The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 25.6.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to Section 25.6.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 25.6.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 184) and support for wait management (for PSRAM and NOR Flash accessed in Burst mode).

### 25.6.3 General timing rules

**Signals synchronization**

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

25.6.4 **NOR Flash/PSRAM controller asynchronous transactions**

**Asynchronous static memories (NOR Flash, PSRAM, SRAM, FRAM)**

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory.
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns).
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register).
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

**Mode 1 - SRAM/FRAM/PSRAM (CRAM)**

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

**Figure 108. Mode 1 read access waveforms**
Figure 109. Mode 1 write access waveforms

The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCSWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

</tbody>
</table>
1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   \[ \text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time} \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   
   if
   
   \[ \text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase} \]
   
   then:
   
   \[ \text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase}) \]
   
   otherwise
   
   \[ \text{DATAST} \geq 4 \times \text{HCLK} \]
   
   where \text{max\_wait\_assertion\_time} is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

\text{Figure 121} and \text{Figure 122} show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

\text{Figure 121. Asynchronous wait during a read access waveforms}

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not allow maintaining the chip select signal (NE) low for longer than the tCEM timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses.

25.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:
• If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration.
register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

**Single-burst transfer**

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

**Cross boundary page for CellularRAM™ 1.5**

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

**Wait management**

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state
The FMC supports both NOR Flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

**Figure 123. Wait configuration waveforms**
Figure 124. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

25.6.6 NOR/PSRAM controller registers

SRAM/NOR-Flash chip-select control register for bank x
(FMC_BCRx) (x = 1 to 4)

Address offset: 8 * (x – 1), (x = 1 to 4)

Reset value: Bank 1: 0x0000 30DB
Reset value: Bank 2: 0x0000 30D2
Reset value: Bank 3: 0x0000 30D2
Reset value: Bank 4: 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR Flash memories.

</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Write FIFO enabled (Default after reset)</td>
</tr>
<tr>
<td>1</td>
<td>Write FIFO disabled</td>
</tr>
</tbody>
</table>

*Note: The WFDIS bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.**
Bit 20 **CCLKEN**: Continuous clock enable
This bit enables the FMC_CLK clock output to external memory devices.
0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

*Note*: The CCLKEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

*Note*: If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don’t care.

*Note*: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRE**: Write burst enable
For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.
0: Write operations are always performed in Asynchronous mode.
1: Write operations are performed in Synchronous mode.

Bits 18:16 **CP_SIZE[2:0]**: CRAM page size
These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).
000: No burst split when crossing page boundary (default after reset)
001: 128 bytes
010: 256 bytes
011: 512 bytes
100: 1024 bytes
Others: reserved

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers
This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.
0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset).
1: NWAIT signal is taken in to account when running an asynchronous protocol.

Bit 14 **EXTMOD**: Extended mode enable
This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.
0: values inside FMC_BWTR register are not taken into account (default after reset)
1: values inside FMC_BWTR register are taken into account

*Note*: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:
- **Mode 1** is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- **Mode 2** is the default mode when the NOR memory type is selected (MTYP = 0x10).
Bit 13 **WAITEN**: Wait enable bit
This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.
- 0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period).
- 1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN**: Write enable bit
This bit indicates whether write operations are enabled/disabled in the bank by the FMC.
- 0: Write operations are disabled in the bank by the FMC, an AHB error is reported.
- 1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration
The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:
- 0: NWAIT signal is active one data cycle before wait state (default after reset).
- 1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit
Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.
- 0: NWAIT active low (default after reset)
- 1: NWAIT active high

Bit 8 **BURSTEN**: Burst enable bit
This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.
- 0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
- 1: Burst mode enabled. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable
Enables NOR Flash memory access operations.
- 0: Corresponding NOR Flash memory access is disabled.
- 1: Corresponding NOR Flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]**: Memory data bus width
Defines the external memory device width, valid for all type of memories.
- 00: 8 bits
- 01: 16 bits (default after reset)
- 10: reserved
- 11: reserved
Bits 3:2  **MTYP[1:0]: Memory type**
  Defines the type of external memory attached to the corresponding memory bank.
  00: SRAM/FRAM (default after reset for Bank 2...4)
  01: PSRAM (CRAM) / FRAM
  10: NOR Flash/OneNAND Flash (default after reset for Bank 1)
  11: reserved

Bit 1  **MUXEN**: Address/data multiplexing enable bit
  When this bit is set, the address and data values are multiplexed on the data bus, valid only with
  NOR and PSRAM memories:
  0: Address/data non multiplexed
  1: Address/data multiplexed on databus (default after reset)

Bit 0  **MBKEN**: Memory bank enable bit
  Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a
disabled bank causes an ERROR on AHB bus.
  0: Corresponding memory bank is disabled.
  1: Corresponding memory bank is enabled.

**SRAM/NOR-Flash chip-select timing register for bank x (FMC_BTRx)**

Address offset: 0x04 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs,
PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then
this register is partitioned for write and read access, that is, 2 registers are available: one to
configure read accesses (this register) and one to configure write accesses (FMC_BWTRx
registers).

Bits 31:30  **DATAHLD[1:0]: Data hold phase duration**
  These bits are written by software to define the duration of the data hold phase in HCLK
cycles (refer to Figure 108 to Figure 120), used in asynchronous accesses:
  For read accesses
  00: DATAHLD phase duration = 0 × HCLK clock cycle (default)
  01: DATAHLD phase duration = 1 × HCLK clock cycle
  10: DATAHLD phase duration = 2 × HCLK clock cycle
  11: DATAHLD phase duration = 3 × HCLK clock cycle
  For write accesses
  00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
  01: DATAHLD phase duration = 2 × HCLK clock cycle
  10: DATAHLD phase duration = 3 × HCLK clock cycle
  11: DATAHLD phase duration = 4 × HCLK clock cycle
Bits 29:28 **ACCMOD[1:0]**: Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: Access mode A
01: Access mode B
10: Access mode C
11: Access mode D

Bits 27:24 **DATLAT[3:0]**: (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.
For asynchronous access, this value is don’t care.
0000: Data latency of 2 CLK clock cycles for first burst access
1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC_CLK signal)

Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:
0000: FMC_CLK period = 1x HCLK period
0001: FMC_CLK period = 2 x HCLK periods
0010: FMC_CLK period = 3 x HCLK periods
1111: FMC_CLK period = 16 x HCLK periods (default value after reset)
In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don’t care.

**Note:** Refer to Section 25.6.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.

This delay allows to match the minimum time between consecutive transactions (tEHEL from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (tEHQZ, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.

(BUSTURN + 1)HCLK period ≥ max(tEHEL min, tEHQZ max)

For FRAM memories, the bus turnaround delay should be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.

(BUSTURN + 1)HCLK period ≥ tPC min

0000: BUSTURN phase duration = 1 HCLK clock cycle added
1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)
Bits 15:8 **DATAST[7:0]**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to Figure 108 to Figure 120), used in asynchronous accesses:

- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × HCLK clock cycles
- 0000 0010: DATAST phase duration = 2 × HCLK clock cycles
- ...
- 1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (Figure 108 to Figure 120).

Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

**Note:** In synchronous accesses, this value is don’t care.

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration

These bits are written by software to define the duration of the address hold phase (refer to Figure 108 to Figure 120), used in mode D or multiplexed accesses:

- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × HCLK clock cycle
- 0010: ADDHLD phase duration = 2 × HCLK clock cycle
- ...
- 1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address-hold phase duration, refer to the respective figure (Figure 108 to Figure 120).

**Note:** In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration

These bits are written by software to define the duration of the address setup phase (refer to Figure 108 to Figure 120), used in SRAMs, ROMs, asynchronous NOR Flash and PSRAM:

- 0000: ADDSET phase duration = 0 × HCLK clock cycle
- ...
- 1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure (Figure 108 to Figure 120).

**Note:** In synchronous accesses, this value is don’t care.

In Muxed mode or mode D, the minimum value for ADDSET is 1.

In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

**Note:** PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.

With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.

This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).
SRAM/NOR-Flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0xFFFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

</tbody>
</table>
Bits 15:8  **DATAST[7:0]**: Data-phase duration.
   These bits are written by software to define the duration of the data phase (refer to Figure 108 to Figure 120), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:
   0000 0000: Reserved
   0000 0001: DATAST phase duration = 1 × HCLK clock cycles
   0000 0010: DATAST phase duration = 2 × HCLK clock cycles
   ...
   1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4  **ADDHLD[3:0]**: Address-hold phase duration.
   These bits are written by software to define the duration of the address hold phase (refer to Figure 117 to Figure 120), used in asynchronous multiplexed accesses:
   0000: Reserved
   0001: ADDHLD phase duration = 1 × HCLK clock cycle
   0010: ADDHLD phase duration = 2 × HCLK clock cycle
   ...
   1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

   **Note:** In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.

Bits 3:0  **ADDSET[3:0]**: Address setup phase duration.
   These bits are written by software to define the duration of the address setup phase in HCLK cycles (refer to Figure 108 to Figure 120), used in asynchronous accesses:
   0000: ADDSET phase duration = 0 × HCLK clock cycle
   ...
   1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

   **Note:** In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

**PSRAM chip select counter register (FMC_PCSCNTR)**

Address offset: 0x20
Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width ($t_{CEM}$) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.
Bits 31:20  Reserved, must be kept at reset value.

Bit 19  **CNTB4EN**: Counter Bank 4 enable
- This bit enables the chip select counter for PSRAM/NOR Bank 4.
  - 0: Counter disabled for Bank 4
  - 1: Counter enabled for Bank 4

Bit 18  **CNTB3EN**: Counter Bank 3 enable
- This bit enables the chip select counter for PSRAM/NOR Bank 3.
  - 0: Counter disabled for Bank 3
  - 1: Counter enabled for Bank 3

Bit 17  **CNTB2EN**: Counter Bank 2 enable
- This bit enables the chip select counter for PSRAM/NOR Bank 2.
  - 0: Counter disabled for Bank 2
  - 1: Counter enabled for Bank 2

Bit 16  **CNTB1EN**: Counter Bank 1 enable
- This bit enables the chip select counter for PSRAM/NOR Bank 1.
  - 0: Counter disabled for Bank 1
  - 1: Counter enabled for Bank 1

Bits 15:0  **CSCOUNT[15:0]**: Chip select counter.
- These bits are written by software to define the maximum chip select low pulse duration. It is expressed in FMC_CLK cycles for synchronous accesses and in HCLK cycles for asynchronous accesses.
- The counter is disabled if the programmed value is 0.

### 25.7 NAND Flash controller

The FMC generates the appropriate signal timings to drive the following types of device:
- 8- and 16-bit NAND Flash memories

The NAND bank is configured through dedicated registers (*Section 25.7.7*). The programmable memory parameters include access timings (shown in *Table 210*) and ECC configuration.

25.7.3 Timing diagrams for NAND Flash memory

The NAND Flash memory bank is managed through a set of registers:
- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed.

_Figure 126_ shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.
25.7.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 25.7.5: NAND Flash prewait functionality) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see Section 25.5.2: NAND Flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used...
to implement the prewait functionality needed by some NAND Flash memories (see details in Section 25.7.5: NAND Flash prewait functionality).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.

6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND Flash device by restarting at step 2

### 25.7.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 127).

**Figure 127. Access to non ‘CE don’t care’ NAND-Flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7–A0 at address 0x7002 0000.
3. CPU wrote byte A16–A9 at address 0x7002 0000.
4. CPU wrote byte A24–A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don’t care).
Flexible static memory controller (FSMC) RM0456

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the \( t_{WB} \) timing. However any CPU read access to the NAND Flash memory has a hold delay of \( (\text{MEMHOLD} + 2) \) HCLK cycles and CPU write access has a hold delay of \( \text{MEMHOLD} \) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the \( t_{WB} \) timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

25.7.6 **Computation of the error correction code (ECC) in NAND Flash memory**

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:
- When accessing NAND Flash memory bank 2 or bank 3, the data present on the \( \text{D}[15:0] \) bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.
To perform an ECC computation:
1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

25.7.7 NAND Flash controller registers

NAND Flash control registers (FMC_PCR)

Address offset: 0x80
Reset value: 0x0000 0018

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 ECCPS[2:0]: ECC page size
Defines the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 TAR[3:0]: ALE to RE delay
Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
Time is: \( t_{ar} = (TAR + SET + 2) \times \text{THCLK} \) where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles

Note: SET is MEMSET or ATTSET according to the addressed space.
Bits 12:9 **TCLR[3:0]**: CLE to RE delay
Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
The time is \( t_{\text{clr}} = (\text{TCLR} + \text{SET} + 2) \times \text{THCLK} \) where THCLK is the HCLK clock period
- 0000: 1 HCLK cycle (default)
- 1111: 16 HCLK cycles
*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit
- 0: ECC logic is disabled and reset (default after reset),
- 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width
Defines the external memory device width.
- 00: 8 bits
- 01: 16 bits (default after reset).
- 10: reserved.
- 11: reserved.

Bit 3 **PTYP**: Memory type
Defines the type of device attached to the corresponding memory bank:
- 0: Reserved, must be kept at reset value
- 1: NAND Flash (default after reset)

Bit 2 **PBKEN**: NAND Flash memory bank enable bit
Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
- 0: Corresponding memory bank is disabled (default after reset)
- 1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit
Enables the Wait feature for the NAND Flash memory bank:
- 0: disabled
- 1: enabled

Bit 0 Reserved, must be kept at reset value.
FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred

Note: If this bit is written by software to 1 it is set.

Bit 1  **ILS**: Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred
Bit 0  **IRS**: Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred
*Note*: If this bit is written by software to 1 it is set.

### Common memory space timing register (FMC_PMEM)

Address offset: Address: 0x88
Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

**Bits 31:24 MEMHIZ[7:0]:** Common memory x data bus Hi-Z time
Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a NAND Flash write access to common memory space on socket. This is only valid for write transactions:
- 0000 0000: 1 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved.

**Bits 23:16 MEMHOLD[7:0]:** Common memory hold time
Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:
- 0000 0000: reserved.
- 0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
- 1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
- 1111 1111: reserved.

**Bits 15:8 MEMWAIT[7:0]:** Common memory wait time
Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to common memory space on socket. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:
- 0000 0000: reserved
- 0000 0001: 2HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1111: reserved.
RM0456 Flexible static memory controller (FSMC)

Bits 7:0 **MEMSET[7:0]**: Common memory x setup time

- Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:
  - 0000 0000: 1 HCLK cycle
  - 1111 1110: 255 HCLK cycles
  - 1111 1111: reserved

Attribute memory space timing register (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to Section 25.7.5: NAND Flash prewait functionality).

Bits 31:24 **ATTHIZ[7:0]**: Attribute memory data bus Hi-Z time

- Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for write transaction:
  - 0000 0000: 0 HCLK cycle
  - 1111 1110: 255 HCLK cycles
  - 1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]**: Attribute memory hold time

- Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:
  - 0000 0000: reserved
  - 0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
  - 1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
  - 1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory wait time

- Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:
  - 0000 0000: reserved
  - 0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)
  - 1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
  - 1111 1111: reserved.
Flexible static memory controller (FSMC) RM0456

ECC result registers (FMC_ECCR)

Address offset: 0x94
Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND Flash memory page at the correct address (refer to Section 25.7.6: Computation of the error correction code (ECC) in NAND Flash memory), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

Refer to Section 2.3 on page 116 for the register boundary addresses.
26  Octo-SPI interface (OCTOSPI)

26.1  Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR Flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data and transfer parameters.
- Automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the Regular-command frame format with the command, address, alternate byte, dummy cycles and data phase
- the HyperBus™ frame format

26.2  OCTOSPI main features

- Functional modes: Indirect, Automatic status-polling, and Memory-mapped
- Read and write support in Memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad and octal communication
- Dual-quad configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for Indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

26.4 OCTOSPI functional description

26.4.1 OCTOSPI block diagram

Figure 128. OCTOSPI block diagram in octal configuration

Figure 129. OCTOSPI block diagram in quad configuration
26.4.2 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:
- Regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in Regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]: data bus MSB used in dual-quad and octal configurations

26.4.3 OCTOSPI Regular-command protocol

When in Regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phases must be present.
The NCS falls before the start of each command and rises again after each command finishes.

In Memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

**Figure 131. SDR read command in octal configuration**

The specific Regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:
- 1 bit at a time from the IO0/SO signal (Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In Memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of OCTOSPI_CCR.

In Indirect and Automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of OCTOSPI_AR. In Memory-mapped mode, the address is given directly via the AHB (from any master in the system).
The address phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ADMODE[2:0] of OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR of OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In Memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

**Alternate-bytes phase**

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ABMODE[2:0] of OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the Dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the Quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 4:3 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In Memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.
Dummy-cycle phase

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the Dual-SPI, the Quad-SPI or the Octal-SPI mode, to receive data from the external device.

In Memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In Indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in Indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In Automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR and the data received from the external device can be obtained by reading OCTOSPI_DR.

In Memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over SO/SI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using DMODE[2:0] of OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in Indirect-write mode.

In Memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS usage

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.
The DQS management can be enabled by setting DQSE of OCTOSPI_CCR.

**Figure 132. DTR read in Octal-SPI mode with DQS (Macronix mode) example**

![Diagram](image)

### 26.4.4 OCTOSPI Regular-command protocol signal interface

#### Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this Single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

#### Dual-SPI mode

In Dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use Dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.
In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In Quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the Quad-SPI mode by setting to 011 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

IO2 and IO3 are used only in Quad-SPI mode. If none of the phases are configured to use the Quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the OCTOSPI is active.

**Octal-SPI mode**

In regular Octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the Octal-SPI mode by setting to 100 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in Octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

IO[4:7] are used only in Octal-SPI mode. If none of the phases are configured to use Octal-SPI mode, then the pins corresponding to IO[4:7] can be used for other functions even while the OCTOSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in Single-data rate (SDR) mode.

In SDR mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.
Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In Memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

In DTR mode, when the OCTOSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid to hold issues on the memory side.

**Note:** DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 100, two external Quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.
The dual-quad configuration can be used in conjunction with the Single-SPI, Dual-SPI, and Quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of OCTOSPI_DCR1, must reflect the total external device capacity, that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in Regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

### 26.4.5 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol. The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.
The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

<table>

<td></td>
</tr>
</tbody>
</table>

The address space is configured through the memory type MTYP[2:0] of OCTOSPI_DCR1. The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

**Read/write operation with initial latency**

The HyperBus read and write operations need to respect two timings:

- \( t_{RWR} \): minimal read/write recovery time for the device (defined in TRWR[7:0] of OCTOSPI_HLCR)
- \( t_{ACC} \): access time for the device (defined in TAC[7:0] of OCTOSPI_HLCR)
During the read operation, the RWDS is used by the device, in two ways (see Figure 135):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation the RWDS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

**Figure 136. HyperBus write operation with initial latency**

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional \( t_{ACC} \) duration is added by the OCTOSPI to meet the device request.

**Figure 137. HyperBus read operation with additional latency**
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to 2 x $t_{\text{ACC}}$ by setting LM of OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI and an additional latency is always added, leading to a fixed 2 x $t_{\text{ACC}}$ latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.

Figure 138. HyperBus write operation with additional latency

![Diagram of HyperBus write operation with additional latency]

Figure 139. HyperBus write operation with no latency

![Diagram of HyperBus write operation with no latency]
Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the $t_{ACC}$ time.

Figure 140. HyperBus read operation page crossing with latency

26.4.6 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

Wrap support

The OCTOSPI supports an hybrid wrap as defined by the HyperBus protocol. An hybrid wrap is also supported in the Regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and Regular-command protocols. To enable wrapped-read accesses, the dedicated registers OCTOSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated OCTOSPI_WPxxx registers apply for both HyperBus and Regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured in CSBOUND[4:0] of OCTOSPI_DCR3 and it is equal to $2^{CSBOUND}$. 
As an example, if CSBOUND(4:0] = 0x4, the boundary is set to $2^4 = 16$ bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled and a minimum value of 3 is recommended.

The NCS boundary feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

**Communication regulation**

The communication regulation feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of OCTOSPI_DCR3.

If the number of clock cycles reach the MAXTRAN + 1 value, and if the second OCTOSPI requests an access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

*Note:* The communication regulation feature cannot be used in write mode for the Flash memory devices that require extra command to re-enable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

**Re-starting after an interrupted transfer**

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

**26.4.7 OCTOSPI operating modes introduction**

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either Regular-command or HyperBus):

- Indirect mode (read or write)
- Automatic status-polling mode
- Memory-mapped mode
26.4.8 OCTOSPI Indirect mode

In Indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 0 in OCTOSPI_CR, the OCTOSPI is in Indirect-write mode: bytes are sent to the external device during the data phase. Data is provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in Indirect-read mode: bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

In Indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:
- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in OCTOSPI_SR and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in Regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in Indirect mode when using Regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in Indirect mode, a transfer starts when one of the following sequence of events occurs:
- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.
Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in Indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in Indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) in Indirect-read mode (when FMODE = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in Indirect-write mode (when FMODE = 00).
- when a write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for both Indirect read and write modes

*Note:* In case of HyperBus, a (dummy) write to OCTOSPI_IR is required to trigger the transfer, as for Regular-command protocol.

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in Indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR and immediately transferred in the internal FIFO.

In Indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In Indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In Indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

26.4.9 OCTOSPI Automatic status-polling mode

In Automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.
The access to the device begins in the same manner as in Indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in Automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In Automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

### 26.4.10 OCTOSPI Memory-mapped mode

When configured in Memory-mapped mode, the external SPI device is seen as an internal memory.

*Note:* More than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were pre-fetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.
BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

26.4.11 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:
1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

26.4.12 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:
- Functional mode with FMODE[1:0]
- Automatic status-polling mode behavior if needed with PMM and APMS
- FIFO level with FTHRES
- DMA usage with DMAEN
- Timeout counter usage with TCEN
- Dual-quad configuration, if needed, with DMM (only for Quad-SPI mode)

In case of an interrupt usage, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

26.4.13 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2. The user must program:
- Device size with DEVSIZE[4:0]
- Chip-select minimum high time with CSHT[5:0]
- Clock mode with FRCK and CKMODE
- Device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:
- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- HyperBus memory mode: the protocol follows the HyperBus specification, and an 8-data-bit DTR mode must be selected.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be non-cacheable, or the Indirect read/write modes must be used.
DEVSIZE[4:0] defines the size of external memory using the following formula:

\[
\text{Number of bytes in the device} = 2^{\text{DEVSIZE}+1}
\]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default. If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing \( t_{\text{ACC}} \) and \( t_{\text{RWR}} \) and the Latency mode must be configured in OCTOSPI_HLCR.

### 26.4.14 OCTOSPI Regular-command mode configuration

#### Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected and data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in Indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.
Automatic status-polling mode configuration

The Automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled; The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the Flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.
The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

When the OCTOSPI is used in Memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for read operation.

All the configuration operations must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed.

**OCTOSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**OCTOSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In certain configuration cases, this external delay block is implemented but is not useful, so it can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

**Sending the instruction only once (SIOO)**

A Flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for Memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

SIOO mode is not supported when any of the communication regulation, NCS boundary or refresh features are used.
26.4.15 OCTOSPI HyperBus protocol configuration

Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:
1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Make a write operation in OCTOSPI_IR and enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In Indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In Indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The Automatic status-polling mode is enabled setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, it can be internally processed to:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set.

In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the targeted address in OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.
Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The Memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

All the configuration operation must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.

26.4.16 OCTOSPI error management

A error can be generated in the following cases:

- in Indirect or Automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in Indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in Memory-mapped mode when an out-of-range access is done by an AHB master. This generates an AHB error as a response to the faulty AHB request.
- when the Memory-mapped mode is disabled. An access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- Memory-mapped mode is disabled and an AHB read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- OCTOSPI is disabled while a read or write burst is ongoing.
- Write wrap burst is received.
- Write request is received while DQSE = 0 in OCTOSPI_WCCR, which means that the DQS output is disabled.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means the HSIZE is different from 4 bytes (only for Memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for Memory-mapped mode).

26.4.17 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In Indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.
In Automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in Memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers.

*Note:* Some devices may misbehave if a write operation to a status register is aborted.

### 26.4.18 OCTOSPI reconfiguration or deactivation

Prior to any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a Memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a Memory-mapped read, the software must perform a synchronization barrier then an abort.

### 26.4.19 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (Mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

*Figure 141. NCS when CKMODE = 0 (T = CLK period)*
When CKMODE = 1 (Mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 142. NCS when CKMODE = 1 in SDR mode (T = CLK period)

When the CKMODE = 1 (Mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 143. NCS when CKMODE = 1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 144. NCS when CKMODE = 1 with an abort (T = CLK period)

When not in dual-quad configuration (DMM = 0), only device A is accessed and thus the BNCS stays high. In dual-quad configuration, the BNCS behaves exactly the same as the ANCS. Thus, if there is a device B and if the application always stays in dual-quad...
configuration, then the device B may use the ANCS and the pin outputting BNCS can be used for other functions.

## 26.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

<table>

4. RDS = read data strobe, WDM = write data mask.
26.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

26.7 OCTOSPI registers

26.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30  Reserved, must be kept at reset value.
Bits 29:28 **FMODE[1:0]**: Functional mode
This field defines the OCTOSPI functional mode of operation.
- 00: Indirect-write mode
- 01: Indirect-read mode
- 10: Automatic status-polling mode
- 11: Memory-mapped mode
If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the Automatic status-polling mode.
- 0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
- 1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the Automatic status-polling mode is stopped after a match.
- 0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
- 1: Automatic status-polling mode stops as soon as there is a match.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
- 0: Interrupt disabled
- 1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.
Bits 12:8  **FTHRES[4:0]**: FIFO threshold level  
This field defines, in Indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.  
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in Indirect-read mode.  
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in Indirect-read mode.  
...  
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in Indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in Indirect-read mode.  
*Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.*  

Bit 7  **FSEL**: Flash select  
This bit selects the Flash memory to be addressed in Single-, Dual-, Quad-SPI mode in single-memory configuration (when DMM = 0).  
0: FLASH 1 selected (data exchanged over IO[3:0])  
1: FLASH 2 selected (data exchanged over IO[7:4])  
This bit is ignored when DMM = 1 or when Octal-SPI mode is selected.  

Bit 6  **DMM**: Dual-memory configuration  
This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity  
0: Dual-quad configuration disabled  
1: Dual-quad configuration enabled  

Bits 5:4  Reserved, must be kept at reset value.  

Bit 3  **TCEN**: Timeout counter enable  
This bit is valid only when the Memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.  
0: Timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in Memory-mapped mode.  
1: Timeout counter is enabled, and thus the chip-select is released in the Memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.  

Bit 2  **DMAEN**: DMA enable  
In Indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.  
0: DMA disabled for Indirect mode  
1: DMA enabled for Indirect mode  
*Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.*  

Bit 1  **ABORT**: Abort request  
This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.  
0: No abort requested  
1: Abort requested  
*Note: This bit is always read as 0.*
26.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008  
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bit indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in Single-, Dual-, Quad- and Octal-SPI modes.

*Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.*

010: Standard mode

100: HyperBus memory mode, the protocol follows the HyperBus specification. 8-data-bit DTR mode must be selected.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or Indirect read/write modes must be used.

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.
Bits 20:16 **DEVSIZE[4:0]: Device size**

This field defines the size of the external device using the following formula:

Number of bytes in device = 2^{(DEVSIZE+1)}

DEVSIZE+1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

In Regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]: Chip-select high time**

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.
0x1: NCS stays high for at least 2 cycles between external device commands.
...
0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP: Delay block bypass**

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).
1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK: Free running clock**

This bit configures the free running clock.
0: CLK is not free running.
1: CLK is free running (always provided).

Bit 0 **CKMODE: Mode 0/Mode 3**

This bit indicates the level taken by the CLK between commands (when NCS = 1).
0: CLK must stay low while NCS is high (chip-select released). This is referred to as Mode 0.
1: CLK must stay high while NCS is high (chip-select released). This is referred to as Mode 3.

### 26.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
26.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary
- This field enables the transaction boundary feature. When active, a minimum value of 3 is recommended.
- The NCS is released on each boundary of $2^{\text{CSBOUND}}$ bytes.
- 0: NCS boundary disabled
- others: NCS boundary set to $2^{\text{CSBOUND}}$ bytes

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer
- This field enables the communication regulation feature.
- The NCS is released every MAXTRAN+1 clock cycles when the other OCTOSPI request the access to the bus.
- 0: Maximum communication disabled
- others: Maximum communication is set to MAXTRAN + 1 bytes

### 26.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bits 31:0 **REFRESH[31:0]**: Refresh rate
- This field enables the refresh rate feature.
- The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads.
- **Note**: These two values can be extended with few clock cycles when refresh occurs during a byte transmission in Single-, Dual- or Quad-SPI mode, because the byte transmission must be completed.
- 0: Refresh disabled
- others: Maximum communication length is set to REFRESH + 1 clock cycles.
### OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020  
Reset value: 0x0000 0000

Bits 31:14  Reserved, must be kept at reset value.

Bits 13:8  **FLEVEL[5:0]: FIFO level**  
This field gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.  
In Automatic status-polling mode, FLEVEL is zero.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **BUSY**: Busy  
This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4  **TOF**: Timeout flag  
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3  **SMF**: Status match flag  
This bit is set in Automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).  
It is cleared by writing 1 to CSMF.

Bit 2  **FTF**: FIFO threshold flag  
In Indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.  
It is cleared automatically as soon as the threshold condition is no longer true.  
In Automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1  **TCF**: Transfer complete flag  
This bit is set in Indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0  **TEF**: Transfer error flag  
This bit is set in Indirect mode when an invalid address is being accessed in Indirect mode. It is cleared by writing 1 to CTEF.
### OCTOSPI flag clear register (OCTOSPI_FCR)

Address offset: 0x0024  
Reset value: 0x0000 0000

</table>

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4**: **CTOF**: Clear timeout flag  
  Writing 1 clears the TOF flag in the OCTOSPI_SR register.

- **Bit 3**: **CSMF**: Clear status match flag  
  Writing 1 clears the SMF flag in the OCTOSPI_SR register.

- **Bit 2**: Reserved, must be kept at reset value.

- **Bit 1**: **CTCF**: Clear transfer complete flag  
  Writing 1 clears the TCF flag in the OCTOSPI_SR register.

- **Bit 0**: **CTEF**: Clear transfer error flag  
  Writing 1 clears the TEF flag in the OCTOSPI_SR register.

### OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

</tbody>
</table>
Bits 31:0 DL[31:0]: Data length

Number of data to be retrieved (value+1) in Indirect and Automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for Automatic status-polling mode.

All 1’s in Indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.

- 0x0000_0000: 1 byte is to be transferred.
- 0x0000_0001: 2 bytes are to be transferred.
- 0x0000_0002: 3 bytes are to be transferred.
- 0x0000_0003: 4 bytes are to be transferred.

... 

- 0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.
- 0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.
- 0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F. DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This field has no effect in Memory-mapped mode.

26.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048

Reset value: 0x0000 0000

<table>

</tr>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:0 ADDRESS[31:0]: Address

Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 1. Writes to this field are ignored when BUSY = 1 or when FMODE = 11 (Memory-mapped mode).
26.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050
Reset value: 0x0000 0000

### Bits 31:0 DATA[31:0]: Data

Data to be sent/received to/from the external SPI device

- In Indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
- In Indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
- In Automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In Indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes. Similarly, in Indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in Indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

26.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
26.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 **SIOO**: Send instruction only once mode
This bit has no effect when IMODE = 00 (see Sending the instruction only once (SIOO)).
0: Send instruction on every transaction
1: Send instruction only for the first command

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes
Bit 19 **ABDTR**: Alternate bytes double transfer rate  
This bit sets the DTR mode for the alternate bytes phase.  
0: DTR mode disabled for alternate bytes phase  
1: DTR mode enabled for alternate bytes phase  
This field can be written only when BUSY = 0.

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode  
This field defines the alternate-byte phase mode of operation.  
000: No alternate bytes  
001: Alternate bytes on a single line  
010: Alternate bytes on two lines  
011: Alternate bytes on four lines  
100: Alternate bytes on eight lines  
101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size  
This field defines address size.  
00: 8-bit address  
01: 16-bit address  
10: 24-bit address  
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate  
This bit sets the DTR mode for the address phase.  
0: DTR mode disabled for address phase  
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode  
This field defines the address phase mode of operation.  
000: No address  
001: Address on a single line  
010: Address on two lines  
011: Address on four lines  
100: Address on eight lines  
101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.
Bits 5:4  **ISIZE[1:0]:** Instruction size

This bit defines instruction size.

- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3  **IDTR:** Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

- 0: DTR mode disabled for instruction phase
- 1: DTR mode enabled for instruction phase

Bits 2:0  **IMODE[2:0]:** Instruction mode

This field defines the instruction phase mode of operation.

- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- 101-111: Reserved

### 26.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bit 31  Reserved, must be kept at reset value.

Bit 30  **SSHIFT:** Sample shift

By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.

- 0: No shift
- 1: 1/2 cycle shift

The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29  Reserved, must be kept at reset value.
26.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

**TIMEOUT[15:0]**

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in Memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.

This field indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

26.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for data phase
1: DTR mode enabled for data phase
Bits 26:24  **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:20  **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19  **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase

Bits 18:16  **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
101-111: Reserved

Device read write recovery time expressed in number of communication clock cycles
Bits 15:8 TACC[7:0]: Access time
Device access time expressed in number of communication clock cycles
Bits 7:2  Reserved, must be kept at reset value.

Bit 1  **WZL**: Write zero latency
This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0  **LM**: Latency mode
This bit selects the Latency mode.
0: Variable initial latency
1: Fixed latency

### 26.7.28 OCTOSPI register map

#### Table 220. OCTOSPI register map and reset values

| Offset | Register   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

27 OCTOSPI I/O manager (OCTOSPIM)

27.1 Introduction
The OCTOSPI I/O manager is a low-level interface that enables:
- An efficient OCTOSPI pin assignment with a full I/O Matrix (before alternate function map)
- Multiplex of single/dual/quad/octal SPI interfaces over the same bus

27.2 OCTOSPIM main features
- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

27.3 OCTOSPIM implementation
The table below describes the OCTOSPIM implementation.

<table>
<thead>

27.4 OCTOSPIM functional description

27.4.1 OCTOSPIM block diagram
The block diagram of the OCTOSPI I/O manager is shown in Figure 145.
1. The number of ports (n) is 2.
2. Arbitration is possible for both I/O matrix input ports.

### 27.4.2 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable pre-mapping of functions:

- Any OCTOSPIM\_Pn\_CLK / OCTOSPIM\_Pn\_NCLK pair can be mapped independently to OCTOSPI1\_CLK/OCTOSPI1\_NCLK or OCTOSPI2\_CLK/OCTOSPI2\_NCLK
- Any OCTOSPIM\_Pn\_DQS can be mapped independently to OCTOSPI1\_DQS or OCTOSPI2\_DQS
- Any OCTOSPIM\_Pn\_NCS can be mapped independently to OCTOSPI1\_NCS or OCTOSPI2\_NCS
- Any OCTOSPIM\_Pn\_IO[3:0] and OCTOSPIM\_Pn\_IO[7:4] can be mapped independently to OCTOSPI1\_IO[3:0], OCTOSPI1\_IO[7:4], OCTOSPI2\_IO[3:0] or OCTOSPI2\_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM\_PnCR).

When several I/O pins have the same configuration, and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when both OCTOSPI1 and OCTOSPI2 are disabled.
27.4.3 OCTOSPIM multiplexed mode

When this mode is set the two OCTOSPIs are time-multiplexed over the same bus. Both OCTOSPIs get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to accurately manage the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPIs. When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when the other OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPIn_nCS are not part of the multiplexing. Only OCTOSPIn_IOs, OCTOSPIn_DQS and OCTOSPIn_CLK / OCTOSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may be increased.

The OCTOSPIM configuration can be changed only when both OCTOSPI1 and OCTOSPI2 are disabled.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.

This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active OCTOSPI releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting OCTOSPI).

The duration is defined by the REQ2ACK_TIME fields of the configuration register OCTOSPIM_CR.

Pin mapping in Multiplexed mode

In Multiplexed mode, the mapping of the bus is done as described below:

- OCTOSP1_nCS and OCTOSP12_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSPI1.
## 27.5 OCTOSPIM registers

### 27.5.1 OCTOSPIM control register (OCTOSPIM_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REQ2ACK_TIME[7:0]:** REQ to ACK time

In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions.
The value is the number of OCTOSPI clock cycles - 1

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MUXEN:** Multiplexed mode enable

This bit enables the multiplexing of the two OCTOSPIs.
0: No multiplexing, hence no arbitration
1: OCTOSPI1 and OCTOSPI2 are multiplexed over the same bus.

### 27.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR)

Address offset: 0x0000 + 0x04*n (n=1 to 2)
Reset value: 0x0301 0111, 0x0705 0333

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:25 **IOHSRC[1:0]:** IO[7:4] source for Port n

This bits select the source of Port n IO[7:4],
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode
Bit 24 **IOHEN**: IO[7:4] enable for Port n
This bit enables the Port n IO[7:4].
0: IO[7:4] for Port n disabled
1: IO[7:4] for Port n enabled

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:17 **IOLSRC[1:0]**: IO[3:0] source for Port n
This bits select the source of Port n IO[3:0].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16 **IOLEN**: IO[3:0] enable for Port n
This bit enables the Port n IO[3:0].
0: IO[3:0] for Port n disabled
1: IO[3:0] for Port n enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **NCSSRC**: nCS source for Port n
This bit selects the source of Port n nCS.
0: OCTOSPI1_nCS
1: OCTOSPI2_nCS

Bit 8 **NCSEN**: nCS enable for Port n
This bit enables the Port n nCS.
0: nCS for Port n is disabled
1: nCS for Port n is enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **DQSSRC**: DQS source for Port n
This bit selects the source of Port n DQS.
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4 **DQSEN**: DQS enable for Port n
This bit enables the Port n DQS.
0: DQS for Port n is disabled
1: DQS for Port n is enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **CLKSRC**: CLK/CLKn source for Port n
This bit selects the source of Port n CLK/CLKn.
0: OCTOSPI1_CLK/CLKn in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode
1: OCTOSPI2_CLK/CLKn in non multiplexed mode / unused port in multiplexed mode

Bit 0 **CLKEN**: CLK/CLKn enable for Port n
This bit enables the Port n CLK/CLKn.
0: CLK/CLKn for Port n is disabled
1: CLK/CLKn for Port n is enabled
### 27.5.3 OCTOSPIM register map

The following table summarizes the OCTOSPI I/O manager registers.

#### Table 222. OCTOSPIM register map and reset values

| Offset  | Register name   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Refer to [Section 2.3 on page 116](#) for the register boundary addresses.
28 Delay block (DLYB)

28.1 Introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Octo-SPI interface.

The delay is voltage- and temperature-dependent, that may require the application to reconfigure and recenter the output clock phase with the receive data.

28.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

28.3 DLYB implementation

28.4 DLYB functional description

28.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer
28.4.2 DLYB pins and internal signals

Table 224 lists the DLYB internal signals.

<table>
<thead>

<tr>
<td>dlyb_out_ck</td>
<td>Digital output</td>
<td>Delay block output clock</td>
</tr>
</tbody>
</table>

28.4.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFRG).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFRG register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFRG.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.
Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 225. Delay block control

<table>
<thead>
<tr>
<th>DEN</th>
<th>SEN</th>
<th>UNIT</th>
<th>SEL</th>
<th>LNG</th>
<th>LNGF</th>
<th>Output clock</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>

<td>1</td>
<td>0</td>
<td>Unit delay(1)</td>
<td>Output clock phase(2)</td>
<td>Don’t care</td>
<td>Don’t care</td>
<td>Enabled (= selected phase)</td>
</tr>
</tbody>
</table>

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

28.4.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].
      If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.
28.4.5 **Output clock phase configuration procedure**

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.
28.5 DLYB registers

All registers can be accessed in word, half-word and byte access.

28.5.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>
Bit 31  **LNGF**: Length valid flag
This flag indicates when the delay line length value contained in LNG[11:0] is valid after
UNIT[6:0] bits changed.
0: Length value in LNG is not valid.
1: Length value in LNG is valid.

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  **LNG[11:0]**: Delay line length value
These bits reflect the 12 unit delay values sampled at the rising edge of the input clock.
The value is only valid when LNGF = 1.

Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **UNIT[6:0]**: Delay of a unit delay cell.
These bits can only be written when SEN = 1.
Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **SEL[3:0]**: Phase for the output clock.
These bits can only be written when SEN = 1.
Output clock phase = input clock + SEL[3:0] x unit delay

Refer to  Section 2.3 on page 116 for the register boundary addresses.
29  Analog-to-digital converter (ADC1)

29.1  Introduction

This section describes the implementation of the 14-bit ADC successive approximation analog-to-digital converter.

The ADC features up to 20 multiplexed channels. Channel A/D conversion can be performed in Single, Continuous, Scan or Discontinuous mode. The result of the ADC can be stored in a left-aligned or right-aligned 32-bit data register.

The ADC is mapped on the AHB bus to enable fast data handling.

In addition, the analog watchdog features enable the application to detect if the input voltage goes outside user-defined high or low thresholds.

The ADC features a built-in hardware oversampler that improves analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is also implemented to achieve very low consumption at low frequency.
29.2 **ADC main features**

- High-performance features
  - 14-, 12-, 10- or 8-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface for fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to four injected channels (fully configurable analog input assignment to regular or injected channels)
  - Hardware assistant to prepare the injected channel context and enable fast context switching
  - Data alignment with in-built data coherency
  - Data management by general-purpose DMA for regular channel conversions with FIFO
  - Data routing to MDF for post processing
  - Four dedicated data registers for injected channels

- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shift

- Data preconditioning
  - Gain compensation
  - Offset compensation

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Support of slow bus frequency applications while keeping optimum ADC performance
  - Automatic control to avoid ADC overrun in AHB bus clock low-frequency application (auto-delayed mode)

- Up to 17 external analog input channels connected to dedicated GPIO pads

- 3 internal dedicated channels
  - One channel for internal reference voltage (VREFINT)
  - One channel for internal temperature sensor (VSENSE)
  - One channel for VBAT monitoring channel (VBAT/4)

- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions or
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
• Conversion modes
  – Single mode: the ADC converts a single channel. The conversion is triggered by a special event.
  – Scan mode: the ADC scans and converts a sequence of channels.
  – Continuous mode: the ADC converts continuously selected inputs.
  – Discontinuous mode: the ADC converts a subset of the conversion sequence.
• Interrupt generation when the ADC is ready, at end of sampling, end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or when an overrun event occurs
• Three analog watchdogs
  The watchdogs can perform filtering to ignore out-of-range data.
• ADC input range: \( V_{\text{REF}_-} \leq V_{\text{IN}} \leq V_{\text{REF}_+} \)

Figure 147 shows the block diagram of one ADC.

29.3 ADC implementation

The tables below describe ADC implementation on STM32U575/585 devices. It also includes ADC4 for comparison.

29.4.3 ADC clocks

Dual clock domain architecture

Dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see Figure 148: ADC clock scheme). This selection is done in the RCC (refer to the RCC section for more information):

1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the AHB clock.
2. The ADC clock can be derived from the AHB clock.

Option 1 has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by a ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, using the prescaler configured through PRESC[3:0] bits in the ADC12_CCR register.

Option 2 enables to bypass the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through the RCC. It must be compliant with the operating frequency specified in the device datasheet.

Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock. However the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.
29.4.4 ADC connectivity

Figure 149. ADC1 connectivity

1. $V_{IN}[i]$ signal can only be used when the corresponding ADC input channel is configured as differential mode.
29.4.5 Slave AHB interface

The ADC implements an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests and never generates AHB errors.

29.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, follow the sequence below:

1. First exit Deep-power-down mode by clearing DEEPPWD bit.
2. Then, enable the ADC internal voltage regulator by setting ADVREGEN bit in the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator (T_{ADCVREG_STUP}) before launching a calibration or enabling the ADC. This can be done by software by polling the LDORDY bit of ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by clearing ADVREGEN bit. Power consumption can be further reduced by reducing the leakage currents. In addition, it is possible to enter again in ADC Deep-power-down mode by setting DEEPPWD bit in ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration factor is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary either to relaunch a calibration or apply again the calibration factor which was previously saved (refer to Section 29.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT)).

29.4.7 Single-ended and differential input channels

ADC channels can be configured either as single-ended input or as differential input. This is done by writing DIFSEL[19:0] bits in the ADC_DIFSEL register. This configuration must be performed while the ADC is disabled (ADEN = 0).

In Single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{REF.}$ (negative input).

In Differential input mode, the analog voltage to be converted for channel "i" is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{INN}[i]$ (negative input).
The output data in Differential mode is an unsigned data:

- When \( V_{\text{INP}[i]} = V_{\text{REF}-} \) \( ; V_{\text{INN}[i]} = V_{\text{REF}+} \) and output data = 0x0000 (14-bit resolution mode),
- When \( V_{\text{INP}[i]} = V_{\text{REF}+} \) \( ; V_{\text{INN}[i]} = V_{\text{REF}-} \) and output data = 0x3FFF.

\[
\text{Converted value} = \frac{\text{ADC Full Scale}}{2} \times \left[ 1 + \frac{V_{\text{INP}} - V_{\text{INN}}}{V_{\text{REF}+}} \right]
\]

When ADC is configured as Differential mode, both inputs must be biased at \( V_{\text{REF}+} / 2 \) voltage.

For a complete description of how the input channels are connected, refer to Section 29.4.4: ADC connectivity.

**Caution:** When channel “i” is configured in Differential input mode, its negative input voltage is connected to \( V_{\text{INN}[i-1]} \).

**29.4.8 Calibration (ADCAL, ADCALLIN, ADC_CALFACT)**

The ADC provides an automatic calibration procedure that controls the whole calibration sequence including the ADC power-on/off. During the procedure, the ADC calculates an offset calibration factor for Single-ended and Differential mode. This factor includes the internal offset and the linearity that are applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until the calibration is complete.

The calibration is a prerequisite to any ADC operation. It removes the systematic errors that may vary from chip to chip and enables to compensate offset and linearity deviation.

The offset calibration is the same for single-ended or differential channels.

The linearity correction must be done only once, regardless of single / differential configuration:

- Set ADCALLIN in ADC_CR before launching a calibration that runs the linearity calibration simultaneously with the offset calibration or
- Clear ADCALLIN in ADC_CR before launching a calibration that does not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting ADCAL bit. The calibration can only be initiated when the ADC is disabled (ADEN = 0). ADCAL bit remains at 1 during all the calibration sequence. It is cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC.

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods of time, the temperature changes, or the supply voltage is modified of more than 10%, it is recommended that a new offset calibration cycle is run before enabling the ADC again.

The internal analog calibration is lost each time the ADC power is switched off (for example, when the device enters Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, the calibration factor can be written again to the ADC analog block without recalibrating, assuming that the software has previously saved the calibration factor generated during the previous calibration.
The calibration factor obtained during factory tests is programmed in a specific device option byte. To reduce the calibration time, this value can be copied to the analog ADC.

The calibration factor can be written if the ADC is enabled and no calibration is ongoing (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This operation is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate the ADC offset when \(V_{\text{REF}^+}\) changes of more than 10%.

Refer to the device datasheet for the offset and linearity calibration time requirements.

**Software procedure to calibrate the ADC**

1. Make sure DEEPPWD = 0, ADVREGEN = 1 and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure ADEN = 0.
3. Either enable the linearity calibration (ADCALLIN = 1) or disable it (ADCALLIN = 0).
4. Make sure CAPTURE_COEF and LATCH_COEF in ADC_CALFACT are cleared.
5. Set ADCAL in ADC_CR register and wait until ADCAL = 0.

*Figure 150* shows the ADC calibration timing diagram.

**Note:** The software can launch the calibration only when ADEN = 0, LDORDY = 1 (ADC disabled and LDO ready).

Single-ended and differential channels cannot be calibrated separately. The offset calibration must be performed within the same sequence.

**Indicative timings**

- by S/W
- by H/W

Note: The software can launch the calibration only when ADEN = 0, LDORDY = 1 (ADC disabled and LDO ready).

Single-ended and differential channels cannot be calibrated separately. The offset calibration must be performed within the same sequence.
Reading calibration factor procedure

Once the calibration is complete (ADCAL bit cleared by hardware), the calibration factor can be read using the ADC_CALFACT2 register. Nine read accesses are required to perform this operation:

1. Make sure DEEPPWD = 0, ADVREGEN = 1, and check that the ADC voltage regulator startup time has elapsed (LDORDY = 1).
2. Make sure that ADEN = 1.
3. Set CAPTURE_COEF and clear LATCH_COEF in ADC_CALFAC register.
4. Select the calibration factor by setting CALLINDEX[0:3] in ADC control register (ADC_CR).
5. Read the calibration factor from ADC_CALFACT2 register.
6. Repeat steps 4 and 5 for each required calibration factor.

Note: The software can access the calibration factor only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Software procedure to reinject the calibration factor into the ADC

1. Make sure ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Clear CAPTURE_COEF and LATCH_COEF bits in ADC_CALFACT register.
3. Set CALINDEX[3:0] to the targeted calibration index to be updated, then write the calibration factor to CALFACT[31:0] in ADC_CALFACT2 register.
4. Repeat step 3 for the necessary calibration index.
5. Set LATCH_COEF bit in ADC_CALFACT register.

Note: The software is allowed to update the calibration factor only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).

Calibration factor index

The calibration factors are stored in the analog block in an indexed way. Index 0b0000 and 0b1000 contains the offset calibration factor while index 0b0001 to 0b0110 contain the linearity factor. The lower two bytes of index 0b0111 contain the linearity calibration factor. The internal offset calibration factor must be programmed into the second byte of index 0b0111. However, it is read at byte 3 of index 0b1000. When programming or reinjecting the calibration factor, make sure to use the correct indexes for read and write operations.

Refer to Table 233 for a summary.

<table>
<thead>
<tr>
<th>CALINDEX[3:0] values</th>
<th>Calibration factor</th>
<th>Byte location</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Byte 3</td>
</tr>
<tr>
<td>0b0000</td>
<td>Differential offset</td>
<td></td>
</tr>
<tr>
<td>0b0001</td>
<td>Linearity factor 1</td>
<td></td>
</tr>
</tbody>
</table>
To run an offset calibration when the linearity calibration factor is programmed by software, first program the linearity calibration factor, then run the offset calibration. Running the offset calibration first would cause the offset calibration factor to be overwritten when the LATCH_COEF bit is programmed.

It is impossible to program the offset calibration alone since byte 1 and byte 0 (linearity factor 7) are overwritten when programming the offset calibration factor into byte 2 of index 0b0111. To avoid this, read the linearity calibration factor then program index 0b0111 with the read value.

### 29.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure described in Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

Once DEEPPWD bit is cleared and ADVREGEN bit is set, the ADC can be enabled. It requires a stabilization time of $t_{\text{STAB}}$ before starting converting accurately (see Figure 151). Two control bits enable or disable the ADC:

- When $\text{ADEN} = 1$: the ADC is enabled. The ADRDY is set as soon as the ADC is ready for operation.
- When $\text{ADDIS} = 1$: the ADC is disabled.

ADEN and ADDIS bits are automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to Section 29.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])) or when an external trigger event occurs if triggers are enabled. Injected conversions start by setting JADSTART or when an external injected trigger event occurs if injected triggers are enabled.
Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing 1.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to make sure that no conversion is ongoing. If required, stop any ongoing regular and injected conversion by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 151. Enabling / Disabling the ADC

29.4.10 Constraints when writing the ADC control bits

The software can program the RCC control bits to configure and enable the ADC clock (refer to the Reset and clock control section), the control DIFSEL bits in the ADC_DIFSEL register, the ADC12_CCR register and the ADCAL and ADEN control bits in the ADC_CR register, only if the ADC is disabled.

The software can program the ADCAL bit to launch the calibration when ADEN is cleared to 0. It can read or update the calibration factor if ADEN is set to 1 and no conversion is ongoing (ADSTART and JADSTART both cleared to 0).

The software is then allowed to write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable it (ADEN must be equal to 1 and ADDIS to 0).
The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRy, ADC_LTRy, ADC_HTRy, ADC_SQRy, ADC_OFRy and ADC_IER registers:

- Control bits related to configuration of regular conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no regular conversion is ongoing (ADSTART must be equal to 0).
- Control bits related to configuration of injected conversions: the software is allowed to write them only if the ADC is enabled (ADEN = 1) and no injected conversion is ongoing (JADSTART must be equal to 0).
- ADC_LTRy, ADC_HTRy registers can be modified when an analog-to-digital conversion is ongoing (refer to Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWĐy) for details).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled, a conversion is ongoing and there is no pending request to disable it (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

Note: There is no hardware protection to prevent these forbidden write accesses which may cause the ADC to enter an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN as well as all the bits of ADC_CR register).

29.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 20 multiplexed channels:

- Up to 17 analog inputs coming from GPIO pads
- The ADC is connected to 3 internal analog inputs:
  - the internal temperature sensor (VS\_SENSE)
  - the internal reference voltage (V\_REFINT)
  - the V\_BAT monitoring channel (V\_BAT/4)

Refer to Table ADC interconnection in Section 29.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC\_IN3, ADC\_IN8, ADC\_IN2, ADC\_IN2, ADC\_IN0, ADC\_IN2, ADC\_IN2, ADC\_IN15.

- A regular group is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An injected group is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions are ongoing. To modify ADC_SQRy registers, the ADC regular conversions must first be stopped by setting ADSTP to 1 (refer to Section 29.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)).

Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VB\_ATEN, VSEN\_SESEL or VREF\_EN bits in the ADC12_CCR registers.
29.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx bits, the corresponding ADC_PCSEL bit must be configured in advance.

This ADC_PCSEL bit controls the analog switch integrated in the I/O level. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed and the analog switch integrated in the I/O cannot react as fast as ADC multiplexer does. To avoid the delay due to on analog switch control on the I/O, it is necessary to preselect the input channels which is selected through the SQRx and JSQRx. The selection is based on the VINP[i] of each ADC input. For example, if the ADC converts ADC_IN1, PCSEL1 bit must also be set in ADC_PCSEL.

29.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time that is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 5 ADC clock cycles
- SMP = 001: 6 ADC clock cycles
- SMP = 010: 12 ADC clock cycles
- SMP = 011: 20 ADC clock cycles
- SMP = 100: 36 ADC clock cycles
- SMP = 101: 68 ADC clock cycles
- SMP = 110: 391 ADC clock cycles
- SMP = 111: 814 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + \text{Conversion time} \]

Example

When converting a single data, the sampling time is 5 cycles and the conversion time is 17 cycles for 14-bit mode. With an \( F_{\text{adc, ker,ck}} \) of 55 MHz:

\[ T_{\text{CONV}} = (5 + 17) \text{ ADC clock cycles} = 22 \text{ ADC clock cycles} = 0.40 \mu\text{s} \]

The above result assumes that \( R_{\text{in}} \ll 1 \text{ K}\Omega \) (refer to the datasheet for additional sampling time to be added depending on the external resistance).

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

I/O analog switches voltage booster

The I/O analog switches resistance increases when the \( V_{\text{DDA}} \) voltage is too low. This requires to adapt the sampling time accordingly (see the device datasheet for electrical
characteristics). This resistance can be minimized at low $V_{DDA}$ by enabling an internal voltage booster (refer to the SYSCFG section for more details).

**Bulb sampling mode**

When the BULB bit is set in ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The Bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The Bulb mode could not be used in continuous conversion mode or with injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

**Figure 152. Bulb mode timing diagram**

![Bulb mode timing diagram](MSv62473V1)

**Sampling time control trigger mode**

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is not compatible with the continuous conversion mode and injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.
29.4.14 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs once the conversions of all channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)
  ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

29.4.15 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set
Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

**Note:**
To convert a single channel, program a sequence with a length of 1.

*It is not possible to have both Discontinuous mode and Continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.*

*Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Section: Auto-injection mode.*

### 29.4.16 Starting conversions (ADSTART, JADSTART)

The software starts ADC regular conversions by setting ADSTART to 1. When ADSTART is set, the conversion starts:
- immediately if EXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 0x0

The software starts ADC injected conversions by setting JADSTART to 1. When JADSTART is set, the conversion starts:
- immediately, if JEXTEN[1:0] = 0x0 (software trigger) or
- at the next active edge of the selected injected hardware trigger if JEXTEN[1:0] is not equal to 0x0

**Note:**
*In Auto-injection mode (JAUTO = 1), use ADSTART bit to start regular conversions followed by auto-injected conversions (JADSTART must be kept cleared).*

ADSTART and JADSTART also provide information on whether any ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both set to 0, (the ADC is idle).

ADSTART is cleared by hardware:
- In Single mode with software trigger (CONT = 0, EXTEN[1:0] = 0x0): at any end of conversion sequence (EOS = 1)
- In Discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN[1:0] = 0x0): at end of conversion (EOC = 1)
- In all other cases (CONT = x, EXTEN[1:0] = x): after executing the ADSTP assertion procedure by software.

**Note:**
*In Continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.*

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN[1:0] ≠ 0x0), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. *This ensures that no further hardware triggers are missed.*

JADSTART is cleared by hardware:
- In Single mode with software injected trigger (JEXTEN[1:0] = 0x0): at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN = 1
- In all other cases (JEXTEN[1:0]=x): after executing the JADSTP assertion procedure by software.
Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

29.4.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution for single conversion and minus the overlap time between the sampling and the previous SAR for continuous conversion.

In Single conversion mode:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [5\text{ min} + 17\times 14\text{ bits}] \times T_{\text{adc ker ck}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 22 \times T_{\text{adc ker ck}} \text{ min for 14 bits} = 400.0 \text{ ns (for } f_{\text{adc ker ck}} = 55 \text{ MHz)}
\]

29.4.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP to 1, and injected conversions ongoing by setting JADSTP to 1.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice-versa. This enables, for instance, to reconfigure the injected conversion sequence and triggers while regular conversions are still ongoing (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion).
The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (in case of regular conversion), or JADSTP/JADSTART bits (in case of injected conversion) are cleared by hardware. The software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

**Note:** In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

29.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN[1:0], JEXTSEL, JEXTEN[1:0])

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware trigger which occurs while a conversion is ongoing are ignored.
- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 234 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

<table>

</tr>
</tbody>
</table>

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which events can trigger regular and injected groups conversion, out of 21 possibilities.

A regular group conversion can be interrupted by an injected trigger.

Note: The trigger selection cannot be changed on-the-fly.
Refer to Table ADC external triggers for regular channels and Table ADC external triggers for injected channels in Section 29.4.2: ADC pins and internal signals for the connection of the above internal analog inputs to external ADC pins or internal signals.

29.4.20 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit must be cleared in the ADC_CFGR1 register:

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

2. If an external injected trigger occurs or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 157 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 44 ADC clock cycles (that is two conversions with a minimum sampling time), the minimum interval between triggers must be 45 ADC clock cycles.
Auto-injection mode

If the JAUTO bit is set in the ADC_CFGR1 register, the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and Discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

![Figure 157. Injected conversion latency](MSv43771V1)

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.
29.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register. It is used to convert a short sequence (sub-group) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example

- DISCEN = 1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  -...

- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC(JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC(JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC(JSQR register.
Example
- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

29.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 14, 12, 10, 8 bits by programming the control bits RES[1:0]. Figure 162, Figure 163, Figure 164 and Figure 165 show the conversion result format with respect to the resolution as well as to the data alignment (in continuous mode assuming no added extra sampling cycle for high input resistance).

Lower resolution enables faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 236.

</tbody>
</table>

29.4.23 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.
The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

29.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

29.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers)

Figure 158. Single conversions of a sequence, software trigger

1. EXTEN[1:0] = 0x0, CONT = 0
2. Channels selected = 1, 9, 10, 17; AUTDLY = 0.
Figure 159. Continuous conversion of a sequence, software trigger

1. EXTEN[1:0] = 0x0, CONT = 1
2. Channels selected = 1, 9, 10, 17; AUTDLY = 0.

Figure 160. Single conversions of a sequence, hardware trigger

1. TRGx (over-frequency) is selected as trigger source, EXTEN[1:0] = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.
29.4.26 Low-frequency trigger mode (LFTRIG)

Once the ADC is enabled or when the last ADC conversion is complete, the ADC is ready to start the next conversion. The ADC needs to be started at a defined time ($T_{idle}$) otherwise the converted data can be corrupted due to transistor leakage (refer to the datasheet for the maximum value of $T_{idle}$).

