19.3.6 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel. The blending is performed according to the following equation:

\[
\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}
\]

\[
C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{Mult}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with} \ C = R \text{ or } G \text{ or } B
\]

*Division is rounded to the nearest lower integer*

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[2:0] field of the DMA2D_CR register.
19.3.7 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D_OPFCCR).

The supported output formats are given in Table 147: Supported color mode in output.

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>001</td>
<td>RGB888</td>
</tr>
<tr>
<td>010</td>
<td>RGB565</td>
</tr>
<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the calculated alpha value is inverted setting the AI bit of the DMA2D_OPFCCR registers. This applies also to the Alpha value used in the DMA2D_OCOLR.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_OPFCCR registers. This applies also to the RGB order used in the DMA2D_OCOLR.

19.3.8 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:
- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D_OPFCCR register.

The data are stored into the memory in the order defined in Table 148: Data order in memory.

<table>
<thead>
<tr>
<th>Color Mode</th>
<th>@ + 3</th>
<th>@ + 2</th>
<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGB8888</td>
<td>A0[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td>RGB565</td>
<td>G2[7:0]</td>
<td>B3[7:0]</td>
<td>R1[7:0]</td>
<td>G1[7:0]</td>
</tr>
<tr>
<td>RGB565</td>
<td>R3[7:0]</td>
<td>G3[7:0]</td>
<td>B3[7:0]</td>
<td>R2[7:0]</td>
</tr>
</tbody>
</table>
The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

### 19.3.9 DMA2D output FIFO byte reordering

The output FIFO bytes is reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
- RBS bit to swap Red and Blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB field of the DMA2D_OPFCR is set), the number of pixel per line (PL field of the DMA2D_NLR) must be even and the output memory address (MA field of the DMA2D_OMAR) must be even, and the output line offset computed in bytes (resulting from LOM field of DMA2D_CR and LO field of DMA2D_OOR values) must be even. If not a configuration error is detected.

### 16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.
18/24-bit mode (RGB888)

This mode needs data reordering.
1. The Red and the Blue have to be swapped (setting the RBS bit)
2. The MSB and the LSB bytes of a half-word as to be swapped (setting the SB bit)

19.3.10 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D_AMPTCR).
19.3.11 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:

1. Data loading from the memory location pointed by the DMA2D_FGMAR register and pixel format conversion as defined in DMA2D_FGCR.
2. Data loading from a memory location pointed by the DMA2D_BGMAR register and pixel format conversion as defined in DMA2D_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D_OCR register and programming of the data to the memory location addressed through the DMA2D_OMAR register.

19.3.12 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[2:0] bits of the DMA2D_CR register:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in the DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D_OCOLR register to the area located at the address pointed by the DMA2D_OMAR and defined in the DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D_FGMAR to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.
Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into the DMA2D_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value is added or changed depending on the value programmed in the DMA2D_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value is modified according to the AM[1:0] bits of the DMA2D_FGPFCCR register:

- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR.
The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

$$\text{Mult} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \text{Mult}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \text{Mult}}{\alpha_{\text{OUT}}} \quad \text{with } C = \text{R or G or B}$$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color FG**

In this mode, only 1 source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by the DMA2D_FGCOLR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_FGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color BG**

In this mode, only 1 source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by the DMA2D_BGCOLR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.
Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Configuration error detection**

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D_CR is set.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D_FGCMAR are not aligned with CCM of DMA2D_FGPFCR.
- Background CLUT automatic loading: MA bits of DMA2D_BGCMAR are not aligned with CCM of DMA2D_BGPFCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_FGMAR are not aligned with CM of DMA2D_FGPFCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): CM bits of DMA2D_FGPFCR are invalid.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): PL bits of DMA2D_NLR are odd while CM of DMA2D_FGPFCR is A4 or L4.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): LO bits of DMA2D_FGOR are odd while CM of DMA2D_FGPFCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_BGMAR are not aligned with the CM of DMA2D_BGPFCR.
- Memory transfer: (only in blending mode and in blending with fixed color FG mode) CM bits of DMA2D_BGPFCR are invalid.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): PL bits of DMA2D_NLR odd while CM of DMA2D_BGPFCR is A4 or L4.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): LO bits of DMA2D_BGOR are odd while CM of DMA2D_BGPFCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (except in memory to memory mode): MA bits of DMA2D_OMAR are not aligned with CM bits of DMA2D_OPFCR.
- Memory transfer (except in memory to memory mode): CM bits of DMA2D_OPFCR are invalid.
- Memory transfer with byte swapping: PL bits of DMA2D_NLR are odd or MA bits of the DMA2D_OMAR are odd or LO in bytes (resulting from LOM bit of the DMA2D_CR and LO bits of DMA2D_OOR values) are odd while SB bit of DMA2D_OPFCR is set.
- Memory transfer: NL bits of DMA2D_NLR = 0.
• Memory transfer: PL bits of DMA2D_NLR = 0
• Memory transfer: MODE bits of DMA2D_CR are invalid

19.3.13 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D_CR register or can be restarted by resetting the SUSP bit of the DMA2D_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using the ABORT or the SUSP bit of the DMA2D_CR register.

19.3.14 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D_CR is set.

19.3.15 Error management

Two kinds of errors can be triggered:
• AHB master port errors signaled by the TEIF flag of the DMA2D_ISR register.
• Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signalled by the CAEIF flag of the DMA2D_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D_CR register to generate an interrupt if need be (TEIE and CAEIE).