If the user application requires a time higher than $T_{idle}$ maximum value between one trigger to another for single conversion mode, or between ADC enable and the first conversion, then the ADC converter input multiplexer must be re-initialized. This operation is selected by setting LFTRIG bit in ADC_CFRG2.

29.4.27 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFRG2 register selects the alignment of the data stored after conversion. By default, data are right-aligned. Refer to Figure 162, Figure 163, Figure 164 and Figure 165 for examples of data alignment.

Note: The data can be re-aligned in normal and in oversampling mode.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by programming a value different from 0 in OFFSETy[23:0] bit field into ADC_OFRy register. The channel to which the offset is applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. The offset
Analog-to-digital converter (ADC1)

can be positive or negative depending on the value of POSOFF bit. When POSOFF is set to 0, the converted value is subtracted by the user-defined offset written in OFFSETy[23:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (e.g. in 14-bit mode, the maximum offset value is 0x3FFF).

The offset can be used to convert unsigned data to signed data (e.g. in 14-bit mode, the offset value is equal to 0x2000).

The offset correction is also supported in Oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

*Table 237* describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

Signed 32-bit or 16-bit format

Signed 8-bit format SSAT = 1
Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data. To limit the original width, the data saturation can be enabled through SSAT and USAT bits of ADC_OFRy register.
Unsigned 14-bit data can be extended to 15-bit signed data by using an offset value different from 0x2000.

The original data width can be preserved by setting SSAT bit to 1 to limit the data width to 14 bits.

Unsigned data can be saturated to the original data width by setting USAT bit to 1.

*Table 238* shows the sign-extended data format corresponding to different resolutions.

*Caution:* SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure this recommendation is respected.
Gain compensation

When the GCOMP bit is set in ADC_CFGR2 register, the gain compensation is activated on all converted data. After each conversion, data is calculated using the following formula.

\[
\text{DATA} = \text{DATA}(\text{adc result}) \times \left(\frac{\text{GCOMPCOEFF}}{4096}\right)
\]

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATA or JDATAx registers, the LSB−1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used for the oversampling mode, the gain calculation is performed after the accumulation and right-shift operations to minimize the power consumption (the gain calculation is done only once instead of at each conversion). The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode the bit ADC_CFGR2.ROVSM bit must be set to resume the pending conversion with the correct value.

ADC overrun (OVRMOD)

The overrun flag (OVR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (eight stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun event occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP bit to 1.

OVR flag is cleared by software by writing 1 to it.

Data can be configured to be preserved or overwritten when an overrun event occurs by programming the OVRMOD control bit of the ADC_CFGR1 register:

- **OVRMOD = 0**
  
  The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (8 data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data are also discarded.

- **OVRMOD = 1**
  
  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, further conversions operate normally and the ADC_DR register always contains the latest converted data.
Figure 166. Example of overrun (OVRMOD = 0)

Figure 167. Example of overrun (OVRMOD = 1)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.
Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (for example if the device features an analog watchdog). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored in a unique data register, it is useful to use DMA to convert more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR register in Single ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of the OVRMOD bit, the data is either preserved or overwritten.

The DMA transfer requests are blocked until the software clears the OSV bit.

Two different DMA modes are proposed depending on the application. They can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register, in Single ADC mode and in dual ADC mode, respectively:

- **DMA one shot mode (DMNGT[1:0] = 01).**
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- **DMA circular mode (DMNGT[1:0] = 11)**
  This mode is suitable when programming the DMA in Circular mode.
DMA one shot mode (DMNGT[1:0] = 01)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):
- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMNGT[1:0] = 11)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. DMA can be programmed either single transfer mode or incremental burst mode (4 beats), according to this mode, correct request line is selected by the DMA. Refer to the DMA chapter for further information.

29.4.28 Managing conversions using the MDF

The ADC conversion results can be transferred directly to the MDF.

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers the 16 least significant bits of the regular data register to the MDF through adcx_dat[15:0] bus, which in turn resets the EOC flag once the transfer is effective.

The data format must be in 16-bit signed format:
- ADC_DR[31:16] = don’t care
- ADC_DR[15] = sign
- ADC_DR[14:0] = data

Any value above 16-bit signed format is truncated.

29.4.29 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to
optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:
- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 168).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 169).

The Auto-delayed conversion mode enables to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

**Note:** There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

**Note:** This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):
- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 169).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 171).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 172).

To stop a conversion in continuous auto-injection mode combined with Auto-delay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:
1. Wait until JEOS = 1 (no more conversions are restarted).
2. Clear JEOS.
3. Set ADSTP = 1.
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.
In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

29.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 173. Analog watchdog guarded area

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 240 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in the HTR1[24:0] bits of the ADC_HTR1 register and LTR1[24:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 25-bits (14-bit resolution with oversampling, OSR=256).

When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBS of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned to the half-word boundary).

Table 241 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

1. The watchdog comparison is performed when the oversampling, the gain compensation and the offset compensation are complete (the data that are compared can be either signed or unsigned).

Analog watchdog filter for watchdog 1

When the ADC is configured with only one input channel (selecting several channels in Scan mode not allowed), a valid ADC conversion data range can be configured through the ADC_LTR1 and ADC_HTR1 register:

- When converted data belong to the range defined in ADC_LTR1 and ADC_HTR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_HTR1, the AWDx flag is set and the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHY[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHY[19:0] (y=2,3) is set.

The threshold can be up to 25 bits (14-bit resolution with oversampling, OSR = 1024, and offset conversion in signed format) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 14 bits (according to bits RES[1:0]), the LSBS of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 14-bit converted data (left aligned).
ADC_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADC_AWDy_OUT (y being the watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

- Converting the injected channels 1, 2, 3, 4
- All injected channels 1, 2, 3, 4 are guarded
Analog watchdog threshold control

LTRx[24:0] and HTRx[24:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTRx[24:0] and HTRx[24:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in a analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWD_OUT signal.

Analog watchdog with gain and offset compensation

When gain and offset compensation are enabled, the analog watchdog compares the threshold after the compensated data.

29.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 24-bit (14-bit values and OSR = 1024).

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)
\]

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OSR[9:0] bits in the ADC_CFGR2 register, and can range from 2x to 1024x. The division coefficient M consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 24 bits (1024 x 14-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

*Figure 178* gives a numerical example of the processing, from a raw 24-bit accumulated data to the final 14-bit result.
The conversion timings in Oversampled mode do not change: the sample time is maintained during the whole oversampling sequence. A new data is provided every N conversions with an equivalent delay equal to N x T\text{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase.
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total).

## Operating modes supported during oversampling

In Oversampling mode, most of the ADC operating modes are maintained:

- Single or Continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (configured through RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 14-bit conversions.

**Note:** The Alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_{EN} bit in ADC_OFRy register is ignored (considered as reset).
**Analog watchdog**

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following differences:

- The RES[1:0] bits are ignored, comparison is always done using the full 25-bit values, HTRx[24:0] and LTRx[24:0].
- The comparison is performed on the oversampled accumulated value before shifting.

*Note:* Care must be taken when using high shifting values, since this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding an 8-bit right-aligned data, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[7:0]/LT[7:0]. HT[11:8]/LT[11:8] must be kept reset.

**Triggered mode**

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The *Figure 179* below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

*Figure 179. Triggered regular oversampling mode (TROVS bit = 1)*

**Injected and regular sequencer management when oversampling**

In Oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).
Oversampling regular channels only

The regular oversampling mode bit, ROVSM, defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In Continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);

- In Resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode guarantees that all data used for oversampling were converted back-to-back within a single time-slot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

*Figure 180* gives examples for an oversampling ratio of 4x.

Resumed mode: ROVSE = 1, JOVSE = 0, ROVSM = 1, TROVS = X

Oversampling Injected channels only

The injected oversampling mode bit, JOVSE, enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and Injected channels

Both ROVSE and JOVSE bits can be set simultaneously. In this case, the Regular oversampling mode is forced to Resumed mode (ROVSM bit ignored), as shown in Figure 181.

**Figure 181. Regular and injected oversampling modes used simultaneously**

![Diagram showing regular and injected oversampling modes](https://example.com/diagram.png)

**Triggered regular oversampling with injected conversions**

Injected conversions can be performed in Triggered regular mode. In this case, the Injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (Resumed mode forced). The JOVSE bit must be reset. The behavior is shown in Figure 182.

**Figure 182. Triggered regular oversampling with injection**

![Diagram showing triggered regular oversampling with injection](https://example.com/diagram.png)
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers. This enables to save a DMA resource. This mode is available only when both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in Auto-injected mode.

*Figure 183* shows how the conversions are sequenced.

![Figure 183. Oversampling in auto-injected mode](image)

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Summary of combined modes

*Table 242* summarizes all mode combinations, including non-supported modes.

29.4.32 Temperature sensor

The temperature sensor can measure the device junction temperature \( T_j \) in the –40 to 125 °C temperature range.

The temperature sensor is internally connected ADC input channels that are used to convert the sensor output voltage to a digital value (see Section 29.4.4: ADC connectivity for more details). The sampling time for the temperature sensor analog pin must be greater than the stabilization time specified in the device datasheet.

When it is not in use, the sensor can be placed in power-down mode.

*Figure 184* shows the block diagram of the temperature sensor.

**Figure 184. Temperature sensor channel block diagram**

---

**Reading the temperature**

To use the sensor:

1. Select the input channels to which the temperature sensor is connected (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the VSENSESEL bit in the ADC12_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting data in the ADC data register.
6. Calculate the actual temperature using the following formula:

\[
\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30 \text{ °C}
\]

Where:
- TS\_CAL2 is the temperature sensor calibration value acquired at TS\_CAL2\_TEMP.
- TS\_CAL1 is the temperature sensor calibration value acquired at TS\_CAL1\_TEMP.
- TS\_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS\_CAL1 and TS\_CAL2 calibration points.

**Note:** The sensor has a startup time after waking from power-down mode and before it can output at the correct level. The ADC also has a startup time after power-on. As a result, to minimize the delay, the ADEN and VSENSESEL bits must be set simultaneously.

### 29.4.33 V\(_{\text{BAT}}\) supply monitoring

The VBATEN bit in the ADC12\_CCR register is used to switch to the battery voltage. As the V\(_{\text{BAT}}\) voltage could be higher than V\(_{\text{DDA}}\), the VBAT pin is internally connected to a bridge divider by 4 to ensure the correct operation of the ADC. This bridge is automatically enabled when VBATEN is set, to connect V\(_{\text{BAT}}/4\) to the corresponding ADC input channels (see Section 29.4.4: ADC connectivity for more details). As a consequence, the converted digital value is one fourth of the V\(_{\text{BAT}}\) voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V\(_{\text{BAT}}/4\) voltage.

*Figure 185* shows the block diagram of the V\(_{\text{BAT}}\) sensing feature.

*Figure 185. V\(_{\text{BAT}}\) channel block diagram*
Note: The VBATEN bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which VBAT is connected (see Section 29.4.4: ADC connectivity for more details).

29.4.34 Monitoring the internal voltage reference

The internal voltage reference can be monitored to have a reference point for evaluating the ADC VREF+ voltage level.

Refer to Section 29.4.4: ADC connectivity for details on the ADC input channels to which the internal voltage reference is internally connected.

The sampling time for this channel must be greater than the stabilization time specified in the device datasheet. Figure 185 shows the block diagram of the VREFINT sensing feature.

Figure 186. VREFINT channel block diagram

Note: The VREFEN bit of the ADC12_CCR register must be set to enable the conversion of the ADC internal channels to which VREFINT is connected (see Section 29.4.4: ADC connectivity for more details).

Calculating the actual VREF+ voltage using the internal reference voltage

The VDDA power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference (VREFINT) and its calibration data acquired by the ADC during the manufacturing process at VREF+ = 3.0 V can be used to evaluate the actual VREF+ voltage level, if VREF+ pin is connected to a variable VDDA power supply.

The following formula gives the actual VREF+ voltage supplying the device:

\[ V_{REF+} = 3.0 \times \frac{V_{REFINT\_CAL}}{V_{REFINT\_DATA}} \]

Where:
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.
Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference VREF+ and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of VDDA. For applications where VDDA is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

\[ V_{\text{CHANNELx}} = \frac{V_{\text{REF+}}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA} \]

For applications where VDDA value is not known, the internal voltage reference and VDDA can be replaced by the expression provided in Section: Calculating the actual VREF+ voltage using the internal reference voltage, resulting in the following formula:

\[ V_{\text{CHANNELx}} = \frac{3.0 \times V_{\text{REFINT\_CAL}} \times \text{ADC\_DATA}}{V_{\text{REFINT\_DATA}} \times \text{FULL\_SCALE}} \]

Where:
- VREFINT_CAL is the VREFINT calibration value
- ADC_DATA is the value measured by the ADC on channel x (right-aligned)
- VREFINT_DATA is the actual VREFINT output value converted by the ADC
- FULL_SCALE is the maximum digital value of the ADC output. For example with 14-bit resolution, it is \(2^{14} - 1 = 16383\) or with 8-bit resolution, \(2^8 - 1 = 255\).

Note: If ADC measurements are done using an output format other than 14-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

### 29.5 ADC interrupts

For each ADC, an interrupt can be generated:
- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.

Bits 31:13 Reserved, must be kept at reset value.

**Bit 12 LDO RDY**: ADC voltage regulator ready

This bit is set by hardware. It indicates that the ADC internal supply is ready. The ADC is available after $t_{AVDREG\_SETUP}$ time.

0: ADC voltage regulator disabled

1: ADC voltage regulator enabled

Bits 11:10 Reserved, must be kept at reset value.

**Bit 9 AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_LTR3 & ADC_HTR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

**Bit 8 AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_LTR2 & ADC_HTR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

**Bit 7 AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_LTR1 & ADC_HTR1 register. It is cleared by software. writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred
Bit 6 JEOS: Injected channel end of sequence flag
This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Injected conversions complete

Bit 5 JEOC: Injected channel end of conversion flag
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Injected channel conversion complete

Bit 4 OVR: ADC overrun
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3 EOS: End of regular sequence flag
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Regular Conversions sequence complete

Bit 2 EOC: End of conversion flag
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Regular channel conversion complete

Bit 1 EOSMP: End of sampling flag
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0 ADRDY: ADC ready
This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion
29.6.2 ADC interrupt enable register (ADC_IER)

Bit 4  **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note:* Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note:* Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2  **EOCIE**: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note:* Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note:* Software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0  **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note:* Software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

#### Bit 31 ADCAL: ADC calibration

This bit is set by software to start the ADC calibration. It is cleared by hardware after calibration is complete.

- 0: Calibration complete
- 1: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.

*Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.*

#### Bit 30 Reserved, must be kept at reset value.

#### Bit 29 DEEPPWD: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

- 0: ADC not in deep-power down
- 1: ADC in Deep-power-down (default reset state)

*Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).*

#### Bit 28 ADVREGEN: ADC voltage regulator enable

This bit is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

- 0: ADC Voltage regulator disabled
- 1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to [Section 29.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)].

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
Bits 27:24 **CALINDEX[3:0]**: Calibration factor

This bitfield controls the calibration factor to be read or written. Calibration index 0 is dedicated to single-ended and differential offsets, calibration index 1 to 7 to the linearity calibration factors, and index 8 to the internal offset:

- 0000: Offset calibration factor
- 0001: linearity calibration factor 1
- 0010: linearity calibration factor 2
- 0011: linearity calibration factor 3
- 0100: linearity calibration factor 4
- 0101: linearity calibration factor 5
- 0110: linearity calibration factor 6
- 0111: linearity calibration factor 7 and internal offset (write access only)
- 1000: internal offset (read access only)
- Others: Reserved, must not be used

**Note:** ADC_CALFACT2[31:0] correspond to the location of CALINDEX[3:0] calibration factor data (see Section 29.4.8: Calibration (ADCAL, ADCALLIN, ADC_CALFACT) for details).

Bits 23:17 Reserved, must be kept at reset value.

**Bit 16** **ADCALLIN**: Linearity calibration

This bit is set and cleared by software to enable the linearity calibration.

- 0: Writing ADCAL launches a calibration without the linearity calibration.
- 1: Writing ADCAL launches a calibration with the linearity calibration.

**Note:** The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 15:6 Reserved, must be kept at reset value.

**Bit 5** **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

- 0: No ADC stop injected conversion command ongoing
- 1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set JADSTP only when JADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)
Bit 4 ADSTP: ADC stop of regular conversion command
This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).
0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART = 1 and ADDIS = 0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).
In Auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 3 JADSTART: ADC start of injected conversion
This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).
It is cleared by hardware:
– in Single conversion mode when software trigger is selected (JEXTSEL = 0x0): at the assertion of the end of injected conversion sequence (JEOS) flag.
– in all cases: after the execution of the JADSTP command, at the same time as JADSTP is cleared by hardware.
0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).
In Auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in Single conversion mode (CONT = 0, DISCEN = 0) when software trigger is selected (EXTEN[1:0] = 0x0): at the assertion of the end of regular conversion sequence (EOS) flag.
- In Discontinuous conversion mode (CONT = 0, DISCEN = 1), when the software trigger is selected (EXTEN[1:0] = 0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note:* The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC)

In Auto-injection mode (JAUTO = 1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note:* The software is allowed to set ADDIS only when ADEN = 1 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note:* The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

</table>

**Bit 31**  Reserved, must be kept at reset value.

**Bits 30:26** **AWD1CH[4:0]:** Analog watchdog 1 channel selection  
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.  
- 00000: ADC analog input channel-0 monitored by AWD1  
- 00001: ADC analog input channel-1 monitored by AWD1  
  ........  
- 10011: ADC analog input channel-19 monitored by AWD1  
Others: Reserved, must not be used  
*Note:* The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

**Bit 25**  **JAUTO:** Automatic injected group conversion  
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.  
- 0: Automatic injected group conversion disabled  
- 1: Automatic injected group conversion enabled  
*Note:* The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no regular nor injected conversion is ongoing).

**Bit 24**  **JAWD1EN:** Analog watchdog 1 enable on injected channels  
This bit is set and cleared by software  
- 0: Analog watchdog 1 disabled on injected channels  
- 1: Analog watchdog 1 enabled on injected channels  
*Note:* The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

**Bit 23**  **AWD1EN:** Analog watchdog 1 enable on regular channels  
This bit is set and cleared by software  
- 0: Analog watchdog 1 disabled on regular channels  
- 1: Analog watchdog 1 enabled on regular channels  
*Note:* The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
   - This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels
   - 0: Analog watchdog 1 enabled on all channels
   - 1: Analog watchdog 1 enabled on a single channel
   - *Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 21 Reserved, must be kept at reset value.

Bit 20 **JDISCEN**: Discontinuous mode on injected channels
   - This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
   - 0: Discontinuous mode on injected channels disabled
   - 1: Discontinuous mode on injected channels enabled
   - *Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*
   - *It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count
   - These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
     - 000: 1 channel
     - 001: 2 channels
     - ...
     - 111: 8 channels
   - *Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 16 **DISCEN**: Discontinuous mode for regular channels
   - This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.
   - 0: Discontinuous mode for regular channels disabled
   - 1: Discontinuous mode for regular channels enabled
   - *Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.*
   - *It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*
   - *The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode
   - This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.
     - 0: Auto-delayed conversion mode off
     - 1: Auto-delayed conversion mode on
   - *Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*
Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode
1: Continuous conversion mode

**Note**: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note**: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EX TEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

**Note**: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0
00001: adc_ext_trg1
...

Refer to the ADC external trigger for regular channels in Section 29.4.2: ADC pins and internal signals for details on trigger mapping.

**Note**: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).
Bit 4  Reserved, must be kept at reset value.

Bits 3:2  \textbf{RES}[1:0]: Data resolution

These bits are written by software to select the resolution of the conversion.

- 00: 14 bits
- 01: 12 bits
- 10: 10 bits
- 11: 8 bits

\textit{Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).}

Bits 1:0  \textbf{DMNGT}[1:0]: Data management configuration

This bit is set and cleared by software to select how the ADC interface output data are managed.

- 00: Regular conversion data stored in DR only
- 01: DMA One-shot mode selected
- 10: MDF mode selected
- 11: DMA Circular mode selected

\textit{Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).}

Bits 31:28 LSHIFT[3:0]: Left shift factor
This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.
0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 27 LFTRIG: Low-frequency trigger
This bit is set and cleared by software
0: Low-frequency trigger mode disabled
1: Low-frequency trigger mode enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.
Bits 25:16 **OSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

- 0: 1x (no oversampling)
- 1: 2x
- 2: 3x
- ...
- 1023: 1024x

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 15 **SMPTTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

- 0: Sampling time control trigger mode disabled
- 1: Sampling time control trigger mode enabled

The sampling time starts on the trigger rising edge, and the conversion on the trigger falling edge.

EXTEN[1:0] bits must be set to 01. BULB bit must not be set when the SMPTTRIG bit is set.

When EXTEN[1:0] bits is set to 00, set SWTRIG to start the sampling and clear SWTRIG bit to start the conversion.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to enable the bulb sampling mode.

- 0: Software trigger starts the conversion for sampling time control trigger mode
- 1: Software trigger starts the sampling for sampling time control trigger mode.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to select the bulb sampling mode.

- 0: Bulb sampling mode disabled
- 1: Bulb sampling mode enabled. The sampling period starts just after the previous end of the conversion.

SMPTTRIG bit must not be set when the BULB bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular Oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

- 0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
- 1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).*
Bit 9 TROVS: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling.
0: All oversampled conversions for a channel are done consecutively following a trigger.
1: Each oversampled conversion for a channel needs a new trigger.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 OVSS[3:0]: Oversampling right shift
This bit field is set and cleared by software to define the right shifting applied to the raw oversampling result.
- 0000: No right shift
- 0001: 1-bit right shift
- 0010: 2-bit right shift
- 0011: 3-bit right shift
- 0100: 4-bit right shift
- 0101: 5-bit right shift
- 0110: 6-bit right shift
- 0111: 7-bit right shift
- 1000: 8-bit right shift
- 1001: 9-bit right shift
- 1010: 10-bit right shift
- 1011: 11-bit right shift
- Others: Reserved, must not be used.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 JOVSE: Injected Oversampling Enable
This bit is set and cleared by software to enable injected oversampling.
0: Injected oversampling disabled
1: Injected oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). 

Bit 0 ROVSE: Regular Oversampling Enable
This bit is set and cleared by software to enable regular oversampling.
0: Regular Oversampling disabled
1: Regular Oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMP[19:10][2:0]**: Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

- 000: 5 ADC clock cycles
- 001: 6 ADC clock cycles
- 010: 12 ADC clock cycles
- 011: 20 ADC clock cycles
- 100: 36 ADC clock cycles
- 101: 68 ADC clock cycles
- 110: 391 ADC clock cycles
- 111: 814 ADC clock cycles

*Note:* The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 31:20: Reserved, must be kept at reset value.

Bits 19:0 **PCSEL[19:0]: Channel i (VINP[i]) preselection**

These bits are written by software to preselect the input channel I/O instance to be converted.

- 0: Input channel i (VINP[i]) is not preselected for conversion, the ADC conversion of this channel shows a wrong result.
- 1: Input channel i (VINP[i]) is preselected for conversion

*Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).*

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

| Bits 31:11 | Reserved, must be kept at reset value. |
| Bits 10:6 | **SQ16[4:0]**: 16th conversion in regular sequence  
These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence. 

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing). |
| Bit 5 | Reserved, must be kept at reset value. |
| Bits 4:0 | **SQ15[4:0]**: 15th conversion in regular sequence  
These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence. 

*Note:* The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing). |
29.6.13  ADC regular data register (ADC_DR)

Address offset: 0x40
Reset value: 0x0000 0000

Bits 31:0 \textbf{RDATA}[31:0]: Regular data converted
These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in \textit{Section 29.4.27: Data management}. 
Analog-to-digital converter (ADC1) RM0456

29.6.14  ADC injected sequence register (ADC_JSQR)

Address offset: 0x4C
Reset value: 0x0000 0000

Bits 31:27  **JSQ4[4:0]**: 4th conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 26  Reserved, must be kept at reset value.

Bits 25:21  **JSQ3[4:0]**: 3rd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 20  Reserved, must be kept at reset value.

Bits 19:15  **JSQ2[4:0]**: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.

Bit 14  Reserved, must be kept at reset value.

Bits 13:9  **JSQ1[4:0]**: 1st conversion in the injected sequence
These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing.
Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels
   - These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
   - 00: Hardware trigger detection disabled (conversions can be launched by software)
   - 01: Hardware trigger detection on the rising edge
   - 10: Hardware trigger detection on the falling edge
   - 11: Hardware trigger detection on both the rising and falling edges
   - **Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group
   - These bits select the external event used to trigger the start of conversion of an injected group:
   - 00000: adc_jext_trg0
   - 00001: adc_jext_trg1
   - ...
   - Refer to the ADC external trigger for injected channels in Section 29.4.2: ADC pins and internal signals for details on trigger mapping.
   - **Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length
   - These bits are written by software to define the total number of conversions in the injected channel conversion sequence.
   - 00: 1 conversion
   - 01: 2 conversions
   - 10: 3 conversions
   - 11: 4 conversions
   - **Note:** The software is allowed to write these bits only when JADSTART = 0 (which ensures that no injected conversion is ongoing).
29.6.15 ADC offset register (ADC_OF Ry)

Address offset: 0x60 + 0x04 * (y-1), (y = 1 to 4)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:27</td>
<td>OFFSET_CH[4:0]: Channel selection for the data offset y</td>
<td>These bits are written by software to define the channel to which the offset programmed into OFFSETy[25:0] bits applies. Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing). If OFFSETy_EN bit is set, it is not allowed to select the same channel in different ADC_OF Ry registers.</td>
</tr>
<tr>
<td>Bit 26</td>
<td>SSAT: Signed saturation enable</td>
<td>This bit is written by software to enable or disable the Signed saturation feature. (see Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, USAT, SSAT) for details). 0: Offset is subtracted maintaining data integrity and extending converted data size (9-bit and 15-bit signed format). 1: Offset is subtracted and result is saturated to maintain converted data size. Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).</td>
</tr>
</tbody>
</table>
Bit 25 **USAT**: Unsigned saturation enable
This bit is written by software to enable or disable the unsigned saturation feature.
0: Offset is subtracted maintaining data integrity and keeping converted data size
1: Offset is subtracted and result is saturated to maintain converted data size.

*Note*: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0
(which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: offset sign
This bit is set and cleared by software to enable the positive offset.
0: Negative offset
1: Positive offset

*Note*: The software is allowed to write these bits only when ADSTART = 0 and
JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 **OFFSET[23:0]**: Data offset y for the channel programmed into OFFSETy.CH[4:0] bits
These bits are written by software to define the offset y to be subtracted from the raw
converted data when converting a channel (regular or injected). The channel to which the
data offset y applies must be programmed to the OFFSETy.CH[4:0] bits. The conversion
result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi
registers (injected conversion).
When OFFSETy[21:0] bitfield is reset, the offset compensation is disabled.

*Note*: The software is allowed to write these bits only when ADSTART = 0 and
JADSTART = 0 (which ensures that no conversion is ongoing).

If several offsets (OFFSETy) point to the same channel, only the offset with the lowest y
value is considered for the subtraction.
For example, if OFFSET1.CH[4:0] = 4 and OFFSET2.CH[4:0] = 4, this is
OFFSET1[25:0] that is subtracted when converting channel 4.
29.6.16 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x70
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>GCOMP</th>
<th>Gain compensation mode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>This bit is set and cleared by software to enable the gain compensation mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: Regular ADC operating mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Gain compensation enabled and applied on all channels</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).</td>
</tr>
</tbody>
</table>

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 GCOMPCOEFF[13:0]: Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

- 00 1000 0000 0000: gain factor of 0.5
- ... 01 0000 0000 0000: gain factor of 1
- 10 0000 0000 0000: gain factor of 2
- 11 0000 0000 0000: gain factor of 3
- ...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.999756.

**Note:** This gain compensation is only applied when GCOMP bit of ADCx_CFG2 register is 1.
### 29.6.17 ADC injected data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y = 1 to 4)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>JDATA[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
</tr>
<tr>
<td>15</td>
</tr>
</tbody>
</table>

Bits 31:0 **JDATA[31:0]**: Injected data
These bits are read-only. They contain the conversion result from injected channel y. The data are left- or right-aligned as described in Section 29.4.27: Data management.

### 29.6.18 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0xA0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>AWD2CH[19:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
</tr>
<tr>
<td>15</td>
</tr>
<tr>
<td>AWD2CH[15:0]</td>
</tr>
<tr>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

- \( \text{AWD2CH[i]} = 0 \): ADC analog input channel-i is not monitored by AWD2
- \( \text{AWD2CH[i]} = 1 \): ADC analog input channel-i is monitored by AWD2

When \( \text{AWD2CH[19:0]} = 000...0 \), the analog Watchdog 2 is disabled

**Note:** The channels selected by AWD2CH must be also selected into the SQRI or JSQRi registers.
Software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).
29.6.19  ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xA4</th>
<th>Reset value: 0x0000 0000</th>
</tr>
</thead>
</table>

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **AWD3CH[19:0]: Analog watchdog 3 channel selection**

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

- AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3
- AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3

When AWD3CH[19:0] = 000..0, the analog Watchdog 3 is disabled

**Note:** The channels selected by AWD3CH must be also selected into the SQRI or JSQRi registers. The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

29.6.20  ADC watchdog threshold register 1 (ADC_LTR1)

Address offset: 0xA8
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xA8</th>
<th>Reset value: 0x0000 0000</th>
</tr>
</thead>
</table>

Bits 31:25  Reserved, must be kept at reset value.

Bits 24:0  **LTR1[24:0]: Analog watchdog 1 lower threshold**

These bits are written by software to define the lower threshold for the analog watchdog 1.

Refer to **Section 29.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy).**
29.6.21 ADC watchdog threshold register 1 (ADC_HTR1)

Bits 31:0 **CALFACT[31:0]**: Linearity or offset calibration factor

- These bits can be written either by hardware or by software.
- They contain the 32-bit offset or linearity calibration factor.
- When **CAPTURE_COEF** is set to 1, the calibration factor of the analog block is read back and stored in CALFACT[31:0], indexed by CALINDEX[3:0] bits.
- When **LATCH_COEF** is set to 1, the calibration factor of the analog block is updated with the value programmed in CALFACT[31:0], indexed by CALINDEX[3:0] bits.
- To read all calibration factors, perform nine accesses to the ADC_CALFACT2 register.
- To write all calibration factors, perform eight accesses to the ADC_CALFACT2 register.

**Note:** The software is allowed to write these bits only when ADEN = 1, ADSTART = 0 and JADSTART = 0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).
29.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

29.7.1 ADC_CCR system control register (ADC12_CCR)

Address offset: 0x08

Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

ADC12_CCR is common to ADC1 and ADC2. ADC2 is not available on all devices (refer to Section 29.3: ADC implementation).

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 \textbf{VBATEN}: VBAT enable

This bit is set and cleared by software to control the V\textsubscript{BAT} channel.

0: V\textsubscript{BAT} channel disabled
1: V\textsubscript{BAT} channel enabled

\textit{Note:} The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 23 \textbf{VSENSESEL}: Temperature sensor voltage selection

This bit is set and cleared by software to control the temperature sensor channel.

0: Temperature sensor channel disabled
1: Temperature sensor channel enabled

\textit{Note:} The software is allowed to write this bit only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).
Bit 22 **VREFEN**: \( V_{\text{REFINT}} \) enable
This bit is set and cleared by software to enable/disable the \( V_{\text{REFINT}} \) buffer.
0: \( V_{\text{REFINT}} \) channel disabled
1: \( V_{\text{REFINT}} \) channel enabled

*Note*: The software is allowed to write this bit only when the ADCs are disabled (\( \text{ADCAL} = 0 \), \( \text{JADSTART} = 0 \), \( \text{ADSTART} = 0 \), \( \text{ADSTP} = 0 \), \( \text{ADDIS} = 0 \) and \( \text{ADEN} = 0 \)).

Bits 21:18 **PRESC[3:0]**: ADC prescaler
These bits are set and cleared by software to select the frequency of the ADC clock. The clock is common to all ADCs.
- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256

Others: Reserved, must not be used

*Note*: The software is allowed to write this bit only when the ADCs are disabled (\( \text{ADCAL} = 0 \), \( \text{JADSTART} = 0 \), \( \text{ADSTART} = 0 \), \( \text{ADSTP} = 0 \), \( \text{ADDIS} = 0 \) and \( \text{ADEN} = 0 \)).

Bits 17:0 Reserved, must be kept at reset value.

### 29.8 ADC register map

The following tables summarize the ADC registers.

**Table 244. ADC register map and reset values**

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 on page 116 for the register boundary addresses.
30 Analog-to-digital converter (ADC4)

30.1 Introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 25 multiplexed channels enabling it to measure signals from 19 external and 6 internal sources. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The analog watchdog feature enables the application to detect if the input voltage goes outside the user-defined higher or lower thresholds.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.
30.2 ADC main features

- **High performance**
  - 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
  - ADC conversion time: 0.4 µs for 12-bit resolution (2.5 Msps), faster conversion times can be obtained by lowering resolution.
  - Self-calibration
  - Programmable sampling time
  - Data alignment with built-in data coherency
  - DMA support

- **Low-power**
  - The application can reduce the bus clock frequency for low-power operation while still keeping optimum ADC performance. For example, 0.4 µs conversion time is kept, whatever the bus clock frequency
  - Wait mode: prevents ADC overrun in applications with low bus clock frequency
  - Auto off mode: ADC is automatically powered off except during the active conversion phase. This dramatically reduces the power consumption of the ADC.

- ** Autonomous mode**
  - Conversion and DMA transfers supported in Stop mode
  - Wakeup from Stop on ADC interrupts
  - Enter and exit from Deep-power-down mode managed automatically

- **Analog input channels**
  - 19 external analog inputs
  - 1 channel for the internal temperature sensor ($V_{\text{SENSE}}$)
  - 1 channel for the internal reference voltage ($V_{\text{REFINT}}$)
  - 1 channel for the internal digital core voltage ($V_{\text{CORE}}$)
  - 1 channel for monitoring the external VBAT power supply pin
  - Connection to DAC internal channels

- **Start-of-conversion can be initiated:**
  - By software
  - By hardware triggers with configurable polarity (timer events or GPIO input events)

- **Conversion modes**
  - Can convert a single channel or can scan a sequence of channels.
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode

- **Interrupt generation at the end of sampling, end of conversion, end of sequence conversion, and in case of analog watchdog or overrun events**

- **Analog watchdog**

- **Oversampler**
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits
• ADC input range: \( V_{SSA} \leq V_{IN} \leq V_{REF+} \)

30.4.3 ADC voltage regulator (ADVREGEN)

The ADC has a specific internal voltage regulator which must be enabled and stable before using the ADC.

The ADC internal voltage regulator can be enabled by setting ADVREGEN bit to 1 in the ADC_CR register. The software must wait for the ADC voltage regulator startup time (t\_{\text{ADCVREG\_SETUP}}) before launching a calibration or enabling the ADC. The LDO status can be verified by checking the LDORDY bit in ADC_ISR register.

After ADC operations are complete, the ADC can be disabled (ADEN = 0). It is then possible to save additional power by disabling the ADC voltage regulator (refer to Section: ADC voltage regulator disable sequence).

**Note:** When the internal voltage regulator is disabled, the internal analog calibration factor is reset, and a new calibration must be performed.

ADC voltage regulator enable sequence

To enable the ADC voltage regulator, follow the sequence below:

1. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1.
2. Set the ADVREGEN bit to 1 in ADC_CR register.
3. Wait until LDORDY = 1 in the ADC_ISR register (LDORDY is set after the ADC voltage regulator startup time). This can be handled by interrupt if the interrupt is enabled by setting the LDORDYIE bit in the ADC_IER register.

ADC voltage regulator disable sequence

To disable the ADC voltage regulator, follow the sequence below:

1. Make sure that the ADC is disabled (ADEN = 0).
2. Clear ADVREGEN bit in ADC_CR register.
3. Clear the LDORDY bit in ADC_ISR register by programming this bit to 1(optional),

30.4.4 Calibration (ADCAL)

The ADC has a calibration feature. During the procedure, the ADC calculates a calibration factor which is internally applied to the ADC until the next ADC power-off. The application must not use the ADC during calibration and must wait until it is complete.

The calibration must be performed before starting analog-to-digital conversion. It removes the offset error which may vary from chip to chip due to process variation, supply voltage and temperature.

The calibration is initiated by software by setting bit ADCAL to 1. It can be initiated only when the ADC voltage regulator is enabled (ADVREGEN = 1 and LDORDY is set to 1), and when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. After this, the calibration factor can be read from the ADC_DR register (from bits 6 to 0).

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). When the ADC operating conditions change (V\text{DDA} changes are the main contributor to ADC offset variations and temperature change to a lesser extent), it is recommended to re-run a calibration cycle. It is recommended to recalibrate when V\text{REF+} voltage changed more than 10%.
The calibration factor is lost in the following cases:

- The power supply is removed from the ADC (for example when the product enters Standby or V_{BAT} mode).
- The ADC peripheral is reset.

The calibration factor is lost each time power is removed from the ADC (for example when the product enters Standby or V_{BAT} mode). Still, it is possible to save and restore the calibration factor by software to save time when re-starting the ADC (as long as temperature and voltage are stable during the ADC power-down).

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion.

**Software calibration procedure**

1. Ensure that ADEN = 0, ADVREGEN = 1, DPD = 0, and DMAEN = 0.
2. Set ADCAL = 1.
3. Wait until ADCAL = 0 (or until EOCAL = 1). This can be handled by interrupt if the interrupt is enabled by setting the EOCALIE bit in the ADC_IER register.
4. The calibration factor can be read from bits 6:0 of ADC_DR or ADC_CALFACT registers.

---

**Figure 188. ADC calibration**

1. Refer to the device datasheet for the value of $t_{CAB}$. 

---

1104/3040

RM0456 Rev 1
Calibration factor forcing software procedure

1. Ensure that ADEN = 1 and ADSTART = 0 (ADC started with no conversion ongoing).
2. Write ADC_CALFACT with the saved calibration factor.
3. The calibration factor is used as soon as a new conversion is launched.

Figure 189. Calibration factor forcing

30.4.5 ADC on-off control (ADEN, ADDIS, ADRDY)

At power-up, the ADC is disabled and put in power-down mode (ADEN = 0).

As shown in Figure 190, the ADC needs a stabilization time of $t_{\text{STAB}}$ before it starts converting accurately.

Two control bits are used to enable or disable the ADC:
- Set ADEN = 1 to enable the ADC. The ADRDY flag is set as soon as the ADC is ready for operation.
- Set ADDIS = 1 to disable the ADC and put the ADC in Power-down. The ADEN and ADDIS bits are then automatically cleared by hardware as soon as the ADC is fully disabled.

Conversion can then start either by setting ADSTART to 1 (refer to Section 30.4.16: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN) on page 1114) or when an external trigger event occurs if triggers are enabled.

Follow the procedure below to enable the ADC:
1. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1.
2. Set ADEN = 1 in the ADC_CR register.
3. Wait until ADRDY = 1 in the ADC_ISR register (ADRDY is set after the ADC startup time). This can be handled by interrupt if the interrupt is enabled by setting the ADRDYIE bit in the ADC_IER register.

Follow the procedure below to disable the ADC:
1. Check that ADSTART = 0 in the ADC_CR register to ensure that no conversion is ongoing. If the Software trigger mode was used, stop the Software trigger mode by writing 1 to the ADSTP bit of the ADC_CR register and waiting until this bit is read at 0.
2. Set ADDIS = 1 in the ADC_CR register.
3. If required by the application, wait until ADEN = 0 in the ADC_CR register, indicating that the ADC is fully disabled (ADDIS is automatically reset once ADEN = 0).
4. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1 (optional).
Note: In Auto-off mode (AUTOFF = 1) the power-on/off phases are performed automatically, by hardware and the ADRDY flag is not set.

### 30.4.6 ADC clock (PRESC[3:0])

The ADC has a dual clock-domain architecture, so that the ADC can be fed with a clock (ADC asynchronous clock) independent from the bus clock.

#### Figure 191. ADC clock scheme

1. Refer to Section Reset and clock control (RCC) for how the bus clock and ADC asynchronous clock are enabled.

The adc_ker_ck input clock can be selected between different clock sources (see Figure 191: ADC clock scheme). This selection is done in the RCC (refer to th RCC section for more information):

   a) The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous with the bus clock.

   b) The ADC clock can be derived from the bus clock.
Option a) has the advantage of reaching the maximum ADC clock frequency whatever the clock scheme selected. The ADC clock can eventually be divided by a programmable ratio of 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256, configured through PRESC[3:0] bits in the ADCx_CCR register.

Option b) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

### Table 250. Latency between trigger and start of conversion$^{(1)}$

1. Refer to the device datasheet for the maximum $F_{ADC}$ frequency.
30.4.7 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described in Figure 192.

Figure 192. ADC4 connectivity
30.4.8 Configuring the ADC

The software can write to the ADCAL and ADEN bits in the ADC_CR and ADC_PWR register if the ADC is disabled (ADEN must be 0).

The software must only write to the ADSTART and ADDIS bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN = 1 and ADDIS = 0).

For all the other control bits in the ADC_IER, ADC_CFGRI, ADC_SMPR, ADC_CHSELR and ADC_CCR registers, refer to the description of the corresponding control bit in Section 30.7: ADC registers. If the ADC operates in Software trigger mode, set the ADSTP bit in ADC_CR register, then wait until ADSTP bit become 0 before reconfiguring the above registers.

ADC_AWDTRi registers can be modified when a conversion is ongoing.

The software must only write to the ADSTP bit in the ADC_CR register if the ADC is enabled (and possibly converting) and there is no pending request to disable the ADC (ADSTART = 1 and ADDIS = 0).

Note: There is no hardware protection preventing software from making write operations forbidden by the above rules. If such a forbidden write access occurs, the ADC may enter an undefined state. To recover correct operation in this case, the ADC must be disabled (clear ADEN = 0 and all the bits in the ADC_CR register).

30.4.9 Channel selection (CHSEL, SCANDIR, CHSELRMOD)

There are up to 24+1 multiplexed channels:

- 19 analog inputs from GPIO pins (ADC_INx)
- 6 internal analog inputs: temperature Sensor, internal reference voltage, \( V_{\text{CORE}} \), \( V_{\text{BAT}} \) channel, DAC internal channels

It is possible to convert a single channel or a sequence of channels.

The sequence of the channels to be converted can be programmed in the ADC_CHSELR channel selection register: each analog input channel has a dedicated selection bit (CHSELx).

The ADC scan sequencer can be used in two different modes:

- Sequencer not fully configurable:
  - The order in which the channels are scanned is defined by the channel number (CHSELRMOD bit must be cleared in ADC_CFGRI register):
    - Sequence length configured through CHSELx bits in ADC_CHSELR register
    - Sequence direction: the channels are scanned in a forward direction (from the lowest to the highest channel number) or backward direction (from the highest to the lowest channel number) depending on the value of SCANDIR bit (SCANDIR = 0: forward scan, SCANDIR = 1: backward scan)
Any channel can belong to these sequences

- Fully-configurable sequencer
  The CHSELRMOD bit is set in ADC_CFGR1 register.
  - Sequencer length is up to eight channels
  - The order in which the channels are scanned is independent from the channel number. Any order can be configured through SQ1[3:0] to SQ8[3:0] bits in ADC_CHSELR register.
  - Only 15 channels can be selected in this sequence (refer to Section 30.7.10: ADC channel selection register [alternate] (ADC_CHSELR).
  - If the sequencer detects SQx[3:0] = 0b1111, the following SQx[3:0] registers are ignored.
  - If no 0b1111 is programmed in SQx[3:0], the sequencer scans full eight channels.

The software is allowed to program the CHSEL, SCANDIR and CHSELRMOD bit only when ADSTART bit is cleared in ADC_CR register. This ensures that no conversion is ongoing. If the ADC operated in Software trigger mode, set ADSTP bit then wait until ADSTP bit become 0 before reconfiguring these registers. This sequence must be respected even if ADSTART bit is cleared to 0 after the conversion.

Temperature sensor, DAC output, VREFINT, VCORE and VBAT internal channels

The temperature sensor, internal reference voltage (VREFINT), VCORE, VBAT channel, the internal DAC channels are connected to ADC internal channels. Refer to Table ADC interconnection in Section 30.4.2: ADC pins and internal signals for details.

### 30.4.10 Programmable sampling time (SMPx[2:0])

Before starting a conversion, the ADC needs to establish a direct connection between the voltage source to be measured and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the sample and hold capacitor to the input voltage level.

Having a programmable sampling time allows the conversion speed to be trimmed according to the input resistance of the input voltage source.

The ADC samples the input voltage for a number of ADC clock cycles that can be modified using the SMP1[2:0] and SMP2[2:0] bits in the ADC_SMPR register.

Each channel can choose one out of two sampling times configured in SMP1[2:0] and SMP2[2:0] bitfields, through SMPSElx bits in ADC_SMPR register.

The total conversion time is calculated as follows:

\[ t_{CONV} = \text{Sampling time} + 12.5 \times \text{ADC clock cycles} \]

Example:

With ADC_CLK = 16 MHz and a sampling time of 1.5 ADC clock cycles:

\[ t_{CONV} = 1.5 + 12.5 = 14 \text{ ADC clock cycles} = 0.875 \mu s \]

The ADC indicates the end of the sampling phase by setting the EOSMP flag.
30.4.11 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs a single sequence of conversions, converting all the channels once. This mode is selected when CONT is cleared in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then the ADC stops until a new external trigger event occurs or the ADSTART bit is set again.

*Note:* To convert a single channel, program a sequence with a length of 1.

30.4.12 Continuous conversion mode (CONT = 1)

In continuous conversion mode, when a software or hardware trigger event occurs, the ADC performs a sequence of conversions, converting all the channels once and then automatically re-starts and continuously performs the same sequence of conversions. This mode is selected when CONT is set to 1 in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

*Note:* To convert a single channel, program a sequence with a length of 1.

*It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.*
30.4.13 Starting conversions (ADSTART)

Software starts ADC conversions by setting ADSTART to 1.

When ADSTART is set, the conversion:

- Starts immediately if EXTEN = 00 (software trigger)
- At the next active edge of the selected hardware trigger if EXTEN ≠ 00

The ADSTART bit is also used to indicate whether an ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART remains at 0, indicating that the ADC is idle.

The ADSTART bit is cleared by hardware:

- In single mode with software trigger (CONT = 0, EXTEN = 00)
  - At any end of conversion sequence (EOS = 1)
- In discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN = 00)
  - At end of conversion (EOC = 1)
- In all cases (CONT = x, EXTEN = XX)
  - After execution of the ADSTP procedure invoked by software (see Section 30.4.15: Stopping an ongoing conversion (ADSTP) on page 1114).

When the ADC operates in Autonomous mode (DPD bit transition from 1 to 0, see Section: Autonomous mode (AUTOFF, DPD)), the ADSTART bit can be set only when the ADC is powered on. (both LDORDY = 1 and ADRDY = 1). In Continuous mode (CONT = 1), the ADSTART bit is not cleared by hardware when the EOS flag is set because the sequence is automatically relaunched.

Note: When hardware trigger is selected in single mode (CONT = 0 and EXTEN = 01), ADSTART is not cleared by hardware when the EOS flag is set. This avoids the need for software having to set the ADSTART bit again and ensures the next trigger event is not missed.

It is necessary to set ADSTP to 1 and wait until ADSTP is cleared before reconfiguring or disabling the ADC, even if ADSTART bit is cleared to after the software triggered ADC conversion mode.
30.4.14 Timings

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[ t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = [1.5 \text{ min} + 12.5 \text{ 12bit}] \times t_{\text{ADC_CLK}} \]

\[ t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = 42.9 \text{ ns min} + 357.1 \text{ ns 12bit} = 0.400 \mu\text{s min} \text{ (for } f_{\text{ADC_CLK}} = 35 \text{ MHz)} \]

**Figure 193. Analog to digital conversion time**

1. EXTEN = 00 or EXTEN \(\neq\) 00.
2. Trigger latency (refer to datasheet for more details).
3. ADC_DR register write latency (refer to datasheet for more details).
30.4.15 Stopping an ongoing conversion (ADSTP)

The software can decide to stop any ongoing conversions by setting ADSTP to 1 in the ADC_CR register.

This resets the ADC operation and the ADC is idle, ready for a new operation.

When the ADSTP bit is set by software, any ongoing conversion is aborted and the result is discarded (ADC_DR register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that restarting the ADC would restart a new sequence).

Once this procedure is complete, the ADSTP and ADSTART bits are both cleared by hardware and the software must wait until ADSTART is cleared to 0 before starting new conversions.

![Figure 195. Stopping an ongoing conversion](image)

30.4.16 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)

A conversion or a sequence of conversion can be triggered either by software or by an external event (for example timer capture). If the EXTEN[1:0] control bits are not equal to “0b00”, then external events are able to trigger a conversion with the selected polarity. The trigger selection is effective once software has set bit ADSTART to 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

If bit ADSTART is cleared, any hardware triggers which occur are ignored.

*Table 251* provides the correspondence between the EXTEN[1:0] values and the trigger polarity.

<table>
<thead>
<tr>
<th>Source</th>
<th>EXTEN[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger detection disabled</td>
<td>00</td>
</tr>
<tr>
<td>Detection on rising edge</td>
<td>01</td>
</tr>
<tr>
<td>Detection on falling edge</td>
<td>10</td>
</tr>
<tr>
<td>Detection on both rising and falling edges</td>
<td>11</td>
</tr>
</tbody>
</table>

*Note:* The polarity of the external trigger can be changed only when the ADC is not converting (ADSTART = 0).

The EXTSEL[2:0] control bits are used to select which of 8 possible events can trigger conversions.
Refer to Table ADC interconnection in Section 30.4.2: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

The software source trigger events can be generated by setting the ADSTART bit in the ADC_CR register.

Note: The trigger selection can be changed only when the ADC is not converting (ADSTART = 0).

30.4.17 Discontinuous mode (DISCEN)

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

In this mode (DISCEN = 1), a hardware or software trigger event is required to start each conversion defined in the sequence. On the contrary, if DISCEN is cleared, a single hardware or software trigger event successively starts all the conversions defined in the sequence.

Example:

- DISCEN = 1, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: channel 0 is converted and an EOC event is generated
  - 2nd trigger: channel 3 is converted and an EOC event is generated
  - 3rd trigger: channel 7 is converted and an EOC event is generated
  - 4th trigger: channel 10 is converted and both EOC and EOS events are generated.
  - 5th trigger: channel 0 is converted an EOC event is generated
  - 6th trigger: channel 3 is converted and an EOC event is generated
  - ...

- DISCEN = 0, channels to be converted are channels 0, 3, 7 and 10
  - 1st trigger: the complete sequence is converted: channel 0, then 3, 7 and 10. Each conversion generates an EOC event and the last one also generates an EOS event.
  - Any subsequent trigger events restarts the complete sequence.

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

30.4.18 Programmable resolution (RES) - fast conversion mode

It is possible to obtain faster conversion times (tSAR) by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] bits in the ADC_CFGR1 register. Lower resolution allows faster conversion times for applications where high data precision is not required.

Note: The RES[1:0] bit must only be changed when the ADEN bit is reset.

The result of the conversion is always 12 bits wide and any unused LSB bits are read as zeros.

Lower resolution reduces the conversion time needed for the successive approximation steps as shown in Table 252.
30.4.19 End of conversion, end of sampling phase (EOC, EOSMP flags)

The ADC indicates each end of conversion (EOC) event.

The ADC sets the EOC flag in the ADC_ISR register as soon as a new conversion data result is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set in the ADC_IER register. The EOC flag is cleared by software either by writing 1 to it, or by reading the ADC_DR register.

The ADC also indicates the end of sampling phase by setting the EOSMP flag in the ADC_ISR register. The EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if the EOSMPIE bit is set in the ADC_IER register.

The aim of this interrupt is to allow the processing to be synchronized with the conversions. Typically, an analog multiplexer can be accessed in hidden time during the conversion phase, so that the multiplexer is positioned when the next sampling starts.

Note: As there is only a very short time left between the end of the sampling and the end of the conversion, it is recommended to use polling or a WFE instruction rather than an interrupt and a WFI instruction.

30.4.20 End of conversion sequence (EOS flag)

The ADC notifies the application of each end of sequence (EOS) event. The ADC sets the EOS flag in the ADC_ISR register as soon as the last data result of a conversion sequence is available in the ADC_DR register. An interrupt can be generated if the EOSIE bit is set in the ADC_IER register. The EOS flag is cleared by software by writing 1 to it.

30.4.21 Example timing diagrams (single/continuous modes hardware/software triggers)

Figure 196. Single conversions of a sequence, software trigger

1. EXTEN = 00, CONT = 0.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.
Figure 197. Continuous conversion of a sequence, software trigger

1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x20601, WAIT = 0, AUTOFF = 0.

Figure 198. Single conversions of a sequence, hardware trigger

1. EXTSEL = TRGx (over-frequency), EXTEN = 01 (rising edge), CONT = 0.
2. CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 0.
30.4.22 Low frequency trigger mode

Once the ADC is enabled or the last ADC conversion is complete, the ADC is ready to start a new conversion. The ADC needs to be started before a predefined time of $t_{\text{idle}}$ otherwise ADC converted data might be corrupted due to the transistor leakage (refer to the device datasheet for the maximum value of $t_{\text{idle}}$).

LFTRIG bit of ADC_CFGR2 register must be set to 1 whatever the application conversion timing and operating conditions. This impacts neither the ADC power consumption nor the ADC timing.

30.4.23 Data management

Data register and data alignment (ADC_DR, ALIGN)

At the end of each conversion (when an EOC event occurs), the result of the converted data is stored in the ADC_DR data register which is 16-bit wide.

The format of the ADC_DR depends on the configured data alignment and resolution.

The ALIGN bit in the ADC_CFGR1 register selects the alignment of the data stored after conversion. Data can be right-aligned (ALIGN = 0) or left-aligned (ALIGN = 1) as shown in Figure 200.
ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) indicates a data overrun event, when the converted data was not read in time by the CPU or the DMA, before the data from a new conversion is available.

The OVR flag is set in the ADC_ISR register if the EOC flag is still at 1 at the time when a new conversion completes. An interrupt can be generated if the OVRIE bit is set in the ADC_IER register.

When an overrun condition occurs, the ADC keeps operating and can continue to convert unless the software decides to stop and reset the sequence by setting the ADSTP bit in the ADC_CR register.

The OVR flag is cleared by software by writing 1 to it.

It is possible to configure if the data is preserved or overwritten when an overrun event occurs by programming the OVRMOD bit in the ADC_CFGR1 register:

- **OVRMOD = 0**
  - An overrun event preserves the data register from being overwritten: the old data is maintained and the new conversion is discarded. If OVR remains at 1, further conversions can be performed but the resulting data is discarded.

- **OVRMOD = 1**
  - The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, further conversions can be performed and the ADC_DR register always contains the data from the latest conversion.
Managing a sequence of data converted without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by software. In this case the software must use the EOC flag and its associated interrupt to handle each data result. Each time a conversion is complete, the EOC bit is set in the ADC_ISR register and the ADC_DR register can be read. The OVRMOD bit in the ADC_CFGR1 register must be configured to 0 to manage overrun events as an error.

Managing converted data without using the DMA without overrun

It may be useful to let the ADC convert one or more channels without reading the data after each conversion. In this case, the OVRMOD bit must be configured at 1 and the OVR flag must be ignored by the software. When OVRMOD is set to 1, an overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion data.

Managing converted data using the DMA

Since all converted channel values are stored in a single data register, it is efficient to use DMA when converting more than one channel. This avoids losing the conversion data results stored in the ADC_DR register.

When DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR1 register), a DMA request is generated after the conversion of each channel. This allows the transfer of the...
converted data from the ADC_DR register to the destination location selected by the software.

Note: The DMAEN bit in the ADC_CFRG1 register must be set after the ADC calibration phase.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD) on page 1120).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG in the ADC_CFRG1 register:

- DMA one shot mode (DMACFG = 0).
  This mode must be selected when the DMA is programmed to transfer a fixed number of data words.
- DMA circular mode (DMACFG = 1)
  This mode must be selected when programming the DMA in circular mode or double buffer mode.

DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a DMA_EOT interrupt occurs, see Section 11: Direct memory access controller (DMA) on page 375) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted and its partial result discarded
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- The scan sequence is stopped and reset
- The DMA is stopped

DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available in the data register, even if the DMA has reached the last DMA transfer. This allows the DMA configuration in circular mode in order to handle a continuous analog input data stream.
30.4.24 Low-power features

Wait conversion mode (WAIT)

Wait conversion mode can be used to simplify the software as well as optimizing the performance of applications clocked at low frequency where there might be a risk of ADC overrun occurring.

When the WAIT bit is set to 1 in the ADC_CFGR1 register, a new conversion can start only if the previous data has been treated, once the ADC_DR register has been read or if the EOC bit has been cleared.

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

Note: Any hardware triggers which occur while a conversion is ongoing or during the wait time preceding the read access are ignored.

Figure 202. Wait conversion mode (continuous mode, software trigger)

1. EXTEN = 00, CONT = 1.
2. CHSEL = 0x3, SCANDIR = 0, WAIT = 1, AUTOFF = 0.
ADC power saving modes

The ADC embeds two power-saving modes, the Auto-off and the Autonomous modes.

Auto-off mode (AUTOFF)

The Auto-off mode is enabled by setting the AUTOFF bit to 1 in the ADC_PWR register.

Below the Auto-off mode operating sequence:

1. When AUTOFF is set to 1, the ADC is always powered off when no conversion is ongoing.
2. It then automatically wakes up when a conversion is triggered by software or by hardware, and a startup time is inserted between the trigger event and the ADC sampling time.
3. The ADC is then automatically disabled once the conversion or sequence of conversions is complete.
4. When consecutive hardware or software triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to Figure 203 for a description of Auto-off mode state diagram.

The Auto-off mode dramatically reduces power consumption in applications requiring a limited number of conversions or conversion requests far between enough (for example with a low frequency hardware trigger) to justify the extra power and time used for switching the ADC on and off.

Auto-off mode can be combined with Wait mode (WAIT = 1) for applications clocked at low frequency. This combination can achieve significant power saving if the ADC is automatically powered off during the wait phase and restarted as soon as the ADC_DR register is read by the application (see Figure 204: ADC behavior with WAIT = 0 and AUTOFF = 1 and Figure 205: ADC behavior with WAIT = 1 and AUTOFF = 1).

Note: Refer to the Section Reset and clock control (RCC) for the description of how to manage the dedicated internal oscillators. The ADC interface can automatically switch on/off these internal oscillators to save power.
1. EXTSEL = TRGx, EXTEN = 01 (rising edge), CONT = x, ADSTART = 1, CHSEL = 0xF, SCANDIR = 0, WAIT = 0, AUTOFF = 1.
Autonomous mode (AUTOFF, DPD)

The Autonomous mode is enabled by setting both AUTOFF and DPD bits to 1 in ADC_PWR register. In addition, the Autonomous mode must be enabled in the RCC.

Below the Autonomous mode operating sequence:

1. When AUTOFF and DPD are both set to 1, the ADC is powered off when no conversion is ongoing.

2. Upon hardware trigger reception, the ADC requests the adc_ker_ck and adc_hclk clocks to the RCC, the ADC voltage regulator is enabled, the calibration factor is loaded, the ADC is enabled and the conversion starts.

3. Once the ADC conversion is complete, the ADC can either generate an AWDx interrupt or a DMA request, depending on peripheral configuration:
   - When DMA mode is enabled, the ADC generates a DMA request to transfer data to memory or to another peripherals.
   - When an analog watchdog is enabled, ADC data do not need to be transferred. The analog watchdog compares the data to the threshold value and generates an AWDx interrupt to wake up the device if the data is under or over the programmed threshold.

4. When the ADC conversion/sequence or conversion is complete, the ADC and the ADC voltage regulator are automatically disabled as well as VREFINT buffer and the temperature sensor, and further clock requests are deasserted. This allows the minimization of current consumption.

5. When consecutive hardware triggers occur, the ADC is automatically enabled and the conversion is processed.

Refer to Figure 206 for a description of Autonomous mode state diagram.

The Autonomous mode enables the ADC peripheral to operate when the device is in Stop mode. However it can also be used in Run or Sleep mode.
30.4.25 Analog window watchdog

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Description of analog watchdog 1

AWD1 analog watchdog is enabled by setting the AWD1EN bit in the ADC_CFGR1 register. It is used to monitor that either one selected channel or all enabled channels (see Table 254: Analog watchdog 1 channel selection) remain within a configured voltage range (window) as shown in Figure 207.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in HT1[11:0] and LT1[11:0] bits of ADC_AWD1TR register. An interrupt can be enabled by setting the AWD1IE bit in the ADC_IER register.

The AWD1 flag is cleared by software by programing it to 1.

When converting data with a resolution of less than 12-bit (according to bits DRES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 253 describes how the comparison is performed for all the possible resolutions.

1. Selected by the AWD1CH[4:0] bits

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the AWDxCHy in ADC_AWDxCR (x = 2, 3).

The corresponding watchdog is enabled when any AWDxCHy bit (x = 2,3) is set in ADC_AWDxCR register.

When converting data with a resolution of less than 12 bits (configured through DRES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

Table 253 describes how the comparison is performed for all the possible resolutions.

The AWD2/3 analog watchdog status bit is set if the analog voltage converted by the ADC is below a low threshold or above a high threshold. These thresholds are programmed in HTx[11:0] and LTx[11:0] of ADC_AWDxTR registers (x = 2 or 3). An interrupt can be enabled by setting the AWDxIE bit in the ADC_IER register.
The AWD2 and AWD3 flags are cleared by software by programming them to 1.

**ADC_AWDx_OUT signal output generation**

Each analog watchdog is associated to an internal hardware signal, ADC_AWDx_OUT (x being the watchdog number) that is directly connected to the ETR input (external trigger) of some on-chip timers (refer to the timers section for details on how to select the ADC_AWDx_OUT signal as ETR).

ADC_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds. It remains at 1 if the next guarded conversions are still outside the programmed thresholds.
- ADC_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS to 1). Note that stopping conversions (ADSTP set to 1), might clear the ADC_AWDx_OUT state.
- ADC_AWDx_OUT state does not change when the ADC converts the none-guarded channel (see Figure 210)

AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADC_AWDx_OUT (as an example, ADC_AWDx_OUT can toggle while AWDx flag remains at 1 if the software has not cleared the flag).

The ADC_AWDx_OUT signal is generated by the ADC_CLK domain. This signal can be generated even the bus clock is stopped.

The AWD comparison is performed at the end of each ADC conversion. The ADC_AWDx_OUT rising edge and falling edge occurs two ADC_CLK clock cycles after the comparison.

As ADC_AWDx_OUT is generated by the ADC_CLK domain and AWD flag is generated by the bus clock domain, the rising edges of these signals are not synchronized.

---

**Figure 208. ADC_AWDx_OUT signal generation**

- Converted channels: 1,2,3,4,5,6,7
- Guarded converted channels: 1,2,3,4,5,6,7
Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed during an analog-to-digital conversion (that is between the start of the conversion and the end of conversion of the ADC internal state). If HTx and LTx bits are programmed during the ADC guarded channel conversion, the watchdog function is masked for this conversion. This mask is cleared when starting a new conversion, and the resulting new AWD threshold is applied starting the next ADC conversion result. AWD comparison is performed at each end of conversion. If the current ADC data are out of the new threshold interval, this does not generated any interrupt or an ADC_AWDx_OUT signal. The Interrupt and the ADC_AWDx_OUT generation only occurs at the end of the ADC conversion that started after the threshold update. If ADC_AWDx_OUT is already asserted, programming the new threshold does not deassert the ADC_AWDx_OUT signal.
30.4.26 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It can handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{N-1} \text{Conversion}(t_n)
\]

It allows the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register. It can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits. It is configured through the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256 x 12-bit), which is first shifted right. The lower bits of the result are then truncated, keeping only the 16 least significant bits rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

**Note:** If the intermediate result after the shifting exceeds 16 bits, the upper bits of the result are simply truncated.

Figure 212. 20-bit to 16-bit result truncation

![Diagram](MS31928V2)
The Figure 213 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

**Figure 213. Numerical example with 5-bits shift and rounding**

![Numerical example with 5-bits shift and rounding](image)

The Table 255 below gives the data format for the various N and M combination, for a raw conversion data equal to 0xFFF.

**Table 255. Maximum output results vs N and M. Grayed values indicates truncation**

</tbody>
</table>

The conversion timings in oversampled mode do not change compared to standard conversion mode: the sample time is maintained equal during the whole oversampling sequence. New data are provided every N conversion, with an equivalent delay equal to N x t\text{CONV} = N x (t\text{SMPL} + t\text{SAR}). The flags features are raised as following:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- the end of sequence (EOCSEQ) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)
ADC operating modes supported when oversampling

In oversampling mode, most of the ADC operating modes are available:

- Single or continuous mode conversions, forward or backward scanned sequences and up to 8 channels programmed sequence
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (WAIT, AUTOFF)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFRG1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFRG1 is ignored and the data are always provided right-aligned.

Analog watchdog

The analog watchdog functionality is available (AWDxSGL, AWD1EN and AWDxCH bits), with the following differences:

- the RES[1:0] bits are ignored, comparison is always done on using the full 12-bits values HTx[11:0] and LTx[11:0]
- the comparison is performed on the most significant 12 bits of the 16 bits oversampled results ADC_DR[15:4]

**Note:** Care must be taken when using high shifting values. This reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0], and HTx[11:8] / LTx[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purposes. Although not a very efficient filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TOVS bit in ADC_CFRG2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

*Figure 214* below shows how conversions are started in response to triggers in discontinuous mode.

If the TOVS bit is set, the content of the DISCEN bit is ignored and considered as 1.
30.4.27 Temperature sensor and internal reference voltage

The temperature sensor can be used to measure the junction temperature ($T_J$) of the device. The temperature sensor is internally connected an ADC internal input channel which is used to convert the sensor’s output voltage to a digital value. The sampling time for the temperature sensor analog pin must be greater than the minimum $T_{S\_temp}$ value specified in the datasheet. When not in use, the sensor can be put in Power-down mode.

The internal voltage reference ($V_{\text{REFINT}}$) provides a stable (bandgap) voltage output for the ADC and the comparators.

Refer to Table ADC interconnection in Section 30.4.2: ADC pins and internal signals for details on the ADC internal input channel to which the above voltages are connected.

Figure 215 shows the block diagram of connections between the temperature sensor, the internal voltage reference and the ADC.

The VSENSESEL bit must be set to enable the conversion of $V_{\text{SENSE}}$ while VREFEN bit must be set to enable the conversion of $V_{\text{REFINT}}$.

When the ADC operates in Autonomous mode, these signals are controlled automatically to reduce power consumption ($V_{\text{SENSESEL}}$ and VREFEN must be set to measure the voltage in Autonomous mode).

The temperature sensor output voltage linearly changes with the temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by STMicroelectronics during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference. Refer to the datasheet for additional information.

During the manufacturing process, the calibration data of the internal voltage reference are stored in the system memory area. The user application can then read them and use them...
to improve the accuracy of the internal reference. Refer to the electrical characteristics section of the device datasheet for additional information.

**Main features**

- Supported temperature range: -40 to 125 °C
- Linearity: ±2 °C max., precision depending on calibration

**Figure 215. Temperature sensor and VREFINT channel block diagram**

Reading the temperature

1. Select the input channel connected to VSENSE (refer to Table ADC interconnection in Section 30.4.2: ADC pins and internal signals).
2. Select an appropriate sampling time specified in the device datasheet (T_{S_temp}).
3. Set the VSENSESEL bit in the ADC_CCR register to wake up the temperature sensor from Power-down mode and wait for its stabilization time (t_{START}).
4. Start the ADC conversion by setting the ADSTART bit in the ADC_CR register (or by external trigger)
5. Read the resulting VSENSE data in the ADC_DR register
6. Calculate the temperature using the following formula

\[
\text{Temperature (in °C)} = \frac{\text{TS}_\text{CAL2}_\text{TEMP} - \text{TS}_\text{CAL1}_\text{TEMP}}{\text{TS}_\text{CAL2} - \text{TS}_\text{CAL1}} \times (\text{TS}_\text{DATA} - \text{TS}_\text{CAL1}) + \text{TS}_\text{CAL1}_\text{TEMP}
\]

Where:

- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP (refer to the datasheet for TS_CAL2 value)
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP (refer to the datasheet for TS_CAL1 value)
- TS_DATA is the actual temperature sensor output value converted by ADC

Refer to the specific device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.
Note: The sensor has a startup time after waking up from Power-down mode before it can output \(V_{\text{SENSE}}\) at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and VSENSESEL bits must be set at the same time.

Calculating the actual \(V_{\text{REF+}}\) voltage using the internal reference voltage

The \(V_{\text{DDA}}\) power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference (VREFINT) and its calibration data acquired by the ADC during the manufacturing process at \(V_{\text{REF+}} = 3.0\) V can be used to evaluate the actual \(V_{\text{REF+}}\) voltage level, if VREF+ pin is connected to a variable \(V_{\text{DDA}}\) power supply.

The following formula gives the actual \(V_{\text{REF+}}\) voltage supplying the device:

\[
V_{\text{REF+}} = 3.0\ V \times \frac{\text{VREFINT\_CAL}}{\text{VREFINT\_DATA}}
\]

Where:
- \(\text{VREFINT\_CAL}\) is the VREFINT calibration value
- \(\text{VREFINT\_DATA}\) is the actual VREFINT output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the voltage reference \(V_{\text{REF+}}\) and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent from \(V_{\text{REF+}}\). For applications where \(V_{\text{REF+}}\) is known and ADC converted values are right-aligned, the following formula can be used to calculate this absolute value:

\[
V_{\text{CHANNEL}x} = \frac{\text{VREF+}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}_x
\]

For applications where \(V_{\text{REF+}}\) value is not known, the internal voltage reference and \(V_{\text{REF+}}\) can be replaced by the expression provided in Section: Calculating the actual \(V_{\text{REF+}}\) voltage using the internal reference voltage, resulting in the following formula:

\[
V_{\text{CHANNEL}x} = \frac{3.0\ V \times \text{VREFINT\_CAL} \times \text{ADC\_DATA}_x}{\text{VREFINT\_DATA} \times \text{FULL\_SCALE}}
\]

Where:
- \(\text{VREFINT\_CAL}\) is the VREFINT calibration value (data acquired by 14-bit ADC)
- \(\text{ADC\_DATA}_x\) is the value measured by the ADC on channel\(x\) (right-aligned)
- \(\text{VREFINT\_DATA}\) is the actual VREFINT output value converted by the ADC
- \(\text{FULL\_SCALE}\) is the maximum digital value of the ADC output. For example with 12-bit resolution, it is \(2^{12} - 1 = 4095\) or with 8-bit resolution, \(2^8 - 1 = 255\).

Note: If ADC measurements are done using an output format other than 12 bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

30.4.28 Battery voltage monitoring

The VBATEN bit in the ADC_CCR register allows the application to measure the battery voltage on the VBAT pin. As the \(V_{\text{BAT}}\) voltage could be higher than \(V_{\text{DDA}}\), to ensure the correct operation of the ADC, the \(V_{\text{BAT}}\) pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect \(V_{\text{BAT}}/4\) to the corresponding ADC input channel (refer to Table ADC interconnection in Section 30.4.2: ADC pins and internal signals). As a consequence, the converted digital value is half the
VBAT voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only during ADC conversion.

Figure 216. VBAT channel block diagram

30.4.29 Concurrent operation with another ADC

When ADC4 is used simultaneously with another ADC (let us call it ADCx, x being different from 4), ADCx operation might generate noise on VREF+ voltage. Since VREF+ is also ADC4 reference voltage, this might cause conversion errors. To prevent this issue from happening, set VREFPRTEN bit in ADC_PWR register. As soon as ADCx sampling phase starts, ADC4 is put on hold during one ADC4 clock cycle, thus resulting in ADC4 conversion time to be longer of one clock cycle.

In addition, ADCx might have two sampling phases during ADC4 conversion. This is due to the injected conversion function of ADCx. By setting VREFSECMP to 1 in ADC_PWR, ADC4 operation can be held twice during the conversion phase. When VREFSECMP bit is set, ADC4 conversion time is longer of two clock cycles.

VREFSECMP and VREFPRTEN bits must be set simultaneously.

ADCx and ADC4 must use the same clock source to be able to use the concurrent operation feature.

It is recommended to use this function when ADC4 works at a frequency greater or equal than ADCx.
### 30.5 ADC low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, DMA requests are functional. ADC interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The content of the ADC register is kept. ADC can be functional. DMA request are functional, and the interrupt cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The ADC peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

#### 30.6 ADC interrupts

An interrupt can be generated by any of the following events:

- End of calibration (EOCAL flag)
- ADC power-up, when the ADC is ready (ADRDY flag)
- End of any conversion (EOC flag)
- End of a sequence of conversions (EOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2, AWD3 flags)
- When the end of sampling phase occurs (EOSMP flag)
- When a data overrun occurs (OVR flag)
- LDO ready, when LDO output is stabilized (LDORDY flag)

Separate interrupt enable bits are available for flexibility.

Bits 31:13 Reserved, must be kept at reset value.

**Bit 12 LDORDY:** LDO Ready

- This bit is set by hardware. It indicates that the ADC internal LDO output is ready.
- It is cleared by software by writing 1 to it.
  - 0: ADC voltage regulator disabled
  - 1: ADC voltage regulator enabled and stabilized

**Bit 11 EOCAL:** End Of Calibration flag

- This bit is set by hardware when calibration is complete. It is cleared by software writing 1 to it.
  - 0: Calibration is not complete
  - 1: Calibration is complete

Bit 10 Reserved, must be kept at reset value.

**Bit 9 AWD3:** Analog watchdog 3 flag

- This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD3TR and ADC_AWD3TR registers. It is cleared by software by writing 1 to it.
  - 0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog event occurred

**Bit 8 AWD2:** Analog watchdog 2 flag

- This bit is set by hardware when the converted voltage crosses the values programmed in ADC_AWD2TR and ADC_AWD2TR registers. It is cleared by software writing 1 to it.
  - 0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog event occurred

**Bit 7 AWD1:** Analog watchdog 1 flag

- This bit is set by hardware when the converted voltage crosses the values programmed in ADC_TR1 and ADC_HR1 registers. It is cleared by software by writing 1 to it.
  - 0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog event occurred

Bits 6:5 Reserved, must be kept at reset value.
Bit 4 **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs, meaning that a new conversion has complete while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3 **EOS**: End of sequence flag
This bit is set by hardware at the end of the conversion of a sequence of channels selected by the CHSSEL bits. It is cleared by software writing 1 to it.
0: Conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Conversion sequence complete

Bit 2 **EOC**: End of conversion flag
This bit is set by hardware at the end of each conversion of a channel when a new data result is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
0: Channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Channel conversion complete

Bit 1 **EOSMP**: End of sampling flag
This bit is set by hardware during the conversion, at the end of the sampling phase. It is cleared by software by writing 1 to it.
0: Not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready
This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion

### 30.7.2 ADC interrupt enable register (ADC_IER)

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDYIE**: LDO ready interrupt enable
This bit is set and cleared by software. It is used to enable/disable the LDORDY interrupt.
0: LDO ready interrupt disabled
1: LDO ready interrupt enabled. An interrupt is generated when the LDO output is ready.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 11 **EOCALIE**: End of calibration interrupt enable
This bit is set and cleared by software to enable/disable the end of calibration interrupt.
0: End of calibration interrupt disabled
1: End of calibration interrupt enabled
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 10 Reserved, must be kept at reset value.

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bits 6:5 Reserved, must be kept at reset value.

Bit 4 **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the overrun interrupt.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 3 **EOSIE**: End of conversion sequence interrupt enable
This bit is set and cleared by software to enable/disable the end of sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*
Bit 2 **EOCIE**: End of conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of conversion interrupt.
0: EOC interrupt disabled
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 0 **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled.
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*
### 30.7.3 ADC control register (ADC_CR)

Address offset: 0x08  
Reset value: 0x0000 0000

| Bit 31 | ADCAL | ADC calibration | 0: Calibration complete  
|        |       |                 | 1: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.  
|        |       |                 | **Note**: The software is allowed to set ADCAL only when the ADC is disabled (ADCAL = 0,  
|        |       |                 | ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).  
|        |       |                 | The software is allowed to update the calibration factor by writing ADC_CALFACT only when  
|        |       |                 | ADEN is set to 1 and ADSTART is cleared to 0 by writing ADSTP to 1 (ADC enabled and no  
|        |       |                 | conversion is ongoing).  
| Bit 30:29 | Reserved, must be kept at reset value.  
| Bit 28 | ADVREGEN | ADC voltage regulator enable | 0: ADC voltage regulator disabled  
|        |       |                 | 1: ADC voltage regulator enabled  
|        |       |                 | **Note**: The software is allowed to program this bit field only when the ADC is disabled (ADCAL = 0,  
|        |       |                 | ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).  
| Bit 27:5 | Reserved, must be kept at reset value.  
| Bit 4 | ADSTP | ADC stop conversion command | 0: No ADC stop conversion command ongoing  
|       |       |                 | 1: Write 1 to stop the ADC. Read 1 means that an ADSTP command is in progress.  
|       |       |                 | **Note**: To clear the A/D converter state, ADSTP must be set to 1 even if ADSTART is cleared to 0 after  
|       |       |                 | the software trigger A/D conversion. It is recommended to set ADSTP to 1 whenever the  
|       |       |                 | configuration needs to be modified.  
| Bit 3 | Reserved, must be kept at reset value.
Bit 2 ADSTART: ADC start conversion command
This bit is set by software to start ADC conversion. Depending on the EXTEN [1:0] configuration bits, a conversion either starts immediately (software trigger configuration) or once a hardware trigger event occurs (hardware trigger configuration).
It is cleared by hardware:
– In single conversion mode (CONT = 0, DISCEN = 0), when software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion Sequence (EOS) flag.
– In discontinuous conversion mode (CONT=0, DISCEN = 1), when the software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion (EOC) flag.
– In all other cases: after the execution of the ADSTP command, at the same time as the ADSTP bit is cleared by hardware.
0: No ADC conversion is ongoing.
1: Write 1 to start the ADC. Read 1 means that the ADC is operating and may be converting.
Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Bit 1 ADDIS: ADC disable command
This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).
It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).
0: No ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.
Note: Setting ADDIS to 1 is only effective when ADEN = 1 and ADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 ADEN: ADC enable command
This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.
It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.
0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.
Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, ADSTP = 0, ADSTART = 0, ADDIS = 0 and ADEN = 0)
### 30.7.4 ADC configuration register 1 (ADC_CFGR1)

#### Bit 31 Reserved, must be kept at reset value.

**Bits 30:26 AWD1CH[4:0]: Analog watchdog channel selection**

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input Channel 0 monitored by AWD
00001: ADC analog input Channel 1 monitored by AWD
.....
10011: ADC analog input Channel 23 monitored by AWD

Others: Reserved

*Note: The channel selected by the AWDCH[4:0] bits must also be set into the CHSERL register. The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

**Bits 25:24 Reserved, must be kept at reset value.**

**Bit 23 AWD1EN: Analog watchdog enable**

This bit is set and cleared by software.

0: Analog watchdog disabled
1: Analog watchdog enabled

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

**Bit 22 AWD1SGL: Enable the watchdog on a single channel or on all channels**

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWDCH[4:0] bits or on all the channels.

0: Analog watchdog enabled on all channels
1: Analog watchdog enabled on a single channel

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

**Bit 21 CHSELRMOD: Mode selection of the ADC_CHSELR register**

This bit is set and cleared by software to control the ADC_CHSELR feature:

0: Each bit of the ADC_CHSELR register enables an input
1: ADC_CHSELR register is able to sequence up to 8 channels

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

**Bits 20:17 Reserved, must be kept at reset value.**
Bit 16 **DISCEN**: Discontinuous mode
- This bit is set and cleared by software to enable/disable discontinuous mode.
- 0: Discontinuous mode disabled
- 1: Discontinuous mode enabled

**Note**: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.
- The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WAIT**: Wait conversion mode
- This bit is set and cleared by software to enable/disable wait conversion mode.
- 0: Wait conversion mode off
- 1: Wait conversion mode on

**Note**: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 13 **CONT**: Single / continuous conversion mode
- This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.
- 0: Single conversion mode
- 1: Continuous conversion mode

**Note**: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.
- The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 12 **OVRMOD**: Overrun management mode
- This bit is set and cleared by software and configure the way data overruns are managed.
- 0: ADC_DR register is preserved with the old data when an overrun is detected.
- 1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note**: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bits 11:10 **EXten[1:0]**: External trigger enable and polarity selection
- These bits are set and cleared by software to select the external trigger polarity and enable the trigger.
- 00: Hardware trigger detection disabled (conversions can be started by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

**Note**: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 9 Reserved, must be kept at reset value.
Bits 8:6 **EXTSEL[2:0]:** External trigger selection

These bits select the external event used to trigger the start of conversion (refer to *Table 249: ADC interconnection* for details):

- 000: adc_trg0
- 001: adc_trg1
- 010: adc_trg2
- 011: adc_trg3
- 100: adc_trg4
- 101: adc_trg5
- 110: adc_trg6
- 111: adc_trg7

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 5 **ALIGN:** Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to *Figure 200: Data alignment and resolution (oversampling disabled: OVSE = 0)* on page 1120

- 0: Right alignment
- 1: Left alignment

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*

Bit 4 **SCANDIR:** Scan sequence direction

This bit is set and cleared by software to select the direction in which the channels is scanned in the sequence. It is effective only if CHSELRMOD bit is cleared to 0.

- 0: Upward scan (from CHSEL0 to CHSEL23)
- 1: Backward scan (from CHSEL23 to CHSEL0)

*Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).*
Bits 3:2  **RES[1:0]:** Data resolution
These bits are written by software to select the resolution of the conversion.
- 00: 12 bits
- 01: 10 bits
- 10: 8 bits
- 11: 6 bits

*Note:* The software is allowed to write these bits only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 1  **DMACFG:** Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
- 0: DMA one shot mode selected
- 1: DMA circular mode selected

For more details, refer to Section: Managing converted data using the DMA on page 1121

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).

Bit 0  **DMAEN:** Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows the automatic management of the converted data by the DMA controller. For more details, refer to Section: Managing converted data using the DMA on page 1121.
- 0: DMA disabled
- 1: DMA enabled

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing).
30.7.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x10
Reset value: 0x0000 0000

| Bit 31:30 | Reserved, must be kept at reset value. |
| Bit 29   | LFTRIG: Low frequency trigger mode enable |
|          | This bit must be set by software.          |
|          | 0: Reserved                                 |
|          | 1: Low frequency trigger mode enabled. LFTRIG must be set whatever the application conditions. |
| Note:    | The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 (this ensures that no conversion is ongoing). |

| Bit 28:10 | Reserved, must be kept at reset value. |
| Bit 9    | TOVS: Triggered Oversampling |
|          | This bit is set and cleared by software. |
|          | 0: All oversampled conversions for a channel are done consecutively after a trigger |
|          | 1: Each oversampled conversion for a channel needs a trigger |
| Note:    | The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing). |

| Bit 8:5  | OVSS[3:0]: Oversampling shift |
| This bit is set and cleared by software. |
| 0000: No shift |
| 0001: Shift 1-bit |
| 0010: Shift 2-bits |
| 0011: Shift 3-bits |
| 0100: Shift 4-bits |
| 0101: Shift 5-bits |
| 0110: Shift 6-bits |
| 0111: Shift 7-bits |
| 1000: Shift 8-bits |
| Others: Reserved |
| Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing). |
Bits 4:2 **OVSR[2:0]**: Oversampling ratio
This bit field defines the number of oversampling ratio.
000: 2x
001: 4x
010: 8x
011: 16x
100: 32x
101: 64x
110: 128x
111: 256x

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 1  Reserved, must be kept at reset value.

Bit 0 **OVSE**: Oversampler Enable
This bit is set and cleared by software.
0: Oversampler disabled
1: Oversampler enabled

Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

### 30.7.6 ADC sampling time register (ADC_SMPR)

Bits 31:8 **SMPSEL[23:0]**: Channel-x sampling time selection
These bits are written by software to define which sampling time is used.
0: Sampling time of CHANNELx use the setting of SMP1[2:0] register.
1: Sampling time of CHANNELx use the setting of SMP2[2:0] register.

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

Bit 7  Reserved, must be kept at reset value.
30.7.7 ADC watchdog threshold register (ADC_AWD1TR)

Address offset: 0x20

Reset value: 0x0FFF 0000

| Bit 31:28 | Reserved, must be kept at reset value. |
| Bit 27:16 | HT1[11:0]: Analog watchdog 1 higher threshold |
|           | These bits are written by software to define the higher threshold for the analog watchdog. |
|           | Refer to Section 30.4.25: Analog window watchdog on page 1127. |
| Bit 15:12 | Reserved, must be kept at reset value. |
| Bit 11:0  | LT1[11:0]: Analog watchdog 1 lower threshold |
|           | These bits are written by software to define the lower threshold for the analog watchdog. |
|           | Refer to Section 30.4.25: Analog window watchdog on page 1127. |
### 30.7.8 ADC watchdog threshold register (ADC_AWD2TR)

</table>

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT2[11:0]: Analog watchdog 2 higher threshold**  
These bits are written by software to define the higher threshold for the analog watchdog.  
Refer to Section 30.4.25: Analog window watchdog on page 1127.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **LT2[11:0]: Analog watchdog 2 lower threshold**  
These bits are written by software to define the lower threshold for the analog watchdog.  
Refer to Section 30.4.25: Analog window watchdog on page 1127.
30.7.9 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28
Reset value: 0x0000 0000

The same register can be used in two different modes:
– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current section.
– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to next section.

CHSELRMOD = 0 in ADC_CFGR1

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 CHSEL[23:0]: Channel-x selection
These bits are written by software and define which channels are part of the sequence of channels to be converted.
0: Input Channel-x is not selected for conversion
1: Input Channel-x is selected for conversion

Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).
30.7.10 ADC channel selection register [alternate] (ADC_CHSELR)

Address offset: 0x28
Reset value: 0x0000 0000

The same register can be used in two different modes:
– Each ADC_CHSELR bit enables an input (CHSELRMOD = 0 in ADC_CFGR1). Refer to the current previous section.
– ADC_CHSELR is able to sequence up to 8 channels (CHSELRMOD = 1 in ADC_CFGR1). Refer to this section.

CHSELRMOD = 1 in ADC_CFGR1

<table>

</tbody>
</table>

Bits 31:28 **SQ8[3:0]**: 8th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 8th conversion of the sequence. 0b1111 indicates the end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
0000: CH0
0001: CH1
...
1010: CH10
1011: CH11
1100: CH12
1101: CH13
1110: CH14
1111: No channel selected (End of sequence)

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 27:24 **SQ7[3:0]**: 7th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 7th conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*
Bits 23:20 **SQ6[3:0]**: 6th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 6th conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 19:16 **SQ5[3:0]**: 5th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 5th conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 15:12 **SQ4[3:0]**: 4th conversion of the sequence
These bits are programmed by software with the channel number assigned to the 4th conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 11:8 **SQ3[3:0]**: 3rd conversion of the sequence
These bits are programmed by software with the channel number assigned to the 3rd conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 7:4 **SQ2[3:0]**: 2nd conversion of the sequence
These bits are programmed by software with the channel number assigned to the 2nd conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*

Bits 3:0 **SQ1[3:0]**: 1st conversion of the sequence
These bits are programmed by software with the channel number assigned to the 1st conversion of the sequence. 0b1111 indicates end of the sequence.
When 0b1111 (end of sequence) is programmed to the lower sequence channels, these bits are ignored.
Refer to SQ8[3:0] for a definition of channel selection.
*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*
30.7.11 ADC watchdog threshold register (ADC_AWD3TR)

30.7.13 ADC data register (ADC_PWR)

Address offset: 0x44
Reset value: 0x0000 0000
### Analog-to-digital converter (ADC4) (RM0456)

#### Bits 31:4
Reserved, must be kept at reset value.

#### Bit 3  VREFSECSMP: $V_{\text{REF+}}$ second sample bit
- This bit is set and cleared by software. It is used to enable/disable the second $V_{\text{REF+}}$ protection when multiple ADCs are working simultaneously and a clock divider of 1 is used.
- 0: $V_{\text{REF+}}$ second sample disabled
- 1: $V_{\text{REF+}}$ second sample enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing)*.

#### Bit 2  VREFPROT: $V_{\text{REF+}}$ protection bit
- This bit is set and cleared by software. It is used to enable/disable $V_{\text{REF+}}$ protection when multiple ADCs are working simultaneously and a clock divider is used.
- 0: $V_{\text{REF+}}$ protection disabled
- 1: $V_{\text{REF+}}$ protection enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing)*.

#### Bit 1  DPD: Deep-power-down mode bit
- This bit is set and cleared by software. It is used to enable/disable Deep-power-down mode in Autonomous mode or when the ADC is not used.
- 0: Deep-power-down mode disabled
- 1: Deep-power-down mode enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*

Setting DPD in Auto-off mode automatically disables the LDO.

#### Bit 0  AUTOFF: Auto-off mode bit
- This bit is set and cleared by software. It is used to enable/disable the Auto-off mode.
- 0: Auto-off mode disabled
- 1: Auto-off mode enabled

*Note: The software is allowed to write this bit only when ADEN bit is cleared to 0 (this ensures that no conversion is ongoing).*
### 30.7.14 ADC Analog Watchdog 2 Configuration register (ADC_AWD2CR)

Address offset: 0xA0
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **AWD2CH[23:0]**: Analog watchdog channel selection

- These bits are set and cleared by software. They enable and select the input channels to be guarded by analog watchdog 2 (AWD2).
- 0: ADC analog channel-x is not monitored by AWD2
- 1: ADC analog channel-x is monitored by AWD2

**Note:** The channels selected through ADC_AWD2CR must be also configured into the ADC_CHSELR registers. Refer to SQ8[3:0] for a definition of channel selection. The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).

### 30.7.15 ADC Analog Watchdog 3 Configuration register (ADC_AWD3CR)

Address offset: 0xA4
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **AWD3CH[23:0]**: Analog watchdog channel selection

- These bits are set and cleared by software. They enable and select the input channels to be guarded by analog watchdog 3 (AWD3).
- 0: ADC analog channel-x is not monitored by AWD3
- 1: ADC analog channel-x is monitored by AWD3

**Note:** The channels selected through ADC_AWD3CR must be also configured into the ADC_CHSELR registers. Refer to SQ8[3:0] for a definition of channel selection. The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).
30.7.16 ADC Calibration factor (ADC_CALFACT)

Address offset: 0xC4
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT[6:0]**: Calibration factor

These bits are written by hardware or by software.
- Once a calibration is complete, they are updated by hardware with the calibration factors.
- Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it is then applied once a new calibration is launched.
- Just after a calibration is complete, DATA[6:0] contains the calibration factor.

Note: Software can write these bits only when ADEN = 1 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

30.7.17 ADC option register (ADC_OR)

</tr>
</thead>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **CHN21SEL**: Channel 21 selection bit

This bit is set and cleared by software. It is used to select the internal source connected to ADC input channel 21:
0: dac1_out1 selected
1: dac1_out2 selected

Note: The software is allowed to write this bit only when ADSTART bit is cleared to 0 by writing ADSTP to 1 = 0 (which ensures that no conversion is ongoing).

</table>

Bits 31:25 Reserved, must be kept at reset value.

**Bit 24 VBATEN**: $V_{BAT}$ enable

This bit is set and cleared by software to enable/disable the $V_{BAT}$ channel.

- 0: $V_{BAT}$ channel disabled
- 1: $V_{BAT}$ channel enabled

*Note: The software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing)*

**Bit 23 VSENSESEL**: Temperature sensor selection

This bit is set and cleared by software to enable/disable the temperature sensor.

- 0: Temperature sensor disabled
- 1: Temperature sensor enabled

*Note: Software is allowed to write this bit only when ADSTART is cleared to 0 by writing ADSTP to 1 (which ensures that no conversion is ongoing).*
Bit 22 **VREFEN**: $V_{REFINT}$ enable
This bit is set and cleared by software to enable/disable the $V_{REFINT}$ buffer.
0: $V_{REFINT}$ disabled
1: $V_{REFINT}$ enabled

**Note**: Software is allowed to write this bit only when **ADSTART** is cleared to 0 by writing **ADSTP** to 1 (which ensures that no conversion is ongoing).

Bits 21:18 **PRESC[3:0]**: ADC prescaler
Set and cleared by software to select the frequency of the clock to the ADC.
0000: input ADC clock not divided
0001: input ADC clock divided by 2
0010: input ADC clock divided by 4
0011: input ADC clock divided by 6
0100: input ADC clock divided by 8
0101: input ADC clock divided by 10
0110: input ADC clock divided by 12
0111: input ADC clock divided by 16
1000: input ADC clock divided by 32
1001: input ADC clock divided by 64
1010: input ADC clock divided by 128
1011: input ADC clock divided by 256
Other: Reserved

**Note**: Software is allowed to write these bits only when the ADC is disabled (**ADCAL** = 0, **ADSTART** = 0, **ADSTP** = 0, **ADDIS** = 0 and **ADEN** = 0).

Bits 17:0 Reserved, must be kept at reset value.

### 30.8 ADC register map

The following table summarizes the ADC registers.

**Table 258. ADC register map and reset values**

| Offset | Register     | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Refer to Section 2.3 on page 116 for the register boundary addresses.
31 Digital-to-analog converter (DAC)

31.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, $V_{REF+}$ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer ($V_{REFBUF}$) section.

The $DAC_{x\_OUTy}$ pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

31.2 DAC main features

The DAC main features are the following (see Figure 217: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the $DAC_{x\_OUTy}$ output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Autonomous mode to reduce the power consumption for the system
- Input voltage reference

*Figure 217* shows the block diagram of a DAC channel and *Table 260* gives the pin description.

2. Refer to Section 31.3: DAC implementation for channel2 availability.
31.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI or LSE clock source (dac_hold_ck).

### 31.4.3 DAC clocks

Two clock sources can be used to update the DAC:
- `dac_hclk`: DAC peripheral clock (AHB clock)
- `dac_ker_ck`: DAC kernel clock: this clock can be used to synchronize DAC and ADC.
- `dac_hold_ck`: low-power clock used in Sample and hold mode

The DAC clock is selected in the RCC.

### 31.4.4 DAC channel enable

Each DAC channel can be powered on by setting its corresponding `ENx` bit in the DAC_CR register. The DAC channel is then enabled after a `tWAKEUP` startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when `ENx` bit is set while DACxRDY signal is reset.

**Note:** The `ENx` bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the `ENx` bit is reset.

**ST**
31.4.5 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel
  
  There are three possibilities:
  
  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx[15:4] bits (stored into the DHRx[11:0] bits)
  
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx[11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

- Dual DAC channels (when available)
  
  There are three possibilities:
  
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD[7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD[15:8] bits (stored into the DHR2[11:4] bits)
  
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD[15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD[31:20] bits (stored into the DHR2[11:0] bits)
  
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD[11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD[27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.
Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB bit of the data written to DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB bit is inverted. The four LSBs are simply ignored.

### 31.4.6 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_hclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_hclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time tSETTLING that depends on the power supply voltage and the analog output load.
To synchronize DAC and ADC, the same clock source can be used for both peripherals. This is done by selecting the dac_ker_ck clock instead of the dac_hclk clock (AHB clock) in the RCC.

HFSEL bits of DAC_MCR must be set when dac_hclk or dac_ker_ck clock speed is faster than 80 MHz. It adds an extra delay to the transfer from DAC_DHRx register to DAC_DORx register.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and dac_hclk clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.

The above timing is only related to the limitation of the DAC interface. Refer also to the \text{iSETTLING} parameter value in the product datasheet.

### Figure 220. Timing diagram for conversion with trigger disabled TEN = 0

![Timing diagram for conversion with trigger disabled TEN = 0](MSiv45319V2)
31.4.7 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and $V_{REF+}$. The analog output voltages on each DAC channel pin are determined by the following equation:

$$DAC_{output} = V_{REF} \times \frac{DOR}{4096}$$

31.4.8 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to the interconnection table in Section 31.4.2: DAC pins and internal signals.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_hclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_hclk clock cycle.

31.4.9 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA
workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channel, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

DMA Double data mode

When the DMA controller is used in Normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.
2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA Double data mode.

In DMA Double mode, DMA requests can only handle one DAC channel. To use two channel outputs in DMA Double mode, each DMA channel has to be configured separately.

The following conditions must be met to change from Double data to single data mode or vice versa:

- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

31.4.10 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three dac_hclk clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1’ is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Figure 222. DAC conversion (SW trigger enabled) with LFSR wave generation**

*Note:* The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
31.4.11 **Triangle-wave generation**

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10”. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_hclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

**Figure 223. DAC triangle wave generation**

![Figure 223. DAC triangle wave generation](image)

**Figure 224. DAC conversion (SW trigger enabled) with triangle wave generation**

![Figure 224. DAC conversion (SW trigger enabled) with triangle wave generation](image)

**Note:**

The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
31.4.12 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI or LSE low-speed clock (dac_hold_ck) in addition to the dac_hclk clock, allowing the DAC channels to be used in deep low power modes such as Stop mode.

The LSI or LSE low-speed clock (dac_hold_ck) must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register
The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
- 62 cycles are required for hold phase: THOLDx[9:0] = 62,
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 265. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{\text{SAMP}}^{(1)(2)}$</th>
<th>$t_{\text{REFRESH}}^{(2)(3)}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu s + (10*R_{\text{BON}}*C_{\text{SH}})$</td>
<td>$7 \mu s + (R_{\text{BON}}<em>C_{\text{SH}})</em>\ln(2*N_{\text{LSB}})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu s + (10*R_{\text{BOFF}}*C_{\text{SH}})$</td>
<td>$3 \mu s + (R_{\text{BOFF}}<em>C_{\text{SH}})</em>\ln(2*N_{\text{LSB}})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. $C_{\text{SH}}$ is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “$V_d$” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires $\ln(2*N_{\text{LSB}})$ constant time of the DAC.

### Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{\text{SH}} = 100 \text{ nF}$

$V_{\text{REF+}} = 3.0 \text{ V}$

**Sampling phase:**

\[
t_{\text{SAMP}} = 7 \mu s + (10 * 2000 * 100 * 10^{-9}) = 2.007 \text{ ms}
\]

(where $R_{\text{BON}} = 2 \text{ k\Omega}$)

**Refresh phase:**

\[
t_{\text{REFRESH}} = 7 \mu s + (2000 * 100 * 10^{-9}) * \ln(2*10) = 606.1 \mu s
\]

(where $N_{\text{LSB}} = 10$ (10 LSB drop during the hold phase))

**Hold phase:**

\[
D_v = i_{\text{leak}} * t_{\text{hold}} / C_{\text{SH}} = 0.0073 \text{ V} \ (10 \text{ LSB of 12bit at 3 V})
\]

\[
i_{\text{leak}} = 150 \text{ nA} \ (\text{worst case on the IO leakage on all the temperature range})
\]

\[
t_{\text{hold}} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 \text{ ms}
\]
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{\text{int}}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

31.4.13 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N} \right) \times G \times V_{\text{ref}} + V_{\text{OS}} \]

Where \( V_{\text{OUT}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{OS}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{OS}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{OS}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{\text{REF}}/2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{\text{DDA}} \) voltage, temperature, \( V_{\text{REF}} \) values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

</table>
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

Note: A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers, then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time. When CENx bit is set, it is not allowed to set ENx bit.

31.4.14 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

15 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_hclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_hclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with single triangle generation
To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation
To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start
To configure the DAC in this conversion mode, the following sequence is required:
- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_hclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation
To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_hclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_hclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three AHB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_hclk clock cycles later). Then the DAC channel2 triangle counter is updated.

**31.4.15 DAC Autonomous mode**

The Autonomous mode can be used to update the DAC output voltage in Stop mode. This allows DMA transfers to be performed when the device operates in Run, Sleep or Stop mode. The Autonomous mode is supported AUTOMODE only when the DAC is in Sample and hold mode. It is enabled by setting the bit in the DAC_AUTOCR register. DMA requests must also be enabled (DMAEN = 1).

When the AUTOMODE bit is set, each hardware trigger signal generates an AHB clock request to the RCC. **Once the peripheral receives the AHB clock**, the content of the DHRx register is loaded into DAC_DOR register and a DMA request is generated. When the DMA transaction is complete, the DAC deasserts the AHB clock request and waits for a new trigger event.

When the Sample and hold mode is selected, the dac_ker_ck low-power clock must be enabled by the RCC.
DMA transfers in Autonomous mode are performed following the sequence described below:
1. The DAC outputs the voltage on a GPIO or on an on-chip peripheral (dac_ker_ck and dac_hclk are not required).
2. The DAC receives a hardware trigger from another peripheral.
3. The DAC asserts the clock request.
4. The DAC loads DHRx register into DAC_DOR register.
5. The DAC generates a DMA request.
6. The DMA transfers the new data from memory to DHRx registers.
7. The DAC deasserts the clock request.

To initialize the DAC to operate autonomously in Stop mode, follow the sequence below:
1. Enable the DAC clock Autonomous mode in the RCC.
2. Select the DAC kernel clock in the RCC.
3. Enable dac_hold_ck clock for the DAC in the RCC.
4. Select a Sample and hold mode through MODEx bit.
5. Configure the Sample and hold mode by setting TSAMPLEx[9:0], THOLDx[9:0], TREFRESHx[7:0] bits.
6. Load the target value into DHRx register.
7. Set TENx bit to output the DAC value.
8. Configure the trigger setting through TSEL[3:0] bits.
9. Set DMAENx bit and configure the DMA interface.
10. Set the AUTOMODE bit.

Timing uncertainty of DHRx to DAC_DOR transfer

After each trigger event, the data contained in DHRx register is transferred to the DAC_DOR register. Since this transfer is based on AHB clock, the transfer timing depends on the clock availability.

When the AHB clock is stopped, a minimum time is required to restart it. This time depends on the clock source.

### 31.5 DAC in low-power modes

<table>

31.7 DAC registers

Refer to Section 1 on page 104 for a list of abbreviations used in register descriptions.
The peripheral registers have to be accessed by words (32-bit).

31.7.1 DAC control register (DAC_CR)

Address offset: 0x00
Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bit 30 CEN2: DAC channel2 calibration enable
This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be
written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only
when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel2 in Normal operating mode
1: DAC channel2 in calibration mode

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC
implementation.

Bit 29 DMAUDRIE2: DAC channel2 DMA underrun interrupt enable
This bit is set and cleared by software.
0: DAC channel2 DMA underrun interrupt disabled
1: DAC channel2 DMA underrun interrupt enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC
implementation.

Bit 28 DMAEN2: DAC channel2 DMA enable
This bit is set and cleared by software.
0: DAC channel2 DMA mode disabled
1: DAC channel2 DMA mode enabled

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC
implementation.
**MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

**WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*

**TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

- 0000: SWTRIG2
- 0001: dac_ch2_trg1
- 0010: dac_ch2_trg2
- ...
- 1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 31.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*

**TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

- 0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_hclk clock cycle later to the DAC_DOR2 register
- 1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_hclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_hclk clock cycle.

*These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*
Bit 16  **EN2**: DAC channel2 enable  
This bit is set and cleared by software to enable/disable DAC channel2.  
0: DAC channel2 disabled  
1: DAC channel2 enabled  

*Note: These bits are available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.*

Bit 15 Reserved, must be kept at reset value.

Bit 14  **CEN1**: DAC channel1 calibration enable  
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.  
0: DAC channel1 in Normal operating mode  
1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable  
This bit is set and cleared by software.  
0: DAC channel1 DMA Underrun Interrupt disabled  
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable  
This bit is set and cleared by software.  
0: DAC channel1 DMA mode disabled  
1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector  
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.  
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable  
These bits are set and cleared by software.  
00: wave generation disabled  
01: Noise wave generation enabled  
1x: Triangle wave generation enabled  
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2 **TSEL[3:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1

- 0000: SWTRIG1
- 0001: dac_ch1_trg1
- 0010: dac_ch1_trg2
- ...
- 1111: dac_ch1_trg15

Refer to the trigger selection tables in Section 31.4.2: DAC pins and internal signals for details on trigger configuration and mapping.

**Note**: Only used if bit **TEN1** = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

- 0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_hclk clock cycle later to the DAC_DOR1 register
- 1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_hclk clock cycles later to the DAC_DOR1 register

**Note**: When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_hclk clock cycle.

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

- 0: DAC channel1 disabled
- 1: DAC channel1 enabled

### 31.7.2 DAC software trigger register (DAC_SWTRGR)

31.7.3 DAC channel 1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DAC1DHRB[11:0]**: DAC channel 1 12-bit right-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel 1 when the DAC operates in Double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DAC1DHR[11:0]**: DAC channel 1 12-bit right-aligned data
These bits are written by software. They specify 12-bit data for DAC channel 1.
31.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1)

Address offset: 0x0C
Reset value: 0x0000 0000

![Table 1: DAC1DHRB(11:0)]

Bits 31:20 **DAC1DHRB[11:0]**: DAC channel1 12-bit left-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in Double data mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DAC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software.
They specify 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

31.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1)

Address offset: 0x10
Reset value: 0x0000 0000

![Table 2: DAC1DHRB[7:0] and DAC1DHR[7:0]]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DAC1DHRB[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1 when the DAC operates in Double data mode.

Bits 7:0 **DAC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software. They specify 8-bit data for DAC channel1.
31.7.6 DAC channel2 12-bit right aligned data holding register (DAC_DHR12R2)

This register is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Address offset: 0x14
Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 SINFO RMAT2: Enable signed format for DAC channel2
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2’s complement). The MSB bit represents the sign.

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bit 24 DMADouble2: DAC channel2 DMA double data mode
This bit is set and cleared by software.
0: DMA Normal mode selected
1: DMA Double data mode selected

Note: This bit is available only on dual-channel DACs. Refer to Section 31.3: DAC implementation.

Bits 23:19 Reserved, must be kept at reset value.

Bits 18:16 MODE2[2:0]: DAC channel2 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2 = 0 and bit CEN2 = 0 in the DAC_CR register). If EN2 = 1 or CEN2 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  000: DAC channel2 is connected to external pin with Buffer enabled
  001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  010: DAC channel2 is connected to external pin with buffer disabled
  011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- DAC channel2 in Sample and hold mode
  100: DAC channel2 is connected to external pin with Buffer enabled
  101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  111: DAC channel2 is connected to on chip peripherals with Buffer disabled

Note: This register can be modified only when EN2 = 0. Refer to Section 31.3: DAC implementation for the availability of DAC channel2.
Bits 15:14 **HFSEL[1:0]:** High frequency interface mode selection
- 00: High frequency interface mode disabled
- 01: High frequency interface mode compatible to AHB>80 MHz enabled
- 10: High frequency interface mode compatible to AHB>160 MHz enabled
- 11: Reserved

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1:** Enable signed format for DAC channel1
- 0: Input data is in unsigned format
- 1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Bit 8 **DMADouble1:** DAC channel1 DMA double data mode
- 0: DMA Normal mode selected
- 1: DMA Double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE[2:0]:** DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:
- **DAC channel1 in Normal mode**
  - 000: DAC channel1 is connected to external pin with Buffer enabled
  - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC channel1 is connected to external pin with Buffer disabled
  - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled
- **DAC channel1 in sample & hold mode**
  - 100: DAC channel1 is connected to external pin with Buffer enabled
  - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN1 = 0.*

### 31.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Refer to Section 2.3 on page 116 for the register boundary addresses.
32 Voltage reference buffer (VREFBUF)

32.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

32.2 VREFBUF implementation

The table below describes the VREFBUF voltages typical values:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VREFUBUF0</td>
<td>1.5 V</td>
</tr>
<tr>
<td>VREFUBUF1</td>
<td>1.8 V</td>
</tr>
<tr>
<td>VREFUBUF2</td>
<td>2.048 V</td>
</tr>
<tr>
<td>VREFUBUF3</td>
<td>2.5 V</td>
</tr>
</tbody>
</table>

Note: Refer to the product datasheet for more details.

32.3 VREFBUF functional description

![VREFBUF block diagram](image)
The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference VREFINT. The VREFBUF supports four voltages\(^a\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.
- VRS = 011: VREFBUF3 voltage selected.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF(+) pin pulled-down to VSSA</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF(+) pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF(+) pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF(+) pin floating. The voltage is held with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

### 32.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

---

\(\text{a. The minimum } V_{\text{DDA}} \text{ voltage depends on VRS setting, refer to the product datasheet.}\)
32.5 **VREFBUF registers**

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

- VRS = 000: VREFBUF0 voltage selected.
- VRS = 001: VREFBUF1 voltage selected.
- VRS = 010: VREFBUF2 voltage selected.
- VRS = 011: VREFBUF3 voltage selected.
- Others: Reserved

*Note: Refer to the product datasheet for each VREFBUFx voltage setting value. The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).*

Bit 3 **VRR**: Voltage reference buffer ready

- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ**: High impedance mode

This bit controls the analog switch to connect or not the VREF+ pin.

- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to Table 271: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR**: Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.

- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
32.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04
Reset value: 0x0000 00XX

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 TRIM[5:0]: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:
TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the Flash memory during the production test.

VRS change:
TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the Flash memory during the production test.

Write in TRIM[5:0]:
User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

32.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

</tbody>
</table>

Refer to Section 2.3 on page 116 for the register boundary addresses.
33 Comparator (COMP)

33.1 Introduction

The device embeds two ultra-low-power comparators COMP1 and COMP2. These comparators can be used for a variety of functions including:

- Wake-up from low-power mode triggered by an analog signal
- Analog signal conditioning
- Cycle-by-cycle current control loop when combined with a PWM output from a timer

33.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - DAC channel1 and channel2
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by a scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed/consumption
- Outputs that can be redirected to an I/O or to timer inputs for triggering break events for fast PWM shutdowns
- Comparator outputs with blanking source
- Comparators that can be combined as a window comparator
- Interrupt generation capability for each comparator with wake-up from Sleep and Stop modes (through the EXTI controller)
33.3 **COMP functional description**

33.3.1 **COMP block diagram**

The block diagram of the comparators is shown in the figure below.

![Comparator block diagrams](image)

33.3.2 **COMP pins and internal signals**

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:
- Emergency shut-down of PWM signals, using BKin and BKin2 inputs
- Cycle-by-cycle current control, using OREF_CLR inputs
- Input capture for timing measures

The comparator output can be simultaneously redirected internally and externally.

33.3.3 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, the comparator programming must not be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPxLOCK bit can be set to 1. This causes the whole COMPx_CSR register to become read-only, including the COMPxLOCK bit.

The write protection can only be reset by a MCU reset.

33.3.4 Window comparator

The purpose of window comparator is to monitor the analog voltage if it is within the voltage range defined by lower and upper threshold.

The two embedded comparators can be used to create a window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together. The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

Two non-inverting inputs can be connected internally together by enabling WINMODE bit to save one IO for other purposes.
33.3.5 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting a low-power mode) to be able to force the hysteresis value using external components.

33.3.6 Comparator output-blanking function

The blanking function prevents the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). This blanking function consists of a selection of a blanking window that is a timer output compare signal. The selection is done by software (refer to the comparator register description for possible blanking signals).

The complementary of the blanking signal is ANDed with the comparator output to provide the wanted comparator output (see the example in the figure below).
33.3.7 COMP power and speed modes

COMP1 and COMP2 power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application.

33.3.8 Scaler function

The scaler block provides the different voltage reference levels to the comparator inputs. This block is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference. The amplifier and the resistor bridge are enabled by setting the INMSEL value in the COMP_CFGRx registers, to connect the corresponding inverting input to the scaler output.

When the resistor divided voltage is not used, the resistor bridge and the amplifier are disabled to reduce the consumption. When the resistor bridge is disconnected, the 1/4 VREF_COMP, 1/2 VREF_COMP and 3/4 VREF_COMP levels are equal to VREF_COMP.
33.4 COMP low-power modes

</tr>
<tr>
<td>Standby</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

33.5 COMP interrupts

The comparator outputs are internally connected to the extended interrupts and events controller (EXTI). Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit the low-power modes.

Refer to Section 21: Extended interrupts and event controller (EXTI) for more details.

To enable the COMPx interrupt, follow this sequence:
1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select the rising, falling or both edges sensitivity.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

**Bit 31 LOCK:** COMP1_CSR register lock

This bit is set by software and cleared by reset. It locks the whole content of COMP1_CSR.

0: COMP1_CSR read/write bits can be written by software.

1: COMP1_CSR bits can be read but not written by software.

**Bit 30 VALUE:** COMP1 output status

This bit is read-only. It reflects the level of the COMP1 output after the polarity selector and blanking (see Figure 230).

**Bits 29:25 Reserved, must be kept at reset value.**

**Bits 24:20 BLANKSEL[4:0]:** COMP1 blanking source selector

This field is controlled by software (if not locked) and selects the PWM signal for comparator output-blanking (see Table 277 for the assignment).

**Bits 19:18 PWRMODE[1:0]:** COMP1 power mode selector

This bitfield is controlled by software (if not locked). It selects the power consumption and, as a consequence, the speed of the COMP1.

00: High speed

01, 10: Medium speed and power

11: Ultra-low-power
Bits 17:16 **HYST[1:0]**: COMP1 hysteresis selector
- This bitfield is controlled by software (if not locked). It selects the COMP1 hysteresis.
  - 00: None
  - 01: Low hysteresis
  - 10: Medium hysteresis
  - 11: High hysteresis

Bit 15 **POLARITY**: COMP1 polarity selector
- This bit is controlled by software (if not locked). It selects the COMP1 output polarity.
  - 0: Non-inverted
  - 1: Inverted

Bit 14 **WINOUT**: COMP1 output selector
- This bit is controlled by software (if not locked). It selects the COMP1 output.
  - 0: COMP1_VALUE
  - 1: COMP1_VALUE XOR COMP2_VALUE (required for window mode, see Figure 228)

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WINMODE**: COMP1 non-inverting input selector for window mode
- This bit is controlled by software (if not locked). It selects the signal for COMP1_INP input of the COMP1.
  - 0: Signal selected with INPSEL[1:0]
  - 1: COMP2_INP signal of COMP2 (required for window mode, see Figure 228)

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **INPSEL[1:0]**: COMP1 signal selector for non-inverting input
- This field is controlled by software (if not locked). It selects the signal for the non-inverting input COMP1_INP (see Table 273 for the assignment).

Bits 7:4 **INMSEL[3:0]**: COMP1 signal selector for inverting input INM
- This field is controlled by software (if not locked). It selects the signal for the inverting input COMP1_INM (see Table 274 for the assignment).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **EN**: COMP1 enable
- This bit is controlled by software (if not locked). It enables COMP1.
  - 0: COMP1 disabled
  - 1: COMP1 enabled

34 Operational amplifier (OPAMP)

34.1 Introduction

The device embeds two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, this enables any type of external interconnections. The operational amplifier can be configured internally as a follower or as an amplifier with a non-inverting gain ranging from 2 to 16.

The positive input can be connected to the internal DAC.

The output can be connected to the internal ADC.

34.2 OPAMP main features

- Rail-to-rail input and output voltage range
- Low input bias current
- Low input offset voltage
- Low-power mode
- High-speed mode to achieve a better slew rate
- Fast wakeup time
- Gain bandwidth of 1.6 MHz

34.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are three functional modes: the low-power mode, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in the Section 34.3.3: Signal routing.

34.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in RCC APB3 peripheral clock enable register (RCC_APB3ENR)).

The OPAEN bit in OPAMPx_CSR enables and disables the OPAMP operation. The OPAMP registers configurations can be changed when the OPAEN bit is set in OPAMPx_CSR. However it can create spurious effects (noise, glitch, overshoot or saturation). If the configuration is changed, the application firmware must take care of these spurious effects (such as ignore the ADC result on the OPAMP output).
When the OPAMP output is no more needed, the OPAMP can be disabled to save power. All the configurations previously set (including the calibration) are maintained while the OPAMP is disabled.

### 34.3.2 Initial configuration

The OPAMP default configuration is a functional mode where the three IOs are connected to external pins. In the default mode, the OPAMP uses the factory trimming values (see "electrical characteristics" section of the datasheet for factory trimming conditions. Usually the temperature is 30 °C and the voltage is 3 V). The trimming values can be adjusted (see [Section 34.3.5: Calibration](#)). The default configuration uses the normal mode, that provides the standard performance. The OPALPM bit in OPAMPx_CSR can be set in order to switch the OPAMP to low-power mode and reduced performance. Normal, low-power and high-speed modes characteristics are defined in the "electrical characteristics" section of the datasheet. Before utilization, the OPA_RANGE bit in OPAMP1_CSR must be set to 1.

As soon as the OPAEN bit in OPAMPx_CSR is set, the OPAMP is functional. The two input pins and the output pin are connected as defined in [Section 34.3.3: Signal routing](#) and the default connection settings can be changed.

**Note:** The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

### 34.3.3 Signal routing

The routing for the OPAMP pins is determined by the OPAMPx_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below:

<table>
<thead>
<tr>
<th>Signal</th>
<th>Pin</th>
<th>Internal</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPAMP1_VINM</td>
<td>PA1 or dedicated pin(^{(1)})</td>
<td>OPAMP1_OUT or PGA</td>
<td>Controlled by OPAMODE and VM_SEL</td>
</tr>
<tr>
<td>OPAMP1_VINP</td>
<td>PA0</td>
<td>DAC1_OUT1</td>
<td>Controlled by bit VP_SEL</td>
</tr>
<tr>
<td>OPAMP1_VOUT</td>
<td>PA3</td>
<td>ADC1_IN8</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.</td>
</tr>
<tr>
<td>OPAMP2_VINM</td>
<td>PA7 or dedicated pin(^{(1)})</td>
<td>OPAMP2_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL</td>
</tr>
<tr>
<td>OPAMP2_VINP</td>
<td>PA6</td>
<td>DAC1_OUT2</td>
<td>Controlled by bit VP_SEL</td>
</tr>
<tr>
<td>OPAMP2_VOUT</td>
<td>PB0</td>
<td>ADC1_IN15, ADC4_IN18</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by the ADC.</td>
</tr>
</tbody>
</table>

\(^{(1)}\) The dedicated pin is only available on BGA132 and BGA169 packages. This configuration provides the lowest input bias current (see datasheet).
34.3.4 OPAMP modes

The OPAMP inputs and outputs are all accessible on terminals. The amplifiers can be used in the following configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

The amplifier output pin is directly connected to the output pad to minimize the output impedance. It cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the ADC channel.

The impedance of the signal must be maintained below a level that avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Refer to the “electrical characteristics” section in the datasheet for further details.

Standalone mode (external gain setting mode)

The procedure to use the OPAMP in standalone mode is detailed below:

1. Keep default value of OPAMPx_CSR and the default state of GPIOx_MODER.
2. As soon as OPAEN is set in OPAMPx_CSR, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (standard performance). The OPAMP behavior can be changed with the following bits in OPAMPx_CSR:

- If OPALPM is set to 1, the OPAMP switches in low-power mode in order to save power.
- If OPAHSM is set to 1, the OPAMP switches in high-speed mode in order to have high slew rate.
- If USERTRIM is set to 1, the input offset values can be trimmed.

Figure 232. Standalone mode: external gain setting mode
Follower configuration mode

The procedure to use the OPAMP in follower mode is detailed below (all bits in OPAMPx_CSR):
2. Clear VP_SEL to 0 (GPIO connected to OPAMPx_VINP, named VINP in this document).
3. As soon as OPAEN is set to 1, the signal on the VINP pin is copied to the OPAMP_VOUT pin.