19.3.16 AHB dead time

To limit the AHB bandwidth usage, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D is running is taken into account for the next AHB transfer.
19.4 DMA2D interrupts

An interrupt can be generated on the following events:
- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]:** DMA2D mode

These bits are set and cleared by software. They cannot be modified while a transfer is ongoing.
- 000: Memory-to-memory (FG fetch only)
- 001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
- 010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
- 011: Register-to-memory (no FG nor BG, only output stage active)
- 100: Memory-to-memory with Blending and fixed color FG (BG fetch only with FG and BG PFC active)
- 101: Memory-to-memory with Blending and fixed color BG (BG fetch only with FG and BG PFC active)
- others: meaningless

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE:** Configuration Error Interrupt Enable

This bit is set and cleared by software.
- 0: CE interrupt disable
- 1: CE interrupt enable

Bit 12 **CTCIE:** CLUT transfer complete interrupt enable

This bit is set and cleared by software.
- 0: CTC interrupt disable
- 1: CTC interrupt enable

Bit 11 **CAEIE:** CLUT access error interrupt enable

This bit is set and cleared by software.
- 0: CAE interrupt disable
- 1: CAE interrupt enable

Bit 10 **TWIE:** Transfer watermark interrupt enable

This bit is set and cleared by software.
- 0: TW interrupt disable
- 1: TW interrupt enable
Bit 9  TCIE: Transfer complete interrupt enable
   This bit is set and cleared by software.
   0: TC interrupt disable
   1: TC interrupt enable

Bit 8  TEIE: Transfer error interrupt enable
   This bit is set and cleared by software.
   0: TE interrupt disable
   1: TE interrupt enable

Bit 7  Reserved, must be kept at reset value.

Bit 6  LOM: Line Offset Mode
   This bit configures how is expressed the line offset (pixels or bytes) for the foreground, background and output.
   This bit is set and cleared by software. It can not be modified while a transfer is on going.
   0: Line offsets are expressed in pixels
   1: Line offsets are expressed in bytes

Bits 5:3  Reserved, must be kept at reset value.

Bit 2  ABORT: Abort
   This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.
   0: No transfer abort requested
   1: Transfer abort requested

Bit 1  SUSP: Suspend
   This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.
   0: Transfer not suspended
   1: Transfer suspended

Bit 0  START: Start
   This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
   - At the end of the transfer
   - When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D_CR
   - When a data transfer error occurs
   - When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).
### 19.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x0004  
Reset value: 0x0000 0000

<table>
<thead>
<tr>

| Bit 5     | **CEIF**: Configuration error interrupt flag  
This bit is set when the START bit of DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCRCR is set and a wrong configuration has been programmed. |
| Bit 4     | **CTCIF**: CLUT transfer complete interrupt flag  
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete. |
| Bit 3     | **CAEIF**: CLUT access error interrupt flag  
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D. |
| Bit 2     | **TWIF**: Transfer watermark interrupt flag  
This bit is set when the last pixel of the watermarked line has been transferred. |
| Bit 1     | **TCIF**: Transfer complete interrupt flag  
This bit is set when a DMA2D transfer operation is complete (data transfer only). |
| Bit 0     | **TEIF**: Transfer error interrupt flag  
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading). |

Bits 31:24 **ALPHA[7:0]:** Alpha value  
These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.  
These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS:** Red Blue Swap  
This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.  
0: Regular mode (RGB or ARGB)  
1: Swap mode (BGR or ABGR)

Bit 20 **AI:** Alpha Inverted  
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.  
0: Regular alpha  
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]:** Alpha mode  
These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.  
00: No modification of the foreground image alpha channel value  
01: Replace original foreground image alpha channel value by ALPHA[7:0]  
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value  
other configurations are meaningless

Bits 15:8 **CS[7:0]:** CLUT size  
These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.  
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **START**: Start
This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM**: CLUT color mode
This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
others: meaningless

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
others: meaningless

</table>

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value  
These bits defines the red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 15:8 **GREEN[7:0]**: Green value  
These bits defines the green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0 **BLUE[7:0]**: Blue value  
These bits defines the blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.
19.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x0024

Bits 31:24 ALPHA[7:0]: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1:0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 RBS: Red Blue Swap
This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 AI: AI: Alpha Inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 AM[1:0]: Alpha mode
These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7:0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
others: meaningless

Bits 15:8 CS[7:0]: CLUT size
These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **START:** Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic foreground CLUT transfer).

Bit 4 **CCM:** CLUT Color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
others: meaningless

Bits 3:0 **CM[3:0]: Color mode**

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
others: meaningless
19.5.11  DMA2D background color register (DMA2D_BGCOLR)

Address offset: 0x0028
Reset value: 0x0000 0000

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **RED[7:0]**: Red value

These bits define the red value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 15:8  **GREEN[7:0]**: Green value

These bits define the green value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0  **BLUE[7:0]**: Blue value

These bits define the blue value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

19.5.12  DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Bits 31:0 **MA[31:0]**: Memory address  
Address of the data used for the CLUT address dedicated to the foreground image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.  
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue Swap
This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha

Bits 19:10  Reserved, must be kept at reset value.

Bit 9 **SB**: Swap bytes
When set, the bytes in the output FIFO are swapped two by two.
When this bit is set, the number of pixel per line (PL) must be even, and the output memory address (OMAR) must be even.
This register can only be written when the transfer is disabled. Once the transfer has started, this register is read-only.
0: Bytes in regular order in the output FIFO
1: Bytes are swapped two by two in the output FIFO

Bits 8:3  Reserved, must be kept at reset value.

Bits 2:0  **CM[2: 0]**: Color mode
These bits define the color format of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB8888 or RGB888 color mode

Bits 31:24 \( \text{ALPHA}[7:0] \): Alpha channel value in ARGB8888 mode otherwise reserved
These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16 \( \text{RED}[7:0] \): Red value in ARGB8888 or RGB888 mode otherwise reserved
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 \( \text{GREEN}[7:0] \): Green value in ARGB8888 or RGB888
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 \( \text{BLUE}[7:0] \): Blue value in ARGB8888 or RGB888
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

RGB565 color mode

Bits 15:11 \( \text{RED}[4:0] \): Red value in RGB565 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 12:5 \( \text{GREEN}[5:0] \): Green value in RGB565 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0 \( \text{BLUE}[4:0] \): Blue value in RGB565 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB1555 color mode

Bit 15 \( A \): Alpha channel value in ARGB1555 mode
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.