Note: The pin corresponding to OPAMP_VINM is free for another usage.

The signal on the OPAMP output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Programmable gain amplifier mode

The procedure to use the OPAMP to amplify the amplitude of an input signal is presented hereafter (all bits in OPAMPx_CSR):
1. Set OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16) in OPAMPx_CSR.
3. Set VM_SEL[1:0] to 1x in OPAMPx_CSR (inverting input not externally connected).
4. Clear VP_SEL to 0 in OPAMPx_CSR (GPIO connected to VINP).
5. As soon as OPAEN is set in OPAMPx_CSR, the signal on the OPAMP_VINP pin is amplified by the selected gain and visible on the OPAMP_VOUT pin.

Note: To avoid saturation, the input voltage must stay below $V_{DDA}$ divided by the selected gain.
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external set, is detailed below (all bits in OPAMPx_CSR):

1. Configure OPAMODE[1:0] to 10 (internal PGA enabled).
2. Set PGA_GAIN[1:0] to the selected PGA gain (2, 4, 8 or 16).
3. Clear VM_SEL[1:0] to 00 or 01 (GPIO connected to VINM).
4. Clear VP_SEL to 0 (GPIO connected to VINP).

Any external connection on VINP can be used in parallel with the internal PGA. For example, a capacitor can be connected between VOUT and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).
**34.3.5 Calibration**

At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each OPAMP offset can be trimmed by the user. Specific registers allow different trimming values for normal and low-power modes.

The calibration purpose is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows the inputs offset voltage to be reduced to less than +/- 1.5 mV within stable voltage and temperature conditions.

For each OPAMP and each mode, two trimming values can be trimmed: one for N differential pair and one for P differential pair.

The registers used to trim the offsets for each operational amplifiers are:

- OPAMPx_OTR for normal mode
- OPAMPx_LPOTR for low-power mode

Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values, with the USERTRIM bit in OPAMPx_CSR. This bit is reset at startup and the ‘factory’ value are applied by default to the OPAMP trimming registers.

The trimming values can be changed in calibration or in functional mode.

The offset trimming registers are typically configured after the initialization of the calibration operation (CALON set to 1 in OPAMPx_CSR). When CALON = 1, the OPAMP inputs are disconnected from the functional environment.

Setting CALSEL to 1 in OPAMPx_CSR initializes the offset calibration for the P differential pair (low-voltage reference used).
Clearing CALSEL to 0 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the CALOUT bit in OPAMPx_CSR reflects the influence of the trimming value selected by CALSEL and OPALPM. When the value of CALOUT switches between two consecutive trimming values, this means that those two values are the best trimming values. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see tOFFTRIM max delay specification in the “electrical characteristics” section of the datasheet).

*Note:* The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

When the calibration operation is done, OPAHSM must be cleared to 0 in OPAMPx_CSR.

</tbody>
</table>
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set OPAEN to 1 in OPAMPx_CSR to enable the OPAMP and set OPA_RANGE = 1 in OPAMP1_CSR.
2. Clear OPAHSM to 0 in OPAMPx_CSR.
3. Set CALON and USERTRIM to 1 in OPAMPx_CSR.
4. Choose a calibration mode (refer to Table 283). Steps 4 to 5 must be repeated four times. For the first iteration, select normal mode, offset cal high (N differential pair), with OPALPM = 0 and CALSEL = 0 in OPAMPx_CSR.
5. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 0, until CALOUT changes to 1 in OPAMPx_CSR.
   Between the write to OPAMP_OTR and the read of the CALOUT value, make sure to wait for the tOFFTRIM max delay specified in the “electrical characteristics” section of the datasheet, to get the correct CALOUT value.
   The commutation means that the offset is correctly compensated and that the corresponding trim code must be saved in OPAMP_OTR.
6. Repeat steps 4 to 5 for:
   - Normal mode and offset cal low
   - Low-power mode and offset cal high
   - Low-power mode and offset cal low
   If a mode is not used, the corresponding calibration can be skipped.

All OPAMPs can be calibrated at the same time.

Note: During the whole calibration phase:
- the external connection of the OPAMP output must not pull up or down currents higher than 500 µA.
- OPAMODE[1:0] must be set up to 00 or 01 (PGA disable) or 11 (internal follower).

34.4 OPAMP low-power modes

Bit 31 **OPA_RANGE**: OPAMP range setting
This bit must be set before enabling the OPAMP and this bit affects all OPAMP instances.
0: reserved
1: OPAMP range set

Bit 30 **OPAHSM**: OPAMP high-speed mode
This bit is effective for both normal and low-power modes.
0: Normal mode (standard slew rate)
1: Increased consumption to improve the slew rate

Bits 29:16 Reserved, must be kept at reset value.

Bit 15 **CALOUT**: OPAMP calibration output
During the calibration mode, the offset is trimmed when this signal toggles.

Bit 14 **USERTRIM**: ‘factory’ or ‘user’ offset trimmed values selection
This bit is active for normal and low-power modes.
0: ‘factory’ trim code used
1: ‘user’ trim code used

Bit 13 **CALSEL**: Calibration selection
0: NMOS calibration (200 mV applied on OPAMP inputs)
1: PMOS calibration (VDDA - 200 mV applied on OPAMP inputs)

Bit 12 **CALON**: Calibration mode enable
0: Normal mode
1: Calibration mode (all switches opened by hardware)

Bit 11 Reserved, must be kept at reset value.

Bit 10 **VP_SEL**: Non-inverted input selection
0: GPIO connected to VINP
1: DAC connected to VINP
34.5.2 **OPAMP1 offset trimming register in normal mode (OPAMP1_OTR)**

Address offset: 0x04
Reset value: 0x0000 XXXX

XXXX are factory trimmed values.

Refer to Section 2.3 for the register boundary addresses.
Multi-function digital filter (MDF)

35.1 Introduction

The multi-function digital filter (MDF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- motor control
- metering

The MDF features 6 digital serial interfaces (SITFx) and digital filters (DFLTx) with flexible digital processing options to offer up to 24-bit final resolution.

The DFLTx of the MDF also include the filters of the audio digital filter (ADF).

The MDF can receive, via its serial interfaces, streams coming from various digital sensors. The MDF supports the following standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

A flexible bitstream matrix (BSMX) allows the connection of any incoming bitstream to any filter.

The MDF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition it is possible to insert a high-pass filter or a DC offset correction block.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, decimation ratio, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible trigger interface can be used to control the conversion start. This timing control can trigger simultaneous conversions or insert a programmable delay between conversions.

The MDF features an out-of-limit detectors (OLD) function. There is one OLD for each digital filter chain. Independent programmable thresholds are available for each OLD, making it very suitable for over-current detection.

A short circuit detector (SCD) is also available for every selected bitstream. The SCD is able to detect a short-circuit condition with a very short latency. Independent programmable thresholds are offered in order to define the short circuit condition.

The digital processing is performed using only the kernel clock. The MDF requests the bus interface clock (AHB clock) only when data must be transfered or when a specific event requests the attention of the system processor.
35.2 MDF main features

- AHB interface
- 6 serial digital inputs:
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- 2 common clocks input/output for ΣΔ modulators
- Flexible matrix (BSMX) for connection between filters and digital inputs
- 2 inputs to connect the internal ADCs
- 6 flexible digital filter paths, including:
  - A configurable CIC filter:
    - Can be split into 2 CIC filters: high-resolution filter and out-of-limit detector
    - Can be configured in Sinc\(^4\) filter
    - Can be configured in Sinc\(^5\) filter
    - Adjustable decimation ratio
  - A reshape filter to improve the out-of-band rejection and in-band ripple
  - A high-pass filter to cancel the DC offset
  - An offset error cancellation
  - Gain control
  - Saturation blocks
  - An out-of-limit detector
- Short-circuit detector
- Clock absence detector
- 16- or 24-bit signed output data resolution
- Continuous or single conversion
- Possibility to delay independently each bitstream
- Various trigger possibilities
- Break generation on out-of-limit or short-circuit detector events
- Autonomous functionality in Stop modes
- DMA can be used to read the conversion data
- Interrupts services
35.3 **MDF implementation**

The devices embed one MDF instance and one ADF instance, both being digital filters with common features.

### 35.4.3 Serial input interfaces (SITF)

The SITFx input interfaces allow the connection of the external sensors to the digital filters, via the bitstream matrix (BSMX). The SITFx serial interface can be configured in the following modes:

- LF_MASTER SPI mode (low-frequency)
- normal SPI mode
- Manchester mode

The amount of SITFx instances is equal to the amount of filters.

The data from each serial interface can be routed to any filter in order to perform:

- the PDM to PCM conversion
- the out-of-limit detection
- the short detection

The serial interfaces are enabled by setting the corresponding SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

**Note:** Before enabling the serial interface, the user must insure that the mdf_proc_ck is already enabled (see Section 35.4.5: Clock generator (CKGEN) for details).

The SITFx are controlled via the **MDF serial interface control register x (MDF_SITFxCR)**.

As shown in Figure 237, for each SITF, there is a large choice of clocking possibilities:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on MDF_CCK0 or MDF_CCK1 or MDF_CKIx pin (see 2 in Figure 237).
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source must be the clock directly provided by the CCKDIV to the MDF_CCK0 or MDF_CCK1 pin (see 1 in Figure 237). In this case MDF_CKIx must not be selected.

See **Table 292** for additional information.
**Note:** Using the common clock (MDF_CCK0 or MDF_CCK1) can be helpful to share the same clock between several SITFx.

**Figure 237. SITFx overview**

**LF_MASTER and normal SPI modes**

The LF_MASTER SPI mode is a special mode allowing the usage of a mdf_proc_ck clock frequency, only two times higher than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the MDF must provide the bitstream clock to the external sensors via MDF_CCK0 and MDF_CCK1 pins, and receives the bitstream data via the serial data input MDF_SDIx.
For each SITFx, the application must select the same clock than the one provided to the external sensor (MDF_CCK0 or MDF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

Warning: The MDF_CKIx pin cannot be used in LF_MASTER SPI mode.

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the mdf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select MDF_CCK0, MDF_CCK1 or MDF_CKIx clock for the capture of the data received via the MDF_SDIx pin.

The MDF can generate a clock to the sensors via MDF_CCK0 or MDF_CCK1 if needed.

For all SPI modes, all SITFs can share the same clock input (MDF_CCK0 or MDF_CCK1), in order to optimize the amount of requested I/Os.

For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITFx always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bsx_f)
- bitstream received using the bitstream clock rising edge (bsx_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.

To properly synchronize/receive the data stream, the frequency of the mdf_proc_ck clock must be adjusted according to the constraints listed in Table 293.

Clock absence detection

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] field of the corresponding SITFx. If the MDF does not detect clock transitions for a duration of STH[4:0] x T_mdf_proc_ck, then the CKABF flag is set.
An interrupt can be generated if CKABIE is set to 1. The STH[4:0] field is in the *MDF serial interface control register x (MDF_SITFxCR)*.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.
   - If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF ≠ 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

*Note:* *The clock absence detection feature is not available in the LF_MASTER SPI mode.*

**Manchester mode**

In Manchester coded format, the MDF receives data stream from the external sensor via the MDF_SDIx pin only.

The MDF_CKIx pins are not needed in this mode.

Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bsx_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0
To decode the incoming Manchester stream, the user must program the STH\[4:0\] field in the MDF serial interface control register x (MDF_SITFxCR). The STH\[4:0\] field is used by the SITFx to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the MDF_SDIx input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. Figure 239 shows a case where the OVR is around height and STH\[4:0\] = 5.

The estimated Manchester symbol rate \(T_{SYMB}\) must respect the following formula:

\[
(STH + 1) \times T_{mdf_{proc_{ck}}} < T_{SYMB} < (2 \times STH \times T_{mdf_{proc_{ck}}})
\]

It is recommended to compute STH as follows:

\[
STH[4:0] = \text{round} \left( \frac{(2 \times OVR) - 1}{3} \right)
\]

where OVR represents the ratio between the mdf_{proc_{ck}} frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the mdf_{proc_{ck}} clock must be adjusted according to the constraints listed in Table 293.

The clock absence flag CKABF is set to 1 when no transition is detected during more than \(2 \times STH[4:0] \times T_{mdf_{proc_{ck}}}\) or when the SITFx is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.
When the serial interface is enabled, the MDF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the Figure 239) is detected.

The end of the synchronization phase can be checked by following the software sequence:
1. Clear the CKABF flag in the MDF DFLTx interrupt status register x (MDF_DFLTxISR) by writing CKABF bit to 1. If the serial interface is not yet synchronized, the hardware immediately sets the CKABF flag to 1.
2. Read the CKABF flag.
   – If CKABF = 1, go back to step 1.
   – If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the MDF kernel clock frequency \( F_{\text{mdf\_ker\_ck}} \) is 100 MHz and the received Manchester stream is at about 6 MHz \( F_{\text{SYMB}} \).
1. Provide a valid \( mdf\_proc\_ck \) to the SITFx.
   The \( mdf\_proc\_ck \) frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).
   \( \text{PROCDIV} \) is programmed to 1 to perform a division by two of the kernel clock. In that case, \( F_{\text{mdf\_proc\_ck}} = 50 \text{ MHz} \) (8.33 times higher than the Manchester symbol frequency).
2. Compute STH.
   OVR is given by: \( OVR = \frac{F_{\text{mdf\_proc\_ck}}}{F_{\text{SYMB}}} = \frac{50 \text{ MHz}}{6 \text{ MHz}} = 8.33 \).

Then \( STH[4:0] = \text{round} \left( \frac{2 \times 8.33 - 1}{3} \right) = 5 \)

The minimum allowed frequency for the Manchester stream is then:
\[ \frac{1}{2 \times STH \times T_{\text{mdf\_proc\_ck}}} = \frac{1}{(10 \times 20 \text{ ns})} = 5 \text{ MHz} \]

The maximum allowed frequency for the Manchester stream is then:
\[ \frac{1}{(STH+1) \times T_{\text{mdf\_proc\_ck}}} = \frac{1}{(6 \times 20 \text{ ns})} = 8.33 \text{ MHz} \]

35.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the MDF. Refer to Section 35.3: MDF implementation to check the situation for this product.

The MDF allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the MDF digital filter configuration register x (MDF_DFLTxCICR) allows the application to select either data from the ADCs.

**Warning:** The MDF does not support receiving interleaved data from one of the ADCITF input.
35.4.5 Clock generator (CKGEN)

The RCC (reset and clock controller) provides the following clocks to the MDF:

- AHB clock (mdf_hclk) used for the register interface
- Kernel clock (mdf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the MDF_CCK0 and MDF_CCK1 pins. All those clocks are generated from the mdf_ker_ck.

The processing clock (mdf_proc_ck) is used to run all the signals processing and to re-sample the incoming serial or parallel stream.

Note: The reshape filter (RSFLT) needs up to 24 cycles of mdf_proc_ck clock to process a sample.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the MDF_CCK0 and MDF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

The mdf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All bits and fields controlling the CKGEN are in the MDF clock generator control register (MDF_CKGCR).
The trigger logic for CKGEN is handled by the TRG_CK block. As shown in Figure 249, the CCKDIV divider can be triggered on the rising or falling edge of one of the 16 trigger sources. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the MDF_CCKy (y = 0, 1) clock of several MDF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the MDF_CCK0 or MDF_CCK1 pin CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

Table 292. Control of the common clock generation

<table>
<thead>
<tr>
<th>CCKyEN</th>
<th>CCKyDIR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The MDF_CCKy pin is in input. An external clock can be connected to the MDF_CCKy pin and used by the SITFx in order to decode the serial stream</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The MDF_CCKy pin is in output. No clock is generated, thus the MDF_CCKy pin is driven low.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MDF_CCKy pin is in output. A clock is generated on the MDF_CCKy pin. The SITFx can use this pin as clock source in order to decode the serial stream</td>
</tr>
</tbody>
</table>

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 must be avoided (no interest).

When CCKyDIR = 1, as soon as the CCKyEN bit is set to 1, a clock is generated to the corresponding output without any spurs.

Note: The mdf_proc_ck must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITFx or DFLTx).
**CKGEN activation sequence example**

1. Set CKGDEN to 0.
2. Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
3. Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0] and TRGSENS.
4. Set CKGDEN to 1.
5. Set CCKxDIR to 1 (optional).
6. Set CCKxEN to 1 (optional).

When needed, at any moment, the CCK0EN or CCK1EN value can be changed without disabling the clock generator.

**Clock frequency constraints**

The table below shows the frequency constraints to receive and process properly the samples.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

1. \( F_{MDF, CKKy} \) represents the frequency of the clock received via MDF_CKIx and MDF_CCKy, or generated via MDF_CCKy. \( F_{SYMB} \) represents the frequency of the received symbol rate for Manchester mode.

**35.4.6 Bitstream matrix (BSMX)**

The BSMX receives the bitstreams from all serial interfaces (SITFx) and provides the selected input to the digital filters (DFLTx) and to the short-circuit detectors (SCDx). For each filter path, any of the bitstream input can be selected.

As shown in the Figure 237, each SITFx block provides two bitstreams (bsx_r and bsx_f) to the BSMX.
The application to select the wanted stream via the MDF bitstream matrix control register x (MDF_BSMXxCR). This selection is intended to be static.

**Figure 241. BSMX overview**

**BSMX programming sequence example**

The BSSEL[4:0] field cannot be changed if the corresponding SCDx, OLDx or DFLTx is enabled. The following steps are needed to change the value of BSMX, for filter path x:

1. Set SCDEN of SCDx to 0.
2. Set DFLTEN of DFLTx to 0.
3. Set OLDEN of OLDx to 0.
4. Wait for BSMXACTIVE = 0.
5. Program BSSEL[4:0] of filter path x.
6. Set SCDEN of SCDx to 1 (optional).
7. Set DFLTEN of DFLTx to 1 (optional).
8. Set OLDEN of OLDx block to 1 (optional).

**35.4.7 Short-circuit detectors (SCD)**

The SCDx detects, with a very fast response time, if an analog signal reached saturated values (out-of-full scale ranges) and remained on this value for a given time.
This behavior can detect short-circuit or open-circuit errors (such as over current or over voltage). An interrupt event or/and a break signal can be generated.

Figure 242. SCD functional view

The SCDx is counting consecutive zeros or consecutive ones received from the serial interface (SITFx). A counter is restarted if there is a change in the data stream received. If this counter reaches a short-circuit threshold value (SCDT[7:0]) in the MDF short circuit detector control register x (MDF_SCDxCR), then a short-circuit event is invoked. Each BSMX output has its own short-circuit detector. Any BSMX output can be continuously monitored by setting the corresponding SCDEN bit to 1 in MDF_SCDxCR. Each SCD has its own threshold settings (SCDT) and its own status bit (SCDF).

The figure below shows an example where SCDT[7:0] is set to six. The break signal remains high as long as the short circuit condition is present.

No overrun event is generated when the interrupt event is pending while a new short-circuit condition is detected.

Figure 243. SCD timing example

The SCDx event generated by the SCDx block can be assigned to break output signals mdf_break[3:0]. The break signal assignment to a given short-circuit detector event is done...
by BKSCD[3:0] in the MDF short circuit detector control register x (MDF_SCDxCR). The break outputs are shared with the over-current function.

Note: SCDs cannot be used to monitor the ADC data interface (ADCITF).

**SCD activation sequence example**

1. Enable and configure CKGEN to generate the mdf_proc_ck.
2. Set SCDEN to 0.
3. Wait for SCDACTIVE = 0. If SCDEN was previously enabled, this phase can take two periods of mdf_hclk, and two periods of mdf_proc_ck.
4. Program BKSCD[3:0] and SCDT[7:0].
5. Set SCDEN to 1.

Note: BKSCD[3:0] and SCDT[7:0] must not be changed when SCDACTIVE = 1.

### 35.4.8 Digital filter processing (DFLT)

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- source selector
- clock skipper delay (DLY)
- CIC decimation filter that can be configured:
  - in single Sinc4 or Sinc5 order CIC (MCIC)
  - in two CIC filters:
    - a main filter (MCIC), high resolution
    - an auxiliary filter (ACIC), low-latency, for the out-of-limit detector (OLD)
    - both MCIC and ACIC can be configured as Sinc1, Sinc2, Sinc3 or FastSinc
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- integrator (INT)
- receive RXFIFO
The figure below shows the filter-path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

**Figure 244. DFLT overview**

### Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

### Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate, must be applied to the incoming stream. This feature is helpful when the MDF is synchronized with other ADF or MDF blocks for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is performed by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

The figure below shows an example of how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example.
CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another ADF or MDF instance.

**Figure 245. Programmable delay**

The CIC of filter 1 (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

*Note:* When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

**Warning:** It is not recommended to apply a delay bigger than the programmed decimation ratio (CIC + RSFLT decimation), especially if the MDF is programmed in interleaved acquisition mode. There is a strong risk of data misalignment inside the FIFOs.
The following steps are needed to program the amount of bitstream clock periods to be skipped:

1. Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the corresponding DFLTx is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the corresponding digital filter is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

When the MDF skipped the amount of wanted data strobes, then SKPBF goes back to 0.
3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the MDF is enabled. In a given filter, if the application performs a D1 delay, followed by a D2 delay, then all other active filters are delayed by D1 + D2.

Data coming from ADCs can also benefit of this feature.

In interleaved acquisition mode, it is up to the application to insure that the delay applied on the different microphones is in line with the depth of the RXFIFO buffers. If the relative delay between each activated filter is less than the decimation ratio, then it costs one FIFO location.

If the interleaved acquisition mode is not used, then the delay value has no impact on the RXFIFO buffering.

Note: If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

Cascaded-integrator-comb (CIC) filter

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a $\text{Sinc}^N$ function, this is why they are often called Sinc filters.

The $\text{Sinc}^N$ digital filter embedded into the MDF is configurable according to the application targeted.

- For audio applications, such as speech capture from digital microphones, the application can select a high-resolution low-pass decimation filter by setting CICMOD to 100 or 101.
- If the targeted application is motor control or any other sensor capture, then the application can configure the CIC in order to offer a main filter path for acquisition (MCIC) and an auxiliary filter for fast-event generation (ACIC). This auxiliary filter can be used for example, to detect over-current conditions. This mode is selected by setting CICMOD[2:0] = 0xx.

When CICMOD[2:0] = 0xx, the following CIC filters are available:

- main filter (MCIC)
- auxiliary CIC filter (ACIC)

Both of them are configurable in FastSinc, Sinc$^1$ to Sinc$^3$. 
When CICMOD[2:0] = 100, the CIC is configured into a single Sinc⁴ and when CICMOD[2:0] = 101, the CIC is configured into a single Sinc⁵ filter.

The filters have the following transfer function (impulse response in z domain):

- Sinc⁴ filter type: \( H(z) = \left( \frac{1 - z^{-D}}{1 - z^{-1}} \right)^N \)

- FastSinc filter type: \( H(z) = \left( \frac{1 - z^{-D}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot D)}) \)

where \( N \) can be 1, 2, 3, 4 or 5, and \( D \) is the decimation ratio.

\( D \) is equal to MCICD+1 or ACICD+1.

Figure 246. CIC3 and CIC5 frequency response with decimation ratio = 32

CIC output data size

The size of samples delivered by the CIC (\( DS_{\text{CIC}} \)) depends on the following parameters:

- CIC order (\( N \))
- CIC decimation ratio (\( D \))
- data size of the input stream (\( DS_{\text{IN}} \))

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (\( DS_{\text{CIC}} \)) according to the parameters above.

\[ DS_{\text{CIC}} = \left( \frac{N \times \ln(D)}{\ln(2)} \right) + DS_{\text{IN}} \]

and the CIC gain is given by this formula:

\[ GCIC = (D)^N \]

The decimation ratio can be adjusted from 2 to 512 for the main CIC filter and from 1 to 32 for the auxiliary CIC filter.
The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

**Note:** $DS_{IN} = 1$ bit for a serial bitstream but can be up to 16 bits when coming from the ADCITF.

The LSB part of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-of-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

The table below shows the maximum allowed decimation ratio for the CIC filter, depending on the input data size. Bigger decimation ratio causes a wrap-around of the signal at CIC output, for strong input signals.

**Note:** The MDF cannot detect or prevent a CIC wrap-around.

**Scaling (SCALE) and saturation (SAT)**

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).
The signal amplitude can be decreased by up to 8 bits (-48.2 dB) and can be increased by up to 12 bits (+72.2 dB).

The gain is adjusted by the SCALE[5:0] field in the MDF digital filter configuration register x (MDF_DFLTxCICR).

SCALE[5:0] can be changed even if the corresponding DLFTx is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

</tbody>
</table>

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The MDF performs saturation operations at the following levels:
- after the SCALE block (performed by the SAT block). The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the MDF DFLTx interrupt enable register x (MDF_DFLTxiER) and MDF DFLTx interrupt status register x (MDF_DFLTxiSR).
Gain adjustment policy

To get the best MDF performances, it is important to properly adjust the gain value via SCALE[5:0].

A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

\[
\frac{\ln(SIN_{pp} \cdot D^N)}{\ln(2)} < 26
\]

where N represents the CIC order, D the decimation ratio and SIN_{pp} the maximum peak-to-peak amplitude of the input signal.

SIN_{pp} can take:
- a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF
- a maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048) for samples coming from a 12-bit ADC

**Example:** a Sinc^4 can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

\[
\frac{\ln(0.7 \cdot 96^4)}{\ln(2)} - 25.82 \text{ bits} < 26 \text{ bits}
\]

2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB is selected using this formula:

\[
\text{SCALE}_{\text{dB}} < 20 \cdot \log_{10}\left(\frac{2^{\text{NB}}}{\text{SIN}_{pp} \cdot D^N}\right)
\]

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. \text{SCALE}_{\text{dB}} represents the gain value selected by SCALE[5:0].
Example: for a Sinc⁴ with a decimation ratio of 96 and a SINpp of 0.7:

- If the RSFLT is bypassed:

  \[ 20 \cdot \log_{10} \left( \frac{2^{24}}{0.7 \cdot 96^4} \right) \approx -11 \text{ dB} \]

  SCALE\_dB value must be lower than -11 dB. The closest lower value is -12 dB (SCALE[5:0] = 0x2C).

- If the RSFLT is enabled:

  \[ 20 \cdot \log_{10} \left( \frac{2^{22}}{0.7 \cdot 96^4} \right) \approx -23 \text{ dB} \]

  SCALE\_dB value must be lower than -23 dB, the closest lower value is -24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITFx, according to the CIC order, and the CIC decimation ratio. This table is not exhaustive, and considers a full-scale input signal (see Section 35.7.5: Total MDF gain for details).

Reshaping filter (RSFLT)

In addition to the CIC, the MDF offers a reshaping IIR filter mainly dedicated to the audio application but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLTD bit in the MDF reshape filter configuration register x (MDF_DFLTxRSFR).

The RSFLT can be bypassed by setting RSFBYP to 1 in MDF_DFLTxRSFR.

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency ($F_C$) depends on the sample rates at its input ($F_{RS}$), and is given by the following formula:

$$F_C = 0.111 \times F_{RS}$$

Table 298. Most common microphone settings

</tr>
<tr>
<td>192</td>
<td>21.3</td>
<td>4</td>
<td>48</td>
</tr>
</tbody>
</table>
The figure below shows the frequency response of the reshape filter.

**Figure 247. Reshape filter frequency response normalized (F_{RS} / 2 = 1)**

The RSFLT gain is about 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of mdf_proc_ck clock to process one sample at F_{RS}. When the RSFLT is enabled, the application must insure that the mdf_proc_ck is at least 24 times faster F_{RS}.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new sample while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provide a faster mdf_proc_ck clock to the RSFLT.

**High-pass filter (HPF)**

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFBYP in the MDF reshape filter configuration register \textit{x} (MDF_DFLT_xRSFR).

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source and it must be removed from the final data.
The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the MDF reshape filter configuration register x (MDF_DFLTxRSFR), among the following values:

- 0.000625 x FPCM
- 0.00125 x FPCM
- 0.00250 x FPCM
- 0.00950 x FPCM

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

**Offset error compensation (OEC)**

Each digital filter has its own OEC. The offset correction is performed by subtracting to the signal provided by the CIC, the OFFSET[25:0] in the MDF offset error compensation control register x (MDF_OECxCR).

Due to the internal resynchronization, there is a delay of some cycles of mdf_proc_ck clock between the moment where the application writes the new offset, and the moment where the new offset value is effectively applied to the samples. If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back OFFSET[25:0] informs the application on the current offset value.

**Integrator (INT)**

The INT performs additional decimation and a resolution increase of data coming from the digital filter. The INT simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The INT is enabled by setting INTVAL[6:0] to a value different from 0.

The amount of integrated values can be defined by INTVAL[6:0] in the range of 2 to 128.

In order to control the data width at the integrator output, the resulting data can be divided by 1, 4, 32 or 128. This feature is controlled by INTDIV[1:0].

**35.4.9 Out-of-limit detector (OLD)**

The OLD triggers an event when a signal reaches or crosses given maximum and minimum threshold values. The generated event can drive an interrupt or break signals (mdf_break[3:0]) when conditions are met.

The OLD can be used only if the CIC filter is configured in motor and sensing mode (CICMOD[2:0] = 0xx).

---

### Table 299. HPF 3 dB cut-off frequencies examples

<td>76</td>
</tr>
</tbody>
</table>
The OLD takes the input signal selected by the main filter, process it using a Sinc\textsuperscript{N} or FastSinc filter (ACIC), and compares the resulting signal to programmed thresholds.

The OLD is enabled via the OLDEN bit in MDF\_OLD0CR. Once enabled, the input data are continuously monitored. There is no need to have the DFLTx enabled for using the OLD function.

The MDF offers a high- and low-threshold register that are compared with given data values. The application can generate an event if the signal is inside or outside the boundary defined by those two thresholds. This behavior is controlled via THINB in the MDF\_OLD0CR.

If the application only wants to generate an event when the input signal is higher than OLDTTH, then THINB and OLDTHL must both be cleared to 0.

If the application only wants to generate an event when the input signal is lower than OLDTTH, then THINB must be set to 1 and OLDTHL must be cleared to 0.

Note: It is not recommended to set a OLDTHL to a value bigger than OLDTTH.

The response time of the OLD depends on several parameters, the most important are listed hereafter:

- sampling rate frequency used by the external sensor
- ACIC decimation ratio
- ACIC order

The OLD can be used for over-current detection but also as current limiter if the PWM signal is generated by a timer receiving a old\_brk signal. Generally, to get a fast response time for over-current detection, it is recommended to use the ACIC with lowest order as possible and the minimum decimation ratio. FastSinc is also a good choice for over-current detection. The application must perform a trade-off between the filter resolution and the response time.
Status flags are available in order to inform the application that an OLD event is detected. Latched events are cleared by writing 1 into the OLDF bit.

As shown in Figure 248, when THINB = 0, the interrupt signal remains active as long as the signal is outside the gray area. At position A, the application clears the interrupt, but the interrupt is re-asserted because the signal is still outside the gray area. When the application clears OLDF, THHF and THLF are cleared as well.

An OLD event can be assigned to one or several break output signals (mdf_break[3:0]). The break signal assignment to a given OLD event is done by BKOLD[3:0] in the MDF out-of limit detector control register x (MDF_OLDxCR).

Note: The generation of break signals is independent from the interrupts generation.
OLD activation sequence example

1. Enable and configure CKGEN.
2. Set OLDEN to 0.
3. Wait for OLDACTIVE = 0. If OLDEN was previously enabled, this phase can take two periods of mdf_hclk and two periods of mdf_proc_ck.
4. Program BKOLD[3:0], ACICN[1:0], ACICD[4:0], THINB, OLDTHL[25:0] and OLDTHH[25:0].
5. Set OLDEN to 1.

35.4.10 Digital filter acquisition modes

The MDF offers the following modes to perform a data capture:

- Asynchronous continuous acquisition mode
- Asynchronous single-shot acquisition mode
- Synchronous continuous acquisition mode
- Synchronous single-shot acquisition mode
- Window continuous acquisition mode
- Synchronous snapshot acquisition mode

For each filter, one of these modes can be selected independently.

Note: To perform a data capture, the filters, the interfaces providing the data (SITFx or ADCITF) and the CKGEN must be enabled. If needed, MDF_CCK0 or MDF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This resets the filters and flushes the RXFIFO of the corresponding filter path. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filters are reset.
The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

**Figure 249. Trigger logic for DFLT and CKGEN**

A block common to all TRIG blocks performs the rising and falling edges detection and the resynchronization of the input triggers to the mdf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the mdf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select one of the following trigger sources:
- mdf_trgi[13:0] signals (refer to Table 289 for the triggers connections)
- TRGO bit in the **MDF global control register (MDF_GCR)**
- OLD event of each filter path

The edge sensitivity can also be selected, except for TRGO and OLD events.

**Asynchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition on one or several filters by simply writing their DFLTEN bits to 1.
The Asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.
The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN) so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in Table 303).

2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.

3. Program the filter configuration and set the ACQMOD[2:0] to 0.

4. Set to 1 the SITFEN bit of the requested data interfaces.

5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.

6. When DFLTEN is set to 1 for the filters to enable, the acquisition sequence starts immediately.

The figure below shows a simplified example of the samples generated by the DFLTx.

**Figure 250. Asynchronous continuous mode (ACQMOD[2:0] = 0)**

![Diagram](MSv62676V1)

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Asynchronous single-shot acquisition mode**

This mode allows the application to start the acquisition of one sample on one or several filters by simply writing their DFLTEN bits to 1.

The Asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are cleared to 0):

1. Configure and enable the clock generator (CKGEN), so that the mdf_proc_ck frequency is compatible with the targeted application (see examples in Table 299).

2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD\[2:0\] to 001.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1 for the filters to enable, each selected filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, for each filter, the application must:
1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

This sequence can be repeated every time a new data must be converted.

As shown in the Figure 251, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.

If the DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:
1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

**Figure 251. Asynchronous single-shot mode (ACQMOD[2:0] = 001)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition on one or several filters by using the following trigger sources:
- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit
The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 299).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 010.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1 for the filters to enable.
8. When the trigger condition is met, the filters start the acquisition.

The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. The next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

Figure 252. Synchronous continuous mode (ACQMOD[2:0] = 010)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.
Synchronous single-shot acquisition mode

This mode allows the application to start a single acquisition on one or several filters by using the following trigger sources:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 299).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter configuration and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. Then when the trigger condition is met, the filters start the acquisition and provide one data to the RXFIFO, then the filters are ready to accept a new trigger.

TRGSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). Every time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

Figure 253. Synchronous single-shot mode (ACQMOD[2:0] = 011)

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA...
transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Figure 253 shows a case where DFLTEN is cleared to 0 while an acquisition is ongoing: thus the sample S2 is lost. This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.

Note: The ongoing DMA transfer is properly terminated.

Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition on one or several filters controlled by consecutive edges of one of the following trigger sources:

• one of the mdf_trg[13:0] signals
• TRGO bit

The Window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 299).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit of the requested data interfaces.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated.
7. Set DFLTEN to 1 for the filters to enable.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 254 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the MDF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the MDF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the MDF waits again for a falling edge on the selected trigger input.
The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

Synchronous snapshot acquisition mode

In the acquisition modes described on previous sections, the application must wait for filters settling time or the end of conversion before getting a new valid sample. For applications very critical in latency, the last valid sample can be get immediately, with an information on the age of this sample by using the snapshot acquisition mode.

In snapshot mode, the DFLTx is continuously acquiring the samples, but the processed samples are not stored into the RXFIFO. When a trigger occurs, the last valid sample, the current decimation value of MCIC and the sample counter of the INT are stored in MDF_SNPS0DR.

The possible trigger sources are the following:

- one of the mdf_trg[13:0] signals
- OLD event of the corresponding filter
- TRGO bit

The Synchronous snapshot acquisition mode is selected when ACQMODE[2:0] = 101.

The sequence below shows the most important programming steps (assuming that DFLTEN bits of the filters are set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of mdf_proc_ck clock is compatible with the targeted application (see examples in Table 299).
2. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
3. Program the wanted filter settings and set the ACQMODE[2:0] to 101. FTH is usually cleared to 0 to receive an interrupt as soon as the RXFIFO is not empty.
4. Set the SITFEN bit of the requested data interfaces to 1.
5. Select the proper trigger source and sensitivity for each filter.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence has been properly terminated,
7. Set DFLTEN to 1 for the filters to enable.
When the trigger condition is met,

1. The MDF stores the last valid data provided by the corresponding filter, the value of the MCIC decimation counter, and the counter value of INT if selected by SNPSFMT into a shadow register.

2. The snps_evt is activated, indicating that a data is ready. If SSDRIE is set to 1, the MDF requests the AHB clock.

3. When the AHB clock is available the shadow register is stored in MDF snapshot data register x (MDF_SNPSxDR) and an interrupt is generated.

4. In the interrupt sub-routine, the application must do the following:
   a) Read the data located in MDF_SNPSxDR.
   b) Clear the SSDRF flag by writing it to 1.

As shown in the Figure 255, in snapshot mode, when the trigger event occurs, it is resynchronized with the processing clock (mdf_proc_ck), the decimation counter of the MCIC (MCIC_CNTR), the integrator counter (INT_CNTR) and the last valid sample (SN+2), are stored into a shadow register, and the snps_evt event is generated. When the AHB clock is available, an interrupt is generated and the shadow register is copied in MDF snapshot data register x (MDF_SNPSxDR). The application can read immediately the sample and the timing information.

The SSOVRF overrun flag is also available, allowing the application to check if an overrun condition occurs. A snapshot overrun condition is detected when the SSDRF flag is set to 1 while a new trigger event occurs.

In that case, the new trigger event is not taken into account. The application must clear the SSOVRF flag.

**Note:** When an activated filter did not receive a data strobe, the filter is frozen. If the interface providing the stream is not enabled (SITF or ADCITF), the filter is frozen. Once a DFLT x is
activated, CIC, HPF, IIR and INT are reinitialized. For each filter a status bit indicates if the filter is currently running or not.

**Starting several filters synchronously**

To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN is set to 0):
1. Enable the CKGEN and, if needed, enable the MDF_CCK0 and MDF_CCK1 clocks.
2. Set the SITFEN bit of the requested data interfaces to 1.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] to 0 (TRGO is selected).
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot), the application must do the following:
1. Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
2. Read TRGO until it is read to 0.
3. Set again TRGO to 1.

**Discarded samples**

The MDF offers the possibility to program the amount of samples to be discarded after each restart:
- to avoid capturing samples affected by the impulse response of the filter
- to delay the acquisition of filters by a specific amount of samples

The discard function is controlled via NBDIS[7:0] as follows:
- When NBDIS[7:0] = 0, the discard function is disabled.
- When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  - when the DFLTEN bit goes to 1
  - every time an acquisition is started in (A)synchronous single-shot modes

Refer to *Figure 250 to Figure 254, Figure 257 and Figure 258.*
In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transferred to the RXFIFO (or INT block if enabled) is S6.

**Figure 256. Discard function example**

Warning: All filters working in interleaved DMA mode must have the same NBDIS[7:0] value.

**Data interface activation**

The data interfaces are enabled by setting the corresponding SITFEN or ADCITFEN bit to 1. Once the digital filter is enabled, it receives the serial data from the external \(\Sigma\Delta\) modulator or parallel internal data sources (ADC).
### 35.4.11 Start-up sequence examples

The figure below details an acquisition sequence start of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLTx is configured for audio application: MCIC, RSFLT and HPF activated. The data interface (SITFx or ADCITF) is assumed to be already activated.

*Note:* NBDIS[7:0] is set on purpose to a low value to simplify the drawing.

**Figure 257. Start sequence with DFLTEN, in continuous mode, audio configuration**

The DFLTEN bit is re-sampled into the MDF processing clock domain. When DFLTEN is detected high, the filter chain is enabled and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC and delivers a sample to the HPF every time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of mdf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0. This counter is decremented every time the HPF delivers a sample.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.
The example shown in Figure 258 is based in a motor-control filter configuration:

- MCIC and INT are enabled.
- SFLT and HPF are disabled.
- ACQMOD[2:0] is set to 1 and uses a mdf_trgiy input as trigger.
- NBDIS[7:0] is set to 3.
- INTVAL[6:0] is set to 2.

The mdf_trgiy input signal is re-sampled into the MDF processing clock domain to avoid any metastability issues. When the trigger condition is met (rising edge), the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reaches its programmed value N, a sample is available. The NDIS function prevents the samples writing in the INT as long as NDIS_CNTR does not reach 0. This counter is decremented every time the MCIC delivers a sample.

When NDIS_CNTR reaches 0, the new samples are provided to the INT, that performs the integration of three consecutive samples and stores them into the RXFIFO.

**Figure 258. Start sequence with trigger input, in continuous mode, motor configuration**

35.4.12 Break interface

The break interface merges the break events coming from the OLDx and SDCx blocks into four break signals connected to various peripherals of the product (see Table 289 for details).

As shown in the figure below, several blocks can share the same break line. A same block can also drive several break lines. The break interface is controlled via MDF out-of limit detector control register x (MDF_OLDxCR) and MDF short circuit detector control register x (MDF_SCDxCR).
35.4.13 Data transfer to memory

Data format

The samples processed by DFLTx are stored into a RXFIFO. The application can read the samples stored into the FIFOs via the MDF digital filter data register x (MDF_DFLTxDR). The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The MDF provides 24-bit left-aligned data. Performing a 16-bit access to MDF_DFLTxDR allows the application to get the 16 most significant bits. Performing a 32-bit access to MDF_DFLTxDR allows the application to get a 24-bit data size.

Data re-synchronization

The samples stored into the RXFIFOs can be transferred into the memory by using either DMA requests or interrupt signaling.

Note: The RXFIFOs are located into the mdf_ker_ck clock domain, while MDF_DFLTxDR are located into the mdf_hclk (AHB) clock domain.
When the AHB clock is available, if MDF_DFLTxDn is empty and if a sample is available into the RXFIFO, this sample is transferred into MDF_DFLTxDn.

The sample transfer from the RXFIFO to MDF_DFLTxDn takes two periods of the AHB clock (mdf_hclk) and two periods of the mdf_ker_ck clock. The MDF inserts automatically wait-states if the application performs a read operation of MDF_DFLTxDn while the transfer of the new sample from the RXFIFO to MDF_DFLTxDn is not yet completed.

**Independent-transfer mode**

In this mode, each RXFIFO has its own DMA channel and its own FTHF flag event. Both single and burst DMA transfers are supported in this mode, but the application must care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

In addition, the application can select the RXFIFO threshold (FTH bit) to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth / 2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the corresponding DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the corresponding RXFIFO is not empty.

The DMA mode of the RXFIFOx is enabled via the corresponding DMAEN bit in the MDF digital filter control register x (MDF_DFLTxCr).

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available into the MDF digital filter data register x (MDF_DFLTxDn), the corresponding FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as MDF_DFLTxDn is read.
- If FTH = 1, as soon as one of the RXFIFO reaches the threshold level and a data is available into MDF_DFLTxDn, the corresponding FTHF is set, allowing the generation of an interrupt. The FTHF flag is released as soon as one data is read. FTHF is set again if the threshold condition is met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE / 2 data.
The independent-transfer mode must be used when the sample rates provided by each filter paths are not perfectly synchronous, or when the streams are independent. This situation may occur for example:

- when SITF is in SLAVE mode and each external sensor provides its own sampling clock
- when the decimation ratios of the DFLTx are not the same
- when all the streams are not starting at the same time

**Interleaved-transfer mode**

This mode optimizes the DMA request resources by sharing a single DMA request with several RXFIFOs.

Only single DMA transfers are supported in this mode.

In interleaved-transfer mode, FTH cannot be used and only the FTHF of RXFIFO0 is available for the interrupt signaling.

For the DMA transfer, when all the RXFIFOs working in interleaved-transfer mode are not empty, some DMA requests are generated in order to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR.

For the RXFIFOs working in interleaved-transfer mode, the DMA channel is enabled by setting to 1 DMAEN in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved mode via ILVNB[3:0]. DMAEN for the other RXFIFOs working in interleaved-transfer mode (RXFIFO 1 to ILVNB[3:0]) are not taken into account.

*Figure 262* shows four RXFIFOs working in interleaved-transfer mode. Each RXFIFO has a delay due to the programming of the DLY block.

When all the RXFIFOs have at least one sample available (in this example the last FIFO receiving a sample is RXFIFO1), the MDF requests the data transfer to the memory (see 1 in *Figure 262*). In this figure, the DMA is assumed to be used for the data transfer to memory.

The acquisition can be simply stopped by setting DFTLEN to 0 for one of the filter configured in interleaved-transfer mode. In the example, when a DFLTEN is set to 0 (see 2 in *Figure 262*), the transfer to memory is immediately stopped. Samples M2S(N), M3S(N) and M4S(N) may be lost.
In interrupt mode, when all the RXFIFOs working in interleaved-transfer mode have a data ready, the FTHF flag of RXFIFO0 is asserted to allow the interrupt generation. The application is then supposed to read sequentially one sample of each RXFIFOs, via MDF_DFLT0DR. The FTHF event is released when the first data is read.

For the RXFIFOs working in interleaved-transfer mode, the interrupt mode is enabled by setting FTHIE to 1 in MDF_DFLT0DR and by defining the amount of RXFIFOs working in interleaved-transfer mode via ILVNB[3:0]. FTHIE of the other RXFIFOs working in interleaved-transfer mode (RXFIFO1 to ILVNB[3:0]) are not taken into account.

The interleaved-transfer mode can only be applied starting at RXFIFO0 up to RXFIFOk. The number of RXFIFOs working in interleaved-transfer mode are defined by ILVNB[3:0].

When ILVNB[3:0] = 0, all RXFIFOs work in independent-transfer mode.

The interleaved-transfer mode can be used only for digital filters delivering samples perfectly synchronous each other. This is typically the case of sound capture with an array of digital microphones sharing the same bitstream clock.

**Caution:**

To make the MDF working properly in interleaved-transfer mode, the following rules must be respected:

- All filters working in interleaved-transfer mode must be all synchronized together, meaning that all filters must select the same ACQMOD[2:0] (must be equal to 010 or 011), the same trigger source and the same trigger sensitivity.
- All filters working in interleaved-transfer mode must have the same configuration.
- All sensors providing the data for the filters working in interleaved-transfer mode must use the same bitstream clock frequency.
- The maximum delay difference applied with SPKDLY[6:0] for the filters working in interleaved-transfer mode must remain strictly lower than the RXFIFO depth. Normally this delay does not need to exceed one TPCM period.
Both independent- and interleaved-transfer modes can work in parallel: for example, the first RXFIFOs (RXFIFO0 to RXFIFOk) may work in interleaved-transfer mode when the others (RXFIFO(k+1) to RXFIFO(N)) works in independent-transfer mode.

If the AHB clock is not present when a data transfer must be performed, the MDF first requests the AHB clock (refer to Section 35.4.5: Clock generator (CKGEN) for details).

The figure below shows the data path for a configuration in independent-transfer mode (left-hand figure) and a configuration mixing both independent- and interleaved-transfer modes (right-hand figure).

Figure 263. Data path for interleaved- and independent-transfer modes

In the right-hand figure, the DFLT0 and DFLT1 filters are configured in interleaved-transfer mode. For those filters, FTH is no longer taken into account by the hardware. The samples provided by DFLT0 and DFLT1 are read from MDF_DFLT0DR. When both RXFIFOs are no longer empty, the MDF generates two DMA requests to read the sample from DFLT0 and the sample from DFLT1. If both RXFIFOs are not empty again, the same sequence is triggered.

Note: When one of the filter working in interleaved-transfer mode is disabled, the data transfer to memory of all filters in interleaved-transfer mode is stopped immediately as well.

RXFIFO overrun

A RXFIFO overrun condition is detected when the RXFIFO is full and a new sample from the DFLTx must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 264 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.
After the S7 sample, the application manages to read data from the RXFIFO and the MDF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the mdf_hclk line, the gray boxes indicate that the MDF requested the AHB clock. The figure below shows the AHB clock available only when the MDF requests it. In real applications, the AHB clock may also be present if the MDF does not request it.

Figure 264. Example of overflow and transfer to memory

Note: If the MDF works in interleaved-transfer mode, the application must check the overrun status of all RXFIFOs that works in interleaved-transfer mode.

35.4.14 Autonomous mode

The MDF can work even if the AHB bus clock is not available (Stop modes). The MDF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the MDF receives a kernel clock if the following conditions are met:
- The MDF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.
In Stop mode, the MDF receives the AHB clock if the following conditions are met:

- The MDF autonomous mode is enabled in the RCC.
- The MDF requests the AHB clock, in the following situations:
  - when the MDF must transfer data into the memory via the DMA
    The data are directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the MDF must generate an interrupt
    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated. The AHB clock request is maintained as long as an enabled interrupt flag is active. More precisely, when an interrupt must be generated, the MDF requests the AHB clock.

### 35.4.15 Register protection

The MDF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

<table>
<thead>
<tr>
<th>Registers</th>
<th>Unprotected fields</th>
<th>Write-protected fields</th>
<th>Write-protection condition</th>
</tr>
</thead>
<tbody>

<td>All fields</td>
<td></td>
</tr>
</tbody>
</table>
All the MDF processing is performed in the mdf_proc_ck clock domain. For that reason, enabling or disabling a MDF sub-block may take some time due to the re-synchronization between the AHB clock domain and the mdf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected field, the application must follow this sequence:
1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for more details.

### 35.5 MDF low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. MDF interrupts cause the device to exit Sleep mode.</td>
</tr>
<tr>
<td>Stop(1)</td>

</tr>
<tr>
<td>Standby</td>
<td>The MDF is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

---

1. Refer to Section 35.3: MDF implementation for details about Stop modes supported by the MDF.
### 35.6 MDF interrupts

To increase the CPU performance, the MDF offers the following interrupt lines per digital filter:
- receive interrupt MDF_FLTx_RX (mdf_fltx_rx_it)
- event interrupt MDF_FLTx_EVT (mdf_fltx_evt_it)
- a combination of both interrupts MDF_FLTx (mdf_fltx_it)

**Note:** Interrupts are not always connected to the device (see Section 35.3: MDF implementation for more details). The status flags are available even if the corresponding interrupt enable flag is not enabled.

The interrupt interface is controlled via the MDF DFLTx interrupt enable register x (MDF_DFLTxIER) and the MDF DFLTx interrupt status register x (MDF_DFLTxISR).

![MDF interrupt interface diagram](image_url)

**Figure 265. MDF interrupt interface**

(1) Not always implemented. Refer to the vector table of the product for details.
The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

**Table 302. MDF interrupt requests**

<table>
<thead>

3. MDF_FLT_x_RX vector corresponds to the assertion of mdf_fltx_rx signal.
4. MDF_FLT_x_EVT vector corresponds to the assertion of mdf_fltx_evt signal.

### 35.7 MDF application informations

#### 35.7.1 MDF configuration examples for audio capture

**Table 303** gives some examples of the MDF settings for the digital microphones, focusing on 16 and 48 kHz output data rate. In these examples, the following is expected:

- The INT block is bypassed (INTVAL = 0).
- The offset error compensation is disabled (OFFSET = 0).

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (mdf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple and a good image rejection.
Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

### 35.7.2 Programming examples

This example describes how to capture sound from four microphones, assuming that each microphone pair shares the same data line. The MDF_SD0 and MDF_SD2 data lines are used. The microphone clock is provided by the MDF via MDF_CCK0 pin.

Enable MDF processing clock:
MDF_CKGCR = 0x0103 0023

ENABLE_MDF = 1 (division by 2): mdf_proc_ck frequency is 6.144 MHz.
CCKDIV = 3 (division by 4): MDF_CCK0 clock frequency is 1.536 MHz.
The MDF_CCK0 pad is set in output and generates a clock so that
the microphones can exit from low-power mode.

Serial interfaces configuration:
MDF_SITF0CR = 0x0000 1F01
MDF_SITF2CR = 0x0000 1F01

SCKSRC = 0 to select MDF_CCK0 as serial clock.
SIFTMOD = 0 to select LF_MASTER mode.
Clock absence feature is not working in this mode.
The serial interfaces are enabled.

Bitstream matrix configuration:
MDF_BSMX0CR = 0x0000 0000
MDF_BSMX1CR = 0x0000 0001
MDF_BSMX2CR = 0x0000 0004
MDF_BSMX3CR = 0x0000 0005

DFLT0 filter takes the bitstream of SITF0, sampled on rising edge.
DFLT1 filter takes the bitstream of SITF0, sampled on falling edge.
DFLT2 filter takes the bitstream of SITF2, sampled on rising edge.
DFLT3 filter takes the bitstream of SITF2, sampled on falling edge.

Filters configuration (CIC):
MDF_DFLT0CICR = 0x02C0 1750
MDF_DFLT1CICR = 0x02C0 1750
MDF_DFLT2CICR = 0x02C0 1750
MDF_DFLT3CICR = 0x02C0 1750

SCALE = 0x2C (-12 dB) to avoid any saturation
MCICD = 0x17 (decimation by 24)
CICMOD = 5 to select a Sinc5
DATSCR = 0 to select data coming from BSMX

Filters configuration (RSFLT and HPF):
MDF_DFLT0RSFR = 0x0000 0100
MDF_DFLT1RSFR = 0x0000 0100
MDF_DFLT2RSFR = 0x0000 0100
MDF_DFLT3RSFR = 0x0000 0100

HPFC = 1: cut-off frequency of 16 kHz * 0.00125 = 20 Hz
HPFBYP = 0: HPF not bypassed
RSFLTD = 0: RSFLT decimates by 4
RSFLTBYP = 0: RSFLT is not bypassed

Filters configuration (INT):
MDF_DFLT0INTR = 0x0000 0000
MDF_DFLT1INTR = 0x0000 0000
MDF_DFLT2INTR = 0x0000 0000
MDF_DFLT3INTR = 0x0000 0000

INTVAL = 0: INT filter not used
Other parameter is not significant.

35.7.3 Connection examples

*Figure 266* shows simple connection examples of the MDF to external sensors:

- Picture on the left: four digital microphones connected to the MDF

In this connection, DMIC1 is intended to be used alone. This is why it uses a dedicated clock (MDF_CCK0). DMIC1 is also connected to a dedicated data line in case the application intends to power-down DMIC2/3/4, when only DMIC1 is used. If the application keeps DMIC2/3/4 powered, DMIC2 and DMIC1 can share the same data line, reducing the connection to four I/Os.

If the power consumption is not an issue, when a single microphone is used, all the microphones can be connected to the same common clock (MDF_CCK0) and each
microphone pair can share the same data line. In this case, only three I/Os are required.

In this example, the data transfer to memory can be performed either using the interleaved- or the independent-transfer mode.

- Picture in the center: sensor providing several data lines with a common clock
  Each data line can represent different parameters (such as current or voltage). The common clock can be provided either by the sensor or by the MDF. The data line can be shared or not by two sensors if the sensor allows it. In the figure below, the sensor does not allow the sharing of the data lines.
  In this example, the data transfer to memory can be performed either using the interleaved- or independent-transfer mode.

- Picture on the right: two independent sensors connected to the MDF
  Each of them has its dedicated clock and data lines. In this case, the data transfer to memory must use the independent-transfer mode.

**Figure 266. Sensor connection examples**

35.7.4 Global frequency response

*Figure 267* shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 40 Hz
The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

**Figure 267. Global frequency response**

![](image1)

**Figure 268** shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:
- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enable with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 for CIC4. The -3 dB cut-off frequency is 7061 Hz.

**Figure 268. Detailed frequency response**

35.7.5 **Total MDF gain**

This section details how to compute the signal level provided by the MDF according to the filter settings. The formula does not take into account the filters transfer function.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50 % of the maximum level, has a - 6 dBFS level (6 dB below full scale).

For example, for the MDF offering a final data width of 24 bits, a signal having an amplitude of $2 \times 10^6$ LSB has a level of:

$$20 \times \log_{10} \left( \frac{2 \times 10^6}{2^{24} - 1} \right) = -12.45 \text{ dBFS}$$
In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:
\[
DS = \left(\frac{\ln(Amp)}{\ln(2)} + 1\right) \text{ bits}
\]

One bit need to be added for negative values.
So a signal having an amplitude of \(2 \times 10^6\) LSB, has a data size of 21.9 bits.

**CIC gain**
The CIC gain (\(G_{\text{CIC}}\) and \(G_{\text{dB CIC}}\)) can be deduced from the following formula giving data size in bits (\(D_{\text{SCIC}}\)).

\[
D_{\text{SCIC}} = (N \times \log_2(D1)) + D_{\text{IN}}
\]

And the bit growth is:

\[
B_{\text{G CIC}} = (N \times \log_2(D1))
\]

where \(N\) represents the CIC order (selected by \(\text{CICMOD}[2:0]\)), and \(D1\) is the decimation ratio (given by \(\text{MCICD}\)).

\(D_{\text{IN}}\) represents the data size (in bits) of the input signal.

---

**Warning:** \(D_{\text{SCIC}}\) is very important for CIC filters. In order to work fine, \(D_{\text{SCIC}}\) must not exceed 26 bits.

\[
G_{\text{CIC}} = 2^{(B_{\text{G CIC}})} = (D1)^N
\]

which gives, in decibels:

\[
G_{\text{dB CIC}} = 20 \times \log_{10}((D1)^N)
\]

**Note:** The same formulas are valid for the ACIC.

**Data size at SCALE output**
The data size at SCALE output (including the CIC gain) is a key information as the RSFLT starts to have some saturations if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.
If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted. The resulting data size is given by:

$$DS_{\text{SCALE}} = N \times \log_2(D1) + \log_2\left(\frac{GDB_{\text{SCALE}}}{10^\frac{9.5}{20}}\right) + DS_{\text{IN}}$$

The data size at SCALE output (DS_{\text{SCALE}}) is expressed in bits and GDB_{\text{SCALE}} represents the gain selected by SCALE[5:0], in dB.

**RSFLT gain**

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.5 dB must be considered. Typically, the RSFLT increases the bit size by BG_{RSFLT}:

$$BG_{RSFLT} = 10^{\frac{9.5}{20}} = 2.98 = 1.6 \text{ bits}$$

**INT gain**

The INT block can also introduce a gain if the rescaling value is different from the integration value.

$$G_{\text{INT}} = \frac{IVAL}{IDIV}$$

and:

$$GdB_{\text{INT}} = 20 \times \log_{10}\left(\frac{IVAL}{IDIV}\right)$$

The bit growth of the INT is then given by the following formula:

$$BG_{\text{INT}} = \log_2\left(\frac{IVAL}{IDIV}\right)$$

IVAL represents the integration value selected by INTVAL[6:0], and IDIV represents the integrator output division selected by INTDIV[1:0].

*Note:* The HPF filter has a gain of 0 dB.
The figure below shows a simplified view of the filter path, and gives for each significant component the expression of the bit growth and the gain.

Figure 269. Simplified DFLT view with gain information

The table below summarizes the final data size for different filter configurations.

Table 305. Output signal levels

<table>
<thead>
<tr>
<th>Filter configurations</th>
<th>Final signal level (dBFS)</th>
<th>Final signal size (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIC + RSFLT (+ HPF)</td>
<td></td>
<td>DS\textsubscript{OUT} = DS\textsubscript{SCALE} + 1.6 bits</td>
</tr>
<tr>
<td>CIC + RSFLT (+ HPF) + INT</td>
<td>S\textsubscript{dB\textsubscript{OUT}} = 20 \times \log_{10} \left( \frac{2^\text{DS\textsubscript{OUT}}}{2^{24}} \right)</td>
<td>DS\textsubscript{SCALE} must be lower than 22 bits.</td>
</tr>
<tr>
<td>CIC (+ HPF) + INT</td>
<td></td>
<td>DS\textsubscript{OUT} = DS\textsubscript{SCALE} + BG\textsubscript{INT} + 1.6 bits</td>
</tr>
</tbody>
</table>

Example using the main filter chain

If the MDF filter is programmed as follows:
- The input signal is coming from a serial interface (DS\textsubscript{IN} = 1 bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT is enabled and the decimation by four is enabled.
- HPF is enabled.
- INT is disabled.

Check first the data size at CIC output:
DS\textsubscript{CIC} = (5 \times \log_{2}(24)) + 1 \text{ bit} = 23.92 \text{ bits}

The size is lower than 26 bits, so the CIC works in good conditions.
The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a signal 22 bits max to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:

$$DS_{SCALE} = DS_{CIC} + \log_2\left(10^{-12/20}\right) = 23.92 - 1.99 = 21.93 \text{ bits}$$

At the end, the final signal amplitude is:

$$DS_{OUT} = DS_{SCALE} \div 1.6 \text{ bits} = (21.93 \div 1.6) = 23.52 \text{ bits}$$

or

$$SDB_{OUT} = 20 \times \log_{10}\left(\frac{2^{23.52}}{2^{24}}\right) = -2.84 \text{ dBFS}$$

The RSFLT ripple a margin of about ± 0.41 dB (in this configuration) must be considered.

**Example using the OLD filter chain**

In the following example, the application wants to trigger an OLD event when the voltage coming from a shunt resistor reaches ± 200 mV.

Hypothesis:
- The ΣΔ sensor is specified to support a full-scale signal of ± 350 mV.
- The ACIC decimation ratio (D2) is fixed to 32.
- The ACIC order (N) is fixed to 3.

The ΣΔ sensor provides a full-scale digital signal (amplitude of one bit) for a signal higher or equal to ± 350 mV. If the input signal is equal 200 mV, then the digital signal amplitude provided by the sensor is 200 / 350 = 0.571.

The gain of the ACIC filter is:

$$G_{CIC} = (D2)^N = 32^3 = 32768$$

A signal having an amplitude of 200 mV at sensor input has then an amplitude of about 32768 * 0.571 = 18725 LSB at ACIC output.

OLDTHH must be set to 18725 and OLDTHL must be set to -18725.
35.8 MDF registers

All the MDF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

35.8.1 MDF global control register (MDF_GCR)

Address offset: 0x000
Reset value: 0x0000 0000

This register is used for controls common to all digital filters.

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 ILVNB[3:0]: Interleaved number
This field is set and reset by software. It enables or disables the interleaved-transfer mode and defines how many digital filters work in this mode. This field cannot be changed when DFLTEN = 1 in MDF_DFLT0CR.
0000: Interleaved-transfer mode disabled
0001: Data from DFLT0 and DFLT1 are interleaved.
0010: Data from DFLT0, DFLT1 and DFLT2 are interleaved.
...
1111: Data from DFLT0 to DFLT15 are interleaved.

Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 TRGO: Trigger output control
This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also able to synchronize several MDF together by controlling the mdf_trgo signal.
0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on mdf_trgo signal and triggers the acquisition on the enabled filters having ACQMOD[2:0] = 0x1 and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.
### 35.8.2 MDF clock generator control register (MDF_CKGCR)

Address offset: 0x004  
Reset value: 0x0000 0000

This register is used to control the clock generator. The mdf_proc_ck clock must be enabled before enabling other MDF parts.

| Bit 31 | CKGACTIVE | | | | | | | | | |
|--------|------------|---|---|---|---|---|---|---|---|
| CKGACTIVE | Clock generator active flag  
This bit is set and cleared by hardware. This flag must be used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (refer to Section 35.4.15: Register protection for details). The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.  
0: The clock generator is not active and can be configured if needed.  
1: The clock generator is active and protected fields cannot be configured. |

<table>
<thead>
<tr>
<th>Bits 30:24</th>
<th>PROCDIV[6:0]</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
</table>
| PROCDIV[6:0]: Divider to control the serial interface clock  
This field is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.  
\[
F_{\text{mdf_ser_ck}} = \frac{F_{\text{mdf_ker_ck}}}{(\text{PROCDIV} + 1)}
\]  
This field must not be changed if one of the filters is enabled (DFTEN = 1).  
0: mdf_ker_ck provided to the SITF  
1: mdf_ker_ck/2 provided to the SITF  
2: mdf_ker_ck/3 provided to the SITF  
...  
127: mdf_ker_ck/128 provided to the SITF  
Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details). |

| Bits 23:20 | Reserved | must be kept at reset value. |
Bits 19:16 **CCKDIV[3:0]**: Divider to control the MDF_CCK clock

This field is set and reset by software. It is used to adjust the frequency of the MDF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the MDF_CCK is given by the following formula:

$$F_{\text{MDF_CCK}} = \frac{F_{\text{mdf_ker_ck}}}{(\text{PROCDIV} + 1) \times (\text{CCKDIV} + 1)}$$

This field must not be changed if one of the filters is enabled (DFTEN = 1).

0000: The MDF_CCK clock is mdf_proc_ck.
0001: The MDF_CCK clock is mdf_proc_ck / 2.
0010: The MDF_CCK clock is mdf_proc_ck / 3.
...
1111: The MDF_CCK clock is mdf_proc_ck / 16.

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This field is set and cleared by software. It is used to select which external signals trigger for the corresponding filter. This field is not significant if CKGMOD = 0.

0000: TRGO selected
0010: mdf_trg[0] selected
0011: mdf_trg[1] selected
...
1111: mdf_trg[13] selected

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.
1: A falling edge event triggers the activation of CKGEN dividers.

*Note: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge. This bit can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: MDF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the MDF_CCK1 pin.

0: MDF_CCK1 pin direction is in input.
1: MDF_CCK1 pin direction is in output.

*Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bit 5 **CCK0DIR**: MDF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the MDF_CCK0.

0: MDF_CCK0 pin direction is in input.
1: MDF_CCK0 pin direction is in output.

*Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).*
Bit 4 **CKGMOD**: Clock generator mode
This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if one of the filters is enabled (DFTEN = 1).
0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.
1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

*Note*: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: MDF_CCK1 clock enable
This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK1 pin.
0: Bitstream clock not generated
1: Bitstream clock generated on the MDF_CCK1 pad

Bit 1 **CCK0EN**: MDF_CCK0 clock enable
This bit is set and reset by software. It is used to control the generation of the bitstream clock on the MDF_CCK0 pin.
0: Bitstream clock not generated
1: Bitstream clock generated on the MDF_CCK0 pad

Bit 0 **CKGDEN**: CKGEN dividers enable
This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.
0: CKGEN dividers disabled
1: CKGEN dividers enabled

### 35.8.3 MDF serial interface control register x (MDF_SITFxCR)

Address offset: 0x080 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 1F00
This register is used to control the serial interfaces (SITFx).
Bit 31 **SITFACTIVE**: Serial interface active flag
   This bit is set and cleared by hardware. It is used by the application to check if the serial interface is effectively enabled (active) or not. The protected fields of this function can only be updated when the SITFACTIVE is set to 0 (refer to Section 35.4.15: Register protection for details).
   The delay between a transition on SITFEN and a transition on SITFACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.
   0: The serial interface is not active and can be configured if needed.
   1: The serial interface is active and protected fields cannot be configured.

Bits 30:13 Reserved, must be kept at reset value.

Bits 12:8 **STH[4:0]**: Manchester symbol threshold/SPI threshold
   This field is set and cleared by software. It is used for Manchester mode to define the expected symbol threshold levels (refer to Manchester mode for details on computation).
   In addition this field is used to define the timeout value for the clock absence detection in Normal SPI mode. STH[4:0] values lower than four are invalid.
   **Note**: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **SITFMOD[1:0]**: Serial interface type
   This field is set and cleared by software. It is used to define the serial interface type.
   00: LF_MASTER SPI mode
   01: Normal SPI mode
   10: Manchester mode: rising edge = logic 0, falling edge = logic 1
   11: Manchester mode: rising edge = logic 1, falling edge = logic 0
   **Note**: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **SCKSRC[1:0]**: Serial clock source
   This field is set and cleared by software. It is used to select the clock source of the serial interface.
   00: Serial clock source is MDF_CCK0.
   01: Serial clock source is MDF_CCK1.
   1x: Serial clock source is MDF_CKix (not allowed in LF_MASTER SPI mode).
   **Note**: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 0 **SITFEN**: Serial interface enable
   This bit is set and cleared by software. It is used to enable/disable the serial interface.
   0: Serial interface disabled
   1: Serial interface enabled
35.8.4 MDF bitstream matrix control register x (MDF_BSMXxCR)

Address offset: 0x084 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to select the bitstream to be provided to the corresponding digital filter and to the SCD.

<table>

**Bit 31  DFLACTIVE:** Digital filter active flag
This bit is set and cleared by hardware. It indicates if the digital filter is active: can be running or waiting for events.
0: Digital filter not active (can be re-enabled again, via DFLTEN, if needed)
1: Digital filter active

**Bit 30  DFLRUN:** Digital filter run status flag
This bit is set and cleared by hardware. It indicates if the digital filter is running or not.
0: Digital filter not running and ready to accept a new trigger event
1: Digital filter running

**Bits 29:28** Reserved, must be kept at reset value.

**Bits 27:20  NBDIS[7:0]:** Number of samples to be discarded
This field is set and cleared by software. It is used to define the number of samples to be discarded every time the DFLTx is re-started.
0: No sample discarded
1: 1 sample discarded
2: 2 samples discarded
...
255: 255 samples discarded

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

**Bits 19:17** Reserved, must be kept at reset value.

**Bit 16  SNPSFMT:** Snapshot data format
This bit is set and cleared by software. It is used to select the data format for the snapshot mode.
0: Integrator counter (INT_CNT) not inserted into MDF_SNPSxDR, leaving a data resolution of 23 bits
1: Integrator counter (INT_CNT) inserted at position [15:9] of MDF_SNPSxDR, leaving a data resolution of 16 bits.

*Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).*
Bits 15:12 **TRGSRC[3:0]**: Digital filter trigger signal selection

This field is set and cleared by software. It is used to select which external signals trigger the corresponding filter.

- 0000: TRGO selected
- 0001: OLDx event selected
- 0010: mdf_trg[0] selected
- ...
- 1111: mdf_trg[13] selected

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **TRGSENS**: Digital filter trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the external signals.

- 0: A rising edge event triggers the acquisition.
- 1: A falling edge event triggers the acquisition.

*Note: When the trigger source is TRGO or OLDx event, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge, when OLDx event is selected, the sensitivity is forced to rising edge.

This bit can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: Digital filter trigger mode

This field is set and cleared by software. It is used to select the filter trigger mode.

- 000: Asynchronous continuous acquisition mode
- 001: Asynchronous single-shot acquisition mode
- 010: Synchronous continuous acquisition mode
- 011: Synchronous, single-shot acquisition mode
- 100: Window continuous acquisition mode
- 101: Synchronous snapshot mode
- Others: same as 000

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bit 3 Reserved, must be kept at reset value.
Bit 2 FTH: RXFIFO Threshold selection
This bit is set and cleared by software. It is used to select the RXFIFO threshold. This bit is not significant for RXFIFOs working in interleaved-transfer mode (see Interleaved-transfer mode for details).
0: RXFIFO threshold event generated when the RXFIFO is not empty
1: RXFIFO threshold event generated when the RXFIFO is half-full
Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 1 DMAEN: DMA requests enable
This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory.
0: DMA interface for the corresponding digital filter disabled
1: DMA interface for the corresponding digital filter enabled
Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 0 DFLTEN: Digital filter enable
This bit is set and cleared by software. It is used to control the start of acquisition of the corresponding digital filter path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well.
0: Acquisition immediately stopped
1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x or 100.

35.8.6 MDF digital filter configuration register x (MDF_DFLTxCICR)
Address offset: 0x08C + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000
This register is used to control the main CIC filter.
Bits 31:26  Reserved, must be kept at reset value.

Bits 25:20 **SCALE[5:0]**: Scaling factor selection
This field is set and cleared by software. It is used to select the gain to be applied at CIC output (refer to Table 296 for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this field informs the application on the current gain value.

- 000000: 0 dB
- 000001: + 3.5 dB
- 000010: + 6 dB or shift left by 1 bit
- ... (continued)
- 011000: + 72 dB or shift left by 12 bits
- 100000: - 48.2 dB or shift right by 8 bits (default value)
- 100001: - 44.6 dB
- 100010: - 42.1 dB or shift right by 7 bits
- 100011: - 38.6 dB
- ... (continued)
- 101110: - 6 dB or shift right by 1 bit
- 101111: - 2.5 dB
- Others: Reserved

Bits 19:17  Reserved, must be kept at reset value.

Bits 16:8 **MCICD[8:0]**: CIC decimation ratio selection
This field is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by \((\text{CICDEC} + 1)\).

- 0: Decimation ratio is 2.
- 1: Decimation ratio is 2.
- 2: Decimation ratio is 3.
- 3: Decimation ratio is 4
- ... (continued)
- 511: Decimation ratio is 512.

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*

Bit 7  Reserved, must be kept at reset value.

Bits 6:4 **CICMOD[2:0]**: Select the CIC mode
This field is set and cleared by software. It is used to select the configuration and the order of the MCIC. When CICMOD[2:0] = 0xx, the CIC is split into two filters: the main CIC (MCIC) and the auxiliary CIC (ACIC, used for the out-of-limit detector).

- 000: CIC split in two filters and MCIC configured in FastSinc filter
- 001: CIC split in two filters and MCIC configured in Sinc^1 filter
- 010: CIC split in two filters and MCIC configured in Sinc^2 filter
- 011: CIC split in two filters and MCIC configured in Sinc^3 filter
- 100: CIC configured in single Sinc^4 filter
- others: CIC configured in single Sinc^5 filter

*Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).*
Multi-function digital filter (MDF) RM0456

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 DATSRC[1:0]: Source data for the digital filter
This field is set and cleared by software.
0x: Stream coming from the BSMX selected
10: Stream coming from the ADCITF1 selected
11: Stream coming from the ADCITF2 selected

Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

35.8.7 MDF reshape filter configuration register x (MDF_DFLTxRSFR)

Address offset: 0x090 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to control the reshape and HPF filters.

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:8 HPFC[1:0]: High-pass filter cut-off frequency
This field is set and cleared by software. It is used to select the cut-off frequency of the high-pass filter. $F_{PCM}$ represents the sampling frequency at HPF input.
00: Cut-off frequency = 0.000625 $F_{PCM}$
01: Cut-off frequency = 0.00125 $F_{PCM}$
10: Cut-off frequency = 0.00250 $F_{PCM}$
11: Cut-off frequency = 0.00950 $F_{PCM}$

Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bit 7 HPFBYP: High-pass filter bypass
This bit is set and cleared by software. It is used to bypass the high-pass filter.
0: HPF not bypassed (default value)
1: HPF bypassed

Note: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 6:5 Reserved, must be kept at reset value.
Bit 4 **RSFLTD**: Reshaper filter decimation ratio
   This bit is set and cleared by software. It is used to select the decimation ratio for the reshape filter.
   0: Decimation ratio is 4 (default value).
   1: Decimation ratio is 1.
   \textit{Note}: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RSFLTBYP**: Reshaper filter bypass
   This bit is set and cleared by software. It is used to bypass the reshape filter and its decimation block.
   0: Reshape filter not bypassed (default value)
   1: Reshape filter bypassed
   \textit{Note}: This bit can be write-protected (refer to Section 35.4.15: Register protection for details).

35.8.8 **MDF integrator configuration register x (MDF_DFLTxINTR)**

Address offset: 0x094 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000
This register is used to the integrator (INT) settings.

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:4 **IntVal[6:0]**: Integration value selection
   This field is set and cleared by software. It is used to select the integration value.
   0: The integration value is 1, meaning bypass mode (default after reset).
   1: The integration value is 2.
   2: The integration value is 3.
   ...
   127: The integration value is 128.
   \textit{Note}: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **IntDiv[1:0]**: Integrator output division
   This field is set and cleared by software. It is used to rescale the signal at the integrator output in order keep the data width lower than 24 bits.
   00: The integrator data outputs are divided by 128 (default value).
   01: The integrator data outputs are divided by 32.
   10: The integrator data outputs are divided by 4.
   11: The integrator data outputs are not divided.
   \textit{Note}: This field can be write-protected (refer to Section 35.4.15: Register protection for details).
35.8.9 MDF out-of limit detector control register x (MDF_OLDxCR)

Address offset: 0x098 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to configure the OLDx.

Bit 31 **OLDACTIVE**: OLDx active flag

This bit is set and cleared by hardware. It is used to check if the OLDx is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the OLDACTIVE is set to 0 (refer to Section 35.4.15: Register protection for details).

The delay between a transition on OLDEN and a transition on OLDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.

0: OLDx not active and can be configured if needed
1: OLDx active and protected fields cannot be configured

Bits 30:22 Reserved, must be kept at reset value.

Bits 21:17 **ACICD[4:0]**: OLDx CIC decimation ratio selection

This field is set and cleared by software. It is used to select the decimation ratio of the ACIC. This field is only taken into account by the MDF when CICMOD[2:0] = 0xx. The decimation ratio is given by (ACICD+1).

0: Decimation ratio is 1.
1: Decimation ratio is 2.
2: Decimation ratio is 3.
3: Decimation ratio is 4.
...
31: Decimation ratio is 32.

**Note**: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:12 **ACICN[1:0]**: OLDx CIC order selection

This field is set and cleared by software. It is used to select the ACIC type and order. This field is only taken into account by the MDF when CICMOD[2:0] = 0xx.

00: FastSinc filter type
01: Sinc\(^1\) filter type
10: Sinc\(^2\) filter type
11: Sinc\(^3\) filter type

**Note**: This field can be write-protected (refer to Section 35.4.15: Register protection for details).

Bits 11:8 Reserved, must be kept at reset value.
35.8.10 MDF OLDx low threshold register x (MDF_OLDxTHLR)

Address offset: 0x09C + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used for the adjustment of the out-of-limit low threshold.

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 OLDTHL[25:0]: OLD low threshold value
This field is set and cleared by software. OLDTHL represents a 26-bit signed value. The real threshold compared to the signal provided by the filter is OLDTHL.

Note: This field can be write-protected (refer to Section 35.4.15: Register protection for details).
35.8.11 MDF OLDx high threshold register x (MDF_OLDxTHHR)

Address offset: 0x0A0 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used for the adjustment of the OLDx high threshold.

Bit 31  **SKPBF**: Skip busy flag
This bit is set and cleared by hardware. It is used to control if the delay sequence is completed.
0: MDF ready to accept a new value into SKPDLY[6:0]
1: Last valid SKPDLY[6:0] still under processing

Bits 30:7  Reserved, must be kept at reset value.

Bits 6:0  **SKPDLY[6:0]**: Delay to apply to a bitstream
This field is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this field, if SKPBF = 0 and the corresponding DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.
0: No input sample skipped
1: 1 input sample skipped
... 127: 127 input samples skipped

### 35.8.13  MDF short circuit detector control register x (MDF_SCDxCR)

Address offset: 0x0A8 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000
This register is used for the adjustment stream delays.

Bit 31  **SCDACTIVE**: SCDx active flag
This bit is set and cleared by hardware. It is used to check if the SCDx is effectively enabled (active) or not. The protected fields of this function can only be updated when the SCDACTIVE is set to 0 (refer to **Section 35.4.15: Register protection** for details).
The delay between a transition on SCDEN and a transition on SCDACTIVE is two periods of AHB clock and two periods of mdf_proc_ck.
0: SCDx not active and can be configured if needed
1: SCDx active and protected fields cannot be configured

Bits 30:20  Reserved, must be kept at reset value.

Bits 19:12  **SCD[7:0]**: SCDx threshold
This field is set and cleared by software. These bits are written by software to define the threshold counter for SCDx. If this value is reached, a short-circuit detector event occurs on a given input stream.
0: 2 consecutive 1's or 0's generate an event.
1: 2 consecutive 1's or 0's generate an event.
2: 3 consecutive 1's or 0's generate an event.
...
255: 256 consecutive 1's or 0's generate an event.

*Note*: This field can be write-protected (refer to **Section 35.4.15: Register protection** for details).

Bits 11:8  Reserved, must be kept at reset value.

Bits 7:4  **BKSCD[3:0]**: Break signal assignment for short circuit detector
This field is set and cleared by software.

**BKSCD[i]** = 0: Break signal (mdf_break[i]) not assigned to this SCD event
**BKSCD[i]** = 1: Break signal (mdf_break[i]) assigned to this SCD event

*Note*: This field can be write-protected (refer to **Section 35.4.15: Register protection** for details).

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **SCDEN**: SCDx enable
This bit is set and cleared by software.
0: SCDx disabled
1: SCDx enabled,

### 35.8.14  **MDF DFLT0 interrupt enable register 0 (MDF_DFLT0IER)**

Address offset: 0x0AC

Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

</tr>
</tbody>
</table>
Bit 7 **SSOVRF**: Snapshot overrun flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

Bit 6 **THHF**: High-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.
0: The signal was lower than OLDTHH when the last OLD0 event occurred.
1: The signal was higher than OLDTHH when the last OLD0 event occurred.

Bit 5 **THLF**: Low-threshold status flag
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLD0 event occurred. This bit gives additional information on the conditions triggering the last OLD0 event. It can be cleared by writing OLDF flag to 1.
0: The signal was higher than OLDTHL when the last OLD0 event occurred.
1: The signal was lower than OLDTHL when the last OLD0 event occurred.

Bit 4 **OLDF**: OLD0 flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no OLD0 event is detected. Write 0 has no effect.
1: Read 1 means that an OLD0 event is detected. Write 1 clears THHF, THLF and OLDF.

Bit 3 **RXNEF**: RXFIFO not-empty flag
This bit is set and cleared by hardware according to the RXFIFO level.
0: RXFIFO empty
1: RXFIFO not empty

Bit 2 **SSDRF**: Snapshot data ready flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no data is available. Write 0 has no effect.
1: Read 1 means that a new data is available. Write 1 clears this flag.

Bit 1 **DOVRF**: Data overflow flag
This bit is set by hardware and cleared by software by writing this bit to 1.
0: Read 0 means that no overflow is detected. Write 0 has no effect.
1: Read 1 means that an overflow is detected; Write 1 clears this flag.

Bit 0 **FTHF**: RXFIFO threshold flag
This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.
0: RXFIFO threshold not reached
1: RXFIFO threshold reached
### 35.8.17 MDF DFLT<sub>x</sub> interrupt status register <sup>x</sup> (MDF_DFLT<sub>x</sub>ISR)

Address offset: 0x130 + 0x80 * (x - 1), (x = 1 to 5)

Reset value: 0x0000 0000

This register contains the status flags for each digital filter path.

Bits 31:12 Reserved, must be kept at reset value.

- **Bit 11 RFOVRF**: Reshape filter overrun detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
  - 1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

- **Bit 10 CKABF**: Clock absence detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no clock absence is detected. Write 0 has no effect.
  - 1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

- **Bit 9 SATF**: Saturation detection flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no saturation is detected. Write 0 has no effect.
  - 1: Read 1 means that a saturation is detected. Write 1 clears this flag.

- **Bit 8 SCDF**: Short-circuit detector flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no SCD event is detected. Write 0 has no effect.
  - 1: Read 1 means that a SCD event is detected. Write 1 clears this flag.

- **Bit 7 SSOVRF**: Snapshot overrun flag
  - This bit is set by hardware and cleared by software by writing this bit to 1.
  - 0: Read 0 means that no snapshot overrun event is detected. Write 0 has no effect.
  - 1: Read 1 means that a snapshot overrun event is detected. Write 1 clears this flag.

- **Bit 6 THHF**: High-threshold status flag
  - This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the high-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.
  - 0: The signal was lower than OLDDTHH when the last OLDx event occurred.
  - 1: The signal was higher than OLDDTHH when the last OLDx event occurred.
Bit 5 **THLF**: Low-threshold status flag  
This bit is set by hardware and cleared by software by writing this bit to 1. It indicates the status of the low-threshold comparator when the last OLDx event occurred. This bit gives additional information on the conditions triggering the last OLDx event. It can be cleared by writing OLDF flag to 1.  
0: The signal was higher than OLDTHL when the last OLDx event occurred.  
1: The signal was lower than OLDTHL when the last OLDx event occurred.  

Bit 4 **OLDF**: OLDx flag  
This bit is set by hardware and cleared by software by writing this bit to 1.  
0: Read 0 means that no OLDx event is detected. Write 0 has no effect.  
1: Read 1 means that an OLDx event is detected Write 1 clears THHF, THLF and OLDF.  

Bit 3 **RXNEF**: RXFIFO not-empty flag  
This bit is set and cleared by hardware according to the RXFIFO level.  
0: RXFIFO empty  
1: RXFIFO not empty  

Bit 2 **SSDRF**: Snapshot data ready flag  
This bit is set by hardware and cleared by software by writing this bit to 1.  
0: Read 0 means that no data is available. Write 0 has no effect.  
1: Read 1 means that a new data is available. Write 1 clears this flag.  

Bit 1 **DOVRF**: Data overflow flag  
This bit is set by hardware and cleared by software by writing this bit to 1.  
0: Read 0 means that no overflow is detected. Write 0 has no effect.  
1: Read 1 means that an overflow is detected; Write 1 clears this flag.  

Bit 0 **FTHF**: RXFIFO threshold flag  
This bit is set by hardware and cleared by hardware when the RXFIFO level is lower than the threshold.  
0: RXFIFO threshold not reached  
1: RXFIFO threshold reached  

### 35.8.18 MDF offset error compensation control register x (MDF_OECxCR)  
Address offset: 0x0B4 + 0x80 * x, (x = 0 to 5)  
Reset value: 0x0000 0000  
This register contains the offset compensation value.

35.8.19 MDF snapshot data register x (MDF_SNPSxDR)

Address offset: 0x0EC + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter in snapshot mode.

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bits 25:0 | OFFSET[25:0]: Offset error compensation |
| This field is set and cleared by software. |
| If the application attempts to write a new offset value while the previous one is not yet applied, this new offset value is ignored. Reading back this field informs the application on the current offset value. |
| This field represents the value to be subtracted to the signal before going to the SCALE. |

35.8.20 MDF digital filter data register x (MDF_DFLTxDR)

Address offset: 0x0F0 + 0x80 * x, (x = 0 to 5)
Reset value: 0x0000 0000

This register is used to read the data processed by each digital filter.

| Bits 31:16 | SDR[15:0]: Contains the 16 MSB of the last valid data processed by the digital filter. |
| Bits 15:9 | EXTSDR[6:0]: Extended data size |
| If SNPSFMT = 0, this field contains the bits 7 to 1 of the last valid data processed by the digital filter. |
| If SNPSFMT = 1, this field contains the INT accumulator counter value when the last trigger event occurs (INT_CNT). |
| Bits 8:0 | MCICDC[8:0]: Contains the MCIC decimation counter value when the last trigger event occurs (MCIC_CNT) |

Bits 31:8 | DR[23:8]: Data processed by digital filter |
| Bits 7:0 | Reserved, must be kept at reset value. |

Refer to Section 2.3 for the register boundary addresses.
36 Audio digital filter (ADF)

36.1 Introduction

The audio digital filter (ADF) is a high-performance module dedicated to the connection of external sigma-delta (ΣΔ) modulators. It is mainly targeted for the following applications:

- audio capture signals
- metering

The ADF features one digital serial interface (SITF0) and one digital filter (DFLT0) with flexible digital processing options in order to offer up to 24-bit final resolution.

The ADF serial interface supports several standards allowing the connection of various ΣΔ modulator sensors:

- SPI interface
- Manchester coded 1-wire interface
- PDM interface

The ADF converts an input data stream into clean decimated digital data words. This conversion is done thanks to low-pass digital filters and decimation blocks. In addition, it is possible to insert a high-pass filter.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter bypass, filter order, decimation ratio. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion and continuous modes. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A sound activity detector (SAD) is available for the detection of sounds or voice signals. The SAD is connected at the output of the DFLT0. Several parameters can be programmed in order to adjust properly the SAD to the sound environment. The SAD strongly reduces the power consumption by preventing the storage of samples into the system memory, as long as the observed signal does not match the programmed criteria.

The digital processing is performed using only the kernel clock. The ADF requests the bus interface clock (AHB clock) only when data must be transferred or when a specific event requests the attention of the system processor.
36.2 **ADF main features**

- **AHB Interface**
- **1 serial digital input:**
  - configurable SPI interface to connect various digital sensors
  - configurable Manchester coded interface support
  - compatible with PDM interface to support digital microphones
- **2 common clocks input/output for ΣΔ modulators**
- **1 flexible digital filter path including:**
  - A MCIC filter configurable in $\text{Sinc}^4$ or $\text{Sinc}^5$ filter with an adjustable decimation ratio
  - A reshape filter to improve the out-of-band rejection and in-band ripple
  - A high-pass filter to cancel the DC offset
  - Gain control
  - Saturation blocks
- **Clock absence detector**
- **Sound activity detector**
- **24-bit signed output data resolution**
- **Continuous or single conversion**
- **Possibility to delay the selected bitstream**
- **One trigger input**
- **Autonomous functionality in Stop modes**
- **DMA can be used to read the conversion data**
- **Interrupts services**
36.3 ADF implementation

The devices embed one MDF instance and one ADF instance, both being digital filters with common features

36.4.3 Serial input interface (SITF)

The SITF0 input interface allows the connection of the external sensor to the digital filter via the bitstream matrix (BSMX). The SITF0 can be configured in the following modes:

- **LF_MASTER SPI mode** (low-frequency)
- **normal SPI mode**
- **Manchester mode**

The data from the serial interface is routed to the filter in order to perform the PDM to PCM conversion and the sound activity detection.

The serial interface is enabled by setting the SITFEN bit to 1. Once the interface is enabled, it receives serial data from the external ΣΔ modulator.

**Note:** Before enabling the serial interface, the user must insure that the adf_proc_ck is already enabled (see Section 36.4.5: Clock generator (CKGEN) for details).

The SITF0 is controlled via the **ADF serial interface control register 0 (ADF_SITF0CR)**.

As shown in the Figure 271, ADF_CCK0 or ADF_CCK1 can be selected as clock source, in order to sample the incoming bitstream:

- If the serial interface is programmed in SPI mode, the selected clock source is a copy of the clock present on the ADF_CCK0 or ADF_CCK1 pin.
- If the serial interface is programmed in LF_MASTER SPI mode, the selected clock source is the clock directly provided by the CCKDIV to the ADF_CCK0 or ADF_CCK1 pin.

See **Table 311** for additional information.
LF_MASTER and normal SPI modes

The LF_MASTER SPI mode is a special mode allowing the use of an adf_proc_ck clock frequency, only two times bigger than the sensor clock. This mode is dedicated to low-power use-cases, using low-speed sensors.

In LF_MASTER SPI mode, the ADF must provide the bitstream clock to the external sensors via ADF_CCK0 and ADF_CCK1 pins. The ADF receives the bitstream data via the serial data input ADF_SDI0.

For the SITF0, the application must select the same clock than the one provided to the external sensor (ADF_CCK0 or ADF_CCK1), in order to guarantee optimal timing performances. This selection is done via SCKSRC[1:0].

The normal SPI interface is a more flexible interface than the LF_MASTER SPI, but the adf_proc_ck frequency must be at least four times higher than the sensor clock.

The application can select ADF_CCK0 or ADF_CCK1 clock for the capture of the data received via the ADF_SDI0 pin.

The ADF can generate a clock to the sensors via ADF_CCK0 or ADF_CCK1 if needed.

For all SPI modes, the serial data is captured using the rising and the falling edge of the selected clock. The SITF0 always provides the following bitstreams:

- bitstream received using the bitstream clock falling edge (bs0_f)
- bitstream received using the bitstream clock rising edge (bs0_r)

According to the sensors connected, one of the two bitstreams may not be available.

The application can select the wanted stream via the BSMX matrix.
To properly synchronize/receive the data stream, the adf_proc_ck frequency must be adjusted according to the constraints listed in Table 312.

**Clock absence detection**

A no-clock-transition period may be detected when the serial interface works in normal SPI mode. This feature can be used to detect a clock failure in the SPI link.

The application can program a timeout value via the STH[4:0] field of the SITF0. If the ADF does not detect clock transitions for a duration of STH[4:0] × T_adf_proc_ck, then the CKABF flag is set.

An interrupt can be generated if CKABIE is set to 1. The STH[4:0] field is in the **ADF serial interface control register 0 (ADF_SITF0CR)**.

When the serial interface is enabled, the CKABF flag remains to 1 until a first clock transition is detected.

To avoid spurious clock absence detection, the following sequence must be respected:

1. Configure the serial interface in normal SPI mode and enable it.
2. Clear the CKABF flag by writing CKABF bit to 1.
   - If no clock transition is detected on the serial interface, the hardware immediately sets the CKABF flag to 1.
3. Read the CKABF flag:
   - If CKABF = 1, go back to step 2.
   - If CKABF = 0, a clock has been detected. The CKABIE bit can be set to 1 if the application wants an interrupt on detection of a clock absence.

*Note:* The clock absence detection feature is not available in the LF_MASTER SPI mode.

**Manchester mode**

In Manchester coded format, the ADF receives data stream from the external sensor via the ADF_SDI0 pin only.

The ADF_CCK0 and ADF_CCK1 pins are not needed in this mode.
Decoded data and clock signals are recovered from serial stream after Manchester decoding. They are available on bs0_r. There are two possible settings of Manchester codings:

- signal rising edge decoded as 0 and signal falling edge decoded as 1
- signal rising edge decoded as 1 and signal falling edge decoded as 0

**Figure 273. Manchester timing example (SITFMODE = 11)**

To decode the incoming Manchester stream, the user must program STH[4:0] in the ADF serial interface control register 0 (ADF_SITF0CR). The STH[4:0] field is used by the SITF0 to estimate the Manchester symbol length and to detect a clock absence. An internal counter (MCNT) is restarted every time a transition is detected in the ADF_SDI0 input. It is used to detect short transitions, long transitions or clock absence. A long transition indicates that the data value changed. **Figure 273** shows a case where the OVR is around height and STH[4:0] = 5.

The estimated Manchester symbol rate (T_SYMB) must respect the following formula:

\[(STH + 1) \times T_{adf\_proc\_ck} < T_{SYMB} < (2 \times STH \times T_{adf\_proc\_ck})\]

It is recommended to compute STH as follows:

\[STH[4:0] = \text{round}\left(\frac{(2 \times \text{OVR}) - 1}{3}\right)\]
where OVR represents the ratio between the adf_proc_ck frequency and the expected Manchester symbol frequency. OVR must be higher than five, and the adf_proc_ck clock must be adjusted according to the constraints listed in Table 312.

The clock absence flag CKABF is set to 1 when no transition is detected during more than 2 x STH[4:0] x Tadf_proc_ck, or when the SITF0 is not yet synchronized to the incoming Manchester stream. In addition, an interrupt can be generated if the bit CKABIE is set to 1.

When the serial interface is enabled, the ADF must first be synchronized to the incoming Manchester stream. The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (pink circle in the Figure 273) is detected.

The end of the synchronization phase can be checked by following the software sequence:

1. Clear the CKABF flag in the ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) by writing CKABF bit to 1. If the serial interface is not yet synchronized the hardware immediately set the CKABF flag to 1.

2. Read the CKABF flag:
   - If CKABF= 1, go back to step 1.
   - If CKABF = 0, the Manchester interface is synchronized and provides valid data.

Programming example

In the following example, the ADF kernel clock frequency (Fadf_ker_ck) is 100 MHz and the received Manchester stream is at about 6 MHz (FSYMB):

1. Provide a valid adf_proc_ck to the SITF0.
   The adf_proc_ck frequency must be at least six times higher than the Manchester symbol frequency (means at least 36 MHz).
   PROCDIV is programmed to 1 to perform a division by two of the kernel clock. In that case, Fadf_proc_ck = 50 MHz (8.33 times higher than the Manchester symbol frequency).

2. Compute STH.
   OVR is given by: OVR = Fadf_proc_ck / FSYMB = 50 MHz / 6 MHz = 8.33.

   Then STH[4:0] = round[(2 x 8.33) / 3] = 5

   The minimum allowed frequency for the Manchester stream is then:
   1 / (2 x STH x Tadf_proc_ck) = 1 / (10 x 20 ns) = 5 MHz

   The maximum allowed frequency for the Manchester stream is then:
   1 / ((STH+1) x Tadf_proc_ck) = 1 / (6 x 20 ns) = 8.33 MHz

36.4.4 ADC slave interface (ADCITF)

The ADCs are not always connected to the ADF. Refer to Section 36.3: ADF implementation to check the situation for this product.

The ADF allows the connection of up to two ADCs to the filter path. For the filter, the DATSRC[1:0] field in the ADF digital filter configuration register 0 (ADF_DFLT0CICR) allows the application to select data from the ADCs.
**Warning:** The ADF does not support receiving interleaved data from one of the ADCITF input.

36.4.5 **Clock generator (CKGEN)**

The RCC (reset and clock controller) provides the following clocks to the ADF:

- AHB clock (adf_hclk) used for the register interface
- Kernel clock (adf_ker_ck) mainly used by all other parts of the circuit via the CKGEN

Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized.

The clock generator (CKGEN) is responsible of the generation of the processing clock, and the clock provided to the ADF_CCK0 and ADF_CCK1 pins. All those clocks are generated from the adf_ker_ck.

The processing clock (adf_proc_ck) is used to run all the signal processing and to re-sample the incoming serial or parallel stream.

To adapt the kernel clock frequency provided by the RCC, the following dividers are available:

- PROCDIV[6:0] used to adapt the kernel clock frequency to the constraints of the parallel and serial interfaces, and to the processing blocks
- CCKDIV[3:0] used to adapt the frequency of the ADF_CCK0 and ADF_CCK1 clocks

PROCDIV[6:0] and CCKDIV[3:0] must be programmed when no clock is provided to the dividers (CKGDEN = 0).

The adf_proc_ck generation is controlled by CKGDEN.

In addition, the CKGMOD bit allows the application to define the way to trigger the CCKDIV divider:

- When CKGMOD = 0, the CCKDIV divider is started as soon as CKGDEN is set to 1.
- When CKGMOD = 1, the CCKDIV divider is started when CKGDEN is set to 1 and the programmed trigger condition occurred.

All the bits and fields controlling the CKGEN are in the **ADF clock generator control register (ADF_CKGCR)**.
The trigger logic for CKGEN is handled by the block TRG_CK. As shown in Figure 280, the CCKDIV divider can be triggered on the rising or falling edge of an external trigger source. When the proper trigger condition occurs, the cck_trg signal goes to high, allowing the CCKDIV divider to start. The TRG_CK logic is reset when CKGDEN is set to 0.

This feature can be helpful to synchronize the ADF_CCKy (y = 0,1) clock of several ADF instances, or to synchronize the clock generation to a timer event.

The application can control the activation of the ADF_CCK0 or ADF_CCK1 pin thanks to CCK0EN/CCK1EN and CCK0DIR/CCK1DIR bits:

- CCKyEN is used to enable the CCKDIV, and thus generates a clock for the external sensors.
- CCKyDIR is used to control the direction of the ADF_CCKy pin (input or output)

### Table 311. Control of the common clock generation\(^{(1)}\)

<table>
<thead>
<tr>
<th>CCKyEN</th>
<th>CCKyDIR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>The ADF_CCKy pin is in input. An external clock can be connected to the ADF_CCKy pin and used by the SITF0 in order to decode the serial stream</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>The ADF_CCKy pin is in output. No clock is generated. The ADF_CCKy pin is driven low.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The ADF_CCKy pin is in output. A clock is generated on the ADF_CCKy pin. The SITF0 can use this pin as clock source in order to decode the serial stream</td>
</tr>
</tbody>
</table>

1. The configuration with CCKyEN = 1 and CCKyDIR = 0 is not shown must be avoided (no interest).

**Note:** The `adf_proc_ck` must be enabled (by CKGDEN = 1) before enabling other blocks (such as SITF0 or DFLT0).
CKGEN activation sequence example

- Set CKGDEN to 0.
- Wait for CKGACTIVE = 0. If CKGDEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
- Program PROCDIV[6:0], CKGMOD, CCKDIV[3:0], TRGSRC[3:0], TRGSENS, CCK1EN and CCK0EN.
- Set CKGDEN to 1.

When needed, at any moment, CCK[1:0]EN field value can be changed without disabling the clock generator.

Clock frequency constraints

The table below shows the frequency constraints to receive and process properly the samples.

Note: The reshape filter (RSFLT) needs up to 24 cycles of adf_proc_ck clock to process one sample.

Table 312. Clock constraints with respect to the incoming stream(1)

<table>
<thead>

</tr>
</tbody>
</table>

1. $F_{ADF\_CCKy}$ represents the frequency of clock received via ADF_CCKy, or generated via ADF_CCKy. $F_{SYMB}$ represents the frequency of the received symbol rate for Manchester mode.

36.4.6 Bitstream matrix (BSMX)

The BSMX receives the bitstreams from the serial interface SITF0 and provides the selected stream to the digital filter DFLT0.

As shown in the Figure 271, the SITF0 provides two bitstreams (bs0_r and bs0_f) to the BSMX.
The application to select the wanted stream via the ADF bitstream matrix control register 0 (ADF_BSMX0CR). This selection is intended to be static.

**Figure 275. BSMX overview**

**BSMX programming sequence example**

The BSSEL[4:0] field cannot be changed if the DFLT0 is enabled. The following steps are needed to change the value of BSMX:

- Set DFLTEN of DFLT0 to 0.
- Wait for BSMXACTIVE = 0.
- Program BSSEL[4:0].
- Set DFLTEN of DFLT0 to 1.

**36.4.7 Digital filter processing (DFLT)**

The digital filter processing includes the following sub-blocks:

- symbol remap (SBR)
- clock skipper delay (DLY)
- MCIC decimation filter that can be configured in Sinc\(^4\) or Sinc\(^5\)
- gain control (SCALE)
- signal saturation (SAT)
- reshape filter (RSFLT)
- high-pass filter (HPF)
- receive RXFIFO
The figure below shows the filter path configuration according to CICMOD[2:0]. Several configuration bits are available to configure the digital filter to the application needs.

**Figure 276. DFLT overview**

Symbol remap and source selection

The symbol remap (SBR) converts the bitstream selected by the BSMX into data usable by the filter path. More especially:

- The high levels are converted into a 16-bit signed number + 1.
- The low levels are converted into a 16-bit signed number - 1.

The signal source of the digital filter can be selected via DATSRC[1:0] between the two following:

- data coming from the BSMX
- data coming from one of the ADC interfaces (ADCITF2 or 1)

Programmable micro-delay control (DLY)

The digital filter has a delay line that allows the timing adjustment of each stream with the resolution of the bitstream clock.

This feature is particularly helpful in the case of microphone beam forming applications where delays smaller than the final sampling rate must be applied to the incoming stream. This feature can be used when the ADF is synchronized with another MDF instance (if present in the product) for a beam forming application for example.

The delay is performed by discarding a given number of samples from the selected input stream, before samples enter into the CIC filter. This data discarding is done by skipping a given number of data strobe, preventing the CIC filter to take into account those data.

When the wanted amount of data strobe has been skipped, the next incoming samples are strobed normally.

The figure below shows an example on how to apply dynamically small delay to an incoming stream. For simplification, the CIC filter performs a decimation by height in this example. CIC1 represents the CIC included in the ADF and CIC0 represents a filter from another MDF instance (if present in the product).
The CIC of the ADF (CIC1) receives a command in order to skip three incoming samples. So the input samples named b10, b11 and b12 are not processed by CIC1. As a consequence, the output sample N+1 generated by CIC0 is built from input samples a[23:16] while the sample N+1 of CIC1 is built from input samples b[26:19].

Finally, the non-skipped data stream looks delayed by three bitstream periods.

**Note:** When the input data strobes are skipped, the decimation counter remains frozen. As a consequence, the samples delivered by the CIC1 are a bit delayed.

The following steps are needed to program the amount of bitstream clock periods to be skipped:

1.Wait for SKPBF equal to 0.
2. Write SKPDLY[6:0] to the wanted number of bitstream clock periods to be skipped. The SKPBF flag goes immediately to 1, indicating that the delay value entered into SKPDLY[6:0] is under process.
   - If the DFLT0 is not yet enabled (DFLTEN = 0), then the DLY logic waits for DFLTEN = 1. When the application sets DFLTEN to 1, the DLY logic starts to skip the amount of wanted data strobes.
   - If the DFLT0 is already enabled (DFLTEN = 1), then the DLY logic immediately starts to skip the amount of wanted data strobes.

When the ADF skipped the amount of wanted data strobes, then SKPBF goes back to 0.

3. If the application needs to skip more data strobes, then the operation must be restarted from step 1.

The effect of the delay performed with this mechanism is cumulative as long as the ADF is enabled. If the application performs a D1 delay followed by a D2 delay, then all other active filters are delayed by D1 + D2.

**Note:** If SKPDLY[6:0] is written when SKPBF = 1, the write operation is ignored.

**Cascaded-integrator-comb (CIC) filter**

The CIC digital filters are an efficient implementation of low-pass filters, often used for decimation and interpolation. The CIC frequency response is equal to a Sinc^N function, this is why they are often called Sinc filters.
The Sinc\(^N\) digital filter embedded into the ADF can be configurable in Sinc\(^4\) or Sinc\(^5\), according to CICMOD:

- If CICMOD\([2:0]\) = 4, Sinc\(^4\) is selected.
- If CICMOD\([2:0]\) = 5, Sinc\(^5\) is selected.

The filters have the following transfer function:

\[
H(z) = \left( \frac{1 - z^{-D}}{1 - z^{-1}} \right)^N
\]

where \(N\) can be 4 or 5, and \(D\) is the decimation ratio. \(D\) is equal to MCICD+1.

**Figure 278. CIC4 and CIC5 frequency response with decimation ratio = 32 or 16**

---

**CIC output data size**

The size of samples delivered by the CIC (DS\(_{\text{CIC}}\)), depends on the following parameters:

- CIC order (\(N\))
- CIC decimation ratio (\(D\))
- data size of the input stream (DS\(_{\text{IN}}\))

The CIC order and decimation ratio must be programmed in order to insure that the data size does not exceed the 26-bit CIC capability.

The following formula gives the output data size (DS\(_{\text{CIC}}\)) according to the parameters above.
The decimation ratio can be adjusted from 2 to 512 for the CIC filter.

The table below gives some data output size in bits for some decimation values, when the data source is a full-scale signal coming from the serial interface or from a 12-bit ADC.

**Note:** \( DS_{IN} = 1\) bit for a serial bitstream, but can be up to 16 bits when coming from the ADCITF.

</tr>
</tbody>
</table>

**Note:** For a full-scale input signal, the decimation ratio must not exceed 76 for a \( Sinc^4 \) and 32 for a \( Sinc^5 \).

The LSB parts of the data provided by the CIC is not necessarily significant: it depends on the sensor performances and the ability of the CIC to reject the out-of-band noise.

The sample size at CIC output can be adjusted thanks to the SCALE block.

**Scaling (SCALE) and saturation (SAT)**

The SCALE block allows the application to adjust the amplitude of the signal provided by the CIC, by steps of 3 dB (± 0.5 dB).

The signal amplitude can be decreased by up to 8 bits (-48.2 dB), and can be increased by up to 12 bits (+72.2 dB).
The gain is adjusted by the SCALE[5:0] field in the *ADF digital filter configuration register 0 (ADF_DFLT0CICR)*.

SCALE[5:0] can be changed even if the DFLT0 is enabled. During the gain transition, the signal provided by the filter is disturbed.

Due to internal resynchronization, there is a delay of some cycles of adf_proc_ck clock between the moment where the application writes the new gain, and the moment where the gain is effectively applied to the samples. If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back SCALE[5:0] informs the application on the current gain value.

The table below shows the possible gain values.

</tbody>
</table>

The SAT blocks avoid having a wrap-around of the binary code when the code exceeds its maximal or minimal value.

The ADF performs saturation operations at the following levels:

- after the SCALE block (performed by the SAT block): The signal is saturated at 24 bits.
- inside the RSFLT, to insure a good filter behavior
- at the output of the HPF, to insure that the output signal does not exceed 24 bits

The SATF bit informs the application that a saturation occurred either after the SCALE, inside the RSFLT or after the HPF. In addition, an interrupt can be generated if SATIE is set to 1. As soon as a saturation is detected, the SATF flag is set to 1. It is up to the application to clear this flag in order to be able to detect a new saturation.

Those bits are in the *ADF DFLT0 interrupt enable register (ADF_DFLT0IER)* and *ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)*.

**Gain adjustment policy**

To get the best ADF performances, it is important to properly adjust the gain value via SCALE[5:0].
A usual way to adjust the gain is to select the SCALE[5:0] value that gives a final signal amplitude as close as possible to the 24-bit full-scale, for the maximum input signal.

A way to select the optimal gain is detailed below:

1. Check that, for the expected input signal, the data size into the CIC filter does not exceed 26 bits. This can be checked using this formula:

\[
\frac{\ln(\text{SIN}_{pp} \cdot D^N)}{\ln(2)} < 26
\]

where \( N \) represents the CIC order, \( D \) the decimation ratio and \( \text{SIN}_{pp} \) the maximum peak-to-peak amplitude of the input signal.

\( \text{SIN}_{pp} \) can take:
- a maximum peak-to-peak amplitude of 2 (± 1), for samples coming from SITF0
- A maximum peak-to-peak amplitude of 4095 (+ 2047, - 2048), for samples coming from a 12-bit ADC

Example: a Sinc\(^4\) can be used with a decimation ratio of 96, if the maximum input signal does not exceed ± 0.35. Indeed:

\[
\frac{\ln(0.7 \cdot 96^4)}{\ln(2)} \approx 25.82 \text{ bits} < 26 \text{ bits}
\]
2. Adjust the SCALE value.

To select the most appropriate SCALE value, the user must check if the RSFLT is used or not. If the RSFLT is used, the data size at SCALE output must not exceed 22 bits, otherwise the data size can be up to 24 bits.

The SCALE value in dB must be selected using this formula:

\[ \text{SCALE}_{\text{dB}} < 20 \cdot \log_{10} \left( \frac{2^{\text{NB}}}{\text{SIN}_{\text{pp}} \cdot D^N} \right) \]

where NB is equal to 22 if RSFLT is enabled, or 24 if RSFLT is bypassed. SCALE\(_{\text{dB}}\) represents the gain value selected by SCALE[5:0].

**Example:** For a Sinc\(^4\) with a decimation ratio of 96 and a \(\text{SIN}_{\text{pp}}\) of 0.7.

- If the RSFLT is bypassed:

  \[
  20 \cdot \log_{10} \left( \frac{2^{24}}{0.7 \cdot 96^4} \right) \approx -11 \text{ dB}
  \]

  SCALE\(_{\text{dB}}\) value must be lower than -11 dB, the closest lower value is -12 dB (SCALE[5:0] = 0x2C).

- If the RSFLT is enabled:

  \[
  20 \cdot \log_{10} \left( \frac{2^{22}}{0.7 \cdot 96^4} \right) \approx -23 \text{ dB}
  \]

  SCALE\(_{\text{dB}}\) value must be lower than -23 dB, the closest lower value is -24.1 dB (SCALE[5:0] = 0x28).

If SCALE[5:0] is set to a higher value, then a saturation may occur. An event flag informs the user if a saturation occurred.

The table below proposes gain values for different filter configurations, when the data comes from the SITF0, according to the MCIC order, and the MCIC decimation ratio. This table is not exhaustive and considers a full-scale input signal (see Section 36.7.5: Total ADF gain for details).

| **Table 315. Recommended maximum gain values versus CIC decimation ratios** |
|----------------|----------------|----------------|----------------|----------------|
| **CIC decimation ratio** | **Gain settings (dB) for configuration SITF + CICx + RSFLT (+ HPF)** | **Gain settings (dB) for configuration SITF + CICx (+ HPF)** |
| 8   | 33.6 | 51.7 | 45.7 | 63.7 |
| 12  | 18.1 | 39.6 | 30.1 | 51.7 |
| 16  | 3.5  | 27.6 | 15.6 | 39.6 |
| 20  | -6.0 | 21.6 | 6.0  | 33.6 |
| 24  | -12.0 | 15.6 | 0    | 27.6 |
| 28  | -20.6 | 9.5  | -8.5 | 21.6 |
Reshaping filter (RSFLT)

In addition to the CIC, the ADF offers a reshaping IIR filter mainly dedicated to the audio application, but also usable in other applications.

When the RSFLT is used, the sample size at its input must not exceed 22 bits.

The samples at the RSFLT output can be decimated by four or not according to the RSFLT bit in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The RSFLT can be bypassed by setting RSFBYP to 1 in the ADF reshape filter configuration register 0 (ADF_DFLT0RSFR).

The table below shows which sampling rate must be provided to the RSFLT in order to process the most common audio streams.

The RSFLT cutoff frequency \( F_C \) depends on the sample rates at its input \( F_{RS} \), and is given by the following formula:

\[
F_C = 0.111 \times F_{RS}
\]

Table 316. Most common microphone settings

</tr>
</tbody>
</table>
The figure below shows the frequency response of the reshape filter.

**Figure 279. Reshape filter frequency response normalized (FRS / 2 = 1)**

The RSFLT gain is close to 9.3 dB, so the output data size is a little bit lower than 24 bits for a 22-bit wide input signal.

The RSFLT takes 24 clock cycles of adf_proc_ck clock to process one sample at FRS. When the RSFLT is enabled, the application must insure that the adf_proc_ck is at least 24 times faster FRS.

The RSFLT generates an event (rfovr_evt) and sets the RFOVRF flag, if the RSFLT receives a new samples while the previous one is still under processing.

When RFOVRF is set, the samples provided by the RSFLT are invalid. The application must then stop the data acquisition and provides a faster adf_proc_ck clock to the RSFLT.

**High-pass filter (HPF)**

The high-pass filter suppresses the low-frequency content from the final output data stream in case of continuous conversion mode. The high-pass filter can be enabled or disabled via HPFYP in the **ADF reshape filter configuration register 0 (ADF_DFLTRORSFR)**.

The HPF is useful when there is parasitic low-frequency noise (or DC signal) in the input data source that must be removed from the final data.
The HPF is a first order IIR filter and the cut-off frequency can be selected via HPFC[1:0] in the **ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)**, among the following values:

- 0.000625 x FPCM
- 0.00125 x FPCM
- 0.00250 x FPCM
- 0.00950 x FPCM

**Table 317. HPF 3 dB cut-off frequencies examples**

The HPF output is saturated at 24 bits. The SATF flag is set if a sample is saturated.

### 36.4.8 Digital filter acquisition modes

The ADF offers the following modes to perform a data capture:
- Asynchronous continuous acquisition mode
- Asynchronous single-shot acquisition mode
- Synchronous continuous acquisition mode
- Synchronous single-shot acquisition mode
- Window continuous acquisition mode

**Note:** To perform a data capture, the filter, the interface providing the data (SITF0 or ADCITF) and the CKGEN must be enabled. If needed, the ADF_CCK0 or ADF_CCK1 must be enabled as well.

The filter can be stopped immediately when DFLTEN is set to 0. This action resets the filter and flushes the RXFIFO. The DFLTACTIVE flag also goes back to 0 when the RXFIFO and the filter is reset.
The figure below shows a simplified view of the trigger logic available for each filter and for the clock generator.

**Figure 280. Trigger logic for DFLT and CKGEN**

A block common to all TRIG blocks performs the rising and falling edges detection and the re-synchronization of the input trigger to the adf_ker_ck clock domain. This implementation allows the application to use triggers with pulse width smaller than the adf_ker_ck period.

In synchronous modes, the TRIG block offers the possibility to select adf_trgi or TRGO bit as trigger sources. The TRGO bit is in the *ADF global control register (ADF_GCR)*.

The edge sensitivity can also be selected.

**Asynchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition by simply writing the DFLTEN bit to 1.

The Asynchronous continuous acquisition mode is selected when ACQMOD[2:0] = 0.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN) so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 323*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 0.
4. Set to 1 the SITFEN bit of the serial data interface.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the acquisition sequence starts immediately.
The figure below shows a simplified example of the samples generated by the DFLT0.

**Figure 281. Asynchronous continuous mode (ACQMOD[2:0] = 0)**

<table>
<thead>

<tr>
<td></td>
<td>X</td>
<td>...</td>
<td>S2</td>
<td>...</td>
</tr>
<tr>
<td></td>
<td>SN</td>
<td></td>
<td></td>
<td>OFF</td>
</tr>
</tbody>
</table>

**Note:** The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Asynchronous single-shot acquisition mode**

This mode allows the application to start the acquisition of one sample by simply writing the DFLTEN bit to 1.

The Asynchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 001.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the adf_proc_ck frequency is compatible with the targeted application (see examples in *Table 323*).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 001.
4. Set to 1 the SITFEN bit.
5. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
6. When DFLTEN is set to 1, the filter provides one data to the RXFIFO and stops the acquisition.

To trigger a new acquisition, the application must:

1. Check that the previous acquisition is completed, by waiting that DFLTRUN = 0.
2. Set again DFLTEN to 1.

This sequence can be repeated every time a new data must be converted.

As shown in the *Figure 282*, every time DFLTEN is set to 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset, and the filter is ready to start a new conversion.
If DFLTEN is set to 0 while an acquisition is ongoing, the ongoing conversion is stopped (in the example, S3 is lost). This situation can be avoided with the following steps:
1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Set DFLTEN to 0.

**Figure 282. Asynchronous single-shot mode (ACQMOD[2:0] = 001)**

Note: the discard phase is optional.

---

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous continuous acquisition mode**

This mode allows the application to start a continuous acquisition by using one of the following trigger sources:
- adf_trgi signal
- TRGO bit

The Synchronous continuous acquisition mode is selected when ACQMOD[2:0] = 010.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):
1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 323).
2. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration and set the ACQMOD[2:0] to 010.
4. Set to 1 the bit SITFEN.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition.
The TRGSENS bit allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSENS = 0). The first rising edge of the trigger signal is ignored because DFLTEN = 0. Then the next rising edge is taken into account and starts the acquisition. All other rising edges are ignored. The trigger logic is re-initialized when DFLTRUN goes back to 0.

**Figure 283. Synchronous continuous mode (ACQMOD[2:0] = 010)**

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Synchronous single-shot acquisition mode**

This mode allows the application to start a single acquisition by using one of the following trigger sources:
- adf_trgi signal
- TRGO bit

The Synchronous single-shot acquisition mode is selected when ACQMOD[2:0] = 011.
The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of `adf_proc_ck` clock is compatible with the targeted application (see examples in Table 323).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter configuration, and set the ACQMOD[2:0] to 011.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. When the trigger condition is met, the filter starts the acquisition and provides one data to the RXFIFO, then the filter is ready to accept a new trigger.

TRGSSENS allows the selection of the trigger edge (rising or falling). The trigger is ignored if an acquisition is ongoing, or if DFLTEN is set to 0.

The figure below shows a simplified example where the trigger logic is sensitive to a rising edge trigger (TRGSSENS = 0). Every-time a trigger rising edge is detected with DFLTEN = 1, an acquisition sequence is triggered. The first samples provided by the filter can be discarded if needed. At the end of each conversion, the decimation counters and filter taps are reset. DFLTRUN is set to 0 and the filter is ready to start a new conversion.

**Figure 284. Synchronous single-shot mode (ACQMOD[2:0] = 011)**

---

**Note:**

The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.

**Figure 284** shows a case where the DFLTEN is set to 0 while an acquisition is ongoing (the sample S2 is lost). This situation can be avoided with the following steps:

1. Wait for DFLTRUN = 0.
2. Read the sample from the RXFIFO.
3. Clear DFLTEN to 0.
Window continuous acquisition mode

This mode allows the application to start or stop a continuous acquisition controlled by consecutive edges of one of the following trigger sources:

- adf_trgi signal
- TRGO bit

The Window continuous acquisition mode is selected when ACQMOD[2:0] = 100.

The sequence below shows the most important programming steps (assuming that DFLTEN is set to 0):

1. Configure and enable the clock generator (CKGEN), so that the frequency of adf_proc_ck clock is compatible with the targeted application (see examples in Table 323).
2. Enable the CKGEN and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
3. Program the filter settings and set the ACQMOD[2:0] to 100.
4. Set to 1 the SITFEN bit.
5. Select the proper trigger source and sensitivity.
6. Before setting DFLTEN to 1, wait for DFLTACTIVE = 0: it insures that the previous filter deactivation sequence terminated properly.
7. Set DFLTEN to 1.
8. If TRGSENS = 0, the acquisition starts on trigger rising edge and stops on trigger falling edge. If TRGSENS = 1, the acquisition starts on trigger falling edge and stops on trigger rising edge.

Note: The acquisition may restart if the trigger condition becomes again active.