Bits 14:10 \( \text{RED}[4:0] \): Red value in ARGB1555 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 9:5 \( \text{GREEN}[4:0] \): Green value in ARGB1555 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0 \( \text{BLUE}[4:0] \): Blue value in ARGB1555 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB4444 color mode

Bits 15:12 \( \text{ALPHA}[3:0] \): Alpha channel value in ARGB4444
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.
Bits 11:8 **RED[3:0]**: Red value in ARGB4444 mode
- These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:4 **GREEN[3:0]**: Green value in ARGB4444 mode
- These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 3:0 **BLUE[3:0]**: Blue value in ARGB4444 mode
- These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

19.5.18 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x0044
Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 PL[13:0]: Pixel per lines
Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 NL[15:0]: Number of lines
Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

19.5.19 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x0048
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LW[15:0]: Line offset
The line offset used for the output expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.
When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.
19.5.20 DMA2D AHB master timer configuration register (DMA2D_AMTCR)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DT[7:0]: Dead Time
Dead time value in the AHB clock cycle inserted between two consecutive accesses on the AHB master port. These bits represent the minimum guaranteed number of cycles between two consecutive AHB accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 EN: Enable
Enables the dead time functionality.
19.5.22 DMA2D background CLUT (DMA2D_BGCLUT[y])

Address offset: 0x0800 + 4*<y>, y=0..255
Reset value: 0xXXXX XXXX

Bits 31:24 **ALPHA<y>[7:0]**: Alpha <y>
Alpha value for index <y> for the background.

Bits 23:16 **RED<y>[7:0]**: Red <y>
Red value for index <y> for the background.

Bits 15:8 **GREEN<y>[7:0]**: Green <y>
Green value for index <y> for the background.

Bits 7:0 **BLUE<y>[7:0]**: Blue <y>
Blue value for index <y> for the background.
### DMA2D register map

The following table summarizes the DMA2D registers.

Table 152. DMA2D register map and reset values

| Offset  | Register     | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|---------|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x0000  | DMA2D_CR     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         |              |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         | DMA2D_ISR    |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         |              |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|         | DMA2D_IFCR   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to Section 2.3 on page 116 for the register boundary addresses.
20 Nested vectored interrupt controller (NVIC)

20.1 NVIC main features

- 125 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and non-secure states.

All interrupts including the core exceptions are managed by the NVIC.

20.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, the following SysTick timers are available:
- SysTick, secure instance
- SysTick, non-secure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK
  reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8)
  reload value = ((HCLK/8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

SysTick reload value = (100 x STCALIB) - 1 = 0x1869F
### 20.3 Interrupt and exception vectors

The grey rows in the table below describe the vectors without specific position.

21 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wakeup through configurable event inputs. It provides wakeup requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wakeup requests allow the system to be woken up from Stop modes. The interrupt request and event request generation can be used also in Run modes. The EXTI also includes the EXTI mux IO port selection.

21.1 EXTI main features

The EXTI main features are the following:
- 23 input events supported
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wakeup flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wakeup event.

The configurable events have the following features:
- Selectable active trigger edge
- Interrupt pending status register bits independent for the rising and falling edge
- Individual interrupt and event generation mask, used for conditioning the CPU wakeup, interrupt and event generation
- Software trigger possibility
- Secure events: The access to control and configuration bits of secure input events can be made secure and or privilege.
- EXTI IO port selection

21.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in Figure 88.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

21.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wakeup or interrupt events when the system is in Stop mode, are connected to the EXTI.

- Peripheral wakeup signals that generate a pulse or do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit that requires to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wakeup signals are connected to the PWR and are used to wake up the system and the CPU sub-system bus clocks.

21.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

21.3 EXTI functional description

The events features are controlled from register bits as follows:

- Active trigger edge enable
  - by rising edge selection in the EXTI rising trigger selection register (EXTI_RTSR1)
  - by falling edge selection in the EXTI falling trigger selection register (EXTI_FTSR1)
- Software trigger in the EXTI software interrupt event register (EXTI_SWIER1)
- Interrupt pending flag in the EXTI rising edge pending register (EXTI_RPR1)
  EXTI falling edge pending register (EXTI_FPR1)
- CPU wakeup and interrupt enable in the EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)
- CPU wakeup and event enable
  EXTI CPU wakeup with interrupt mask register (EXTI_IMR1)

21.3.1 EXTI configurable event input wakeup

The figure below is a detailed representation of the logic associated with configurable event inputs that wake up the CPU sub-system bus clocks and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wakeup event.

**Figure 89. Configurable event trigger logic CPU wakeup**

1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wakeup (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.
The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wakeup (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.

21.3.2 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wakeup. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The selection of GPIO port as EXTI mux output is controlled in the EXTI external interrupt selection register (EXTI_EXTICRn) (n = 1 to 4).

Figure 90. EXTI mux GPIO selection

The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

21.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wakeup generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 157. Masking functionality

<table>
<thead>
<tr>
<th>CPU interrupt enable (in EXTI_IMR.IMn)</th>
<th>CPU event enable (in EXTI_EMR.EMn)</th>
<th>Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)</th>
<th>Exti(n) interrupt(1)</th>
<th>CPU event</th>
<th>CPU wakeup</th>
</tr>
</thead>
<tbody>
<tr>

<td>0</td>
<td>No</td>
<td>Masked</td>
<td>Masked</td>
<td>Masked</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>No</td>
<td>Masked</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set: the CPU sub-system is woken up and the CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn pending bits must be cleared by software writing it to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

### 21.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by non-secure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:
- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

<table>
<thead>
<tr>

<td>Always privilege. Security can be bit-wise enabled in EXTI_SECCFGR.</td>
</tr>
</tbody>
</table>

---

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. Only if CPU interrupt is enabled in EXTI_IMR.IMn.
When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A non-secure write access is discarded and a read returns 0.