Figure 285 shows a simplified example of window continuous acquisition mode, with TRGSENS = 1. Once DFLTEN is set to 1, the ADF waits for a falling edge on the selected trigger input. When the trigger condition is met, DFLTRUN goes to 1 and the acquisition starts. The acquisition stops if the ADF detects a rising edge on the selected trigger input. If DFLTEN is still set to 1, the ADF waits again for a falling edge on the selected trigger input.

Note: The acquisition can be stopped by setting DFLTEN back to 0. This resets the filter and flushes the RXFIFO, so the samples located into the RXFIFO are lost. The ongoing DMA transfer is properly terminated. DFLTACTIVE goes back to 0 when the filter chain is reset and the RXFIFO flushed.
Starting several filters synchronously

If the ADF is used with MDF instances (if present in the product), it is possible to start simultaneously the acquisition of all the filters. This synchronization capability depends on the way the triggers are connected in the product. Generally, an ADF is able to trigger MDF instances, if its adf_trgo signal is connected as trigger input to those blocks (see Section 36.4.2: ADF pins and internal signals to check trigger capabilities).

In the following programing example, one ADF has its adf_trgo signal connected to some MDFs. To start the acquisition of several filters synchronously, the following sequence must be performed (assuming that DFLTEN bits of the filters are set to 0):

On MDFs receiving the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK0 and ADF_CCK1 clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. For each filter, set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. For each filter, set TRGSRC[3:0] in order to select the adf_trgo trigger input.
5. For each filter, set TRGSENS to 0 (rising edge).
6. For each filter, set DFLTEN to 1.

On the ADF generating the adf_trgo trigger:
1. Enable the CKGEN (CKGDEN = 1) and, if needed, enable the ADF_CCK[1:0] clocks.
2. Set to 1 the SITFEN bit of the requested data interfaces.
3. Set the acquisition mode to synchronous (ACQMOD[2:0] = 01x).
4. Set TRGSRC[3:0] to 0 (TRGO selected).
5. Set TRGSENS to 0 (rising edge).
6. Set DFLTEN to 1.
7. Read TRGO bit until it is read to 0.
8. Set TRGO to 1. Then the acquisition sequence for all selected filters starts immediately.

To trigger a new acquisition (in case of single-shot) the application must do the following:
• Check that the previous acquisition is completed, by waiting DFLTRUN = 0.
• Read TRGO until it is read to 0.
• Set again the bit TRGO to 1.

Discarded samples

The ADF offers the possibility to program the amount of samples to be discarded after each restart:
• to avoid capturing samples affected by the impulse response of the filter
• to delay the acquisition of filters by a specific amount of samples

The discard function is controlled via NBDIS[7:0] as follows:
• When NBDIS[7:0] = 0, the discard function is disabled.
• When NBDIS[7:0] ≠ 0, the discard function is activated in one of the following condition:
  – when the DFLTEN bit goes to 1
  – every time an acquisition is started in (A)synchronous single-shot modes

Refer to Figure 281 to Figure 285, and Figure 287.
In the example shown in the figure below, the discard function is used to drop the first five samples provided by the digital filter (S1 to S5). The first sample transferred to the RXFIFO is S6.

**Figure 286. Discard function example**

### 36.4.9 Start-up sequence examples

The figure below details a start of acquisition sequence of a digital filter triggered by DFLTEN (ACQMOD[2:0] = 0), with NBDIS[7:0] = 3 (three samples to discard before acquisition).

The DFLT0 is configured for audio application: MCIC, RSFLT and HPF activated. The data interface (SITF0 or ADCITF) is assumed to be already activated.

*Note:* NBDIS[7:0] is set on purpose to a small value to simplify the drawing.

**Figure 287. Start sequence with DFLTEN, in continuous mode, audio configuration**
The DFLTEN bit is re-sampled into the ADF processing clock domain. When DFLTEN is detected high, the filter chain is enabled, and the decimation counter of the MCIC filter is incremented at the rate of the bitstream clock.

When the MCIC decimation counter reached its programmed value N, a sample is available for the RSFLT.

The RSFLT processes all the samples provided by the MCIC, and delivers a sample to the HPF every-time it processes four samples (decimation by 4). The RSFLT needs up to 24 cycles of adf_proc_ck clock before delivering a sample (P1).

The HPF processes all the samples provided by the RSFLT, but the NBDIS function prevents the data writing in the RXFIFO as long as NBDIS_CNTR does not reach 0.

When NBDIS_CNTR reaches 0, the samples provided by the HPF are stored into the RXFIFO.

### 36.4.10 Sound activity detection (SAD)

The SAD is based on the computation of the ambient noise level (ANLVL) and of the short-term sound level (SDLVL). The SAD offers the following ways to detect a sound:

- when the SDLVL reaches a threshold referenced to the ambient noise level
- when the SDLVL reaches a fixed threshold
- when the ANLVL reaches a fixed threshold

As shown in the figure below, the SAD takes the 16 MSB samples from the DFLT0 output.

![Figure 288. SAD block diagram](image-url)
The SAD is highly configurable, and the application can adjust several parameters:

- SAD detection behavior (SADMOD)
- number of samples used to compute the sound level (FRSIZE)
- number of frames used to compute the ambient noise level during the learning phase (LFRNB)
- slope of the ambient noise estimator (ANSLP)
- minimum expected ambient noise level (ANMIN)
- threshold level (SNTHR)
- threshold hysteresis (HYSTEN)
- hangover window in order to filter spurious transitions between DETECT and MONITOR states (HGOVR)
- data capture mode (DATCAP)

**SAD detection behavior**

The SAD can use the following ways to detect a sound, selected by SADMOD[1:0]:

- When SADMOD[1:0] = 0, the SAD works like a voice-activity detection. In this mode, the SAD estimates the ambient noise level according to the computed sound level values. The threshold of the trigger is elaborated from the estimated ambient noise. Finally the current sound level is compared to this threshold. In a first approximation, the SAD triggers if the peak-to-average value of the input signal reaches a level defined by SNTHR[3:0].

- When SADMOD[1:0] = 01, the SAD compares the current sound level (SDLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode allows a fast SAD reaction as the amount of samples used to compute the sound level can be configured via FRSIZE[2:0].

- When SADMOD[1:0] = 1x, the SAD compares the estimated ambient noise level (ANLVL) to a fixed trigger value defined by the application via SNTHR[3:0] and ANMIN[12:0]. This mode avoids unwanted triggers, due to peak levels, but the SAD reacts more slowly to an input signal variation. It is nevertheless possible to adjust the reaction time via FRSIZE[2:0] and ANSLP[2:0].

**SAD states**

As shown in Figure 289, the SAD works as follows:

1. When enabled (SADEN = 1), the SAD is first in LEARN state to perform a first estimation of the ambient noise level.

2. The SAD continuously computes the short-term sound level (SDLVL) using the samples provided by the DFLT0. The amount of samples used to compute the sound
level is given by \( FRSIZE[2:0] \). The samples processed by the DFLT0 can be transferred into the memory or not depending on DATCAP[1:0] value.

3. The initial ambient noise level (ANLVL) is computed using the consecutive sound level values. The application can define how much sound level values are used to perform the computation of this initial ambient noise estimation (LFRNB).

4. When the initial ambient noise level (ANLVL) is computed, the SAD switches to the MONITOR state.

5. Every time a new short-term sound level value is available, the SAD updates the ambient noise level and the thresholds according to the selected detection mode.

6. If the SAD triggers, then the following happens:
   - The SAD switches to DETECT state.
   - The sddet_evt event is asserted.
   - The adf_sad_det signal is set to high.

7. The hangover function insures that the DETECT state is maintained even if the sound level goes below the threshold level for a time given by HGOVR.

**Figure 289. SAD flow diagram**
Sound level computation (SDLVL)

Once enabled, the SAD computes continuously the sound level value. The sound level represents the average of the absolute value of an amount of PCM samples given by FRSIZE[2:0].

\[
SDLVL = \frac{1}{N_{\text{FRSIZE}}} \times \sum_{n=1}^{N_{\text{FRSIZE}}} |\text{PCM}(n)|
\]

where \(N_{\text{FRSIZE}}\) is the amount of PCM samples given by FRSIZE[2:0].

Ambient noise estimation (ANLVL)

The ambient noise level (ANLVL) is computed when SADMOD[1:0] is 00 or 10.

The ambient noise level is computed differently according to the state of the SAD as detailed below:

- ANLVL computation during the LEARN state
  Every time the SAD is enabled, a learning phase is initiated in order to estimate a first value of the ambient noise level. During this phase, the SAD cannot trigger.
  During the LEARN phase, the ambient noise level is computed as follows:

\[
ANLVL = \frac{1}{N_{\text{LFRNB}}} \times \sum_{n=1}^{N_{\text{LFRNB}}} |SDLVL(n)|
\]

where \(N_{\text{LFRNB}}\) is the amount of frames given by LFRNB[2:0] field.

- ANLVL computation during the MONITOR or DETECT state
  When the learning phase is completed, the SAD updates the ambient noise level in the following way:
  a) The SAD computes the new possible values for the ambient noise level:
     \[
     \text{ANLVL\_UP} = \text{ANLVL} \times (1 + 2^{\text{ANSLP} - 12}) \\
     \text{ANLVL\_DN} = \text{ANLVL} \times (1 - 2^{\text{ANSLP} - 10})
     \]
  b) The ANLVL takes the ANLVL\_DN value if the current sound level is lower than ANLVL\_DN, otherwise ANLVL takes the value of ANLVL\_UP.
      The ANLVL is not updated if the current sound level is higher than the threshold level, except if SADMOD[1:0] = 10.
  c) When SADMOD[1:0] = 0, if the new ANLVL value is lower than ANMIN[12:0], ANLVL is replaced by ANMIN.

The slope of the noise estimator can be adjusted to optimize the detection of the wanted signal. This slope is adjusted via ANSLP[2:0] in the ADF SAD configuration register (ADF_SADCFGR).
The table below shows the allowed values according to the frame size and the sampling rate of the data observed by the SAD. The recommended values when the SADMOD[1:0] = 0 are the ones into the gray shaded cells.

Table 318. ANSLP values versus FRSIZE and sampling rates

<table>
<thead>
<tr>
<th>FRSIZE</th>
<th>ANSLP values for Fs = 8 kHz</th>
<th>ANSLP values for Fs = 16 kHz</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>6 (512 samples)</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

1. The slow slope is equal to - 8.5 dB/s for the negative slope and + 2.1 dB/s for the positive slope.
2. The typical slope is equal to - 17.1 dB/s for the negative slope and + 4.2 dB/s for the positive slope.
3. The fast slope is equal to - 34.2 dB/s for the negative slope and + 8.5 dB/s for the positive slope.

The slopes can also be computed using the following formulas:

\[
SLC_{UP} = 20 \times \frac{F_s}{FSIZE} \times \log 10(1 + 2^{(ANSLP - 12)})
\]

\[
SLC_{DN} = 20 \times \frac{F_s}{FSIZE} \times \log 10(1 - 2^{(ANSLP - 10)})
\]

where \(F_s\) is the sampling rate of the stream observed by the SAD and \(FSIZE\) is the frame size defined by FRSIZE[2:0].

Threshold computation

The way the threshold value is computed depends on SADMOD[1:0]:

- If SADMOD[1:0] = 0, THRH is obtained by multiplying the current ANLVL value with the gain defined in SNTHR[3:0].
  \[
  THR_H = ANLVL \times 10^{\frac{GdB_{SNTHR}}{20}}
  \]
  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 01, THRH is obtained by multiplying the current ANMIN[12:0] with the gain defined by SNTHR[3:0].
  \[
  THR_H = ANMIN \times 10^{\frac{GdB_{SNTHR}}{20}}
  \]
  This threshold value is then compared to the current sound level (SDLVL).

- If SADMOD[1:0] = 1x, THRH is obtained by multiplying the current ANMIN[12:0] by 4.
\[ \text{THR}_H = \text{ANMIN} \times 4 \]

This threshold value is then compared to:

\[ \frac{\text{ANLVL} \times 10}{20} \]

\[ \text{GdB}_{\text{SNTHR}} \]

The hysteresis mode can be enabled to reduce the spurious transitions between MONITOR and DETECT states. In hysteresis mode (HYSTEN = 1), the following threshold values are used:

- \( \text{THR}_H \) when the SAD is in MONITOR state.
- \( \text{THR}_L \) when the SAD is in DETECT state.

The table below shows the thresholds values according to SNTHR.

**Table 319. Threshold values according SNTHR\(^{(1)}\)**

</tr>
</tbody>
</table>

1. LVL must be replaced by ANLVL when SADMOD[1:0] = 0 and by ANMIN for other SADMOD[1:0] values.

When the hysteresis function is disabled, the SAD always use THR\(_H\).

**Note:** The hysteresis mode must not be used when SADMOD[1:0] = 1x.

**Trigger logic**

The signal compared to this threshold depends also on SADMOD[1:0].

The trigger condition is reached when the selected signal (SELSIG) is bigger than the threshold level.

If the trigger condition is met, the following happens:

- The SAD switches to DETECT state.
- The SAD refreshes the hangover counter with HGOVR.
- The sdset_evt event is asserted if the SAD transits from MONITOR to DETECT.
- The adf_sad_det signal is set to high.
The SAD remains in DETECT state as long as the trigger condition is met or the hangover
down-counter is different from 0.

The sddet_evt event indicates when the SAD enters and/or exits the DETECT state. This
event is used to generate an interrupt when a sound is detected or when a sound is no
longer detected:
- When DETCFG = 0, the application receives an event only when the SAD enters the
  DETECT state.
- When DETCFG = 1, the application receives an event when the SAD enters or exits the
  DETECT state.

The adf_sad_det signal remains high as long as the SAD is in DETECT state.

The SAD also provides a flag indicating that a new sound level value is available (SDLVLF).
The last computed sound level value (SDLVL[14:0]) is available in the ADF SAD sound level
register (ADF_SADSDLVR), and the last computed ambient noise level (ANLVL[14:0]), in
the ADF SAD ambient noise level register (ADF_SADANLVR).

Note: The SAD can work even when the AHB clock is not present. In that case, the SAD does not
update SDLVL[14:0] and ANLVL[14:0].

To get the latest valid SDLVL[14:0] and ANLVL[14:0] values, the application must read the
ADF_SADSDLVR, and ADF_SADANLVR registers, when the SDLVLF flag goes high. This
can be done in the following ways:
- by polling the SDLVLF flag:
  a) Clear the SDLVLF flag by writing SDLVLF to 1.
  b) Wait for SDLVL = 1, by reading ADF_DFLTxISR.
  c) Read ADF_SADSDLVR and ADF_SADANLVR.
  d) Clear SDLVLF by writing it to 1.
  e) Go to step 2 if other values must to be read.
- by generating an interrupt:
  a) Read ADF_DFLTxISR.
  b) If SDLVL = 1, read ADF_SADSDLVR and ADF_SADANLVR, and clear SDLVLF
     by writing it to 1.
  c) Handle other status flags and exit from ISR.

Sample transfer to memory

The SAD offers the following options to control the samples transfer from DFLT0 to the
system memory:
- If DATCAP[1:0] = 1x, the samples are transferred into the system memory as soon as
  DFLT0 and SAD are enabled. The transfer does not depend on the SAD state.
- If DATCAP[1:0] = 01, the samples are transferred into the system memory when the
  SAD detects a sound (when the SAD is in DETECT state), assuming that DFLT0 and
  SAD are enabled.
- If DATCAP[1:0] = 0, the samples are not transferred into the memory. This mode can
  be used if the application only wants to observe but does not need samples for other
  processing.

Note: DATCAP[1:0] is taken into account only when the SADEN = 1. For example, if the SAD
configuration is DATCAP[1:0] = 0, SADEN = DFLTEN = 1, and if the application sets now
SADEN to 0, the samples provided by the DFLT0 are transferred to the RXFIFO.
Programming recommendations

To make the SAD function working properly, the ADF must be programmed as follows:

1. Provide the proper kernel clock (adf_ker_ck) to the ADF.
2. Configure the CKGEN and enable it.
3. Configure the SITF and enable it (note that microphones have a settling time of several milliseconds).
4. Configure the DFLT0. A typical setting is the following:
   - CIC5 with a decimation ratio of 12, 16 or 24
   - RSFLT with a decimation ratio of 4
   - HPF with HPFC = 2 or 3
   For a very-low power implementation, the RSFLT can be bypassed.
5. Set SADEN to 0.
6. Wait for SADACTIVE = 0. If SADEN was previously enabled, this phase can take two periods of adf_hclk, and two periods of adf_proc_ck.
7. Configure the SAD as follows:
   - Set DATCAP[1:0] to 0, if the application does not want to store the samples into the system memory.
   - Set DATCAP[1:0] to 01, if the application wants to store the samples into the system memory only when the SAD detects a sound.
   - Set DATCAP[1:0] to 11, if the application wants to store the samples into the system memory continuously.
8. Configure the DMA (optional).
9. Enable the SAD.
10. Enable the DFLT0.

*Figure 290* shows a simplified timing diagram when the SAD works with DATCAP[1:0] = 01.

Thanks to the kernel clock (adf_ker_ck), the SAD continuously monitors the audio signal provided by the DFLT0. The threshold is also continuously updated according to the ambient noise level estimation.

- When the SAD detects a sound higher than the programmed threshold (1), the ADF requests the bus clock (adf_bus_ckreq asserted).
- When the bus clock is available (see 2 in *Figure 290*) then:
  - The data transfer to the memory is triggered.
  - The event interrupt (adf_evt_it) can be generated.
- In this example, the event interrupt (adf_evt_it) is used to wake up the application. The interrupt line is released by clearing SDET by writing 1 to it.
- As long as the SAD remains in DETECT state, the application waits to get enough samples and calls, for example the keyword recognition algorithm (see 3 in *Figure 290*).
- In the case shown in the figure below, the SAD state (SADST) goes back to MONITOR before the keyword is recognized. If DETCFG is set to 1, an event signals when the SAD goes back to MONITOR state. The SAD stops the transfer of samples into the memory and the application can clean up the receive buffer for the next detection (see 4 in *Figure 290*).
36.4.11 Data transfer to memory

**Data format**

The samples processed by DFLT0 are stored into a RXFIFO. The application can read the samples stored into these FIFOs via the **ADF digital filter data register 0 (ADF_DFLT0DR)**. The samples inside this register are signed and left aligned. The bit 31 always represents the sign.

The ADF provides 24-bit left-aligned data. Performing a 16-bit access to ADF_DFLT0DR allows the application to get the 16 most significant bits. Performing a 32-bit access to ADF_DFLT0DR allows the application to get a 24-bit data size.
**Data re-synchronization**

The samples stored into the RXFIFO can be transferred into the memory by using either DMA requests or interrupt signaling.

*Note:*  
*The RXFIFO is located into the adf_ker_ck clock domain, while ADF_DFLT0DR is located into the adf_hclk (AHB) clock domain.*

When the AHB clock is available, if ADF_DFLT0DR is empty and if a sample is available into the RXFIFO, this sample is transferred into ADF_DFLT0DR.

The sample transfer from the RXFIFO to ADF_DFLT0DR takes two periods of the AHB clock (adf_hclk) and two periods of the adf_ker_ck clock. The ADF inserts automatically wait-states if the application performs a read operation of ADF_DFLT0DR while the transfer of the new sample from the RXFIFO to ADF_DFLT0DR is not yet completed.

**Figure 292. Data re-synchronization**

**Data transfer**

The content of the RXFIFO can be transferred to the memory either by using a DMA channel or interrupt services.

Both single and burst, DMA transfers are supported by the ADF, but the application has to care about the following points:

- The RXFIFO must contain at least the same amount of samples than the burst size.
- The burst mode efficiency may be reduced due to the data re-synchronization explained in the previous section.

*Note:*  
*The burst mode is not available in all products (see the DMA section to check if the product supports it).*

In addition, the application can select the RXFIFO threshold (FTH bit) in order to trigger the data transfer: a data transfer can be triggered as soon as the RXFIFO is not empty, or when the RXFIFO is half-full (containing depth/2 samples).

For the DMA transfer, as soon as one of the RXFIFO reaches the threshold level, the DMA request is asserted in order to ask for data transfer. Successive DMA requests are performed as long as the RXFIFO is not empty.

The DMA mode of the RXFIFO is enabled via the DMAEN bit in ADF_DFLT0DR.

For the interrupt signaling, the following cases must be considered:

- If FTH = 0, as soon as a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as ADF_DFLT0DR is read.
- If FTH = 1, as soon as the RXFIFO reaches the threshold level and a data is available in ADF_DFLT0DR, the FTHF is set, allowing the generation of an interrupt. FTHF is released as soon as one data is read. FTHF is set again if the threshold condition is
met again. In this mode, every time an interrupt occurs, the application is supposed to read FIFO_SIZE/2 data.

**RXFIFO Overrun**

A RXFIFO overrun condition is detected when the RXFIFO is full, and a new sample from the DFLT0 must be written.

In this case, DOVRF is set and the new sample is dropped. When the RXFIFO has at least one location available, the new incoming sample is written into the RXFIFO.

Figure 293 shows an example based on a RXFIFO depth of four words and FTH set to 1, so that FTHF goes to 1 when the RXFIFO is half-full.

The S7 sample is lost due to an overrun: the RXFIFO is full while S7 must be written into the RXFIFO. The S7 write operation is not performed. DOVRF is set to 1 at the moment where the write operation was expected. The overflow event remains to 1 as long as it is not cleared by the application.

In this example, DOVRIE is set to 1 to have an interrupt if an overrun condition is detected.

After the S7 sample, the application manages to read data from the RXFIFO, and the ADF can write the S8 sample and consecutive. Later, the application clears DOVR, allowing the detection of a new overrun situation.

In the adf_hclk line, the gray boxes indicate that the ADF requested the AHB clock. The figure below shows the AHB clock available only when the ADF requests it. In real applications, the AHB clock may also be present if the ADF does not request it.

**Figure 293. Example of overflow and transfer to memory**
36.4.12 **Autonomous mode**

The ADF can work even if the AHB bus clock is not available (Stop modes). The ADF uses the AHB clock only for the register interface. All the processing part is clocked with the kernel clock.

In Stop mode, the ADF receives a kernel clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The selected kernel clock source is taken from an oscillator available in Stop mode.

In Stop mode, the ADF receives the AHB clock if the following conditions are met:
- The ADF autonomous mode is enabled in the RCC.
- The ADF requests the AHB clock in the following situations:
  - when the ADF must transfer data into memory via the DMA
    The data is directly transferred to the SRAM thanks to the DMA while the product remains in Stop mode. The AHB clock request is maintained until the DMA transfer is completed.
  - when the ADF needs to generate an interrupt
    An interrupt generally wakes up the device from Stop mode, as an action from the application is needed. Once the AHB clock is available, the interrupt is generated. The AHB clock request is maintained as long as an enabled interrupt flag is still active.

36.4.13 **Register protection**

The ADF embeds some hardware protection to prevent invalid situations. The table below shows the list of write-protected and unprotected fields.

<table>
<thead>
<tr>
<th>Registers</th>

<td>SKPBF = 1</td>
</tr>
</tbody>
</table>
All the ADF processing is performed in the adf_proc_ck clock domain. For that reason, enabling or disabling an ADF sub-block may take some time due to the re-synchronization between the AHB clock domain and the adf_proc_ck clock domain. XXXACTIVE flags are available to allow the application to check that the synchronization between the two clock domains is completed.

To change a write-protected field, the application must follow this sequence:

1. Set the enable bit of the sub-block to 0.
2. Wait for corresponding flag XXXACTIVE = 0.
3. Modify the wanted fields.
4. Set the enable bit of the sub-block to 1.

Refer to the description of each sub-block for details.

### 36.5 ADF low-power modes

#### Table 321. Effect of low-power modes on ADF

<td>No effect. ADF interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop(1)</td>
<td>The ADF registers content is kept. If the autonomous mode is enabled in the RCC and the ADF is clocked by an internal oscillator available in Stop mode, the ADF remains active. The DMA requests are functional and the interrupts in these modes cause the device to exit Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The ADF is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to Section 36.3: ADF implementation for details about Stop modes supported by the ADF.

#### 36.6 ADF interrupts

To increase the CPU performance, the ADF offers an interrupt line (adf_flt0_it), sensitive to several events.

**Note:** The status flags are available even if the corresponding interrupt enable flag is not enabled.
The interrupt interface is controlled via the ADF DFLT0 interrupt enable register (ADF_DFLT0IER) and the ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR).

Figure 294. ADF interrupt interface

The table below shows which interrupt line is affected by which event, and how to clear and activate each interrupt/event.

36.7  ADF application informations

36.7.1  ADF configuration examples for audio capture

Table 323 gives some examples of the ADF settings for the digital microphones, focusing on 16 and 48 kHz output data rate.

Configurations #1 and #2 are for very low-power use-cases and have a reduced signal-to-noise ratio. The user must also insure that the selected digital microphone can work properly at 512 kHz. These configurations can be used for sound detection. The RSFLT is not used to reduce as much as possible the frequency of the kernel clock (adf_ker_ck).

Configurations #3, #4, #9, #10, #11 give signal-to-noise ratios around 115 dB, with an ideal microphone model, with a sinus signal of 997 Hz. Using the RSFLT allows a good control on the in-band ripple, and a good image rejection.

Configurations #7, #8, #10 give signal-to-noise ratio around 120 dB, with an ideal microphone model, using a sinus signal of 997 Hz.

1. Refer to Section 36.3: ADF implementation for details.

2. ADF_FLT0 vector corresponds to the assertion of adf_flt0_it signal.

36.7.3 Connection examples

Figure 295 shows simple connection examples of the ADF to external sensors.

- Picture on the left: two digital microphones connected to the ADF
  In this connection, the amount of connections is optimized; DMIC1 and DMIC2 are sharing the same data line, and the same clock line. BSMX allows the application to connect the digital filter either to DMIC1 or to DMIC2. In this configuration when one of the microphone is used, the other is activated as well, as they share the same clock.

- Picture in the center: two digital microphones connected to the ADF
  In this connection, DMIC1 and DMIC2 are sharing the same data line, but have a dedicated clock line. BSMX allows the application to connect the filter either to DMIC1
or to DMIC2. When the application wants to use a microphone, it is possible to keep the other in low-power mode by forcing its clock line to 0 (CCKyEN = 0, CCKyDIR = 1).

- Picture on the right: single sensor connected to the ADF
  It is also possible to configure the CCK0 and CCK1 pins to input in order to connect sensors providing the clock.

### 36.7.4 Global frequency response

*Figure 296* shows the global frequency response for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 40 Hz

The figure below shows the theoretical frequency response using a CIC4 and a CIC5.

**Figure 296. Global frequency response**

*Figure 297* shows the in-band ripple for a 16 kHz audio signal with a digital microphone working at 1.024 MHz. The filter configuration is the following:

- CIC order 4 or 5, with a decimation ratio of 16
- RSFLT enabled, with a decimation ratio of 4
- HPF enabled with a cut-off frequency of 20 Hz

The resulting in-band ripple is ± 0.41 dB for CIC5, and ± 0.45 dB for CIC4.
The -3 dB cut-off frequency is 7061 Hz.

**Figure 297. Detailed frequency response**

### 36.7.5 Total ADF gain

This section details how to compute the signal level provided by the ADF according to the filter settings.

A signal level may be expressed in dBFS (decibel full scale). A 0 dBFS level is assigned to the maximum possible digital level. For example, a signal that reaches 50% of the maximum level, has a -6 dBFS level (6 dB below full scale).

For example, for the ADF offering a final data width of 24 bits, a signal having an amplitude of $2 \times 10^6$ LSB has a level of:

$$20 \log_{10} \left( \frac{2 \times 10^6}{2^{24-1}} \right) = -12.45 \text{ dBFS}$$

In addition, the data size of a signal having an amplitude (Amp) expressed in LSB is given by:

$$DS = \left( \frac{\ln(Amp)}{\ln(2)} + 1 \right) \text{ bits}$$

One bit need to be added for negative values.

So a signal having an amplitude of $2 \times 10^6$ LSB, has a data size of 21.9 bits.

### CIC gain

The CIC gain ($G_{CIC}$ and $GdB_{CIC}$) can be deduced from the following formula giving data size in bits ($DS_{CIC}$).

$$DS_{CIC} = (N \times \log_2(D1)) + DSin$$

where $N$ represents the CIC order (selected by CICMOD[2:0]), and $D1$ is the decimation ratio (given by MCICD[8:0]).
DSin represents the data size (in bits) of the signal at CIC input.

Warning: \( D_{\text{CIC}} \) is very important for CIC filter. In order to work fine, \( D_{\text{CIC}} \) must not exceed 26 bits.

The CIC gain \( G_{\text{CIC}} \) is given by:

\[
G_{\text{CIC}} = (D_1)^N
\]

which gives in decibels:

\[
G_{\text{dB}} = 20 \times \log_{10}((D_1)^N)
\]

Data size at SCALE output

The data size at SCALE output (including the CIC gain), is a key information as the RSFLT starts to have some saturations, if the peak-to-peak signal amplitude at SCALE output is higher than 22 bits.

If the RSFLT is bypassed, then a peak-to-peak signal amplitude of 24 bits is accepted.

The signal amplitude at SCALE output is:

\[
A_{\text{out SCALE}} = D_1^N \times 10^{\frac{G_{\text{dB SCALE}}}{20}} \times A_{\text{in DFLT}}
\]

\( G_{\text{dB SCALE}} \) represents the gain selected by SCALE[5:0], in dB.
\( A_{\text{out SCALE}} \) is the signal amplitude at SCALE output (in LSB), and \( A_{\text{in DFLT}} \) is the signal amplitude at CIC input (LSB).

\[
D_{\text{SCALE}} = \frac{\ln(A_{\text{out SCALE}})}{\ln(2)} + 1
\]

The data size at SCALE output (\( D_{\text{SCALE}} \)) is expressed in bits.

RSFLT gain

The RSFLT gain in the useful bandwidth is typically 9.5 dB, but due to ripple a margin of about ± 0.41 dB must be considered.

\[
G_{\text{RSFLT}} = 10^{\frac{9.5}{20}} = 2.98 \text{ typical}
\]

Note: The HPF filter has a gain of 0 dB.
**SAD gain**

The SAD is using only the 16 MSB on the signal, as a consequence, from the SAD point of view, the truncation from 24 to 16 bits can be seen as an attenuation.

\[
G_{\text{dB SAD}} = -48.1 \text{dB}
\]

and

\[
G_{\text{SAD}} = 0.003906
\]

The figure below shows a simplified view of the filter path and gives, for each significant component, the expression of the bit growth and the gain.

**Figure 298. Simplified DFLT view with gain information**

The table below summarizes of the final data size for different filter configurations.

**Table 326. Output signal levels**

</tr>
</tbody>
</table>

Example using the main filter chain

If the ADF filter is programmed as follows:
- The input signal is coming from a serial interface (\( D_{\text{in,RSFLT}} = 1 \) bit).
- CIC order = 5 (N), with a decimation value of 24 (D1).
- SCALE[5:0] is set to -12 dB.
- RSFLT enabled, and the decimation by four is enabled.
- HPF is enabled.

Check first the data size at CIC output:
\[ DS_{\text{CIC}} = (5 \times \log_2(24)) + 1 \text{ bit} = 23.92 \text{ bits} \]

The size is lower than 26 bits, so the CIC works in good conditions.

The data size at CIC output is very close to 24 bits, so the SCALE must be adjusted in order to provide a 22-bit max signal to the RSFLT. An attenuation of 12 dB is needed.

Then the signal level provided to the RSFLT is:
\[ AS_{\text{out,SCALE}} = 2^{4.5} \times 10^{\frac{-12}{20}} \times 1 = 2.10^6 \]
\[ DS_{\text{SCALE}} = \frac{\ln(2.10^6)}{\ln(2)} + 1 = 21.93 \text{ bits} \]

If a higher gain is used, the RSFLT may saturate the output signal for strong input signals.

At the end, the final signal amplitude is:
\[ AS_{\text{out,HPF}} = 2^{4.5} \times 10^{\frac{-12}{20}} \times 10^{\frac{9.5}{20}} \times 1 = 5.9711 \times 10^6 \]
\[ DS_{\text{out,HPF}} = \left( \frac{\ln(5.9711 \times 10^6)}{\ln(2)} + 1 \right) = 23.51 \text{ bits} \]

or:
36.7.6 How to compute SAD thresholds

The SAD does not compute the RMS value of the converted signal, but the average of the absolute values. As a consequence, the estimated level differs from the RMS value of the signal:

- For a sine signal having an RMS value of 1, the SAD computes a level of 0.9.
- For a white or pink noise signal having an RMS value of 1, the SAD computes a level of about 0.8.

Note: \( \text{FRSIZE}[2:0] \) has a big influence on the accuracy of the level estimation: big \( \text{FRSIZE}[2:0] \) values give better results.

Threshold programming with SADMOD = 01

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 63 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02.

The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 63 dBSPL produces a digital signal of about:

- 26 dBFS - (94 - 63) = -57 dBFS.

- **SCALE value adjustment**
  - For this example, the filter configuration is the following:
    - CIC5 with a decimation by 16
    - RSFLT enabled with a decimation by 4
    - HPF enabled
  
  A SCALE value of 3.5 dB is recommended for this configuration. As DFTL0 provides samples only used for a sound detection (samples not provided to the application), a bigger gain value can be applied: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 15.6 dB).

- **Input signal amplitude**
  - The input signal is -57 dBFS, corresponding to an amplitude
    \( \text{Asin} = 10^{(-57/20)} = 0.00141 \text{ LSB}. \)

- **Signal level at SAD input**
  - The total filter gain for the SAD is:
    \[
    G_{\text{SAD}} = 16^5 \times 10^{15.6/20} \times 10^{9.5/20} \times \frac{1}{256} = 73.68 \times 10^3 \text{ or } 97.3 \text{ dB}
    \]

  The signal amplitude received by the SAD is:

  \[
  \text{Ain}_{\text{SAD}} = 0.00141 \times G_{\text{SAD}} \sim 104 \text{ LSB}
  \]
The gain can be increased if the expected amplitude is too small. For the targeted application, 104 LSB is fine.

If the input signal is expected to be a sine, the sound level for a signal amplitude of 104 LSB is:

\[ \text{SDLVL} = \frac{\text{Ain}_{\text{SAD}} \times \sqrt{2}}{2} \times 0.9 - 66 \text{ LSB} \]

where 0.9 is the correction factor to apply with respect to the RMS value.

- Program the trigger value
- ANMIN and SNTHR must be programmed to trigger the SAD when the input signal level reaches 66 LSB.

For SADMOD[1:0] = 01, the threshold value is given by:

\[ \text{THRH} = \text{ANMIN} \times 10^{\frac{\text{GdB}_{\text{SNTHR}}}{20}} \]

where GdB_{SNTHR} represents the decibel value selected by SNTHR[3:0].

When SNTHR[3:0] = 6 dB for example, this formula becomes:

\[ \text{THRH} = 2 \times \text{ANMIN} \]

So ANMIN = THRHi/2 = 66 /2 = 33 LSB.

In Figure 299, the trigger value (THRH in red) is fixed to 66 LSB. The input signal is at -65dBFS during 256 samples, then its value goes to -55 dB for 256 samples, and finally it is reduced to -60 dBFS.

The blue curve is showing the sound level estimation (SDLVL) versus time. Fluctuation on the estimated value can be observed due to windowing effect of FRSIZE samples.

The SAD DETECT state (when green signal is high) is maintained during four additional frames due to hangover function value.

In this example ANSLP = FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 33.
Threshold programming with SADMOD = 1x

Consider the case of a sound capture where the application wants to wake up the system when the captured sound is bigger than 57 dBSPL.

The sound capture can be performed with a digital microphone such as the MP45DT02. The sensitivity of this microphone is typically -26 dBFS for an input signal of 94 dBSPL.

An acoustic signal at 57 dBSPL produces a digital signal of about:
- 26 dBFS - (94-63) = -63 dBFS.

- Adjust SCALE value
  For this example, the filter configuration is the following:
  - CIC4 with a decimation by 48
  - RSFLT bypassed
  - HPF enabled

  A SCALE value of 3.5 dB is recommended for this configuration. The samples provided by DFTL0 are only used for a sound detection, without providing the samples to the application, a bigger gain value can be provided: it increases the SAD accuracy and a saturation does not affect the SAD behavior (for example, a SCALE value of 24 dB).

- Input signal amplitude
  The input signal is -63 dBFS, corresponding to an amplitude:
  \[ \text{Asin} = 10^{(-63/20)} = 0.000708 \text{ LSB}. \]

- Signal level at SAD input
  The total filter gain for the SAD is:

  \[ G_{\text{SAD}} = 48^4 \times 10^{-11} \times 0.003906 = 328.6 \times 10^3 \text{ or } 110.3 \text{ dB} \]

  The signal amplitude received by the SAD is:

  \[ A_{\text{in SAD}} = 0.000708 \times G_{\text{SAD}} \sim 232 \text{ LSB} \]

  The gain can be increased if the expected amplitude is too small.
  If the input signal is expected to be a sine, the sound level for a signal amplitude of 232 LSB is:

  \[ \text{SDLVL} = \frac{A_{\text{in SAD}} \times \sqrt{2}}{2} \times 0.9 \sim 148 \text{ LSB} \]

  where 0.9 is the correction factor to apply with respect to the RMS value.
Note: ANLVL converges to average of SDLVL values, with a long constant time. So SDLVL ~ ANLVL = 148 LSB for a constant input signal at 57 dBSPL.

- Programming trigger value
  
  For SADMOD = 1', the SAD compares the estimated ambient noise multiplied by the gain selected by SNTHR[3:0] to ANMIN[12:0] * 4.
  
  For simplification, SNTHR[3:0] is set to 1 (6 dB), meaning that ANLVL is multiplied by two.
  
  The SAD triggers if $2 \times ANLVL > THRH$.

  In this mode,

  $$THRH = 4 \times ANMIN$$

  So the SAD triggers if:

  $$ANLVL > 2 \times ANMIN$$

  So $ANMIN = 148 / 2 = 74$ LSB

In Figure 300, the trigger value (THRH in red) is fixed to 148 LSB. The input signal is at -75 dBFS during 512 samples, then its value goes to -62 dB for 11000 samples, and finally it is reduced to -70 dBFS.

The blue curve shows the sound level estimation (SDLVL) versus time. The black curve shows the ambient noise estimation versus time, increasing or decreasing logarithmically. During the learning phase, it reaches the SDLVL value.

In this example ANSLP = 6, FRSIZE = 3 (64 samples), LFRNB = 0 (2 frames), HGOVR = 0 (4 frames), SNTHR = 1 (6 dB) and ANMIN = 74.

Figure 300. SAD example working with SADMOD = 1x
36.8 ADF registers

All the ADF registers must be accessed either in word (32-bit) or half-word (16-bit) formats.

Bit 0 TRGO: Trigger output control

This bit is set by software and reset by hardware. It is used to start the acquisition of several filters synchronously. It is also used to synchronize several ADF together by controlling the adf_trgo signal.

0: Write 0 has no effect. Read 0 means that the trigger can be set again to 1.
1: Write 1 generates a positive pulse on the adf_trgo signal and triggers the acquisition on enabled filter having their ACQMOD[2:0] = 01x and selecting TRGO as trigger. Read 1 means that the trigger pulse is still active.

36.8.2 ADF clock generator control register (ADF_CKGCR)

Address offset: 0x004
Reset value: 0x0000 0000

This register is used to control the clock generator. The clock adf_proc_ck must be enabled before enabling other ADF parts.

Bit 31  **CKGACTIVE**: Clock generator active flag
This bit is set and cleared by hardware. It is used by the application to check if the clock generator is effectively enabled (active) or not. The protected fields of this function can only be updated when CKGACTIVE = 0 (see **Section 36.4.13: Register protection** for details).
The delay between a transition on CKGDEN and a transition on CKGACTIVE is two periods of AHB clock and two periods of adf_proc_ck.
0: The clock generator is not active and can be configured if needed.
1: The clock generator is active and protected fields cannot be configured.

Bits 30:24  **PROCDIV[6:0]**: Divider to control the serial interface clock
This field is set and reset by software. It is used to adjust the frequency of the clock provided to the SITF.

\[
F_{\text{adf_ift_ck}} = \frac{F_{\text{adf_ker_ck}}}{(\text{PROCDIV} + 1)}
\]

This field must not be changed if the filter is enabled (DFTEN = 1).
0: adf_ker_ck provided to the SITF
1: adf_ker_ck / 2 provided to the SITF
2: adf_ker_ck / 3 provided to the SITF
... 127: adf_ker_ck / 128 provided to the SITF
**Note:** This field can be write-protected (see **Section 36.4.13: Register protection** for details).

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **CCKDIV[3:0]**: Divider to control the ADF_CCK clock
This field is set and reset by software. It is used to adjust the frequency of the ADF_CCK clock. The input clock of this divider is the clock provided to the SITF. More globally, the frequency of the ADF_CCK is given by the following formula:

\[
F_{\text{ADF_CCK}} = \frac{F_{\text{adf_ker_ck}}}{(\text{PROCDIV} + 1) \times (\text{CCKDIV} + 1)}
\]

This field must not be changed if the filter is enabled (DFTEN = 1).
0000: The ADF_CCK clock is adf_proc_ck.
0001: The ADF_CCK clock is adf_proc_ck / 2.
0010: The ADF_CCK clock is adf_proc_ck / 3.
... 1111: The ADF_CCK clock is adf_proc_ck / 16.
**Note:** This field can be write-protected (see **Section 36.4.13: Register protection** for details).

Bits 15:12  **TRGSRC[3:0]**: Digital filter trigger signal selection
This field is set and cleared by software. It is used to select which external signals trigger the corresponding filter. This field is not significant if the CKGMOD = 0.
000x: TRGO selected
0010: adf_trg1 selected
others: reserved
**Note:** This field can be write-protected (see **Section 36.4.13: Register protection** for details).

Bits 11:9  Reserved, must be kept at reset value.
Bit 8 **TRGSENS**: CKGEN trigger sensitivity selection

This bit is set and cleared by software. It is used to select the trigger sensitivity of the trigger signals. This bit is not significant if the CKGMOD = 0.

0: A rising edge event triggers the activation of CKGEN dividers.
1: A falling edge even triggers the activation of CKGEN dividers.

*Note*: When the trigger source is TRGO, the sensitivity is forced to falling edge, thus TRGSENS value is not taken into account. This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CCK1DIR**: ADF_CCK1 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK1 pin.

0: The ADF_CCK1 pin direction is in input.
1: The ADF_CCK1 pin direction is in output.

*Note*: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 5 **CCK0DIR**: ADF_CCK0 direction

This bit is set and reset by software. It is used to control the direction of the ADF_CCK0 pin.

0: The ADF_CCK0 pin direction is in input.
1: The ADF_CCK0 pin direction is in output.

*Note*: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 4 **CKGMOD**: Clock generator mode

This bit is set and reset by software. It is used to define the way the clock generator is enabled. This bit must not be changed if the filter is enabled (DFTEN = 1).

0: The kernel clock is provided to the dividers as soon as CKGDEN is set to 1.
1: The kernel clock is provided to the dividers when CKGDEN is set to 1 and the trigger condition met.

*Note*: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CCK1EN**: ADF_CCK1 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK1 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the ADF_CCK1 pin.

Bit 1 **CCK0EN**: ADF_CCK0 clock enable

This bit is set and reset by software. It is used to control the generation of the bitstream clock on the ADF_CCK0 pin.

0: Bitstream clock not generated
1: Bitstream clock generated on the ADF_CCK0 pin

Bit 0 **CKGDEN**: CKGEN dividers enable

This bit is set and reset by software. It is used to enable/disable the clock dividers of the CKGEN: PROCDIV and CCKDIV.

0: CKGEN dividers disabled
1: CKGEN dividers enabled
36.8.3 ADF serial interface control register 0 (ADF_SITF0CR)

| Bit 3 | Reserved, must be kept at reset value. |
**Bits 2:1 SCKSRC[1:0]: Serial clock source**

This field is set and cleared by software. It is used to select the clock source of the serial interface.

- 00: Serial clock source is ADF_CCK0.
- 01: Serial clock source is ADF_CCK1.
- others: reserved

*Note:* This field can be write-protected (see Section 36.4.13: Register protection for details).

**Bit 0 SITFEN: Serial interface enable**

This bit is set and cleared by software. It is used to enable/disable the serial interface.

- 0: Serial interface disabled
- 1: Serial interface enabled

### 36.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR)

**Address offset:** 0x084  
**Reset value:** 0x0000 0000

This register is used to select the bitstream to be provided to DFLT0.

<table>

**Bit 31 BSMXACTIVE: BSMX active flag**

This bit is set and cleared by hardware. It is used by the application to check if the BSMX is effectively enabled (active) or not. BSSEL[4:0] can only be updated when BSMXACTIVE is set to 0. This BSMXACTIVE flag cannot go to 0 if DFLT0 is enabled.

- 0: BSMX is not active and can be configured if needed.
- 1: BSMX is active and protected fields cannot be configured.

**Bits 30:5** Reserved, must be kept at reset value.

**Bits 4:0 BSSEL[4:0]: Bitstream selection**

This field is set and cleared by software. It is used to select the bitstream to be processed for DFLT0.

- 00000: bs0_r provided to DFLT0
- 00001: bs0_f provided to DFLT0
- others: reserved

*Note:* This field can be write-protected (see Section 36.4.13: Register protection for details).
36.8.5 ADF digital filter control register 0 (ADF_DFLT0CR)

Address offset: 0x088
Reset value: 0x0000 0000

Bit 31 **DFLACTIVE**: DFLT0 active flag
This bit is set and cleared by hardware. It indicates if DFLT0 is active: can be running or waiting for events.
0: DFLT0 not active (can be re-enabled again, via DFLTEN bit, if needed)
1: DFLT0 active

Bit 30 **DFLTRUN**: DFLT0 run status flag
This bit is set and cleared by hardware. It indicates if DFLT0 is running or not.
0: DFLT0 not running and ready to accept a new trigger event
1: DFLT0 running

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **NBDIS[7:0]**: Number of samples to be discarded
This field is set and cleared by software. It is used to define the number of samples to be discarded every time DFLT0 is re-started.
0: No sample discarded
1: 1 sample discarded
2: 2 samples discarded
... 255: 255 samples discarded

*Note: This field can be write-protected (see Section 36.4.13: Register protection for details).*

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:12 **TRGSRC[3:0]**: DFLT0 trigger signal selection
This field is set and cleared by software. It is used to select which external signals trigger DFLT0.
0000: TRGO selected
0010: adf_trgi selected
others: Reserved

*Note: This field can be write-protected (see Section 36.4.13: Register protection for details).*

Bits 11:9 Reserved, must be kept at reset value.
Bit 8 **TRGSENS**: DFLT0 trigger sensitivity selection
   This field is set and cleared by software. It is used to select the trigger sensitivity of the external signals:
   0: A rising edge event triggers the acquisition.
   1: A falling edge even triggers the acquisition.
   **Note**: When the trigger source is TRGO, TRGSENS value is not taken into account. When TRGO is selected, the sensitivity is forced to falling edge.
   This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ACQMOD[2:0]**: DFLT0 trigger mode
   This field is set and cleared by software. It is used to select the filter trigger mode:
   000: Asynchronous continuous acquisition mode
   001: Asynchronous single-shot acquisition mode
   010: Synchronous continuous acquisition mode
   011: Synchronous single-shot acquisition mode
   100: Window continuous acquisition mode
   others: same as 000
   **Note**: This field can be write-protected (see Section 36.4.13: Register protection for details).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **FTH**: RXFIFO threshold selection
   This bit is set and cleared by software. It is used to select the RXFIFO threshold:
   0: RXFIFO threshold event generated when the RXFIFO is not empty
   1: RXFIFO threshold event generated when the RXFIFO is half-full
   **Note**: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 1 **DMAEN**: DMA requests enable
   This bit is set and cleared by software. It is used to control the generation of DMA request to transfer the processed samples into the memory:
   0: DMA interface for the corresponding digital filter disabled
   1: DMA interface for the corresponding digital filter enabled
   **Note**: This bit can be write-protected (see Section 36.4.13: Register protection for details).

Bit 0 **DFLTEN**: DFLT0 enable
   This bit is set and cleared by software. It is used to control the start of acquisition of the DFLT0 path. This bit behavior depends on ACQMOD[2:0] and external events. The serial or parallel interface delivering the samples must be enabled as well:
   0: Acquisition immediately stopped
   1: Acquisition immediately started if ACQMOD[2:0] = 00x or 101, or acquisition started when the proper trigger event occurs if ACQMOD[2:0] = 01x.
36.8.6 ADF digital filer configuration register 0 (ADF_DFLT0CICR)

Address offset: 0x08C
Reset value: 0x0000 0000

This register is used to control the main CIC filter.

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bits 25:20 | **SCALE[5:0]**: Scaling factor selection |
|           | This field is set and cleared by software. It is used to select the gain to be applied at CIC output (see Table 314 for details). If the application attempts to write a new gain value while the previous one is not yet applied, this new gain value is ignored. Reading back this field informs the application on the current gain value. |
|           | 000000: 0 dB |
|           | 000001: + 3.5 dB |
|           | 000010: + 6 dB or shift left by 1 bit |
|           | ... |
|           | 011000: + 72 dB or shift left by 12 bits |
|           | 100000: - 48.2 dB or shift right by 8 bits (default value) |
|           | 100001: - 44.6 dB |
|           | 100010: - 42.1 dB or shift right by 7 bits |
|           | 100011: - 38.6 dB |
|           | ... |
|           | 101110: -6 dB or shift right by 1 bit |
|           | 101111: -2.5 dB |
|           | others: Reserved |

| Bits 19:17 | Reserved, must be kept at reset value. |
| Bits 16:8  | **MCICD[8:0]**: CIC decimation ratio selection |
|           | This field is set and cleared by software. It is used to select the CIC decimation ratio. A decimation ratio smaller than two is not allowed. The decimation ratio is given by \((\text{CICDEC}+1)\). |
|           | 0: Decimation ratio is 2. |
|           | 1: Decimation ratio is 2. |
|           | 2: Decimation ratio is 3. |
|           | 3: Decimation ratio is 4. |
|           | ... |
|           | 511: Decimation ratio is 512. |

*Note: This field can be write-protected (see Section 36.4.13: Register protection for details).*

| Bit 7     | Reserved, must be kept at reset value. |
### 36.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR)

Address offset: 0x090  
Reset value: 0x0000 0000  
This register is used to control the reshape and HPF filter.

- **Bits 31:10** Reserved, must be kept at reset value.
- **Bits 9:8** **HPFC[1:0]**: High-pass filter cut-off frequency  
  This field is set and cleared by software, it is used to select the cut-off frequency of the high-pass filter. $F_{\text{PCM}}$ represents the sampling frequency at HPF input.  
  00: Cut-off frequency = 0.000625 x $F_{\text{PCM}}$  
  01: Cut-off frequency = 0.00125 x $F_{\text{PCM}}$  
  10: Cut-off frequency = 0.00250 x $F_{\text{PCM}}$  
  11: Cut-off frequency = 0.00950 x $F_{\text{PCM}}$  
  Note: This field can be write-protected (see Section 36.4.13: Register protection for details).
- **Bit 7** **HPFBYP**: High-pass filter bypass  
  This bit is set and cleared by software. It is used to bypass the high-pass filter.  
  0: HPF not bypassed (default value)  
  1: HPF bypassed  
  Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).
- **Bits 6:5** Reserved, must be kept at reset value.
36.8.8 ADF delay control register 0 (ADF_DLY0CR)

Bits 30:7 Reserved, must be kept at reset value.

Bits 6:0 SKPDLY[6:0]: Delay to apply to a bitstream
This field is set and cleared by software. It defines the number of input samples that are skipped. Skipping is applied immediately after writing to this field, if SKPBF = 0 and DFLTEN = 1. If SKPBF = 1, the value written into the register is ignored by the delay state machine.
0: No input sample skipped
1: 1 input sample skipped
...
127: 127 input samples skipped
### 36.8.9 ADF DFLT0 interrupt enable register (ADF_DFLT0IER)

Address offset: 0x0AC
Reset value: 0x0000 0000

This register is used for allowing or not the events to generate an interrupt.

Bits 31:14 Reserved, must be kept at reset value.

- **Bit 13 SDLVLIE**: SAD sound-level value ready enable
  This bit is set and cleared by software.
  - 0: Sound-level-ready interrupt disabled
  - 1: Sound-level-ready interrupt enabled

- **Bit 12 SDDETIE**: Sound activity detection interrupt enable
  This bit is set and cleared by software.
  - 0: Sound-trigger interrupt disabled
  - 1: Sound-trigger interrupt enabled

- **Bit 11 RFOVRIE**: Reshape filter overrun interrupt enable
  This bit is set and cleared by software.
  - 0: Reshape filter overrun interrupt disabled
  - 1: Reshape filter overrun interrupt enabled

- **Bit 10 CKABIE**: Clock absence detection interrupt enable
  This bit is set and cleared by software.
  - 0: Clock absence interrupt disabled
  - 1: Clock absence interrupt enabled

- **Bit 9 SATIE**: Saturation detection interrupt enable
  This bit is set and cleared by software.
  - 0: Saturation interrupt disabled
  - 1: Saturation interrupt enabled

Bits 8:2 Reserved, must be kept at reset value.

- **Bit 1 DOVRIE**: Data overflow interrupt enable
  This bit is set and cleared by software.
  - 0: Data overflow interrupt disabled
  - 1: Data overflow interrupt enabled

- **Bit 0 FTHIE**: RXFIFO threshold interrupt enable
  This bit is set and cleared by software.
  - 0: RXFIFO threshold interrupt disabled
  - 1: RXFIFO threshold interrupt enabled
### 36.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR)

Address offset: 0x0B0
Reset value: 0x0000 0000

This register contains the status flags for the digital filter path.

<table>
<thead>
<tr>
<th>Bit 31:14</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bit 13** SDLVLF: Sound level value ready flag
- This bit is set by hardware and cleared by software by writing this bit to 1.
- 0: Read 0 means that new sound level value is not ready. Write 0 has no effect.
- 1: Read 1 means that new sound level value is ready. Write 1 clears this flag.

**Bit 12** SDDETF: Sound activity detection flag
- This bit is set by hardware and cleared by software by writing this bit to 1.
- 0: Read 0 means that no sound activity is detected. Write 0 has no effect.
- 1: Read 1 means that sound activity is detected. Write 1 clears this flag.

**Bit 11** RFOVRF: Reshape filter overrun detection flag
- This bit is set by hardware and cleared by software by writing this bit to 1.
- 0: Read 0 means that no reshape filter overrun is detected. Write 0 has no effect.
- 1: Read 1 means that reshape filter overrun is detected. Write 1 clears this flag.

**Bit 10** CKABF: Clock absence detection flag
- This bit is set by hardware and cleared by software by writing this bit to 1.
- 0: Read 0 means that no clock absence is detected. Write 0 has no effect.
- 1: Read 1 means that a clock absence is detected. Write 1 clears this flag.

**Bit 9** SATF: Saturation detection flag
- This bit is set by hardware and cleared by software by writing this bit to 1.
- 0: Read 0 means that no saturation is detected. Write 0 has no effect.
- 1: Read 1 means that a saturation is detected. Write 1 clears this flag.

**Bits 8:4** Reserved, must be kept at reset value.

**Bit 3** RXNEF: RXFIFO not empty flag
- This bit is set and cleared by hardware according to the RXFIFO level.
- 0: RXFIFO empty
- 1: RXFIFO not empty
36.8.11  ADF SAD control register (ADF_SADCR)

Address offset: 0x0B8
Reset value: 0x0000 0000

This register is used for the configuration and the control of the sound activity detection.

Bit 31  SADACTIVE: SAD Active flag
This bit is set and cleared by hardware. It is used to check if the SAD is effectively enabled (active) or not. The protected fields and registers of this function can only be updated when the SADACTIVE is set to 0 (see Section 36.4.13: Register protection for details).
The delay between a transition on SADEN and a transition on SADACTIVE is two periods of AHB clock and two periods of adf_proc_ck.
0: SAD not active and can be configured if needed
1: SAD active and protected fields cannot be configured.

Bits 30:14  Reserved, must be kept at reset value.
Bits 13:12 **SADMOD[1:0]: SAD working mode**

This field is set and cleared by software. It is used to define the way the SAD works.

- **00**: Threshold value computed according to the estimated ambient noise
  The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a voice activity detector.

- **01**: Threshold value equal to ANMIN[12:0], multiplied by the gain selected by SNTHR[3:0]
  The SAD triggers when the sound level (SDLVL) is bigger than the defined threshold. In this mode, the SAD works like a sound detector.

- **1x**: Threshold value given by 4 x ANMIN[12:0]
  The SAD triggers when the estimated ambient noise (ANLVL), multiplied by the gain selected by SNTHR[3:0] is bigger than the defined threshold. In this mode, the SAD is working like an ambient noise estimator. Hysteresis function cannot be used in this mode.

*Note: This field can be write-protected (see Section 36.4.13: Register protection for details).*

Bit 11 **Reserved, must be kept at reset value.**

Bits 10:8 **FRSIZE[2:0]: Frame size**

This field is set and cleared by software. It is used to define the size of one frame and also to define how many samples are taken into account to compute the short-term signal level.

- **000**: 8 PCM samples used to compute the short-term signal level
- **001**: 16 PCM samples used to compute the short-term signal level
- **010**: 32 PCM samples used to compute the short-term signal level
- **011**: 64 PCM samples used to compute the short-term signal level
- **100**: 128 PCM samples used to compute the short-term signal level
- **101**: 256 PCM samples used to compute the short-term signal level
- **11x**: 512 PCM samples used to compute the short-term signal level

*Note: This field can be write-protected (see Section 36.4.13: Register protection for details).*

Bit 7 **HYSTEN: Hysteresis enable**

This bit is set and cleared by software. It is used to enable/disable the hysteresis function (see Table 314 for details). This bit must be kept to 0 when SADMOD[1:0] = 1x.

- **0**: Hysteresis function disabled. THRH is always used.
- **1**: Hysteresis function enabled. THRH is used for MONITOR to DETECT transition and THRL is used for DETECT to MONITOR transition.

*Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).*

Bit 6 **Reserved, must be kept at reset value.**

Bits 5:4 **SADST[1:0]: SAD state**

This field is set and cleared by hardware. It indicates the SAD state and is meaningful only when SADEN = 1. The SAD state can be:

- **0**: SAD in LEARN state
- **1**: SAD in MONITOR state
- **11**: SAD in DETECT state

Bit 3 **DETCFG: Sound trigger event configuration**

This bit is set and cleared by software. It is used to define if the sddet_evt event is generated only when the SAD enters to MONITOR state or when the SAD enters or exits the DETECT state.

- **0**: sddet_evt generated when SAD enters the MONITOR state
- **1**: sddet_evt generated when SAD enters or exits the DETECT state

*Note: This bit can be write-protected (see Section 36.4.13: Register protection for details).*
Bits 2:1  **DATCAP[1:0]**: Data capture mode
This field is set and cleared by software. It is used to define in which conditions, the samples provided by DLFT0 are stored into the memory.
00: Samples from DFLT0 not transferred into the memory
01: Samples from DFLT0 transferred into the memory when SAD is in DETECT state
1x: Samples from DFLT0 transferred into memory when SAD and DFLT0 are enabled
*Note:* This field can be write-protected (see Section 36.4.13: Register protection for details).

Bit 0  **SADEN**: Sound activity detector enable
This bit is set and cleared by software. It is used to enable/disable the SAD.
0: SAD disabled and SAD state reset
1: SAD enabled

### 36.8.12  ADF SAD configuration register (ADF_SADCFGR)

Address offset: 0x0BC
Reset value: 0x0000 0000
This register is used for the configuration of the sound activity detection.

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:16  **ANMIN[12:0]**: Minimum noise level
This field is set and cleared by software. It is used to define the minimum noise level and then the sensitivity. It represents a positive number.
*Note:* This field can be write-protected (see Section 36.4.13: Register protection for details).

Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **HGOVR[2:0]**: Hangover time window
This field is set and cleared by software. Once the SAD state is DETECT, this parameter is used to define the amount of time the sound is allowed to remain below the threshold, before switching the SAD to MONITOR state (see FRSIZE field for the description of a frame).
000: SAD back to MONITOR state if sound is below threshold for 4 frames
001: SAD back to MONITOR state if sound is below threshold for 8 frames
010: SAD back to MONITOR state if sound is below threshold for 16 frames
011: SAD back to MONITOR state if sound is below threshold for 32 frames
100: SAD back to MONITOR state if sound is below threshold for 64 frames
101: SAD back to MONITOR state if sound is below threshold for 128 frames
110: SAD back to MONITOR state if sound is below threshold for 256 frames
111: SAD back to MONITOR state if sound is below threshold for 512 frames
*Note:* This field can be write-protected (see Section 36.4.13: Register protection for details).

Bit 11  Reserved, must be kept at reset value.
36.8.13 ADF SAD sound level register (ADF_SADSDLVR)

Address offset: 0x0C0
Reset value: 0x0000 0000

This register contains the short term sound level computed by the SAD.

<table>
<thead>
<tr>
<th>Bit 31:15</th>
<th>SDLVL[14:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1 0 3 4 5 6 7 8 9 10 11 12 13 14 15</td>
</tr>
</tbody>
</table>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:0 SDLVL[14:0]: Short term sound level
This field is set by hardware. It contains the latest sound level computed by the SAD. To refresh this value, SDLVLF must be cleared.
36.8.14  ADF SAD ambient noise level register (ADF_SADANLVR)

Address offset: 0x0C4
Reset value: 0x0000 0000

This register contains the ambient noise level computed by the SAD.

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  ANLVL[14:0]: Ambient noise level estimation
   This field is set by hardware. It contains the latest ambient noise level computed by the SAD.
   To refresh this field, the SDLVLF flag must be cleared.

36.8.15  ADF digital filter data register 0 (ADF_DFLT0DR)

Address offset: 0x0F0
Reset value: 0x0000 0000

This register is used to read the data processed by the digital filter.

Bits 31:8  DR[23:0]: Data processed by DFT0
   Bits 7:0  Reserved, must be kept at reset value.

**Table 327. ADF register map and reset values**

- **Offset**: Offset in hexadecimal form.
- **Register name**: Name of the register.
- **Register**: Register value.
- **Reset value**: Reset value of the register.

The table lists the register map and reset values for the ADF register. Each register is assigned a specific offset and is detailed with its corresponding register name and reset value.

Refer to Section 2.3 for the register boundary addresses.
37 Digital camera interface (DCMI)

37.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

37.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

37.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.
### 37.3.1 DCMI block diagram

Figure 301 shows the DCMI block diagram.

</tbody>
</table>
37.3.3 **DCMI clocks**

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

37.3.4 **DCMI DMA interface**

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

37.3.5 **DCMI physical interface**

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 328.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.

![DCMI signal waveforms](image)

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

**8-bit data**

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>D_{n+3}[7:0]</td>
<td>D_{n+2}[7:0]</td>
<td>D_{n+1}[7:0]</td>
<td>D_{n}[7:0]</td>
</tr>
<tr>
<td>4</td>
<td>D_{n+7}[7:0]</td>
<td>D_{n+6}[7:0]</td>
<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>

### 10-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:26</th>
<th>25:16</th>
<th>15:10</th>
<th>9:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>D_{n+1}[9:0]</td>
<td>0</td>
<td>D_{n}[9:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[9:0]</td>
<td>0</td>
<td>D_{n+2}[9:0]</td>
</tr>
</tbody>
</table>

### 12-bit data

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:28</th>
<th>27:16</th>
<th>15:12</th>
<th>11:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>D_{n+1}[11:0]</td>
<td>0</td>
<td>D_{n}[11:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[11:0]</td>
<td>0</td>
<td>D_{n+2}[11:0]</td>
</tr>
</tbody>
</table>

### 14-bit data

When EDM[1:0] = 11 in DCMI_CR, the camera interface captures the 14-bit data at its input DCMI_D[13:0] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in the table below.
37.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 303 shows the corresponding timing diagram.

### Table 333. Positioning of captured data bytes in 32-bit words (14-bit width)

<table>
<thead>
<tr>
<th>Byte address</th>

<td>0</td>
<td>D_{n}[13:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[13:0]</td>
<td>0</td>
<td>D_{n+2}[13:0]</td>
</tr>
</tbody>
</table>

**Figure 303. Timing diagram**

Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and
capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are not used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable results and must not be used.

Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- **Mode 2**
  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see Section 37.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- **Mode 1**
  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

  This mode can be supported by programming the following codes:
  - FS ≤ 0xFF
  - FE ≤ 0xFF
  - LS ≤ SAV (active)
  - LE ≤ EAV (active)

  An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example
FS = 0xA5
Unmask code for FS = 0x10
In this case the frame start code is embedded in the bit 4 of the frame start code.

37.3.7 DCMI capture modes
This interface supports two types of capture: snapshot (single frame) and continuous grab.

Snapshot mode (single frame)
In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

Continuous grab mode
In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
Figure 305. Frame capture waveforms in continuous grab mode

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, the FCRC[1:0] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

37.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

Figure 306. Coordinates and size of the window after cropping

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

**Figure 307. Data capture waveforms**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

### 37.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

### 37.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
37.3.11 DCMI data format description

Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

![Figure 308. Pixel raster scan order](image)

Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>n + 3</td>
<td>n + 2</td>
<td>n + 1</td>
<td>n</td>
</tr>
<tr>
<td>4</td>
<td>n + 7</td>
<td>n + 6</td>
<td>n + 5</td>
<td>n + 4</td>
</tr>
</tbody>
</table>

RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

### Table 335. Data storage in RGB progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Red n + 1</td>
<td>Green n + 1</td>
<td>Blue n + 1</td>
<td>Red n</td>
<td>Green n</td>
<td>Blue n</td>
</tr>
<tr>
<td>4</td>
<td>Red n + 4</td>
<td>Green n + 3</td>
<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

### Table 336. Data storage in YCbCr progressive video format

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Y n + 1</td>
<td>Cr n</td>
<td>Y n</td>
<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in *Table 337*.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

### 37.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>

</table>
37.5 DCMI registers

Refer to Section 1.2 on page 104 for list of abbreviations used in register descriptions. All DCMI registers must be accessed as 32-bit words, otherwise a bus error occurs.

37.5.1 DCMI control register (DCMI_CR)

Address offset: 0x00
Reset value: 0x0000 0000

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS**: Odd/Even Line Select (Line Select Start)

This bit works in conjunction with the LSM field (LSM = 1).
0: Interface captures first line after the frame start, second one being dropped.
1: Interface captures second line from the frame start, first one being dropped.

Bit 19 **LSM**: Line Select mode

0: Interface captures all received lines.
1: Interface captures one line out of two.

Bit 18 **OEB**: Odd/Even Byte Select (Byte Select Start)

This bit works in conjunction with BSM field (BSM ≠ 00).
0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

Bits 17:16 **BSM[1:0]**: Byte Select mode

00: Interface captures all received data.
01: Interface captures every other byte from the received data.
10: Interface captures one byte out of four.
11: Interface captures two bytes out of four.

*Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE**: DCMI enable

0: DCMI disabled
1: DCMI enabled

*Note: The DCMI configuration registers must be programmed correctly before enabling this bit.*

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:10  **EDM[1:0]:** Extended data mode

- 00: Interface captures 8-bit data on every pixel clock.
- 01: Interface captures 10-bit data on every pixel clock.
- 10: Interface captures 12-bit data on every pixel clock.
- 11: Interface captures 14-bit data on every pixel clock.

Bits 9:8  **FCRC[1:0]:** Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.

- 00: All frames are captured.
- 01: Every alternate frame captured (50% bandwidth reduction)
- 10: One frame out of four captured (75% bandwidth reduction)
- 11: reserved

Bit 7  **VSPOL:** Vertical synchronization polarity

This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.

- 0: DCMI_VSYNC active low
- 1: DCMI_VSYNC active high

Bit 6  **HSPOL:** Horizontal synchronization polarity

This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.

- 0: DCMI_HSYNC active low
- 1: DCMI_HSYNC active high

Bit 5  **PCKPOL:** Pixel clock polarity

This bit configures the capture edge of the pixel clock.

- 0: Falling edge active
- 1: Rising edge active

Bit 4  **ESS:** Embedded synchronization select

- 0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
- 1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

*Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.*

This bit is disabled in JPEG mode.

Bit 3  **JPEG:** JPEG format

- 0: Uncompressed video format
- 1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2  **CROP:** Crop feature

- 0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
- 1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1  **CM:** Capture mode

- 0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
- 1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
37.5.2  DCMI status register (DCMI_SR)

Address offset: 0x04
Reset value: 0x0000 0000

<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **FNE**: FIFO not empty
This bit gives the status of the FIFO.
1: FIFO contains valid data.
0: FIFO empty

Bit 1  **VSYNC**: Vertical synchronization
This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active frame
1: synchronization between frames
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

Bit 0  **HSYNC**: Horizontal synchronization
This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
0: active line
1: synchronization between lines
In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
37.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 LINE_RIS: Line raw interrupt status
This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.
It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

Bit 3 VSYNC_RIS: DCMI_VSYNC raw interrupt status
This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.
In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.
It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

Bit 2 ERR_RIS: Synchronization error raw interrupt status
0: No synchronization error detected
1: Embedded synchronization characters are not received in the correct order.
This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.
Note: This bit is available only in embedded synchronization mode.

Bit 1 OVR_RIS: Overrun raw interrupt status
0: No data buffer overrun occurred
1: A data buffer overrun occurred and the data FIFO is corrupted.
The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

Bit 0 FRAME_RIS: Capture complete raw interrupt status
0: No new capture
1: A frame has been captured.
This bit is set when a frame or window has been captured.
In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (e.g. window cropped outside the frame).
The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.
37.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Address offset: 0x0C
Reset value: 0x0000 0000

### 37.5.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10

Reset value: 0x0000 0000

</table>

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4** **LINE_MIS**: Line masked interrupt status
- This bit gives the status of the masked line interrupt.
- 0: No interrupt generation when the line is received
- 1: An interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

**Bit 3** **VSYNC_MIS**: VSYNC masked interrupt status
- This bit gives the status of the masked VSYNC interrupt.
- 0: No interrupt is generated on DCMI_VSYNC transitions.
- 1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.

The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

**Bit 2** **ERR_MIS**: Synchronization error masked interrupt status
- This bit gives the status of the masked synchronization error interrupt.
- 0: No interrupt is generated on a synchronization error.
- 1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.

_Note:_ This bit is available only in embedded synchronization mode.

**Bit 1** **OVR_MIS**: Overrun masked interrupt status
- This bit gives the status of the masked overflow interrupt.
- 0: No interrupt is generated on overrun.
- 1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

**Bit 0** **FRAME_MIS**: Capture complete masked interrupt status
- This bit gives the status of the masked capture complete interrupt
- 0: No interrupt is generated after a complete capture.
- 1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.
37.5.6  DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Address offset: 0x14
Reset value: 0x0000 0000

</table>

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **LINE_ISC**: line interrupt status clear
Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

Bit 3  **VSYNC_ISC**: Vertical Synchronization interrupt status clear
Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

Bit 2  **ERR_ISC**: Synchronization error interrupt status clear
Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.

*Note: This bit is available only in embedded synchronization mode.*

Bit 1  **OVR_ISC**: Overrun interrupt status clear
Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

Bit 0  **FRAME_ISC**: Capture complete interrupt status clear
Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

37.5.7  DCMI embedded synchronization code register (DCMI_ESCR)

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

1420/3040  RM0456 Rev 1
Bits 31:24 **FEC[7:0]**: Frame end delimiter code  
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.  
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code  
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code  
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code  
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.  
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

#### Bits 31:24 FEU[7:0]: Frame end delimiter unmask
This byte specifies the mask to be applied to the code of the frame end delimiter.
- 0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
- 1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

#### Bits 23:16 LEU[7:0]: Line end delimiter unmask
This byte specifies the mask to be applied to the code of the line end delimiter.
- 0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
- 1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

#### Bits 15:8 LSU[7:0]: Line start delimiter unmask
This byte specifies the mask to be applied to the code of the line start delimiter.
- 0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
- 1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.

#### Bits 7:0 FSU[7:0]: Frame start delimiter unmask
This byte specifies the mask to be applied to the code of the frame start delimiter.
- 0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
- 1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

| Bits 13:0  | HOFFCNT[13:0]: Horizontal offset count |
|           | This value gives the number of pixel clocks to count before starting a capture. |

37.5.11  DCMI data register (DCMI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

The digital camera interface packages all the received data in 32-bit format before requesting a DMA transfer. A 8-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

Refer to *Section 2.3* for the register boundary addresses.
38 Parallel synchronous slave interface (PSSI)

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see Section 38.3.2: PSSI pins and internal signals).

38.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

38.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output
  
  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

38.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

*Figure 309* shows the PSSI block diagram.
38.3.1 PSSI block diagram

![PSSI block diagram](image1)

![Top-level block diagram](image2)

38.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. Table 340 shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.

<td>Input</td>
<td>AHB clock</td>
</tr>
</tbody>
</table>

38.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

38.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:

- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly performs transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. Table 342 illustrates the positioning of the data bytes in two 32-bit words.

| Table 342. Positioning of captured data bytes in 32-bit words (8-bit width) |
|-------------------|---------------|-------------|-------------|-------------|
| Byte address      | 31:24         | 23:16       | 15:8        | 7:0         |
| 0                 | D_{n+3}[7:0]  | D_{n+2}[7:0] | D_{n+1}[7:0] | D_{n}[7:0]  |
| 4                 | D_{n+7}[7:0]  | D_{n+6}[7:0] | D_{n+5}[7:0] | D_{n+4}[7:0] |
16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 343 illustrates the positioning of the data in two 32-bit words.

Table 343. Positioning of captured data bytes in 32-bit words (16-bit width)

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

38.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

**Ready (PSSI_RDY) alternate function output**

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples
the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Figure 313. Ready in receive mode waveform diagram (CKPOL=0)

If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI_DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

Bidirectional PSSI_DE/PSSI_RDY signal

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.
38.4 PSSI interrupts

The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 344 for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

Bit 14 **ENABLE**: PSSI enable
- 0: PSSI disabled
- 1: PSSI enabled

The contents of the FIFO are flushed when ENABLE is cleared to 0.

**Note:** When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.

The ENABLE bit and the DTCI ENABLE bit (bit 15 of DTCI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode
- 00: Interface captures 8-bit data on every parallel data clock
- 01: Reserved, must not be selected
- 10: Reserved, must not be selected
- 11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL**: Ready (PSSI_RDY) polarity
- 0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)
- 1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL**: Data enable (PSSI_DE) polarity
- 0: PSSI_DE active low (0 indicates that data is valid)
- 1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL**: Parallel data clock polarity
- 0: Falling edge active for inputs or rising edge active for outputs
- 1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

Bits 31:2 Reserved, must be kept at reset value.

- Bit 1 **OVR_IE**: Data buffer overrun/underrun interrupt enable
  - 0: No interrupt generation
  - 1: An interrupt is generated if either an overrun or an underrun error occurred.

- Bit 0 Reserved, must be kept at reset value.