When input events are non-secure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and non-secure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

21.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in registers EXTI_PRIVCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

21.6 EXTI registers

The EXTI register map is divided in the following sections:

Table 159. EXTI register map sections

</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 RTx: Rising trigger event configuration bit of configurable event input x\(^{(1)}\) (x = 22 to 0)

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with non-secure and secure access.

When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access.

Non-secure write to this bit x is discarded and non-secure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access.

Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

---

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.

If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.

Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

21.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Contains only register bits for configurable events.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **SWIx**: Software interrupt on event x (x = 22 to 0)

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access.
Non-secure write to this SWIx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access.
Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

0: Writing 0 has no effect.
1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.
## 21.6.4 EXTI rising edge pending register (EXTI_RPR1)

814/3040 RM0456 Rev 1
Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **FPIFx**: configurable event inputs x falling edge pending bit (x = 22 to 0)

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access.
Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can only be accessed with privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access.
Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

### 21.6.6 EXTI security configuration register (**EXTI_SECCFGR1**)  

Address offset: 0x014  
Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for security capable input events.

Table 160. EXTI register map and reset values
Refer to Section 2.3 for the register boundary addresses.
22 Cyclic redundancy check calculation unit (CRC)

22.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

22.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[ X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1 \]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes
22.3 CRC functional description

</tbody>
</table>

22.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.
Cyclic redundancy check calculation unit (CRC) RM0456

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register. The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

*Note:* The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size cannot be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
22.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

22.4.1 CRC data register (CRC_DR)

Refer to Section 2.3 on page 116 for the register boundary addresses.
23 CORDIC co-processor (CORDIC)

23.1 CORDIC introduction

The CORDIC co-processor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making it possible the use of a lower operating frequency, or freeing up processor cycles in order to perform other tasks.

23.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

23.3 CORDIC functional description

23.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle \( \theta \) are determined by rotating the unit vector \([1, 0]\) through decreasing angles until the cumulative sum of the rotation angles equals the input angle \( \theta \). The \( x \) and \( y \) cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of \( \theta \). Inversely, the angle of a vector \([x, y]\) corresponding to arctangent \((y / x)\), is determined by rotating \([x, y]\) through successively decreasing angles to obtain the unit vector \([1, 0]\). The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

23.3.2 CORDIC functions

The first step when using the co-processor is to select the required function, by programming the FUNC field of the CORDIC_CR register accordingly.
Table 163 lists the functions supported by the CORDIC co-processor.

</tbody>
</table>

Several functions take two input arguments (ARG1 and ARG2) and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: \( \sin \theta \) also generates \( \cos \theta \), \( \cos \theta \) also generates \( \sin \theta \). Similarly for rectangular-to-polar conversion (phase\( (x,y) \), modulus\( (x,y) \)) and for hyperbolic functions (\( \cosh \theta \), \( \sinh \theta \)).

**Note:** The exponential function, \( \exp x \), can be obtained as the sum of \( \sinh x \) and \( \cosh x \).
Furthermore, base \( N \) logarithms, \( \log_N x \), can be derived by multiplying \( \ln x \) by a constant \( K \), where \( K = 1/\ln N \).

For certain functions (atan, log, sqrt) a scaling factor (see Section 23.3.4) can be applied to extend the range of the function beyond the maximum \([-1, 1]\) supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

**Cosine**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

</tbody>
</table>
This function calculates the cosine of an angle in the range \(-\pi\) to \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

### Sine

This function calculates the sine of an angle in the range \(-\pi\) to \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

### Phase

This function calculates the phase of an angle in the range \(-\pi\) to \(\pi\). It can also be used to perform polar to rectangular conversion.

The primary argument is the angle \(\theta\) in radians. It must be divided by \(\pi\) before programming ARG1.

The secondary argument is the modulus \(m\). If \(m\) is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle \(\theta\), divided by \(\pi\).

The secondary result, RES2, is the cos of the angle, multiplied by the modulus.

</tr>
<tr>
<td>RES1</td>
<td>Phase angle (\theta) in radians, divided by (\pi)</td>
<td>([-1, 1])</td>
</tr>
</tbody>
</table>
This function calculates the phase angle in the range $-\pi$ to $\pi$ of a vector $v = [x \ y]$ (also known as $\text{atan2}(y,x)$). It can also be used to perform rectangular to polar conversion.

The primary argument is the $x$ coordinate, that is, the magnitude of the vector in the direction of the $x$ axis. If $|x| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the $y$ coordinate, that is, the magnitude of the vector in the direction of the $y$ axis. If $|y| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle $\theta$ of the vector $v$. RES1 must be multiplied by $\pi$ to obtain the angle in radians. Note that values close to $\pi$ may sometimes wrap to $-\pi$ due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If $|v| > 1$ the result in RES2 is saturated to 1.

### Modulus

This function calculates the magnitude, or modulus, of a vector $v = [x \ y]$. It can also be used to perform rectangular to polar conversion.

The primary argument is the $x$ coordinate, that is, the magnitude of the vector in the direction of the $x$ axis. If $|x| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the $y$ coordinate, that is, the magnitude of the vector in the direction of the $y$ axis. If $|y| > 1$, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If $|v| > 1$ the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle $\theta$ of the vector $v$. RES2 must be multiplied by $\pi$ to obtain the angle in radians. Note that values close to $\pi$ may sometimes wrap to $-\pi$ due to the circular nature of the phase angle.
**Arctangent**

This function calculates the arctangent, or inverse tangent, of the input argument \( x \).

The primary argument, **ARG1**, is the input value, \( x = \tan \theta \). If \(|x| > 1\), a scaling factor of \( 2^{-n} \) must be applied in software such that \(-1 < x \cdot 2^{-n} < 1\). The scaled value \( x \cdot 2^{-n} \) is programmed in ARG1 and the scale factor \( n \) must be programmed in the SCALE parameter.

Note that the maximum input value allowed is \( \tan \theta = 128 \), which corresponds to an angle \( \theta = 89.55 \) degrees. For \(|x| > 128\), a software method must be used to find \( \tan^{-1} x \).

The secondary argument, **ARG2**, is unused.

The primary result, **RES1**, is the angle \( \theta = \tan^{-1} x \). RES1 must be multiplied by \( 2^n \cdot \pi \) to obtain the angle in radians.

The secondary result, **RES2**, is unused.

**Hyperbolic cosine**

This function calculates the hyperbolic cosine of a hyperbolic angle \( x \). It can also be used to calculate the exponential functions \( e^x = \cosh x + \sinh x \), and \( e^{-x} = \cosh x - \sinh x \).

The primary argument is the hyperbolic angle \( x \). Only values of \( x \) in the range \(-1.118\) to \(+1.118\) are supported. Since the minimum value of \( \cosh x \) is \( 1 \), which is beyond the range of the q1.31 format, a scaling factor of \( 2^n \) must be applied in software. The factor \( n = 1 \) must be programmed in the SCALE parameter.

The secondary argument is not used.

<td>RES2</td>
<td>Not applicable</td>
<td>-</td>
</tr>
<tr>
<td>SCALE</td>
<td>$n$</td>
<td>[0 2]</td>
</tr>
</tbody>
</table>

This function calculates the square root of the input argument $x$.

The primary argument is the input value $x$. Only values of $x$ in the range 0.027 to 2.34 are supported. The value $x$ must be scaled by a factor $2^n$, such that $x \cdot 2^n < (1 - 2^{-(n+2)})$.

The scaled value $x \cdot 2^n$ is programmed in ARG1 and the factor $n$ must be programmed in the SCALE parameter.

Table 175 lists the valid scaling factors, $n$, and the corresponding ranges of $x$ and ARG1.

Table 175. Square root scaling factors and corresponding ranges

<table>
<thead>
<tr>
<th>$n$</th>
<th>$x$ range</th>
<th>ARG1 range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$0.027 \leq x &lt; 0.75$</td>
<td>$0.027 \leq \text{ARG1} &lt; 0.75$</td>
</tr>
<tr>
<td>1</td>
<td>$0.75 \leq x &lt; 1.75$</td>
<td>$0.375 \leq \text{ARG1} &lt; 0.875$</td>
</tr>
<tr>
<td>2</td>
<td>$1.75 \leq x \leq 2.341$</td>
<td>$0.4375 \leq \text{ARG1} \leq 0.585$</td>
</tr>
</tbody>
</table>

The secondary argument is not used.

The primary result is the square root of $x$. RES1 must be multiplied by $2^n$ to obtain the correct value.

The secondary result is not used.

23.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore $-1 (0x80000000)$ to $1 - 2^{-31} (0x7FFFFFFFFFFF)$.

In q1.15 format, the numeric range is $1 (0x8000)$ to $1 - 2^{-15} (0x7FFF)$. This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

23.3.4 Scaling factor

Several of the functions listed in Section 23.3.2 specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output or internal registers. If the scaling factor is
required, it has to be calculated in software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

23.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see Figure 92.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see Figure 93). The square root function converges at roughly twice the speed of the hyperbolic functions (see Figure 94).

Figure 92. CORDIC convergence for trigonometric functions
Figure 93. CORDIC convergence for hyperbolic functions
The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in Table 176, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The co-processor stops as soon as the programmed number of iterations has completed, and the result can be read immediately.

Table 176. Precision vs. number of iterations

</tbody>
</table>
The fastest way to use the co-processor is to pre-program the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable. Subsequently, a calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished) a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to re-program the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument, ARG1, must be written first, followed by the secondary argument, ARG2. If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

</table>

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.

2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.

3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.

4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.
Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait states until the calculation is completed, before returning the result. Hence it is possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation and prepare the next input data, if needed. The CORDIC_CSR register can be re-programmed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous arguments have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed in order to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be one calculation in progress, or waiting for the results to be read, and one operation pending. Any further access to CORDIC_WDATA while an operation is pending, cancels the pending operation and overwrite the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:
1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step 3.

### 23.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. However the processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (e.g. if low latency interrupts must be serviced).
23.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

23.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. Note that the sequence is started by the processor setting the DMAWEN flag. Thereafter the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generate a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore only useful when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.
Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and could block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

23.4 CORDIC registers

The CORDIC registers can only be accessed in 32-bit word format

23.4.1 CORDIC control/status register (CORDIC_CSR)

Bit 31 RRDY: Result ready flag
0: No new result in output register
1: CORDIC_RDATA register contains new data.
This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.
When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 ARGSIZE: Width of input data
0: 32-bit
1: 16-bit
ARGSIZE selects the number of bits used to represent input data.
If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.
If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format.
The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 RESSIZE: Width of output data
0: 32-bit
1: 16-bit
RESSIZE selects the number of bits used to represent output data.
If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.
If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.
Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register
- 0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
- 1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
  Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register
- 0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
- 1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
  Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
- 0: Disabled. No DMA write requests are generated.
- 1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending.
  This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
- 0: Disabled. No DMA read requests are generated.
- 1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
  This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt
- 0: Disabled. No interrupt requests are generated.
- 1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
  This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to Section 23.3.2 for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 PRECISION[3:0]: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to Table 176.
Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 FUNC[3:0]: Function
0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square Root
10 to 15: reserved

Bits 10:8 SCALE[2:0]: Scaling factor
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to Table 176.

Bits 7:4 PRECISION[3:0]: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to Table 176.
Note that for most functions, the recommended range for this field is 3 to 6.
Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 23.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

Bits 31:0  **RES[31:0]**: Function result
If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.
If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.
If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed. A read from this register resets the RRDY flag in the CORDIC_CSR register.

23.4.4  CORDIC register map

Refer to *Section 2.3* for the register boundary addresses.
24 Filter math accelerator (FMAC)

24.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

24.2 FMAC main features

- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels
24.3 Filter math accelerator (FMAC)

24.3.1 General description

The FMAC is shown in Figure 95.

Figure 95. Block diagram

The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in Section 24.3.6: Filter functions.
24.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (Section 24.3.5: Initialization functions) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in Section 24.3.6: Filter functions. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.

There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level should be chosen according to the application performance requirements. For maximum throughput, the input buffer should never go empty, so d should be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

24.3.3 Input buffers

The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.
The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.
The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) should generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. Figure 97 illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.

The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.
Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in Figure 98. This example shows an 8-tap FIR filter with a watermark set to four.

### Figure 98. Circular input buffer operation

Filter using eight samples \(x[n-7]\) to \(x[n]\)

Filter finishes current output sample and starts using next sample in buffer freeing up a space, since oldest sample is no longer needed. No new samples available, so buffer empty flag is set.

Four new samples written into buffer. Write pointer is incremented by 4. If write pointer reaches the end of the buffer space it wraps to the beginning. Number of free spaces left in buffer is less than watermark, so buffer full flag is set.

Buffer empty flag is reset, so filter continues with next sample

#### 24.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.
The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, \( y[n-M] \) to \( y[n-1] \), used for calculating the next output sample \( y[n] \). Each time a new sample is added to the set, the least recent sample \( y[n-M] \) drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in Figure 100. This example shows a 7-tap IIR filter with a watermark set to four.
**Initialization functions**

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

**Load X1 buffer**

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

**Parameters**

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.
Load X2 buffer

This function pre-loads the X2 buffer with \(N + M\) values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the \(N\) feed-forward and \(M\) feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to \(N + M\). For an FIR, there are no feedback coefficients, so \(M = 0\).

**Parameters**

- The parameter \(P\) contains the number of values, \(N\), to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter \(Q\) contains the number of values, \(M\), to be loaded into the X2 buffer starting from address X2_BASE + \(N\).
- The parameter \(R\) is not used.

The function completes when \(N + M\) writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with \(N\) values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + \(N\) when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

**Parameters**

- The parameter \(P\) contains the number of values to be loaded into the Y buffer.
- The parameters \(Q\) and \(R\) are not used.

The function completes when \(N\) writes have been performed to the FMAC_WDATA register.

---

**24.3.6 Filter functions**

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

**Convolution (FIR filter)**

\[ Y = B \ast X \]

\[ y_n = 2^R \sum_{k=0}^{N} b_k x_{n-k} \]

This function performs a convolution of a vector \(B\) of length \(N+1\) and a vector \(X\) of indefinite length. The elements of \(Y\) for incrementing values of \(n\) are calculated as the dot product,
$y_n = \mathbf{B} \mathbf{X}_n$, where $\mathbf{X}_n = [x_{n-N},...,x_n]$ is composed of the N+1 elements of $\mathbf{X}$ at indexes $n - N$ to $n$.

This function corresponds to a finite impulse response (FIR) filter, where vector $\mathbf{B}$ contains the filter coefficients and vector $\mathbf{X}$ the sampled data.

The structure of the filter (direct form) is shown in Figure 101.

**Figure 101. FIR filter structure**

Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector $\mathbf{B}$.

**Input:**
- $X1$ buffer contains the elements of vector $\mathbf{X}$. It is a circular buffer of length $N + 1 + d$.
- $X2$ buffer contains the elements of vector $\mathbf{B}$. It is a fixed buffer of length $N + 1$.

**Output:**
- $Y$ buffer contains the output values, $y_n$. It is a circular buffer of length $d$. 
Parameters:

- The parameter P contains the length, N+1, of the coefficient vector \( B \) in the range \([2:127]\).
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by \( 2^R \), where R is in the range \([0:7]\).
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.

IIR filter

\[ Y = B^\top X + A^\top Y' \]

\[ y_n = 2^R \cdot \left( \sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right) \]

This function implements an infinite impulse response (IIR) filter. The filter output vector \( Y \) is the convolution of a coefficient vector \( B \) of length N+1 and a vector \( X \) of indefinite length, plus the convolution of the delayed output vector \( Y' \) with a second coefficient vector \( A \) of length M. The elements of \( Y \) for incrementing values of \( n \) are calculated as \( y_n = B^\top X_n + A^\top Y_{n-1} \), where \( X_n = [x_{n-N}, \ldots, x_n] \) comprises the N+1 elements of \( X \) at indexes n - N to n, while \( Y_{n-1} = [y_{n-M}, \ldots, y_{n-1}] \) comprises the M elements of \( Y \) at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in Figure 102.
Input:
- X1 buffer contains the elements of vector X. It is a circular buffer of length N + 1 + d.
- X2 buffer contains the elements of coefficient vectors B and A concatenated (b₀, b₁, b₂..., bₙ, a₁, a₂, ..., aₘ). It is a fixed buffer of length M+N+1.

Output:
- Y buffer contains the output values, yₙ. It is a circular buffer of length M + d.

Parameters
- The parameter P contains the length, N + 1, of the coefficient vector B in the range [2:64].
- The parameter Q contains the length, M, of the coefficient vector A in the range [1:63].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7].
The function completes when the START bit in the FMAC_PARAM register is reset by software.

### 24.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15. In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2\(^{-15}\) (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2\(^{-15}\) or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

### 24.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers should be configured as follows:

- **X1_BUF_SIZE** = N + d1;
- **X2_BUF_SIZE** = N;
- **Y_BUF_SIZE** = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration could be:

- **X2_BASE** = 0;
- **X1_BASE** = N;
- **Y_BASE** = 2N + d1
However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

**Note:** The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to \(\log_2(d1)\), otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to \(\log_2(d2)\).

The filter coefficients must be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register should be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- **Polling:** No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- **Interrupt:** The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- **DMA:** DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation\(^a\). The valid combinations are listed in **Table 178**.

**Table 178. Valid combinations for read and write methods**

</tbody>
</table>

\(^a\) If both interrupts and DMA requests are enabled then only DMA should perform the transfer.
The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- **FUNC** = 8 (FIR filter);
- **P** = N (number of coefficients);
- **Q** = “Don’t care”;
- **R** = Gain;
- **START** = 1;

If less than \(N + d - 2^{\text{FULL_WM}}\) values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write \(2^{\text{FULL_WM}}\) additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine should check the X1FULL flag after every \(2^{\text{FULL_WM}}\) writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When \(2^{\text{EMPTY_WM}}\) output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read \(2^{\text{EMPTY_WM}}\) samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine should check the YEMPTY flag after every \(2^{\text{EMPTY_WM}}\) reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

### 24.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length \(N\), where \(N\) is the number of feed-forward taps or coefficients. The number of feedback coefficients, \(M\), can be any value from 1 to \(N-1\). Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with \(N\) feed-forward coefficients and \(M\) feed-back coefficients is \(2N + 2M\):

- **N + M coefficients**
- **N input samples**
- **M output samples**

If \(M = N-1\), then the maximum filter length that can be implemented is \(N = 64\).

As for the FIR, for maximum throughput a small amount of additional space, \(d1\) and \(d2\), should be allowed in the input and output buffer size respectively, making the total memory requirement \(2M + 2N + d1 + d2\).

The buffers must be configured as follows:

- **X1_BUF_SIZE** = \(N + d1\);
- **X2_BUF_SIZE** = \(N + M\);
- **Y_BUF_SIZE** = \(M + d2\);
The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- \( \text{X2\_BASE} = 0 \);
- \( \text{X1\_BASE} = N + M \);
- \( \text{Y\_BASE} = 2N + M + d1 \);

**Note:** The \( \text{FULL\_WM} \) bitfield of X1 buffer configuration register must be programmed with a value less than or equal to \( \log_2(d1) \), otherwise the buffer is flagged full before \( N \) input samples have been written, and no more samples are requested. Similarly, the \( \text{EMPTY\_WM} \) bitfield of the Y buffer configuration register must be less than or equal to \( \log_2(d2) \).

The filter coefficients (N feed-forward followed by M feedback) **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of \( N \). The Y buffer can optionally be pre-loaded with any number of values up to a maximum of \( M \). This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC\_CR register should be programmed in the same way as for the FIR filter (see Section 24.3.8: Implementing FIR filters with the FMAC).

The filter is started by writing to the FMAC\_PARAM register with the following bitfield values:

- \( \text{FUNC} = 9 \) (IIR filter);
- \( \text{P} = N \) (number of feed-forward coefficients);
- \( \text{Q} = M \) (number of feed-back coefficients);
- \( \text{R} = \text{Gain} \);
- \( \text{START} = 1 \);

If less than \( N + d - 2^{\text{FULL\_WM}} \) values have been pre-loaded in the X1 buffer, the X1\FULL\_flag remains low. If the WIEN bit is set in the FMAC\_CR register, then the interrupt request is asserted immediately to request the processor to write \( 2^{\text{FULL\_WM}} \) additional samples into the buffer, via the FMAC\_WDATA register. It remains asserted until the X1\FULL\_flag goes high in the FMAC\_SR register. The interrupt service routine should check the X1\FULL\_flag after every \( 2^{\text{FULL\_WM}} \) writes to the FMAC\_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMA\_WEN bit is set in the FMAC\_CR register, DMA write channel requests are generated until the X1\FULL\_flag goes high.

The filter calculates the first output sample when at least \( N \) samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first \( N \) samples in the X1 buffer, and the first \( M \) samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at \( \text{Y\_BASE} + M \). When \( 2^{\text{EMPTY\_WM}} \) new output samples have been written into the Y buffer, the Y\EMPTY\_flag in the FMAC\_SR register goes low. If the RIEN bit is set in the FMAC\_CR register, the interrupt request is asserted to request the processor to read \( 2^{\text{EMPTY\_WM}} \) samples from the buffer, via the FMAC\_RDATA register. It remains asserted until the Y\EMPTY\_flag goes high. The interrupt service routine should check the Y\EMPTY\_flag after every \( 2^{\text{EMPTY\_WM}} \) reads from the FMAC\_RDATA register, and repeat the transfer until the flag goes high. If the DMA\_REN bit is set in the FMAC\_CR, DMA read channel requests are generated until the Y\EMPTY\_flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.
24.3.10 Examples of filter initialization

Figure 103. X1 buffer initialization

The example in Figure 103 illustrates a X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.
### 24.3.11 Examples of filter operation

The example in **Figure 104** illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in **Figure 103**. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.

In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

**Note:** In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the...
Filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size would not help.

**Figure 105. Filtering example 2**

The example in Figure 105 illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in Figure 103. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.
24.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms should be converted to direct form 1.

2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.

3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients’ absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is “undone” before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.

4. The IIR filter has feed-forward (numerator) coefficients \([b_0, b_1, ..., b_{N-1}]\), and feed-back (denominator) coefficients \([1, a_1, ..., a_M]\). Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor \(2^R\), such that \(2^{-R}[1, a_1, ..., a_M]\) are all less than 1, such filters can be implemented. However an inverse gain of \(2^R\) must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.
## 24.4 FMAC registers

### 24.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00  
Reset value: 0x0000 0000  
Access: word access  

This register can only be modified if START = 0 in the FMAC_PARAM register.

Bit 31  **START**: Enable execution
0: Stop execution
1: Start execution
Setting this bit triggers the execution of the function selected in the FUNC bitfield. Resetting it by software stops any ongoing function. For initialization functions, this bit is reset by hardware.

Bits 30:24  **FUNC[6:0]**: Function
0: Reserved
1: Load X1 buffer
2: Load X2 buffer
3: Load Y buffer
4 to 7: Reserved
8: Convolution (FIR filter)
9: IIR filter (direct form 1)
10 to 127: Reserved
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 23:16  **R[7:0]**: Input parameter R.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 15:8  **Q[7:0]**: Input parameter Q.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 7:0  **P[7:0]**: Input parameter P.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)
### 24.4.5 FMAC control register (FMAC_CR)

Address offset: 0x10  
Reset value: 0x0000 0000  
Access: word access

<table>
<thead>
<tr>
<th>Bit 31:17</th>
<th>Description</th>
<th>Value if Activate</th>
<th>Value if Deactivate</th>

</tr>
</tbody>
</table>

**Bit 16** **RESET**: Reset FMAC unit  
This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.  
0: Reset inactive  
1: Reset active

**Bit 15** **CLIPEN**: Enable clipping  
0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.  
1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

**Bit 14:10** Reserved, must be kept at reset value.

**Bit 9** **DMAWEN**: Enable DMA write channel requests  
0: Disable. No DMA requests are generated  
1: Enable. DMA requests are generated while the X1 buffer is not full.  
This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

**Bit 8** **DMAREN**: Enable DMA read channel requests  
0: Disable. No DMA requests are generated  
1: Enable. DMA requests are generated while the Y buffer is not empty.  
This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

**Bit 7:5** Reserved, must be kept at reset value.

**Bit 4** **SATIEN**: Enable saturation error interrupts  
0: Disabled. No interrupts are generated upon saturation detection.  
1: Enabled. An interrupt request is generated if the SAT flag is set  
This bit is set and cleared by software. A read returns the current state of the bit.

**Bit 3** **UNFLIEN**: Enable underflow error interrupts  
0: Disabled. No interrupts are generated upon underflow detection.  
1: Enabled. An interrupt request is generated if the UNFL flag is set  
This bit is set and cleared by software. A read returns the current state of the bit.
Bit 2 **OVFLIEN**: Enable overflow error interrupts
0: Disabled. No interrupts are generated upon overflow detection.
1: Enabled. An interrupt request is generated if the OVFL flag is set
   This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt
0: Disabled. No write interrupt requests are generated.
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.
   This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt
0: Disabled. No read interrupt requests are generated.
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.
   This bit is set and cleared by software. A read returns the current state of the bit.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.
0: No saturation detected
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.
0: No underflow detected
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.
0: No overflow detected
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.
Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **X1FULL:** X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.

1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

*Note:* after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0  **YEMPTY:** Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.

1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

*Note:* after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

### 24.4.7  **FMAC write data register (FMAC_WDATA)**

Address offset: 0x18

Reset value: 0x0000 0000

Access: word and half-word access

**Bits 31:16** Reserved, must be kept at reset value.

**Bits 15:0** **RDATA[15:0]:** Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.
# 24.4.9 FMAC register map

## Table 179. FMAC register map and reset values

| Offset | Register name | D | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | N | |
25 Flexible static memory controller (FSMC)

25.1 Introduction

The flexible static memory controller (FSMC) includes two memory controllers:
- The NOR/PSRAM memory controller
- The NAND memory controller

This memory controller is also named flexible memory controller (FMC).

25.2 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND Flash memory. Its main purposes are:
- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:
- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:
- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM). In this case, the AHB burst is broken into two FIFO entries.
At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up.

However, only a few bits can be changed on-the-fly:

- MBKEN, FMCEN, WEN bits in FMC_BCRx register
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register

Follow the below sequence to modify parameters while the FMC is enabled:
1. First disable the FMC controller to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC controller again.

### 25.3 FMC block diagram

The FMC consists of the following main blocks:

- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller

The block diagram is shown in the figure below.

![FMC block diagram](image-url)
25.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:
• When reading or writing to a FMC bank (Bank 1 to 4) which is not enabled.
• When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC_BCRx register.

The effect of an AHB error depends on the AHB master which has attempted the R/W access:
• If the access has been attempted by the Cortex®-M33 CPU, a hard fault interrupt is generated.
• If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

25.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:
• AHB transaction size and memory data size are equal
  There is no issue in this case.
• AHB transaction size is greater than the memory size:
  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured
to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.

- **AHB transaction size is smaller than the memory size:**
  The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)
    In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[1:0].
    Bytes to be written are addressed by NBL[1:0].
    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)
    This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

**Wrap support for NOR Flash/PSRAM**

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

**Configuration registers**

The FMC can be configured through a set of registers. Refer to Section 25.6.6, for a detailed description of the NOR Flash/PSRAM controller registers. Refer to Section 25.7.7, for a detailed description of the NAND Flash registers.

### 25.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 107):

- **Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices.** This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - **Bank 1 - NOR/PSRAM 1**
  - **Bank 1 - NOR/PSRAM 2**
  - **Bank 1 - NOR/PSRAM 3**
  - **Bank 1 - NOR/PSRAM 4**

- **Bank 3 used to address NAND Flash memory devices.** The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.
25.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in Table 180.

Table 180. NOR/PSRAM bank selection

<table>
<thead>
<tr>
<th>HADDR[27:26]</th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 181. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>HADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbits</td>
</tr>
<tr>
<td>16-bit</td>
<td>HADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbits</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0]. Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].
25.5.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 182.

Table 182. NAND memory mapping and timing registers

<table>
<thead>
<tr>
<th>Start address</th>
<th>End address</th>
<th>FMC bank</th>
<th>Memory space</th>
<th>Timing register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8800 0000</td>
<td>0xBFFFF</td>
<td>Bank 3 - NAND Flash</td>
<td>Attribute</td>
<td>FMC_PATT (0x8C)</td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>0x83FFFF</td>
<td></td>
<td>Common</td>
<td>FMC_PMEM (0x88)</td>
</tr>
</tbody>
</table>

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 183 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 183. NAND bank selection

<table>
<thead>
<tr>
<th>Section name</th>
<th>HADDR[17:16]</th>
<th>Address range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address section</td>
<td>1X</td>
<td>0x020000-0x03FFFF</td>
</tr>
<tr>
<td>Command section</td>
<td>01</td>
<td>0x010000-0x01FFFF</td>
</tr>
<tr>
<td>Data section</td>
<td>00</td>
<td>0x000000-0x0FFFF</td>
</tr>
</tbody>
</table>

The application software uses the 3 sections to access the NAND Flash memory:

- **To sending a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.
25.6 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.