38.5.5 **PSSI masked interrupt status register (PSSI_MIS)**

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is

```markdown```

<table>
<thead>
<tr>
<th>31</th>

38.5.6 PSSI interrupt clear register (PSSI_ICR)

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_MIS**: Data buffer overrun/underrun masked interrupt status

This bit is set to 1 only when PSSI_IER/OVR_IE and PSSI_RIS/OVR_RIS are both set to 1.
0: No interrupt is generated when an overrun/underrun error occurs
1: An interrupt is generated if there is either an overrun or an underrun error and the OVR_IE bit is set in PSSI_IER.

Bit 0 Reserved, must be kept at reset value.

**38.5.6 PSSI interrupt clear register (PSSI_ICR)**

Address offset: 0x14
Reset value: 0x0000 0000

The PSSI_ICR register is write-only. Writing a 1 into a bit of this register clears the corresponding bit in the PSSI_RIS and PSSI_MIS registers. Writing a 0 has no effect. Reading this register always gives zeros.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OVR_ISC**: Data buffer overrun/underrun interrupt status clear

Writing this bit to 1 clears the OVR_RIS bit in PSSI_RIS.

Bit 0 Reserved, must be kept at reset value.
38.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN=0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN=1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

39 Touch sensing controller (TSC)

39.1 Introduction

The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

39.2 TSC main features

The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 24 capacitive sensing channels
- Up to 8 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library

Note: The number of capacitive sensing channels is dependent on the size of the packages and subject to IO availability.
39.3  TSC functional description

39.3.1  TSC block diagram

The block diagram of the touch sensing controller is shown in Figure 316.

Figure 316. TSC block diagram

39.3.2  Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see Figure 317). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor $C_S$. Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.
The surface charge transfer acquisition principle consists of charging an electrode capacitance \( C_X \) and transferring a part of the accumulated charge into a sampling capacitor \( C_S \). This sequence is repeated until the voltage across \( C_S \) reaches a given threshold \( V_{IH} \) in our case. The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

Table 346 details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across \( C_S \) reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor \( R_S \) improves the ESD immunity of the solution.

**Note:** \( Gx\_IOy \) where \( x \) is the analog I/O group number and \( y \) the GPIO number within the selected group.
The voltage variation over the time on the sampling capacitor CS is detailed below:

**Note:** Gx_IOy where x is the analog I/O group number and y the GPIO number within the selected group.

The voltage variation over the time on the sampling capacitor CS is detailed below:

**Figure 318. Sampling capacitor voltage variation**

39.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:

- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC_CR register
The Reset and Clock Controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to Section 11: Reset and clock control (RCC).

39.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in Figure 319.

**Figure 319. Charge transfer acquisition sequence**

For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of \( C_X \)) and the pulse low state (transfer of charge from \( C_X \) to \( C_S \)) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 µs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that \( C_X \) is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 2 periods of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.

The reading of the sampling capacitor I/O, to determine if the voltage across \( C_S \) has reached the given threshold, is performed at the end of the pulse low state.

**Note:** The following TSC control register configurations are forbidden:
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0000’
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0001’
- bits PGPSC are set to ‘001’ and bits CTPL are set to ‘0000’
39.3.5 Spread spectrum feature

The spread spectrum feature generates a variation of the charge transfer frequency. This is done to improve the robustness of the charge transfer acquisition in noisy environments and also to reduce the induced emission. The maximum frequency variation is in the range of 10% to 50% of the nominal charge transfer period. For instance, for a nominal charge transfer frequency of 250 kHz (4 µs), the typical spread spectrum deviation is 10% (400 ns) which leads to a minimum charge transfer frequency of ~227 kHz.

In practice, the spread spectrum consists of adding a variable number of SSCLK periods to the pulse high state using the principle shown below:

![Figure 320. Spread spectrum variation principle](MS30933V1)

The table below details the maximum frequency deviation with different HCLK settings:

<table>
<thead>
<tr>
<th>f_HCLK</th>
<th>Spread spectrum step</th>
<th>Maximum spread spectrum deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>24 MHz</td>
<td>41.6 ns</td>
<td>10666.6 ns</td>
</tr>
<tr>
<td>48 MHz</td>
<td>20.8 ns</td>
<td>5333.3 ns</td>
</tr>
</tbody>
</table>

The spread spectrum feature can be disabled/enabled using the SSE bit in the TSC_CR register. The frequency deviation is also configurable to accommodate the device HCLK clock frequency and the selected charge transfer frequency through the SSPSC and SSD[6:0] bits in the TSC_CR register.

39.3.6 Max count error

The max count error prevents long acquisition times resulting from a faulty capacitive sensing channel. It consists of specifying a maximum count value for the analog I/O group counters. This maximum count value is specified using the MCV[2:0] bits in the TSC_CR register. As soon as an acquisition group counter reaches this maximum value, the ongoing acquisition is stopped and the end of acquisition (EOAF bit) and max count error (MCEF bit) flags are both set. An interrupt can also be generated if the corresponding end of acquisition (EOAIE bit) or/and max count error (MCEIE bit) interrupt enable bits are set.
39.3.7 Sampling capacitor I/O and channel I/O mode selection

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC_IOSCR and TSC_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

Table 348. I/O state depending on its mode and IODEF bit value

<table>
<thead>

<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Unused I/O mode

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

Sampling capacitor I/O mode

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx_IOy bit in the TSC_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

Channel I/O mode

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx_IOy bit in the TSC_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

Note: During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR or TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.
39.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC_IOGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The CS voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the CS voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC_IOGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC_ISR register is set. An interrupt request is generated if the EOAIE bit in the TSC_IER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAIE and MCEIE bits of the TSCIER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAIC and MCEIC bits in the TSC_ICR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

39.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller is able to take the control of the Schmitt trigger hysteresis and analog switch of each Gx_IOy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx_IOy bit in the TSC_IOHCR register.

Bits 31:28 **CTPH[3:0]**: Charge transfer pulse high

These bits are set and cleared by software. They define the duration of the high state of the charge transfer pulse (charge of C_X).

- 0000: 1x t_PGCLK
- 0001: 2x t_PGCLK
- ...
- 1111: 16x t_PGCLK

*Note: These bits must not be modified when an acquisition is ongoing.*

Bits 27:24 **CTPL[3:0]**: Charge transfer pulse low

These bits are set and cleared by software. They define the duration of the low state of the charge transfer pulse (transfer of charge from C_X to C_S).

- 0000: 1x t_PGCLK
- 0001: 2x t_PGCLK
- ...
- 1111: 16x t_PGCLK

*Note: These bits must not be modified when an acquisition is ongoing.*

*Note: Some configurations are forbidden. Refer to the Section 39.3.4: Charge transfer acquisition sequence for details.*

Bits 23:17 **SSD[6:0]**: Spread spectrum deviation

These bits are set and cleared by software. They define the spread spectrum deviation which consists in adding a variable number of periods of the SSCLK clock to the charge transfer pulse high state.

- 0000000: 1x t_SSCLK
- 0000001: 2x t_SSCLK
- ...
- 1111111: 128x t_SSCLK

*Note: These bits must not be modified when an acquisition is ongoing.*
Bit 16 **SSE**: Spread spectrum enable
This bit is set and cleared by software to enable/disable the spread spectrum feature.
0: Spread spectrum disabled
1: Spread spectrum enabled
*Note*: This bit must not be modified when an acquisition is ongoing.

Bit 15 **SSPSC**: Spread spectrum prescaler
This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).
0: \( f_{\text{HCLK}} \)
1: \( f_{\text{HCLK}} /2 \)
*Note*: This bit must not be modified when an acquisition is ongoing.

Bits 14:12 **PGPSC[2:0]**: Pulse generator prescaler
These bits are set and cleared by software. They select the AHB clock divider used to generate the pulse generator clock (PGCLK).
000: \( f_{\text{HCLK}} \)
001: \( f_{\text{HCLK}} /2 \)
010: \( f_{\text{HCLK}} /4 \)
011: \( f_{\text{HCLK}} /8 \)
100: \( f_{\text{HCLK}} /16 \)
101: \( f_{\text{HCLK}} /32 \)
110: \( f_{\text{HCLK}} /64 \)
111: \( f_{\text{HCLK}} /128 \)
*Note*: These bits must not be modified when an acquisition is ongoing.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:5 **MCV[2:0]**: Max count value
These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.
000: 255
001: 511
010: 1023
011: 2047
100: 4095
101: 8191
110: 16383
111: reserved
*Note*: These bits must not be modified when an acquisition is ongoing.

Bit 4 **IODEF**: I/O Default mode
This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).
0: I/Os are forced to output push-pull low
1: I/Os are in input floating
*Note*: This bit must not be modified when an acquisition is ongoing.

Bit 3 **SYNCPOL**: Synchronization pin polarity
This bit is set and cleared by software to select the polarity of the synchronization input pin.
0: Falling edge only
1: Rising edge and high level
39.6.2 **TSC interrupt enable register (TSC_IER)**

Address offset: 0x04

Reset value: 0x0000 0000

</table>

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 MCEIE**: Max count error interrupt enable

This bit is set and cleared by software to enable/disable the max count error interrupt.

- 0: Max count error interrupt disabled
- 1: Max count error interrupt enabled

**Bit 0 EOAIE**: End of acquisition interrupt enable

This bit is set and cleared by software to enable/disable the end of acquisition interrupt.

- 0: End of acquisition interrupt disabled
- 1: End of acquisition interrupt enabled
### 39.6.3 TSC interrupt clear register (TSC_ICR)

Address offset: 0x08  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:2</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 1     | **MCEIC**: Max count error interrupt clear  
        | This bit is set by software to clear the max count error flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.  
        | 0: No effect  
        | 1: Clears the corresponding MCEF of the TSC_ISR register |
| Bit 0     | **EOAIC**: End of acquisition interrupt clear  
        | This bit is set by software to clear the end of acquisition flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.  
        | 0: No effect  
        | 1: Clears the corresponding EOAF of the TSC_ISR register |
### 39.6.4 TSC interrupt status register (TSC_ISR)

Address offset: 0x0C  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

</table>

- **Bits 31:2**: Reserved, must be kept at reset value.
- **Bit 1 MCEF**: Max count error flag
  - This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC_ICR register.
  - 0: No max count error (MCE) detected
  - 1: Max count error (MCE) detected
- **Bit 0 EOAF**: End of acquisition flag
  - This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC_ICR register.
  - 0: Acquisition is ongoing or not started
  - 1: Acquisition is complete

### 39.6.5 TSC I/O hysteresis control register (TSC_IOHCR)

- **Bits 31:0 Gx_IOy**: Gx_IOy Schmitt trigger hysteresis mode
  - These bits are set and cleared by software to enable/disable the Gx_IOy Schmitt trigger hysteresis.
  - 0: Gx_IOy Schmitt trigger hysteresis disabled
  - 1: Gx_IOy Schmitt trigger hysteresis enabled

**Note**: These bits control the I/O Schmitt trigger hysteresis whatever the I/O control mode is (even if controlled by standard GPIO registers).
39.6.6 TSC I/O analog switch control register (TSC_IOASCR)

Address offset: 0x18
Reset value: 0x0000 0000

Bits 31:0 Gx_IOy: Gx_IOy analog switch enable
These bits are set and cleared by software to enable/disable the Gx_IOy analog switch.
0: Gx_IOy analog switch disabled (opened)
1: Gx_IOy analog switch enabled (closed)

Note: These bits control the I/O analog switch whatever the I/O control mode is (even if controlled by standard GPIO registers).

39.6.7 TSC I/O sampling control register (TSC_IOSCR)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:0 Gx_IOy: Gx_IOy sampling mode
These bits are set and cleared by software to configure the Gx_IOy as a sampling capacitor I/O. Only one I/O per analog I/O group must be defined as sampling capacitor.
0: Gx_IOy unused
1: Gx_IOy used as sampling capacitor

Note: These bits must not be modified when an acquisition is ongoing.
During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.
39.6.8  TSC I/O channel control register (TSC_IOCCR)

Address offset: 0x28
Reset value: 0x0000 0000

Bits 31:0  Gx_IOy: Gx_IOy channel mode
These bits are set and cleared by software to configure the Gx_IOy as a channel I/O.
0: Gx_IOy unused
1: Gx_IOy used as channel
Note: These bits must not be modified when an acquisition is ongoing.

During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

39.6.9  TSC I/O group control status register (TSC_IOGCSR)

</table>

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  GxS: Analog I/O group x status
These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started.
0: Acquisition on analog I/O group x is ongoing or not started
1: Acquisition on analog I/O group x is complete
Note: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  GxE: Analog I/O group x enable
These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x.
0: Acquisition on analog I/O group x disabled
1: Acquisition on analog I/O group x enabled
### 39.6.10 TSC I/O group x counter register (TSC\_IOG\_xCR)

x represents the analog I/O group number.

Address offset: 0x30 + 0x04 * x, (x = 1..8)

Reset value: 0x0000 0000

Bits 31:14  Reserved, must be kept at reset value.

Bits 13:0  CNT[13:0]: Counter value

These bits represent the number of charge transfer cycles generated on the analog I/O group x to complete its acquisition (voltage across CS has reached the threshold).

Refer to Section 2.3 on page 116 for the register boundary addresses.
40 True random number generator (RNG)

40.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a non-deterministic random bit generator (NDRBG).

The RNG true random number generator has been pre-certified NIST SP800-90B. It has also been tested using German BSI statistical tests of AIS-31 (T0 to T8).

40.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as entropy source to construct a non-deterministic random bit generator (NDRBG).
- It produces four 32-bit random samples every 412 AHB clock cycles if $f_{AHB} < 77$ MHz (256 RNG clock cycles otherwise).
- It embeds start-up and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
40.3 RNG functional description

40.3.1 RNG block diagram

*Figure 321* shows the RNG block diagram.

![RNG block diagram]

40.3.2 RNG internal signals

</tr>
</tbody>
</table>
40.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 322. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

Figure 322. NIST SP800-90B entropy source model

The components pictured above are detailed hereafter:

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 40.3.8: RNG low-power usage.
- The XORing of the six noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (\texttt{rng_clk} with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (\texttt{rng_hclk}), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

Note: In Section 40.6: RNG entropy source validation recommended RNG clock frequencies and associated divider value are given.
**Post processing**

In NIST configuration no post-processing is applied to sampled noise source. In non-NIST configuration B (as defined in Section 40.6.2) a normalization debiasing is applied, i.e. half of the bits are taken from the sampled noise source, half of the bits are taken from inverted sampled noise source.

**Conditioning**

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 40.5: RNG processing time.

**Output buffer**

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 40.5: RNG processing time.

Whenever a random number is available through the RNG_DR register the DRDY flag transitions from 0 to 1. This flag remains high until output buffer becomes empty after reading four words from the RNG_DR register.

*Note:* When interrupts are enabled an interrupt is generated when this data ready flag transitions from 0 to 1. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (in Section 40.6.2).

1. Start-up health tests, performed after reset and before the first use of the RNG as entropy source
   - Adaptive proportion test running on one 1024 bit windows: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 691 times.
   - Known-answer tests, to verify the conditioning stage.
   - Repetition count test, flagging an error when the noise source has provided more than 40 consecutive bits at a constant value (0 or 1)

2. Continuous health tests, running indefinitely on the outputs of the noise source
   - Repetition count test, similar to the one running in start-up tests
   - Adaptive proportion test running on 1024 consecutive samples, like during start-up health tests.

3. Vendor specific continuous tests
   - Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrence of two bits patterns (01 or 10).
   - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and re-running the startup tests (see software reset sequence in Section 40.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 40.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

Above health test thresholds are modified by changing value in RNG_HTCR register. See Section 40.6: RNG entropy source validation for details.
40.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 323

After enabling the RNG (RNGEN = 1 in RNG_Cr) the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample analog output and filling 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering start-up behavior test on the raw data samples and known-answer tests.
3. When start-up health tests are completed. During this time three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 40.5: RNG processing time.

Figure 323. RNG initialization overview
Figure 323 also highlights a possible software reset sequence, implemented by:

a) Writing bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.

b) Then writing RNGEN = 1 and CONDRST = 0 in the RNG_CR register.

c) Wait for random number to be ready, after initialization completes.

Note: When RNG peripheral is reset through RCC (hardware reset) the RNG configuration for optimal randomness is lost in RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

40.3.5 RNG operation

Normal operations

To run the RNG using interrupts the following steps are recommended:

1. Consult the Section 40.6: RNG entropy source validation on page 1469 and verify if a specific RNG configuration is required for your application.
   - If it is the case, write in the RNG_CR register the bit CONDRST = 1 together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0, the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.
   - If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE = 1 and the RNG enable bit RNGEN = 1.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 40.3.7 must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult the Section 40.6: RNG entropy source validation on page 1469 and verify if a specific RNG configuration is required for your application.
   - If it is the case write in the RNG_CR register the bit CONDRST = 1 together with the correction RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If it is not the case only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.

2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)

3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 40.3.7 must be used.

Note: When data is not ready (DRDY = 0) RNG_DR returns zero. It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 40.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 40.5: RNG processing time.

Low-power operations

If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 40.3.8: RNG low-power usage.

Software post-processing

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in Section 40.3.3: Random number generation.

40.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in Section 40.6: RNG entropy source validation.

Note: When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before internal divider must be higher than AHB clock frequency divided by 32, otherwise the clock checker always flags a clock error (CECS = 1 in the RNG_SR register).

See Section 40.3.1: RNG block diagram for details (AHB and RNG clock domains).

40.3.7 Error management

In parallel to random number generation an health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application should check that the RNG clock is configured correctly (see Section 40.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when clocking condition is normal.

Note: The clock error has no impact on generated random numbers, i.e. application can still read RNG_DR register.
CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection
When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy.

The following sequence must be used to fully recover from a seed error:
1. Software reset by writing CONDRST at 1 and at 0 (see bitfield description for details). This step is needed only if SECS is set. Indeed, when SEIS is set and SECS is cleared it means RNG performed the reset automatically (auto-reset).
2. If SECS was set in step 1 (no auto-reset) wait for CONDRST to be cleared in the RNG_CR register, then confirm that SEIS is cleared in the RNG_SR register. Otherwise just clear SEIS bit in the RNG_SR register.
3. If SECS was set in step 1 (no auto-reset) wait for SECS to be cleared by RNG. The random number generation is now back to normal.

Note: After a seed error RNG restarts generating random numbers when SECS is cleared. When application sets ARDIS bit in RNG_CR register auto-reset is disabled. CONDRST must be used in step 1.

RNG tamper errors
When an unexpected error is found by the RNG an internal tamper event is triggered in TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, secure application needs to reset the RNG peripheral either using the central reset management or the global SoC reset. Then a proper initialization of the RNG is required, again.

40.3.8 RNG low-power usage
If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN = 0 following features are available to software:
- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case RNG must be re-enabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode) and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in Section 40.5: RNG processing time on page 1469.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.
If the RNG block is disabled during initialization (i.e. well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when RNGEN bit is set to 1, unless the application resets the conditioning logic using CONDRST bit in the RNG_CR register.

### 40.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 40.3.7: Error management
- Clock error, see Section 40.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 353.

#### Table 353. RNG interrupt requests

<table>
<thead>
<tr>
<th>Interrupt acronym</th>

</tr>
<tr>
<td></td>
<td>Clock error flag</td>
<td>CEIS</td>
<td>IE</td>
<td>Write 0 to CEIS</td>
</tr>
</tbody>
</table>

The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

*Note: Interrupts are generated only when RNG is enabled.*

### 40.5 RNG processing time

In NIST compliant configuration, the time between two sets of four 32-bit data is either:

- 412 AHB cycles if $f_{AHB} < f_{\text{threshold}}$ (conditioning stage is limiting), or
- 256 RNG cycles $f_{AHB} \geq f_{\text{threshold}}$ (noise source stage is limiting).

With $f_{\text{threshold}} = 1.6 \times f_{RNG}$, e.g. 77 MHz if $f_{RNG}= 48$ MHz.

*Note: When CLKDIV is different from zero, $f_{RNG}$ must take into account the internal divider ratio.*

### 40.6 RNG entropy source validation

#### 40.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite. The results can be provided on demand or the customer can reproduce the tests.
40.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:
- RNG clock rng_clk= 48 MHz
- RNG configurations described in Table 354. Note that only configuration A can be certified NIST SP800-90B.

40.6.3 Data collection

In order to run statistical tests it is required to collect samples from the entropy source at raw data level as well as at the output of the entropy source. For details on data collection and the running of statistical test suites refer to “STM32 microcontrollers random number generation validation using NIST statistical test suite” application note (AN4230) available from [www.st.com](http://www.st.com).

Contact STMicroelectronics if above samples need to be retrieved for your product.

40.7 RNG registers

The RNG is associated with a control register, a data register and a status register.

40.7.1 RNG control register (RNG_CR)

Bit 31  **CONFIGLOCK**: RNG Config lock
0: Writes to the RNG_CR configuration bits [29:4] are allowed.
1: Writes to the RNG_CR configuration bits [29:4] are ignored until the next RNG reset.
This bitfield is set once: if this bit is set it can only be reset to 0 if RNG is reset.

Bit 30  **CONDRST**: Conditioning soft reset
Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new
RNG initialization process, with RNG_SR cleared. Registers RNG_CR and RNG_NSCR are
not changed by CONDRST.
This bit must be set to 1 in the same access that set any configuration bits [29:4]. In other
words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be
written.
When CONDRST is set to 0 by software its value goes to 0 when the reset process is done.
It takes about 2 AHB clock cycles + 2 RNG clock cycles.

Bits 29:26  Reserved, must be kept at reset value.

Bits 25:20  **RNG_CONFIG1[5:0]**: RNG configuration 1
Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended
value documented in *Section 40.6: RNG entropy source validation*.
Writing any bit of RNG_CONFIG1 is taken into account only if CONDRST bit is set to 1 in the
same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if
CONFIGLOCK = 1.

Bits 19:16  **CLKDIV[3:0]**: Clock divider factor
This value used to configure an internal programmable divider (from 1 to 16) acting on the
incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).
0x0: internal RNG clock after divider is similar to incoming RNG clock.
0x1: two RNG clock cycles per internal RNG clock.
... 0xF: $2^{15}$ RNG clock cycles per internal clock (for example. an incoming 48MHz RNG clock
becomes a 1.5 kHz internal RNG clock)
Writing these bits is taken into account only if CONDRST bit is set to 1 in the same access,
while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 15:13  **RNG_CONFIG2[2:0]**: RNG configuration 2
Reserved to the RNG configuration (bitfield 2). Refer to RNG_CONFIG1 bitfield for details.

Bit 12  **NISTC**: Non NIST compliant
0: Hardware default values for NIST compliant RNG. In this configuration per 128-bit output
two conditioning loops are performed and 512 bits of noise source are used.
1: Custom values for NIST compliant RNG. See *Section 40.6: RNG entropy source
validation* for proposed configuration.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access,
while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bits 11:8  **RNG_CONFIG3[3:0]**: RNG configuration 3
Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details.
If NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7  **ARDIS**: Auto reset disable
0: When a noise source error occurs RNG performs an automatic reset to clear SECS bit.
1: When a noise source error occurs application must reset RNG by writing CONDRST to 1
then to 0, in order to restart random number generation.
When auto-reset is enabled application still need to clear SEIS bit after a noise source error.
Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access,
while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.
Bit 6  Reserved, must be kept at reset value.

Bit 5  CED: Clock error detection
      0: Clock error detection is enable
      1: Clock error detection is disable
      The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, i.e. to enable or disable CED the RNG must be disabled.
      Writing this bit is taken into account only if CONDRST bit is set to 1 in the same access, while CONFIGLOCK remains at 0. Writing to this bit is ignored if CONFIGLOCK = 1.

Bit 4  Reserved, must be kept at reset value.

Bit 3  IE: Interrupt Enable
      0: RNG Interrupt is disabled
      1: RNG Interrupt is enabled. An interrupt is pending as soon as DRDY = 1, SEIS = 1 or CEIS = 1 in the RNG_SR register.

Bit 2  RNGEN: True random number generator enable
      0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
      1: True random number generator is enabled.

Bits 1:0  Reserved, must be kept at reset value.
40.7.2 RNG status register (RNG_SR)

Address offset: 0x004
Reset value: 0x0000 0000

<table>

Bits 31:0 **RNDATA[31:0]**: Random data
32-bit random data which are valid when DRDY = 1. When DRDY = 0 RNDATA value is zero.
It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

40.7.4 **RNG health test control register (RNG_HTCR)**

Address offset: 0x010
Reset value: 0x000072AC

Writing in RNG_HTCR is taken into account only if CONDRST bit is set, and CONFIGLOCK bit is cleared in RNG_CR. Writing to this register is ignored if CONFIGLOCK=1.

Refer to Section 2.3 for the register boundary addresses.
41 AES hardware accelerator (AES)

41.1 Introduction

The AES hardware accelerator (AES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197.

The peripheral supports CTR, GCM, GMAC, CCM, ECB, and CBC chaining modes for key sizes of 128 or 256 bits.

AES is an AMBA AHB slave peripheral accessible through 32-bit single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels required).

41.2 AES main features

- Compliance with NIST “Advanced encryption standard (AES), FIPS publication 197” from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated round key scheduler to compute the last round key for ECB/CBC decryption
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit write-only register for storing the cryptographic key (eight 32-bit registers)
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if AES needs to process another message with a higher priority, then resume the original message
- Hardware key sharing with side-channel resistant SAES peripheral (Shared-key mode), controlled by SAES
41.3 AES implementation

The devices have one AES and one SAES peripheral, implemented as shown in the following table.

<table>

41.4 AES functional description

41.4.1 AES block diagram

*Figure 324* shows the block diagram of AES.

![Figure 324. AES block diagram](image)

41.4.2 AES internal signals

*Table 357* describes the user relevant internal signals interfacing the AES peripheral.
The AES cryptographic core consists of the following components:

- AES core algorithm (AEA)
- multiplier over a binary Galois field (GF2mul)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the AES requires zero or one 128-bit initialization vector IV.

The AES features the following modes of operation:

- **Mode 1:** Plaintext encryption using a key stored in the AES_KEYRx registers
- **Mode 2:** ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the AES_KEYRx registers. Now the AES peripheral is ready to switch to Mode 3 for executing data decryption.
- **Mode 3:** Ciphertext decryption using a key stored in the AES_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.

**Note:** *Mode 2 is only used when performing ECB and CBC decryption.*

The operating mode is selected by programming the MODE[1:0] bitfield of the AES_CR register. It may be done only when the AES peripheral is disabled.

Special key operation is selected using the KMOD[1:0] bitfield of the AES_CR register. See Section 41.4.13 for details.
Typical data processing

Typical usage of the AES is described in Section 41.4.4: AES procedure to perform a cipher operation on page 1483.

Note: The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IVI bitfield.

Chaining modes

The following chaining modes are supported by AES, selected through the CHMOD[2:0] bitfield of the AES_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)
- Counter (CTR)
- Galois counter mode (GCM)
- Galois message authentication code (GMAC)
- Counter with CBC-MAC (CCM)

Note: The chaining mode may be changed only when AES is disabled (bit EN of the AES_CR register cleared).

Principle of each AES chaining mode is provided in the following subsections.

Detailed information is in dedicated sections, starting from Section 41.4.8: AES basic chaining modes (ECB, CBC).

Electronic codebook (ECB) mode

Figure 325. ECB encryption and decryption principle
ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

**Note:** For decryption, a special key scheduling is required before processing the first block.

**Cipher block chaining (CBC) mode**

Figure 326. CBC encryption and decryption principle

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

**Note:** For decryption, a special key scheduling is required before processing the first block.
Counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation*.

**Note:** Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the key stream, or counter blocks.
Galois/counter mode (GCM)

In Galois/counter mode (GCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

Galois message authentication code (GMAC) principle

Galois message authentication code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload).

Counter with CBC-MAC (CCM) principle

In Counter with cipher block chaining-message authentication code (CCM) mode, the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in *Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM, the CCM chaining mode can be applied on a message composed only by plaintext authenticated data (that is, only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its use is not recommended by NIST.

41.4.4 AES procedure to perform a cipher operation

Introduction

A typical cipher operation is explained below. Detailed information is provided in sections starting from *Section 41.4.8: AES basic chaining modes (ECB, CBC)*.
Initialization of AES

To initialize AES, first disable it by clearing the EN bit of the AES_CR register. Then perform the following steps in any order:

- Configure the AES mode, by programming the MODE[1:0] bitfield of the AES_CR register.
  - For encryption, select Mode 1 (MODE[1:0] = 00).
  - For decryption, select Mode 3 (MODE[1:0] = 10), unless ECB or CBC chaining modes are used. In this latter case, perform an initial key derivation of the encryption key, as described in Section 41.4.5: AES decryption round key preparation.

- Select the chaining mode, by programming the CHMOD[2:0] bitfield of the AES_CR register.

- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the AES_CR register.

- When it is required (for example in CBC or CTR chaining modes), write the initialization vector into the AES_IVRx registers.

- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the AES_CR register. This step must be done before writing into key registers.

- Write a symmetric key into the AES_KEYRx registers (4 or 8 registers depending on the key size).

Note: AES sets KEYVALID in AES_SR when key information defined by KEYSIZE is loaded in AES_KEYRx.

Data append

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits when KMOD[1:0] = 00. For other KMOD values refer to Section 41.4.13.

For ECB or CBC mode, refer to Section 41.4.6: AES ciphertext stealing and data padding. The last block management in these cases is more complex than in the sequence described in this section.

Data append through polling

This method uses flag polling to control the data append through the following sequence:

1. Enable the AES peripheral by setting the EN bit of the AES_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_SR, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag.
3. As it is the last block, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register.
Note: **Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.**

**NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.**

**Data append using interrupt**

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES by setting the CCFIE bit of the AES_IER register.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine, upon interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the data block just processed is the second-last block of a message and the significant data in the last block to process is inferior to 128 bits, pad the remainder of the last block with zeros and, in case of GCM payload encryption or CCM payload decryption, specify the number of non-valid bytes, using the NPBLB bitfield of the AES_CR register, for AES to compute a correct tag. Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, discard the data that is not part of the data, then disable the AES peripheral by clearing the EN bit of the AES_CR register and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: **AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations. NPBLB bits are not used in header phase of GCM, GMAC and CCM chaining modes.**

**Data append using DMA**

With this method, all the transfers and processing are managed by DMA and AES. To use the method, proceed as follows:

1. Prepare the last four-word data block (if the data to process does not fill it completely), by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in Section 41.4.17: AES DMA interface. Configure the DMA controller so as to generate an interrupt on transfer completion. In case of GCM payload encryption or CCM payload decryption, DMA transfer must not include the last four-word block if padded with zeros. The sequence described in Data append through polling must be used instead for this last block, because NPBLB bits must be setup before processing the block, for AES to compute a correct tag.
3. Enable the AES peripheral by setting the EN bit of the AES_CR register.
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.
Note: The CCF flag has no use with this method, because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

NPBLB bits are not used in header phase of GCM, GMAC, and CCM chaining modes.

41.4.5 AES decryption round key preparation

Internal key schedule is used to generate AES round keys. In AES encryption, the round 0 key is the one stored in the key registers. AES decryption must start using the last round key. As the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key. This key scheduling is only required for AES decryption in ECB and CBC modes.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the AES_CR. The CHMOD[2:0] bitfield is not significant in this case because this key derivation mode is independent of the chaining algorithm selected. Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD values, refer to Section 41.4.13.
3. Set key length to 128 or 256 bits, via KEYSIZE bit of AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key. Writes to the AES_IVRx registers have no effect.
5. Enable the AES peripheral, by setting the EN bit of the AES_CR register.
6. Wait until the CCF flag is set in the AES_SR register.
7. Clear the CCF flag. Derived key is available in AES core, ready to use for decryption.

Note: The AES is disabled by hardware when the derivation key is available.

To restart a derivation key computation, repeat steps 4, 5, 6, and 7.

Note: The operation of the key preparation lasts 59 or 82 clock cycles, depending on the key size (128- or 256-bit).

41.4.6 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the AES peripheral does not support such techniques, the application must complete the last block of input data using data from the second last block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when AES is used in other modes than ECB or CBC, an incomplete input data block (that is, block with input data shorter than 128 bits) must be padded with zeros prior to encryption (that is, extra bits must be appended to the trailing end of the data string). After decryption, the extra bits must be discarded. As AES does not implement automatic data padding operation to the last block, the application must follow the recommendation given in Section 41.4.4: AES procedure to perform a cipher operation on page 1483 to manage messages the size of which is not a multiple of 128 bits.
Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the AES_CR register (see Section 41.4.14: AES data registers and data swapping for details).

41.4.7 AES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as AES is enabled again to receive the next data block. 

*Figure 331* gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

![Figure 331. Example of suspend mode management](image)

A detailed description of suspend/resume operations is in the sections dedicated to each AES mode.

41.4.8 AES basic chaining modes (ECB, CBC)

**Overview**

This section gives a brief explanation of the four basic operation modes provided by the AES core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.
Figure 332 illustrates the electronic codebook (ECB) encryption.

In ECB encrypt mode, the 128-bit plaintext input data block P\(_x\) in the AES_DINR register first goes through bit/byte/half-word swapping. The swap result I\(_x\) is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result O\(_x\) goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit ciphertext output data block C\(_x\). The ECB encryption continues in this way until the last complete plaintext block is encrypted.

Figure 333 illustrates the electronic codebook (ECB) decryption.

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.

In ECB decrypt mode, the 128-bit ciphertext input data block C\(_1\) in the AES_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result I\(_1\) is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the AES_DOUTR register as 128-bit plaintext output data block P\(_1\). The ECB decryption continues in this way until the last complete ciphertext block is decrypted.
Figure 334 illustrates the cipher block chaining (CBC) encryption.

**Figure 334. CBC encryption**

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping (P1'), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the I1 input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block O1, after swapping operation, is used as ciphertext C1. The O1 data is then XOR-ed with the second-block plaintext data P2' to produce the I2 input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in Section 41.4.6: AES ciphertext stealing and data padding.

Figure 335 illustrates the cipher block chaining (CBC) decryption.

**Figure 335. CBC decryption**

In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IVI field (that must be identical to that used during encryption) to produce the first plaintext block P1.
The second ciphertext block is processed in the same way as the first block, except that the I1 data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted.

If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in Section 41.4.6: AES ciphertext stealing and data padding.

For more information on data swapping, refer to Section 41.4.14: AES data registers and data swapping.

**ECB/CBC encryption sequence**

The sequence of events to perform an ECB/CBC encryption (more detail in Section 41.4.4):

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select the Mode 1 by setting to 00 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. Select normal key mode by setting KMOD[1:0] to 00. For encryption with other KMOD values, refer to Section 41.4.13.
3. Select 128- or 256-bit key length through the KEYSIZE bit of the AES_CR register.
4. Write the AES_KEYRx registers (128 or 256 bits) with encryption key. Fill the AES_IVRx registers with the initialization vector data if CBC mode has been selected.
5. Enable the AES peripheral by setting the EN bit of the AES_CR register.
6. Write the AES_DINR register four times to input the plaintext (MSB first), as shown in Figure 336.
7. Wait until the CCF flag is set in the AES_SR register.
8. Read the AES_DOUTR register four times to get the ciphertext (MSB first) as shown in Figure 336. Then clear the CCF flag by setting the CCF bit of the AES_ICR register.
9. Repeat steps 6-7-8 to process all the blocks with the same encryption key.

**Figure 336. ECB/CBC encryption (Mode 1)**

**ECB/CBC decryption sequence**

The sequence of events to perform an AES ECB/CBC decryption is as follows (More detail in Section 41.4.4). Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD values, refer to Section 41.4.13.
1. Follow the steps described in Section 41.4.5: AES decryption round key preparation, in order to prepare the decryption key in AES core.

2. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the AES_CR register and select ECB or CBC chaining mode by setting the CHMOD[2:0] bitfield of the AES_CR register to 000 or 001, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. KEYSIZE bitfield must be kept as-is.

3. Write the AES_IVRx registers with the initialization vector (required in CBC mode only).

4. Enable AES by setting the EN bit of the AES_CR register.

5. Write the AES_DINR register four times to input the cipher text (MSB first), as shown in Figure 337.

6. Wait until the CCF flag is set in the AES_SR register.

7. Read the AES_DOUTR register four times to get the plain text (MSB first), as shown in Figure 337. Then clear the CCF flag by setting the CCF bit of the AES_ICR register.

8. Repeat steps 5-6-7 to process all the blocks encrypted with the same key.

---

**Suspend/resume operations in ECB/CBC modes**

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register.

2. If DMA is not used, read four times the AES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. If DMA is not used, poll the CCF flag of the AES_SR register until it becomes 1 (computation completed).

4. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

5. Save initialization vector registers (only required in CBC mode as AES_IVRx registers are altered during the data processing).

6. Disable the AES peripheral by clearing the bit EN of the AES_CR register.

7. Save the AES_CR register and clear the key registers if they are not needed, to process the higher priority message.

8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).
To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
3. Restore AES_CR register (with correct KEYSIZE) then restore AES_KEYRx registers.
4. Prepare the decryption key as described in Section 41.4.5: AES decryption round key preparation (only required for ECB or CBC decryption).
5. Restore AES_IVRx registers using the saved configuration (only required in CBC mode).
6. Enable the AES peripheral by setting the EN bit of the AES_CR register.
7. If DMA is used, enable AES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the AES_CR register.

### 41.4.9 AES counter (CTR) mode

#### Overview

The counter mode (CTR) uses AES as a key-stream generator. The generated keys are then XOR-ed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation. A typical message construction in CTR mode is given in Figure 338.

![Figure 338. Message construction in CTR mode](MSv42156V1)

The structure of this message is:

- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.
CTR encryption and decryption

Figure 339 and Figure 340 describe the CTR encryption and decryption process, respectively, as implemented in the AES peripheral. The CTR mode is selected by writing 010 to the CHMOD[2:0] bitfield of AES_CR register.

In CTR mode, the cryptographic core output (also called keystream) Ox is XOR-ed with relevant input block (Px' for encryption, Cx' for decryption), to produce the correct output block (Cx' for encryption, Px' for decryption). Initialization vectors in AES must be initialized as shown in Table 358.

Table 358. CTR mode initialization vector definition

<table>
<thead>
<tr>
<th>AES_IVR3[31:0]</th>
<th>AES_IVR2[31:0]</th>
<th>AES_IVR1[31:0]</th>
<th>AES_IVR0[31:0]</th>
</tr>
</thead>
</table>

32-bit counter = 0x00001
Unlike in CBC mode that uses the AES_IVRx registers only once when processing the first data block, in CTR mode AES_IVRx registers are used for processing each data block, and the AES peripheral increments the counter bits of the initialization vector (leaving the nonce bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that is then XOR-ed with the plaintext (CTR encryption) or ciphertext (CTR decryption) input. In CTR mode, the MODE[1:0] bitfield setting 01 (key derivation) is forbidden and all the other settings default to encryption mode.

The sequence of events to perform an encryption or a decryption in CTR chaining mode:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CTR chaining mode by setting to 010 the CHMOD[2:0] bitfield of the AES_CR register. Set MODE[1:0] bitfield to any value other than 01.
3. Initialize the AES_KEYRx registers, and load the AES_IVRx registers as described in Table 358.
4. Set the EN bit of the AES_CR register, to start encrypting the current counter (EN is automatically reset when the calculation finishes).
5. If it is the last block, pad the data with zeros to have a complete block, if needed.
6. Append data in AES, and read the result. The three possible scenarios are described in Section 41.4.4: AES procedure to perform a cipher operation.
7. Repeat the previous step till the second-last block is processed. For the last block, apply the two previous steps and discard the bits that are not part of the payload (if the size of the significant data in the last input block is less than 16 bytes).

**Suspend/resume operations in CTR mode**

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message that was interrupted. Detailed CBC suspend/resume sequence is described in Section 41.4.8: AES basic chaining modes (ECB, CBC).

**Note:** Like for CBC mode, the AES_IVRx registers must be reloaded during the resume operation.

### 41.4.10 AES Galois/counter mode (GCM)

**Overview**

The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 341.
The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV)**: a 96-bit value that must be unique for each encryption cycle with a given key. Note that the GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- **Authenticated header AAD** (also known as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} - 1$ bits. This part of the message is only authenticated, not encrypted.

- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2^{128}$ blocks.

- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in Table 359.

The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

</table>
GCM processing

Figure 342 describes the GCM implementation in the AES peripheral. The GCM is selected by writing 011 to the CHMOD[2:0] bitfield of the AES_CR register.

Figure 342. GCM authenticated encryption

The mechanism for the confidentiality of the plaintext in GCM mode is similar to that in the Counter mode, with a particular increment function (denoted 32-bit increment) that generates the sequence of input counter blocks.

AES_IVRx registers keeping the counter block of data are used for processing each data block. The AES peripheral automatically increments the Counter[31:0] bitfield. The first counter block (CB1) is derived from the initial counter block ICB by the application software (see Table 360).

Table 360. Initialization of SAES_IVRx registers in GCM mode

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>32-bit counter = 0x0002</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: In this mode, the setting 01 of the MODE[1:0] bitfield (key derivation) is forbidden.
The authentication mechanism in GCM mode is based on a hash function called GF2mul that performs multiplication by a fixed parameter, called hash subkey (H), within a binary Galois field.

A GCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES prepares the GCM hash subkey (H).
- **Header phase**: AES processes the additional authenticated data (AAD), with hash computation only.
- **Payload phase**: AES processes the plaintext (P) with hash computation, counter block encryption and data XOR-ing. It operates in a similar way for ciphertext (C).
- **Final phase**: AES generates the authenticated tag (T) using the last block of the message.

**GCM init phase**

During this first step, the GCM hash subkey (H) is calculated and saved internally, to be used for processing all the blocks. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select GCM chaining mode, by setting to 011 the CHMOD[2:0] bitfield of the AES_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES_CR register.
4. Set the MODE[1:0] bitfield of the AES_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES_KEYRx registers with a key, and initialize AES_IVRx registers with the information as defined in Table 360.
6. Start the calculation of the hash key, by setting to 1 the EN bit of the AES_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag of the AES_SR register, by setting the CCF bit of the AES_ICR register.

**GCM header phase**

This phase coming after the GCM Init phase must be completed before the payload phase. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in Section 41.4.4: AES procedure to perform a cipher operation. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

**Note:** *The header phase can be skipped if there is no AAD, that is, Len(A) = 0.*
GCM payload phase

This phase, identical for encryption and decryption, is executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:

1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 41.4.4: AES procedure to perform a cipher operation on page 1483, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the previous two steps. For the last block, discard the bits that are not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, Len(C) = 0 (see GMAC mode).

GCM final phase

In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:

1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Compose the data of the block, by concatenating the AAD bit length and the payload bit length, as shown in Table 359. Write the block into the AES_DINR register.
3. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1.
4. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
5. Clear the CCF flag of the AES_SR register, by setting the CCF bit of the AES_ICR register.
6. Disable the AES peripheral, by clearing the bit EN of the AES_CR register. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data is written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.
Suspend/resume operations in GCM mode

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.

2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. Clear the CCF flag of the AES_SR register, by setting the CCF bit of the AES_ICR register.

4. Save the AES_SUSPxR registers in the memory, where x is from 0 to 7.

5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.

6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.

7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.

2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.

3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPxR registers, where x is from 0 to 7.

4. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.

5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.

6. Enable the AES peripheral by setting the EN bit of the AES_CR register.

If DMA is used, enable AES DMA requests by setting the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

41.4.11 AES Galois message authentication code (GMAC)

Overview
The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.
A typical message construction for GMAC is given in Figure 343.

**Figure 343. Message construction in GMAC mode**

![Message construction in GMAC mode](image)

The GMAC algorithm corresponds to the GCM algorithm applied on a message only containing a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

**Suspend/resume operations in GMAC**

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.
41.4.12 AES counter with CBC-MAC (CCM)

Overview

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES in counter mode. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction for CCM is given in Figure 345.

Figure 345. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q**: a bit string representation of the octet length of P (Len(P))
  - **Nonce (N)**: a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags**: most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and Q (plaintext length such that Len(P) < 2^8q bytes). The counter blocks range associated to Q is equal to 2^(8Q-4), that is, if the maximum value of Q is 8, the counter blocks used in cipher must be on 60 bits.

- **16-byte blocks (B)** associated to the Associated Data (A).

This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see Figure 345). The
standard also states that, on MSB bits of the first message block (B1), the associated
data length expressed in bytes (a) must be encoded as follows:

- If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
- If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as $0xff || 0xfe || [a]_{32}$, that is, on six bytes.
- If $2^{32} < a < 2^{64}$, then it is encoded as $0xff || 0xff || [a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated
and encrypted as ciphertext C, with a known length Len(P). This length can be a non-
multiple of 16 bytes (see Figure 345).

- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length
Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a
special padding scheme is required.

**Note:** CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following
values (hexadecimal numbers):

- N: 10111213 141516 (Len(N)= 56 bits or 7 bytes)
- A: 00010203 04050607 (Len(A)= 64 bits or 8 bytes)
- P: 20212223 (Len(P)= 32 bits or 4 bytes)

Generation of formatted input data blocks Bx (especially B0 and B1) must be managed by
the application.
CCM processing

Figure 346 describes the CCM implementation within the AES peripheral (encryption example). This mode is selected by writing 100 into the CHMOD[2:0] bitfield of the AES_CR register.

Figure 346. CCM mode authenticated encryption

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted plaintext data to generate a MAC, with a known length. Counter mode encryption that requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting ciphertext C is the output of the generation-encryption process on plaintext P.

AES_IVRx registers are used for processing each data block, AES automatically incrementing the CTR counter with a bit length defined by the first block B0. Table 361 shows how the application must load the B0 data.

Note: The AES peripheral in CCM mode supports counters up to 64 bits, as specified by NIST.

Table 361. Initialization of AES_IVRx registers in CCM mode

<table>
<thead>

<td>B0[95:64]</td>
<td>B0[63:32]</td>
<td>B0[31:0]</td>
</tr>
</tbody>
</table>
A CCM message is processed through the following phases, further described in next subsections:

- **Init phase**: AES processes the first block and prepares the first counter block.
- **Header phase**: AES processes associated data (A), with tag computation only.
- **Payload phase**: IP processes plaintext (P), with tag computation, counter block encryption, and data XOR-ing. It works in a similar way for ciphertext (C).
- **Final phase**: AES generates the message authentication code (MAC).

**CCM Init phase**

In this phase, the first block $B_0$ of the CCM message is written into the AES_IVRx register. The AES_DOUTR register does not contain any output data. The recommended sequence is:

1. Disable the AES peripheral by clearing the EN bit of the AES_CR register.
2. Select CCM chaining mode, by setting to 100 the CHMOD[2:0] bitfield of the AES_CR register, and optionally, set the DATATYPE[1:0] bitfield.
3. Indicate the Init phase, by setting to 00 the GCMPH[1:0] bitfield of the AES_CR register.
4. Set the MODE[1:0] bitfield of the AES_CR register to 00 or 10. Although the bitfield is only used in payload phase, it is recommended to set it in the Init phase and keep it unchanged in all subsequent phases.
5. Initialize the AES_KEYRx registers with a key, and initialize AES_IVRx registers with $B_0$ data as described in Table 361.
6. Start the calculation of the counter, by setting to 1 the EN bit of the AES_CR register (EN is automatically reset when the calculation finishes).
7. Wait until the end of computation, indicated by the CCF flag of the AES_SR transiting to 1. Alternatively, use the corresponding interrupt.
8. Clear the CCF flag in the AES_SR register, by setting to 1 the CCF bit of the AES_ICR register.

**CCM header phase**

This phase coming after the GCM Init phase must be completed before the payload phase. During this phase, the AES_DOUTR register does not contain any output data. The sequence to execute, identical for encryption and decryption, is:

1. Indicate the header phase, by setting to 01 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. Enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last block and the AAD size in the block is inferior to 128 bits, pad the remainder of the block with zeros. Then append the data block into AES in one of ways described in Section 41.4.4: AES procedure to perform a cipher operation. No data is read during this phase.
4. Repeat the step 3 until the last additional authenticated data block is processed.

**Note:** The header phase can be skipped if there is no associated data, that is, Len(A) = 0.

The first block of the associated data (B1) must be formatted by software, with the associated data length.
CCM payload phase (encryption or decryption)
This phase, identical for encryption and decryption, is executed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the AES_DOUTR register. The sequence to execute is:
1. Indicate the payload phase, by setting to 10 the GCMPH[1:0] bitfield of the AES_CR register. Do not modify the MODE[1:0] bitfield as set in the Init phase.
2. If the header phase was skipped, enable the AES peripheral by setting the EN bit of the AES_CR register.
3. If it is the last data block to encrypt and the plaintext size in the block is inferior to 128 bits, pad the remainder of the block with zeros.
4. Append the data block into AES in one of ways described in Section 41.4.4: AES procedure to perform a cipher operation on page 1483, and read the result.
5. Repeat the previous step till the second-last plaintext block is encrypted or till the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), apply the two previous steps. For the last block, discard the data that is not part of the payload when the last block size is less than 16 bytes.

Note: The payload phase can be skipped if there is no payload data, that is, Len(P) = 0 or Len(C) = Len(T).
Remove LSBLen(T)(C) encrypted tag information when decrypting ciphertext C.

CCM final phase
In this last phase, the AES peripheral generates the GCM authentication tag and stores it in the AES_DOUTR register. The sequence to execute is:
1. Indicate the final phase, by setting to 11 the GCMPH[1:0] bitfield of the AES_CR register.
2. Wait until the end-of-computation flag CCF of the AES_SR register is set.
3. Read four times the AES_DOUTR register: the output corresponds to the CCM authentication tag.
4. Clear the CCF flag of the AES_SR register by setting the CCF bit of the AES_ICR register.
5. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.
6. For authenticated decryption, compare the generated encrypted tag with the encrypted tag padded in the ciphertext.

Note: In this final phase, swapping is applied to tag data read from AES_DOUTR register.
When transiting from the header phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.
Application must mask the authentication tag output with tag length to obtain a valid tag.

Suspend/resume operations in CCM mode
To suspend the processing of a message in header or payload phase, proceed as follows:
1. If DMA is used, stop the AES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the AES_CR register. If DMA is not used, make sure that the current computation is completed, which is indicated by the CCF flag of the AES_SR register set to 1.
2. In the payload phase, if DMA is not used, read four times the AES_DOUTR register to save the last-processed block. If DMA is used, wait until the CCF flag is set in the
AES hardware accelerator (AES) RM0456

AES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the AES_CR register.

3. Clear the CCF flag of the AES_SR register, by setting to 1 the CCF bit of the AES_ICR register.

4. Save the AES_SUSPxR registers (where x is from 0 to 7) in the memory.

5. Save the AES_IVRx registers as, during the data processing, they changed from their initial values.

6. Disable the AES peripheral, by clearing the EN bit of the AES_CR register.

7. Save the current AES configuration in the memory, excluding the initialization vector registers AES_IVRx. Key registers do not need to be saved as the original key value is known by the application.

8. If DMA is used, save the DMA controller status (pointers for IN data transfers, number of remaining bytes, and so on). In the payload phase, pointers for OUT data transfers must also be saved.

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller in order to complete the rest of the FIFO IN transfers. In the payload phase, the rest of the FIFO OUT transfers must also be configured in the DMA controller.

2. Disable the AES peripheral by clearing the EN bit of the AES_CR register.

3. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPxR registers (where x is from 0 to 7).

4. Write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers.

5. Restore the initial setting values in the AES_CR and AES_KEYRx registers.

6. Enable the AES peripheral by setting the EN bit of the AES_CR register.

7. If DMA is used, enable AES DMA requests by setting to 1 the DMAINEN bit (and DMAOUTEN bit if in payload phase) of the AES_CR register.

41.4.13 AES operation with shared keys

The AES peripheral can use the SAES peripheral as security co-processor. In this case, secure application prepares the key in the robust SAES peripheral. When ready, the AES application can load this prepared key through a dedicated hardware key bus.

Recommended sequences are described below and in SAES peripheral section Section 42.4.10: SAES operation with shared keys.

1. In SAES peripheral application encrypts the key to be shared, once, in Shared-key mode (KMOD[1:0]=10).

2. Each time shared key is needed in AES peripheral application needs to decrypt it in SAES peripheral, selecting the same Shared-key mode (KMOD[1:0]=10).

3. Once the shared key is decrypted and loaded in SAES_KEYRx registers it can be shared with the AES peripheral. Indeed, when shared key must be loaded in AES peripheral, application sets correct KEYSIZE and write KMOD[1:0] =10 in AES_CR register. When KEYVALID is cleared, the key information is automatically transferred by hardware into AES_KEYRx, with BUSY set in AES_SR.

4. Once transfer is completed BUSY bit is cleared and KEYVALID bit is set in AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if a key error flag (KEIF) is set it means that an unexpected event occurred during the transfer (for example...
hardware fault) or the KEYVALID bit in SAES_SR was cleared before the end of the transfer. When such errors occur, the whole SAES key sharing process must be restarted through the IPRST bits of control registers in both SAES and AES peripherals (see Section 41.4.18 for details).

At that point AES is initialized with a valid, shared key. Application can proceed with the processing of data, setting KMOD[1:0] to 00.

Note: While KMOD=10 and BUSY=1, if KEYSIZE in AES peripheral is different from the KEYSIZE in SAES peripheral the key sharing fails and KEIF is set in both peripherals.

41.4.14 AES data registers and data swapping

Data input and output

A 128-bit data block is entered into the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the AES peripheral with four successive 32-bit word reads from the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for AES_DINR register or from AES_DOUTR register is organized in big endian order, that is:

• the most significant byte of a word to write into AES_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
• the most significant byte of a word read from AES_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into AES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See Section 41.4.17: AES DMA interface.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the AES_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, Figure 347 shows the construction of AES processing core input buffer data P127 to P0, from the input data entered through the AES_DINR register, or the construction of the output data available through the AES_DOUTR register, from the AES processing core output buffer data P127 to P0.
Figure 347. 128-bit block construction with respect to data swap

**Note:** The data in AES key registers (AES_KEYRx) and initialization registers (AES_IVRx) are not sensitive to the swap mode selection.

**Data padding**

*Figure 347* also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11
41.4.15 AES key registers

The AES_KEYRx write-only registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address (reads are not allowed for security reason).

The key is spread over eight registers as shown in Table 362.

Table 362. Key endianness in AES_KEYRx registers (128- or 256-bit key length)

<table>
<thead>
<tr>
<th>AES_KEYR7 [31:0]</th>
<th>AES_KEYR6 [31:0]</th>
<th>AES_KEYR5 [31:0]</th>
<th>AES_KEYR4 [31:0]</th>
<th>AES_KEYR3 [31:0]</th>
<th>AES_KEYR2 [31:0]</th>
<th>AES_KEYR1 [31:0]</th>
<th>AES_KEYR0 [31:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>KEY[127:96]</td>
<td>KEY[95:64]</td>
<td>KEY[63:32]</td>
<td>KEY[31:0]</td>
</tr>
</tbody>
</table>

The key for encryption or decryption may be written into these registers when the AES peripheral is disabled, by clearing the EN bit of the AES_CR register.

The key registers are not affected by the data swapping controlled by DATATYPE[1:0] bitfield of the AES_CR register.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] = 00), the AES_KEYRx (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) registers must always be written in either ascending or descending order.

Note: Initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the AES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 41.4.18: AES error management for details).

For additional information on key modes, refer to Section 41.4.13.

41.4.16 AES initialization vector registers

The four AES_IVRx registers keep the initialization vector input bitfield IVI[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (AES_IVR0) to highest address (AES_IVR3).

The signification of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the AES_IVRx registers when the AES peripheral is enabled have no effect to the register contents. For modifying the contents of the AES_IVRx registers, the EN bit of the AES_CR register must first be cleared.

Reading the AES_IVRx registers returns the latest counter value (useful for managing suspend mode).

The AES_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the AES_CR register.
41.4.17 AES DMA interface

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the AES_CR register.

Data input using DMA

Setting the DMAINEN bit of the AES_CR register enables DMA writing into AES. The AES peripheral then initiates a DMA request during the input phase each time it requires to write a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 348.

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required. For example, in case of AES GCM encryption or AES CCM decryption, a DMA transfer must not include the last block. For details, refer to Section 41.4.4: AES procedure to perform a cipher operation.

Figure 348. DMA transfer of a 128-bit data block during input phase

Data output using DMA

Setting the DMAOUTEN bit of the AES_CR register enables DMA reading from AES. The AES peripheral then initiates a DMA request during the Output phase each time it requires to read a 128-bit block (quadruple word) to the AES_DINR register, as shown in Figure 349.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.
DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register AES_CR. As in Mode 2 (key derivation) the AES_KEYRx registers must be written by software, enabling the DMA transfer through the DMAINEN and DMAOUTEN bits of the AES_CR register have no effect in that mode.

DMA single requests are generated by AES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, AES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between AES and memory is managed by DMA, the CCF flag is not relevant and can be ignored (left set) by software. It must only be cleared when transiting back to data transferring managed by software. See Suspend/resume operations in ECB/CBC modes in Section 41.4.8: AES basic chaining modes (ECB, CBC) as example.

41.4.18 AES error management

AES configuration can be changed at any moment by clearing the EN bit of the AES_CR register.

Read error flag (RDERR)

Unexpected read attempt of the AES_DOUTR register sets the RDERR flag of the AES_SR register and the RWEIF flag of the AES_ISR register, and returns zero.

RDERR is triggered during the computation phase or during the input phase.

Note: AES is not disabled upon a RDERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the AES_IER register is set. For more details, refer to Section 41.5: AES interrupts.

The RDERR and RWEIF flag is cleared by setting the RWEIE bit of the AES_ICR register.

Write error flag (WDERR)

Unexpected write attempt of the AES_DINR register sets the WRERR flag of the AES_SR register and the RWEIF flag of the AES_ISR register, and has no effect on the AES_DINR register. The WRERR is triggered during the computation phase or during the output phase.
AES is not disabled after a WRERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the AES_IER register is set. For more details, refer to Section 41.5: AES interrupts.

The WRERR and RWEIF flag is cleared by setting the RWEIF bit of the AES_ICR register.

Key error interrupt flag (KEIF)

Failure to load a key into key registers, sets the KEIF flag of the AES_ISR register and clears the KEYVALID bit of the AES_SR register.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to Section 41.5: AES interrupts.

The possible sources of key errors are:

- Key writing sequence error: an incorrect sequence has been detected when writing key registers. See Section 41.4.15: AES key registers for details.
- Key sharing size mismatch: error is triggered when KMOD=10 and application sets a KEYSIZE information in AES peripheral that does not match the KEYSIZE stored in SAES peripheral.
- Key sharing error: the copy of key registers from SAES peripheral to AES failed. See Section 41.4.13: AES operation with shared keys for details.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

For any key error, clear KEIF flag prior to re-configuring AES.

41.5 AES interrupts

Individual maskable interrupt sources generated by the AES peripheral signal the following events:

- computation completed
- read error
- write error
- key error

The individual sources are combined into the common interrupt signal aes_it that connects to NVIC (nested vectored interrupt controller). Each can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the AES_IER register, and cleared by setting the corresponding bit of the AES_ICR register.

The status of each can be read from the AES_SR and AES_ISR registers.

Table 363 gives a summary of the interrupt sources, their event flags and enable bits.

1514/3040 RM0456 Rev 1
Bit 31  **IPRST**: AES peripheral software reset
Setting the bit resets the AES peripheral, putting all registers to their default values, except the
IPRST bit itself. Hence, any key-relative data is lost. For this reason, it is recommended to set the bit
before handing over the AES to a less secure application.
The bit must be low while writing any configuration registers.

Bits 30:26  Reserved, must be kept at reset value.

Bits 25:24  **KMOD[1:0]**: Key mode selection
The bitfield defines how the AES key can be used by the application:
00: Normal key
10: Shared key from SAES co-processor
Others: Reserved
With normal key selection, the key registers are freely usable, no specific usage or protection
applies to AES_DIN and AES_DOUT registers.
With selection of shared key from SAES co-processor, the AES peripheral automatically loads its
key registers with the data stored in the key registers of the SAES peripheral. The key value is
available in key registers when BUSY bit is cleared and KEYVALID is set in the AES_SR register.
Key error flag KEIF is set otherwise in the AES_ISR register.
The bitfield must be set only when KEYSIZE is correct, and when a shared key decryption sequence
has been successfully completed in SAES co-processor.
Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as
when the EN bit of the AES_CR register is set before the write access and it is not cleared by that
write access.

Bits 23:20  **NPBLB[3:0]**: Number of padding bytes in last block
The bitfield sets the number of padding bytes in last block of payload:
0000: All bytes are valid (no padding)
0001: Padding for one least-significant byte of last block
...  
1111: Padding for 15 least-significant bytes of last block
Bit 19  Reserved, must be kept at reset value.

Bit 18  **KEYSIZE**: Key size selection
This bitfield defines the length of the key used in the AES cryptographic core, in bits:
0: 128
1: 256
Attempts to write the bit are ignored when the BUSY flag of AES_SR register is set, as well as when
the EN bit of the AES_CR register is set before the write access and it is not cleared by that write
access.

Bit 17  Reserved, must be kept at reset value.

Bit 15  Reserved, must be kept at reset value.

Bits 14:13  **GCMPH[1:0]**: GCM or CCM phase selection
This bitfield selects the phase of GCM, GMAC or CCM algorithm:
00: Init phase
01: Header phase
10: Payload phase
11: Final phase
The bitfield has no effect if other than GCM, GMAC or CCM algorithms are selected (through the
ALGOMODE bitfield).
Bit 12  **DMAOUTEN**: DMA output enable
This bit enables/disables data transferring with DMA, in the output phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by AES during the output data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bit 11  **DMAINEN**: DMA input enable
This bit enables/disables data transferring with DMA, in the input phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by AES during the input data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bits 10:7  Reserved, must be kept at reset value.

Bits 16, 6:5  **CHMOD[2:0]**: Chaining mode selection
This bitfield selects the AES chaining mode:
000: Electronic codebook (ECB)
001: Cipher-block chaining (CBC)
010: Counter mode (CTR)
011: Galois counter mode (GCM) and Galois message authentication code (GMAC)
100: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as when the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.

Bits 4:3  **MODE[1:0]**: AES operating mode
This bitfield selects the AES operating mode:
00: Mode 1: encryption
01: Mode 2: key derivation (or key preparation for ECB/CBC decryption)
10: Mode 3: decryption
11: Reserved
Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as when the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.

Bits 2:1  **DATATYPE[1:0]**: Data type selection
This bitfield defines the format of data written in the AES_DINR register or read from the AES_DOUTR register, through selecting the mode of data swapping:
00: None
01: Half-word (16-bit)
10: Byte (8-bit)
11: Bit
For more details, refer to Section 41.4.14: AES data registers and data swapping.
Attempts to write the bitfield are ignored when the BUSY flag of AES_SR register is set, as well as when the EN bit of the AES_CR register is set before the write access and it is not cleared by that write access.
41.7.2 AES status register (AES_SR)

Address offset: 0x04
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 KEYVALID: Key Valid flag
This bit is set by hardware when the amount of key information defined by KEYSIZE in AES_CR has been loaded in AES_KEYx key registers.
0: No valid key information is available in key registers. EN bit in AES_CR cannot be set.
1: Valid key information, defined by KEYSIZE in AES_CR, is loaded in key registers.
In normal mode when KEYSEL equals to zero, the application must write the key registers in the correct sequence, otherwise the KEIF flag of the AES_ISR register is set and KEYVALID stays at zero.
When KEYSEL is different from zero the BUSY flag is automatically set by AES. When key is loaded successfully, the BUSY flag is cleared and KEYVALID set. Upon an error, the KEIF flag of the AES_ISR register is set, the BUSY flag cleared and KEYVALID kept at zero.
When the KEIF flag is set, the application must clear it through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF bit description for more details.
For more information on key loading please refer to Section 41.4.15: AES key registers.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 BUSY: Busy
This flag indicates whether AES is idle or busy during GCM payload encryption phase:
0: Idle
1: Busy
When the flag indicates "idle", the current GCM encryption processing may be suspended to process a higher-priority message. In other chaining modes, or in GCM phases other than payload encryption, the flag must be ignored for the suspend process.
The flag is set when transferring a shared key from SAES peripheral.
Bit 2 **WRERR**: Write error
This flag indicates the detection of an unexpected write operation to the AES_DINR register (during computation or data output phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the AES_ICR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the AES_ICR register.
The flag setting has no impact on the AES operation. Unexpected write is ignored.

Bit 1 **RDERR**: Read error flag
This flag indicates the detection of an unexpected read operation from the AES_DOUTR register (during computation or data input phase):
0: Not detected
1: Detected
The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the AES_ICR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the AES_ICR register.
The flag setting has no impact on the AES operation. Unexpected read returns zero.

Bit 0 **CCF**: Computation completed flag
This bit mirrors the CCF bit of the AES_ISR register.

### 41.7.3 AES data input register (AES_DINR)
Address offset: 0x08
Reset value: 0x0000 0000
Only 32-bit write access type is supported.

</tr>
</tbody>
</table>

Bits 31:0 **DIN[31:0]**: Input data word
A four-fold sequential write to this bitfield during the input phase results in writing a complete 128-bit block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.
The data signification of the input data block depends on the AES operating mode:
- **Mode 1** (encryption): plaintext
- **Mode 2** (key derivation): the bitfield is not used (AES_KEYRx registers used for input)
- **Mode 3** (decryption): ciphertext
The data swap operation is described in Section 41.4.14: AES data registers and data swapping on page 1507.
41.7.4 AES data output register (AES_DOUTR)

Address offset: 0x0C
Reset value: 0x0000 0000

Only 32-bit read access type is supported.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|0C|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **DOUT[31:0]**: Output data word

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF set), virtually reads a complete 128-bit block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

The data signification of the output data block depends on the AES operating mode:

- **Mode 1** (encryption): ciphertext
- **Mode 2** (key derivation): the bitfield is not used
- **Mode 3** (decryption): plaintext

The data swap operation is described in Section 41.4.14: AES data registers and data swapping on page 1507.

41.7.5 AES key register 0 (AES_KEYR0)

Address offset: 0x10
Reset value: 0x0000 0000

Bits 31:0 **KEY[255:224]:** Cryptographic key, bits [255:224]  
Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield.

**Note:** The key registers from 4 to 7 are used only when the key length of 256 bits is selected. They have no effect when the key length of 128 bits is selected (only key registers 0 to 3 are used in that case).
41.7.17 AES suspend registers (AES_SUSPxR)

Address offset: 0x040 + x * 0x4, (x = 0 to 7)
Reset value: 0x0000 0000

These registers contain the complete internal register states of the AES processor when the AES processing of the current task is suspended to process a higher-priority task. Upon suspend, the software reads and saves the AES_SUSPxR register contents (where x is from 0 to 7) into memory, before using the AES processor for the higher-priority task. Upon completion, the software restores the saved contents back into the corresponding suspend registers, before resuming the original task.

Note: These registers are used only when GCM, GMAC, or CCM chaining mode is selected.
These registers can be read only when AES is enabled. Reading these registers while AES is disabled returns 0x0000 0000.

Bits 31:0 SUSP[31:0]: AES suspend
Upon suspend operation, this bitfield of the corresponding AES_SUSPxR register takes the value of one of internal AES registers.

41.7.18 AES interrupt enable register (AES_IER)

Address offset: 0x300
Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 KEIE: Key error interrupt enable
This bit enables or disables (masks) the AES interrupt generation when KEIF (key error flag) is set.
0: Disabled (masked)
1: Enabled (not masked)
Bit 1 **RWEIE:** Read or write error interrupt enable
This bit enables or disables (masks) the AES interrupt generation when RWEIF (read and/or write error flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable
This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set.
0: Disabled (masked)
1: Enabled (not masked)

### 41.7.19 AES interrupt status register (AES_ISR)

Address offset: 0x304
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag
This read-only bit is set by hardware when key information failed to load into key registers.
0: No key error detected
1: Key information failed to load into key registers
Setting the corresponding bit of the AES_ICR register clears the KEIF and generates interrupt if the KEIE bit of the AES_IER register is set.
KEIF is triggered upon any of the following errors:
- AES_KEYR<sub>rx</sub> register write does not respect the correct order. (For KEYSIZE = 0, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE = 1, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse).
KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag
This read-only bit is set by hardware when a RDERR or a WRERR error flag is set in the AES_SR register.
0: No read or write error detected
1: Read or write error detected (see AES_SR register for details)
RWEIF bit is cleared when application sets the corresponding bit of AES_ICR register. An interrupt is generated if the RWEIE bit has been previously set in the AES_IER register.
This flags has no meaning when key derivation mode is selected.
Bit 0  **CCF**: Computation complete flag

This flag indicates whether the computation is completed:
0: Not completed
1: Completed

The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCF bit of the AES_I CR register.

Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the AES_IER register.

The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA_EN is 1.

### 41.7.20 AES interrupt clear register (AES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

**Bits 31:3** Reserved, must be kept at reset value.

- **Bit 2 KEIF**: Key error interrupt flag clear
  Setting this bit clears the KEIF status bit of the AES_ISR register.

- **Bit 1 RWEIF**: Read or write error interrupt flag clear
  Setting this bit clears the RWEIF status bit of the AES_ISR register, and both RDERR and WRERR flags in the AES_SR register.

- **Bit 0 CCF**: Computation complete flag clear
  Setting this bit clears the CCF status bit of the AES_SR and AES_ISR registers.

42 Secure AES coprocessor (SAES)

42.1 Introduction

The secure AES coprocessor (SAES) encrypts or decrypts data, using an algorithm and implementation fully compliant with the advanced encryption standard (AES) defined in Federal information processing standards (FIPS) publication 197. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA).

The peripheral supports ECB, and CBC chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/decryption (Wrapped-key mode) and key sharing with faster AES peripheral (Shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by application.

SAES is an AMBA AHB slave peripheral accessible through 32-bit single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.
42.2 SAES main features

- Compliance with NIST “Advanced encryption standard (AES), FIPS publication 197” from November 2001
- 128-bit data block processing
- Support for cipher key lengths of 128-bit and 256-bit
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
- 528 or 743 clock cycle latency in ECB mode for processing one 128-bit block of data with, respectively, 128-bit or 256-bit key
- Integrated round key scheduler to compute the last round key for ECB/CBC decryption
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
- 256-bit write-only register for storing the cryptographic key (eight 32-bit registers)
  - Optional hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together
- 128-bit register for storing initialization vector (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control with support of single-transfer direct memory access (DMA) using two channels (one for incoming data, one for processed data)
- Data-swapping logic to support 1-, 8-, 16- or 32-bit data
- Possibility for software to suspend a message if SAES needs to process another message with a higher priority, then resume the original message
- Security context enforcement for keys
- Hardware secret key encryption/decryption (Wrapped-key mode)
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA)
- Hardware key sharing with faster AES peripheral (Shared-key mode), controlled by SAES

42.3 SAES implementation

The devices have one SAES and one AES peripheral, implemented as shown in the following table.

42.4.3 SAES cryptographic core

Overview

The SAES cryptographic core consists of the following components:

- AES core algorithm (AEA)
- key input
- initialization vector (IV) input
- chaining algorithm logic (XOR)

The SAES core works on 128-bit data blocks (four words) with 128-bit or 256-bit key length. Depending on the chaining mode, the SAES requires zero or one 128-bit initialization vector IV.

The SAES features the following modes of operation:

- **Mode 1:**
  Plaintext encryption using a key stored in the SAES_KEYRx registers or read using a dedicated hardware bus

- **Mode 2:**
  ECB or CBC decryption key preparation. It must be used prior to selecting Mode 3 with ECB or CBC chaining modes. The key prepared for decryption is stored automatically in the SAES_KEYRx registers. Now the SAES peripheral is ready to switch to Mode 3 for executing data decryption.

- **Mode 3:**
  Ciphertext decryption using a key stored in the SAES_KEYRx registers. When ECB and CBC chaining modes are selected, the key must be prepared beforehand, through Mode 2.

*Note:* Mode 2 is only used when performing ECB and CBC decryption.

The operating mode is selected by programming the MODE[1:0] bitfield of the SAES_CR register. It may be done only when the SAES peripheral is disabled.

Special key operation is selected using the KMOD[1:0] bitfield of the SAES_CR register. See Section 42.4.10 and Section 42.4.9 for details.

---

1. Connected to a set of backup registers in TAMP peripheral that are written, then read/write locked, by the application software (see Section 42.4.12 for details).

</tr>
</tbody>
</table>
Typical data processing

Typical usage of the SAES is described in Section 42.4.4: SAES procedure to perform a cipher operation on page 1534.

Note: The outputs of the intermediate AEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IVI bitfield.

Chaining modes

The following chaining modes are supported by SAES, selected through the CHMOD bit of the SAES_CR register:

- Electronic code book (ECB)
- Cipher block chaining (CBC)

Note: The chaining mode may be changed only when SAES is disabled (bit EN of the SAES_CR register cleared).

Principle of each SAES chaining mode is provided in the following subsections.

Detailed information is in dedicated sections, starting from Section 42.4.8: SAES basic chaining modes (ECB, CBC).

Electronic codebook (ECB) mode

Figure 351. ECB encryption and decryption principle

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

Note: For decryption, a special key scheduling is required before processing the first block.
Cipher block chaining (CBC) mode

Figure 352. CBC encryption and decryption principle

In CBC mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

Note: For decryption, a special key scheduling is required before processing the first block.

42.4.4 SAES procedure to perform a cipher operation

Introduction

A typical cipher operation is explained below. Detailed information is provided in sections starting from Section 42.4.8: SAES basic chaining modes (ECB, CBC).
Initialization of SAES

To initialize SAES, first disable it by clearing the EN bit of the SAES_CR register. Then perform the following steps in any order (except KEYSIZE):

- Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress), and RNGEIF = 0 in SAES_ISR (no random number fetching error flagged).
- Configure the SAES mode, by programming the MODE[1:0] bitfield of the SAES_CR register.
  - For encryption, select Mode 1 (MODE[1:0] = 00).
  - For decryption, select Mode 2 (MODE[1:0] = 01) then Mode 3 (MODE[1:0] = 10), as described in Section 42.4.8: SAES basic chaining modes (ECB, CBC).
- Select the chaining mode, by programming the CHMOD bit of the SAES_CR register. Select normal key mode by setting KMOD[1:0] to 00. For the other KMOD values, refer to Section 42.4.9 and Section 42.4.10.
- Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE[1:0] bitfield in the SAES_CR register.
- When it is required (for example in CBC chaining mode), write the initialization vector into the SAES_IVRx registers.
- Configure the key size (128-bit or 256-bit), with the KEYSIZE bitfield of the SAES_CR register. This step must be done before writing into key registers or selecting a different key source using KEYSEL. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
- Write a symmetric key into the SAES_KEYRx registers (4 or 8 registers depending on the key size). Alternatively, select a key source different from the key registers by setting KEYSEL[2:0] to a value different from 0x0. See Section 42.4.12 for details.

Note: SAES sets KEYVALID in SAES_SR when key information defined by KEYSIZE is loaded in SAES_KEYRx.

Data append

This section describes different ways of appending data for processing, where the size of data to process is not a multiple of 128 bits when KMOD[1:0] = 00. For other KMOD values refer to Section 42.4.10 and Section 42.4.9.

Data append through polling

This method uses flag polling to control the data append through the following sequence:

1. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_SR, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ISR register.
   d) If the data block just processed is the second-last block of the message and the significant data in the last block to process is inferior to 128 bits, refer to Section 42.4.6: SAES ciphertext stealing and data padding.
3. As it is the last block, follow the instructions in Section 42.4.6: SAES ciphertext stealing and data padding, then disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
Note: **Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.**

**Data append using interrupt**

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES by setting the CCFIE bit of the SAES_IER register.
2. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine, upon interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ISR register.
   c) If the data block just processed is the second-last block of an message and the significant data in the last block to process is inferior to 128 bits, refer to Section 42.4.6: SAES ciphertext stealing and data padding. Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, follow if needed Section 42.4.6: SAES ciphertext stealing and data padding, then disable the SAES peripheral by clearing the EN bit of the SAES_CR register and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

**Data append using DMA**

With this method, all the transfers and processing are managed by DMA and SAES. To use the method, proceed as follows:

1. If the last block to process is inferior to 128 bits, refer to Section 42.4.6: SAES ciphertext stealing and data padding to prepare the last four-word data block.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in Section 42.4.14: SAES DMA interface. Configure the DMA controller so as to generate an interrupt on transfer completion.
3. Enable the SAES peripheral by setting the EN bit of the SAES_CR register
4. Enable DMA requests by setting the DMAINEN and DMAOUTEN bits of the SAES_CR register.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

**Note:** The CCF flag has no use with this method, because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.
42.4.5 SAES decryption round key preparation

Internal key schedule is used to generate AES round keys. In AES encryption, the round 0 key is the one stored in the key registers. AES decryption must start using the last round key. As the encryption key is stored in memory, a special key scheduling must be performed to obtain the decryption key.

Recommended method is to select the Mode 2 by setting to 01 the MODE[1:0] bitfield of the SAES_CR (key process only), then proceed with the decryption by setting MODE[1:0] to 10 (Mode 3, decryption only). Mode 2 usage is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. Select Mode 2 by setting to 01 the MODE[1:0] bitfield of the SAES_CR. The CHMOD bit is not significant in this case because this key derivation mode is independent of the chaining algorithm selected. Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD values, refer to Section 42.4.10 and Section 42.4.9.
4. Set key length to 128 or 256 bits, via KEYSIZE bit of SAES_CR register. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
5. Write the SAES_KEYRx registers (128 or 256 bits) with encryption key, or, alternatively, select a key source different from the key registers, through KEYSEL[2:0]. Refer to Section 42.4.12: SAES key registers for details. Writes to the SAES_IVRx registers have no effect.
6. Enable the SAES peripheral, by setting the EN bit of the SAES_CR register.
7. Wait until the CCF flag is set in the SAES_SR register.
8. Clear the CCF flag. Derived key is available in AES core, ready to use for decryption.

Note: The SAES is disabled by hardware when the derivation key is available.

Note: To restart a derivation key computation, repeat steps 5, 6, 7, and 8.

Note: The operation of the key preparation lasts 200 or 324 clock cycles, depending on the key size (128- or 256-bit).

42.4.6 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (128 bits), ciphertext stealing techniques are used, such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the SAES peripheral does not support such techniques, the application must complete the last block of input data using data from the second last block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Note: Padding data are swapped in a similar way as normal data, according to the DATATYPE[1:0] field of the SAES_CR register (see Section 42.4.11: SAES data registers and data swapping for details).
42.4.7 SAES task suspend and resume

A message can be suspended if another message with a higher priority must be processed. When this highest priority message is sent, the suspended message can resume in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can resume as soon as SAES is enabled again to receive the next data block. *Figure 353* gives an example of suspend/resume operation: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

*Figure 353. Example of suspend mode management*

A detailed description of suspend/resume operations is in the sections dedicated to each SAES mode.

42.4.8 SAES basic chaining modes (ECB, CBC)

Overview

This section gives a brief explanation of the four basic operation modes provided by the SAES core: ECB encryption, ECB decryption, CBC encryption and CBC decryption. For detailed information, refer to the FIPS publication 197 from November 26, 2001.
Figure 354 illustrates the electronic codebook (ECB) encryption.

**Figure 354. ECB encryption**

In ECB encrypt mode, the 128-bit plaintext input data block \( P_x \) in the SAES_DINR register first goes through bit/byte/half-word swapping. The swap result \( I_x \) is processed with the AES core set in encrypt mode, using a 128- or 256-bit key. The encryption result \( O_x \) goes through bit/byte/half-word swapping, then is stored in the SAES_DOUTR register as 128-bit ciphertext output data block \( C_x \). The ECB encryption continues in this way until the last complete plaintext block is encrypted.

Figure 355 illustrates the electronic codebook (ECB) decryption.

**Figure 355. ECB decryption**

To perform an AES decryption in the ECB mode, the secret key has to be prepared by collecting the last-round encryption key (which requires to first execute the complete key schedule for encryption), and using it as the first-round key for the decryption of the ciphertext. This preparation is supported by the AES core.

In ECB decrypt mode, the 128-bit ciphertext input data block \( C_1 \) in the SAES_DINR register first goes through bit/byte/half-word swapping. The keying sequence is reversed compared to that of the ECB encryption. The swap result \( I_1 \) is processed with the AES core set in decrypt mode, using the formerly prepared decryption key. The decryption result goes through bit/byte/half-word swapping, then is stored in the SAES_DOUTR register as 128-bit plaintext output data block \( P_1 \). The ECB decryption continues in this way until the last complete ciphertext block is decrypted.
Figure 356 illustrates the cipher block chaining (CBC) encryption.

### Figure 356. CBC encryption

In CBC encrypt mode, the first plaintext input block, after bit/byte/half-word swapping (P1'), is XOR-ed with a 128-bit IVI bitfield (initialization vector and counter), producing the I1 input data for encrypt with the AES core, using a 128- or 256-bit key. The resulting 128-bit output block O1, after swapping operation, is used as ciphertext C1. The O1 data is then XOR-ed with the second-block plaintext data P2' to produce the I2 input data for the AES core to produce the second block of ciphertext data. The chaining of data blocks continues in this way until the last plaintext block in the message is encrypted.

If the message size is not a multiple of 128 bits, the final partial data block is encrypted in the way explained in Section 42.4.6: SAES ciphertext stealing and data padding.

Figure 357 illustrates the cipher block chaining (CBC) decryption.

### Figure 357. CBC decryption

In CBC decrypt mode, like in ECB decrypt mode, the secret key must be prepared to perform an AES decryption.

After the key preparation process, the decryption goes as follows: the first 128-bit ciphertext block (after the swap operation) is used directly as the AES core input block I1 for decrypt operation, using the 128-bit or 256-bit key. Its output O1 is XOR-ed with the 128-bit IVI field (that must be identical to that used during encryption) to produce the first plaintext block P1.
The second ciphertext block is processed in the same way as the first block, except that the \( I_1 \) data from the first block is used in place of the initialization vector.

The decryption continues in this way until the last complete ciphertext block is decrypted.

If the message size is not a multiple of 128 bits, the final partial data block is decrypted in the way explained in **Section 42.4.6: SAES ciphertext stealing and data padding**.

For more information on data swapping, refer to **Section 42.4.11: SAES data registers and data swapping**.

**ECB/CBC encryption sequence**

The sequence of events to perform an ECB/CBC encryption (more detail in **Section 42.4.4**):

1. Verify that \( BUSY = 0 \) in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. Select the Mode 1 by setting to 00 the MODE[1:0] bitfield of the SAES_CR register and select ECB or CBC chaining mode by setting the CMOD bit of the SAES_CR register to 0 or 1, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. Select normal key mode by setting KMOD[1:0] to 00. For encryption with other KMOD values, refer to **Section 42.4.10** and **Section 42.4.9**.
4. Select 128- or 256-bit key length through the KEYSIZE bit of the SAES_CR register. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit of the SAES_CR register must also be set.
5. Write the SAES_KEYRx registers (128 or 256 bits) with encryption key. Alternatively, select a key source different from the key registers, through KEYSEL[2:0]. Refer to **Section 42.4.12: SAES key registers** for details. Fill the SAES_IVRx registers with the initialization vector data if CBC mode has been selected.
6. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.
7. Write the SAES_DINR register four times to input the plaintext (MSB first), as shown in **Figure 358**.
8. Wait until the CCF flag is set in the SAES_SR register.
9. Read the SAES_DOUTR register four times to get the ciphertext (MSB first) as shown in **Figure 358**. Then clear the CCF flag by setting the CCF bit of the SAES_ISR register.
10. Repeat steps 7-8-9 to process all the blocks with the same encryption key.

**Figure 358. ECB/CBC encryption (Mode 1)**

CT = ciphertext = 4 words (CT3, ..., CT0)
**ECB/CBC decryption sequence**

The sequence of events to perform an AES ECB/CBC decryption is as follows (More detail in Section 42.4.4). Select normal key mode by setting KMOD[1:0] to 00. For decryption with other KMOD values, refer to Section 42.4.10 and Section 42.4.9.

1. Follow the steps described in Section 42.4.5: SAES decryption round key preparation, in order to prepare the decryption key in AES core.

2. Select the Mode 3 by setting to 10 the MODE[1:0] bitfield of the SAES_CR register and select ECB or CBC chaining mode by setting the CHMOD bit of the SAES_CR register to 0 or 1, respectively. Data type can also be defined, using DATATYPE[1:0] bitfield. KEYSIZE and KMOD bitfields must be kept as-is.

3. Write the SAES_IVRx registers with the initialization vector (required in CBC mode only).

4. Enable SAES by setting the EN bit of the SAES_CR register.

5. Write the SAES_DINR register four times to input the cipher text (MSB first), as shown in Figure 359.

6. Wait until the CCF flag is set in the SAES_SR register.

7. Read the SAES_DOUTR register four times to get the plain text (MSB first), as shown in Figure 359. Then clear the CCF flag by setting the CCF bit of the SAES_ISR register.

8. Repeat steps 5-6-7 to process all the blocks encrypted with the same key.

**Figure 359. ECB/CBC decryption (Mode 3)**

![Figure 359. ECB/CBC decryption (Mode 3)](image)

**Suspend/resume operations in ECB/CBC modes**

The following sequences are valid for normal key mode (KMOD[1:0] = 00).

To suspend the processing of a message, proceed as follows:

1. If DMA is used, stop the SAES DMA transfers to the IN FIFO by clearing the DMAINEN bit of the SAES_CR register.

2. If DMA is not used, read four times the SAES_DOUTR register to save the last processed block. If DMA is used, wait until the CCF flag is set in the SAES_SR register then stop the DMA transfers from the OUT FIFO by clearing the DMAOUTEN bit of the SAES_CR register.

3. If DMA is not used, poll the CCF flag of the SAES_SR register until it becomes 1 (computation completed).

4. Clear the CCF flag by setting the CCF bit of the SAES_ISR register.
5. Save initialization vector registers (only required in CBC mode as SAES_IVRx registers are altered during the data processing).

6. Disable the SAES peripheral by clearing the bit EN of the SAES_CR register.

7. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher priority message.

8. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, and so on).

To resume the processing of a message, proceed as follows:

1. If DMA is used, configure the DMA controller so as to complete the rest of the FIFO IN and FIFO OUT transfers.

2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.

3. Restore SAES_CR register (with correct KEYSIZE) then restore SAES_KEYRx registers. Alternatively, select a key source different from key registers, using KEYSEL[2:0]. Refer to Section 42.4.12: SAES key registers for details.

4. Prepare the decryption key as described in Section 42.4.5: SAES decryption round key preparation (only required for ECB or CBC decryption).

5. Restore SAES_IVRx registers using the saved configuration (only required in CBC mode).

6. Enable the SAES peripheral by setting the EN bit of the SAES_CR register.

7. If DMA is used, enable SAES DMA transfers by setting the DMAINEN and DMAOUTEN bits of the SAES_CR register.

**42.4.9 SAES operation with wrapped keys**

SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret keys DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed.

*Figure 360* summarizes the operation with wrapped keys. To protect the wrapped key, select DHUK by setting KEYSEL[2:0] to 001 or 100. Alternatively, select BHK by setting KEYSEL to 010 if the corresponding registers are read/write-locked in the TAMP peripheral.
Encryption in Wrapped-key mode

Recommended sequence to wrap (that is, encrypt) a key is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. In SAES_CR register, select the Mode 1 (encryption) by setting to 00 the MODE[1:0] bitfield, and select ECB or CBC chaining mode by setting CHMOD bit to 0 or 1, respectively. Data type can be defined as 32-bit, with DATATYPE[1:0] bitfield set to 00. Key size must be properly configured using KEYSIZE bit, and KMOD[1:0] bitfield must be set as 01 (wrapped key). KEYSIZE information is used both for the encryption key and for the key to be encrypted.

4. Write the SAES_IVRx registers with the initialization vector if CBC mode has been selected in previous step.
5. Select the DHUK by setting the KEYSEL[2-0] bitfield of the SAES_CR register to 001 or 100. Upon successful key loading BUSY bit is cleared and KEYVALID bit is set in SAES_SR register. Refer to Section 42.4.12: SAES key registers for detail on KEYSEL=100 usage.
6. Enable SAES by setting the EN bit of the SAES_CR register.
7. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see Table 369 on page 1550).
8. Wait until the CCF flag is set in the SAES_SR register.
9. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF flag by setting the CCF bit in SAES_ICR register.
10. Repeat steps 6 to 8 if KEYSIZE is 256 bits.
Decryption in Wrapped-key mode

Recommended sequence to unwrap (i.e. decrypt) a wrapped key is described below:

1. Verify that BUSY = 0 in SAES_SR (no RNG random number fetch in progress).
2. Disable the SAES peripheral by clearing the EN bit of the SAES_CR register.
3. SAES_CR register, select the Mode 2 by setting to 01 the MODE[1:0] bitfield, and select ECB or CBC chaining mode by setting CHMOD to 0 or 1, respectively. Key size must be properly configured using KEYSIZE bit, and KMOD[1:0] bitfield must be set as 01 (wrapped key). Data type selection with DATATYPE[1:0] bitfield must be the same as the one used during encryption (that is, 0x0). The KEYSIZE information is used both for the decryption key and for the key to be decrypted.

If the decrypted key is not to share with a different security context (different security attribute), the KEYPROT bit of the SAES_CR register must also be set.

4. Select the DHUK by setting the KEYSEL[2:0] bitfield of the SAES_CR register to 001 or 100. Upon successful key loading, the SAES_SR register BUSY bit is cleared and KEYVALID bit set. Refer to Section 42.4.12: SAES key registers for detail on KEYSEL=100 usage.

5. Enable SAES by setting the EN bit of the SAES_CR register.
6. Wait until the CCF flag is set in the SAES_SR register.
7. Clear the CCF flag. Decryption key is available in AES core, and SAES is disabled automatically.
8. In SAES_CR register select the Mode 3 by setting to 10 the MODE[1:0] bitfield.
9. Write the SAES_IVRx registers with the initialization vector if CBC mode has been selected in previous step.
10. Enable SAES by setting the EN bit of the SAES_CR register.
11. Write the SAES_DINR register four times to input the encrypted random key (MSB first, see Table 369 on page 1550).
12. Wait until the CCF flag is set in the SAES_SR register.
13. Clear the CCF flag, then repeat steps 10 and 11 if KEYSIZE is 256 bits.

When the decrypted key is loaded in key registers, KEYSEL[2:0] of the SAES_CR register is automatically cleared. Hence, after this sequence, the decrypted wrapped key is available in SAES_KEYRx registers, immediately usable by the application software for any AES operation (normal key mode).

Decrypted wrapped key can be shared with an application running in a different security context (different security attribute) if KEYPROT bit was cleared during step 2.

Note: When KMOD[1:0] = 01 (wrapped key) and MODE[1:0] = 10 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] = 001 (DHUK) or 100 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0], CHMOD and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.
42.4.10 SAES operation with shared keys

SAES peripheral can share application keys wrapped with hardware-secret key DHUK XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES.

Shared key sequences are too small to be suspended/resumed.

**Note:** When a key stored in SAES is shared with AES, the protection given by KEYPROT bit is lost. The protection is detailed in Section 42.4.12: SAES key registers.

*Figure 361* summarizes how to use Shared-key mode. To protect the shared key, DHUK must be selected, by setting KEYSEL[2:0] to 001 or 100. Alternatively, select BHK by setting KEYSEL to 010 if the corresponding registers are read/write-locked in the TAMP peripheral.

*Pink: hardware secret (not readable by application)*

**Note:** DHUK value depends on privilege, KMOD, KSHAREID, KEYSEL, CHMOD, and on whether SAES peripheral is secure or non-secure.

In the step 3, AES represents the AES peripheral.

**Encryption in Shared-key mode**

Before SAES can share a key with the AES peripheral, the key must be encrypted once. The encryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0]
set to 10 (shared key) and KSHAREID[1:0] kept at 00 in the step 3 in Figure 361. See "Encryption in Wrapped-key mode" for details.

Decryption in Shared-key mode

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted in SAES, then loaded by the AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] set to 10 (shared key) and KSHAREID[1:0] kept at 00 in the step 3 in Figure 361. See "Decryption in Wrapped-key mode" for details.

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD must be set to 00 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] = 10 and KEYVALID = 1 in the SAES_SR register. The sequence in the AES key share target peripheral is as follows:

1. Initialize the AES processor to process some data
2. When the key must be loaded, set the same KEYSIZE as for the SAES peripheral and write the KMOD[1:0] bitfield of the AES_CR register to 10 (shared key). If the previous sequence in the SAES peripheral completed successfully, with KMOD[1:0] kept at 10 and KSHAREID[1:0] kept at 00, the SAES_KEYRx registers are automatically copied into the AES_KEYRx registers, with BUSY set in AES_SR.
3. Once the transfer is completed, the BUSY flag is cleared and KEYVALID set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if a key error flag (KEIF) is set an unexpected event occurred during the transfer, such as a DPA error, a tamper event or the KEYVALID SAES flag was cleared before the end of the transfer. When such errors occur, the whole key sharing process starting from the SAES peripheral must be restarted, through the IPRST bits of both control registers.
4. As KEYVALID is set, the key share target peripheral is initialized with a valid, shared key. The application can proceed with the data processing of data, setting KMOD[1:0] to 00.

This sequence can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES is unused and duly remains in key sharing state.

Note: in SAES peripheral, when KMOD[1:0] = 10 (shared key) and MODE[1:0] = 10 (decryption), a read access to the SAES_DOUTR register triggers a read error (RDERR).

When KEYSEL[2:0] = 001 (DHUK) or 100 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD, and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

When KMOD = 10 and BUSY = 1 in the AES peripheral and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.
42.4.11 SAES data registers and data swapping

Data input and output

A 128-bit data block is entered into the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 128-bit data block is retrieved from the SAES peripheral with four successive 32-bit word reads from the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The 32-bit data word for SAES_DINR register or from SAES_DOUTR register is organized in big endian order, that is:

- the most significant byte of a word to write into SAES_DINR must be put on the lowest address out of the four adjacent memory locations keeping the word to write, or
- the most significant byte of a word read from SAES_DOUTR goes to the lowest address out of the four adjacent memory locations receiving the word

For using DMA for input data block write into SAES, the four words of the input block must be stored in the memory consecutively and in big-endian order, that is, the most significant word on the lowest address. See Section 42.4.14: SAES DMA interface.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through the DATATYPE[1:0] bitfield of the SAES_CR register. The selection applies both to the input and the output of the AES core.

For different data swap types, Figure 362 shows the construction of AES processing core input buffer data P127 to P0, from the input data entered through the SAES_DINR register, or the construction of the output data available through the SAES_DOUTR register, from the AES processing core output buffer data P127 to P0.

**Legend:**
- AES input/output data block in memory
- AES core input/output buffer data
- Zero padding (example)
- Data swap
- MSB most significant bit (127) of memory data block / AEC core buffer
- LSB least significant bit (0) of memory data block / AEC core buffer
- Order of write to AES_DINR / read from AES_DOUTR
- Input/output data bit ‘x’

**Note:** The data in SAES key registers (SAES_KEYRx) and initialization registers (SAES_IVRx) are not sensitive to the swap mode selection.

**Data padding**

Figure 362 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 48 message bits, with DATATYPE[1:0] = 01
- 56 message bits, with DATATYPE[1:0] = 10
- 34 message bits, with DATATYPE[1:0] = 11
42.4.12 SAES key registers

The SAES_KEYRx write-only registers store the encryption or decryption key bitfield KEY[127:0] or KEY[255:0]. The data to write to each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address (reads are not allowed for security reason).

The key is spread over eight registers as shown in Table 369.

Table 369. Key endianness in SAES_KEYRx registers (128- or 256-bit key length)

|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|-------------------|

The key for encryption or decryption may be written into these registers when the SAES peripheral is disabled, by clearing the EN bit and the KEYSEL[2:0] bitfield of the SAES_CR register.

The key registers are not affected by the data swapping controlled by DATATYPE[1:0] bitfield of the SAES_CR register.

The entire key must be written before starting an AES computation. In normal key mode (KMOD[1:0] = 00), with KEYSEL[2:0] = 000, the SAES_KEYRx (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) registers must always be written in either ascending or descending order.

With KEYSEL[2:0] set to 001, a derived hardware unique key (DHUK), computed inside the SAES engine from a non-volatile OTP-based root hardware unique key, is loaded directly into key registers, based on KEYSIZE information.

With KEYSEL[2:0] set to 010, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) in either ascending or descending order. Refer to Table 369.

With KEYSEL[2:0] set to 100, the XOR combination of DHUK and BHK is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE = 0, x = 0 to 7 for KEYSIZE = 1) in either ascending or descending order. Refer to Table 369.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID = 0. The recommended method to clear KEYVALID is to set the IPRST bit in the SAES_CR register. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] = 010).
The KEYPROT bit of SAES_CR register must be set if the key to load in key registers must not be shared with an application executing in a different security context (for example, different security attribute). Setting KEYPROT and KEYVALID makes KEIF flag an error upon SAES access attempts by an application executing in a different security context than the one that loaded the key, as shown in Figure 363.

**Note:**

KEYSEL[2:0] values different from zero (normal key) automatically protect the key registers.

DHUK, BHK and their XOR combination are not visible by any software (even secure).

Secure SAES uses secure DHUK. Non-secure SAES uses non-secure DHUK.

![Figure 363. Key protection mechanisms](image)

**Note:**

Initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transferred to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see Section 42.4.15: SAES error management for details). This holds for all KEYSEL values.

For additional information on key modes, refer to Section 42.4.10 and Section 42.4.9.

**42.4.13 SAES initialization vector registers**

The four SAES_IVRx registers keep the initialization vector input bitfield IVI[127:0]. The data to write to or to read from each register is organized in the memory in little-endian order, that is, with most significant byte on the highest address. The registers are also ordered from lowest address (SAES_IVR0) to highest address (SAES_IVR3).

The signification of data in the bitfield depends on the chaining mode selected. When used, the bitfield is updated upon each computation cycle of the AES core.

Write operations to the SAES_IVRx registers when the SAES peripheral is enabled have no effect to the register contents. For modifying the contents of the SAES_IVRx registers, the EN bit of the SAES_CR register must first be cleared.
Reading the SAES_IVRx registers returns the latest counter value (useful for managing suspend mode).

The SAES_IVRx registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield of the SAES_CR register.

### 42.4.14 SAES DMA interface

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the SAES_CR register.

#### Data input using DMA

Setting the DMAINEN bit of the SAES_CR register enables DMA writing into SAES. The SAES peripheral then initiates a DMA request during the input phase each time it requires to write a 128-bit block (quadruple word) to the SAES_DINR register, as shown in Figure 364.

**Note:** According to the algorithm and the mode selected, special padding / ciphertext stealing might be required. For details, refer to Section 42.4.6: SAES ciphertext stealing and data padding.

**Figure 364. DMA transfer of a 128-bit data block during input phase**

![DMA transfer diagram](image)

#### Data output using DMA

Setting the DMAOUTEN bit of the SAES_CR register enables DMA reading from SAES. The SAES peripheral then initiates a DMA request during the Output phase each time it requires to read a 128-bit block (quadruple word) to the SAES_DINR register, as shown in Figure 365.

**Note:** According to the message size, extra bytes might need to be discarded by application in the last block.
DMA operation in different operating modes

DMA operations are usable when Mode 1 (encryption) or Mode 3 (decryption) are selected via the MODE[1:0] bitfield of the register SAES_CR. As in Mode 2 (key derivation) the SAES_KEYRx registers must be written by software, enabling the DMA transfer through the DMA INEN and DMA OUTEN bits of the SAES_CR register have no effect in that mode.

DMA single requests are generated by SAES until it is disabled. So, after the data output phase at the end of processing of a 128-bit data block, SAES switches automatically to a new data input phase for the next data block, if any.

When the data transferring between SAES and memory is managed by DMA, the CCF flag is not relevant and can be ignored (left set) by software. It must only be cleared when transiting back to data transferring managed by software. See Suspend/resume operations in ECB/CBC modes in Section 42.4.8: SAES basic chaining modes (ECB, CBC) as example.

42.4.15 SAES error management

Unless indicated otherwise, SAES configuration can be changed at any moment by clearing the EN bit of the SAES_CR register.

Read error flag (RDERR)

Unexpected read attempt of the SAES_DOUTR register sets the RDERR flag of the SAES_SR register and the RWEIF flag of the SAES_ISR register, and returns zero.

RDERR is triggered during the computation phase or during the input phase.

Note: Unless indicated otherwise, SAES is not disabled upon a RDERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the SAES_IER register is set. For more details, refer to Section 42.5: SAES interrupts.

The RDERR and RWEIF flag is cleared by setting the RWEIE bit of the SAES_ISR register.

Write error flag (WDERR)

Unexpected write attempt of the SAES_DINR register sets the WRERR flag of the SAES_SR register and the RWEIF flag of the SAES_ISR register, and has no effect on the...
SAES_DINR register. The WRERR is triggered during the computation phase or during the output phase.

**Note:** Unless indicated otherwise, SAES is not disabled after a WRERR error detection and continues processing.

An interrupt is generated if the RWEIE bit of the SAES_IER register is set. For more details, refer to Section 42.5: SAES interrupts.

The WRERR and RWEIF flag is cleared by setting the RWEIF bit of the SAES_ISR register.

**Key error interrupt flag (KEIF)**

Failure to load a key into key registers, or attempt to load a key while the key is protected, sets the KEIF flag of the SAES_ISR register and clears the KEYVALID bit of the SAES_SR register.

The KEIF flag is cleared with corresponding bit of the SAES_ISR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to Section 42.5: SAES interrupts.

The possible sources of key errors are:

- Key protection error: while KEYVALID is set, if KEYPROT=1 or KEYSEL is different from zero this error is triggered when an application executing in a security context different from the one used to load the key is detected accessing the SAES (for example, different security attribute).

- Key writing sequence error: an incorrect sequence has been detected when writing key registers. See Section 42.4.12: SAES key registers for details.

- Key sharing size mismatch: error is triggered when KMOD= 10 and application sets a KEYSIZE information in AES peripheral that does not match the KEYSIZE stored in SAES peripheral.

- Key sharing error: the copy of key registers from SAES peripheral to AES failed. See Section 42.4.10: SAES operation with shared keys for details.

- Key selection error: the DHUK or BHK failed to load into SAES. KEYSEL = 001 (DHUK), 010 (BHK) or 100 (DHUK XOR BHK) is not functional.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

**Note:** For any key error, clear KEIF flag prior to re-configuring SAES.

**RNG error interrupt flag (RNGEIF)**

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC, or when RESEED bit of the SAES_DPACFGR register is set. In the latter case, SAES fetches random numbers every 65535 AES computations. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared...
by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the RNGEIF bit of the SAES_IER register is set. For more details, refer to Section 42.5: SAES interrupts.

Upon an RNG error:
- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear the RNGEIF bit of the SAES_ISR register, or reset the peripheral by setting the IPRST bit of the SAES_CR register. The clearance of the BUSY flag in the SAES_SR register then indicates the completion of the random number fetch from RNG.

Note: To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

About DPA errors

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, application must reset the SAES peripheral through RCC or global reset.

42.5 SAES interrupts

Individual maskable interrupt sources generated by the SAES peripheral signal the following events:
- computation completed
- read error
- write error
- key error
- RNG error

The individual sources are combined into the common interrupt signal saes_it that connects to NVIC (nested vectored interrupt controller). Each can individually be enabled/disabled, by setting/clearing the corresponding enable bit of the SAES_IER register, and cleared by setting the corresponding bit of the SAES_ISR register.

The status of each can be read from the SAES_SR and SAES_ISR registers.

Table 370 gives a summary of the interrupt sources, their event flags and enable bits.

42.7 **SAES registers**

42.7.1 **SAES control register (SAES_CR)**

Address offset: 0x00

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>IPRST: SAES peripheral software reset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself and the SAES_DPACFG register. Hence, any key-relative data is lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application. The bit must be low while writing any configuration registers.</td>
</tr>
</tbody>
</table>
Bits 30:28 **KEYSEL[2:0]:** Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

- 000: Software key, loaded in key registers SAES_KEYx
- 001: Derived hardware unique key (DHUK)
- 010: Boot hardware key (BHK)
- 100: XOR of DHUK and BHK
- 111: Test mode key (256-bit hardware constant 0xA5A5...A5A5)
- Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID = 0.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared. With the bitfield value other than zero and KEYVALID set, the application cannot transfer the ownership of SAES with a loaded key to an application running in another security context (such as secure, non-secure). More specifically, when security of an access to any register does not match the information recorded by SAES, the KEIF flag is set.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 27:26 **KSHAREID[1:0]:** Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0]=10 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

- 00: AES peripheral
- Others: Reserved

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]:** Key mode selection

The bitfield defines how the SAES key can be used by the application:

- 00: Normal key
- 01: Wrapped key
- 10: Shared key
- Others: Reserved

With normal key selection, the key registers are freely usable, no specific usage or protection applies to SAES_DIN and SAES_DOUT registers.

With wrapped key selection, the key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected in Wrapped-key mode read-as-zero SAES_DOUT register is automatically loaded into SAES key registers after a successful decryption process.

With shared key selection, after a successful decryption process, SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0]=10 and KEYVALID = 1. When a decryption is selected, read-as-zero SAES_DOUT register is automatically loaded into SAES key registers after a successful decryption process.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 23:20 Reserved, must be kept at reset value.
Bit 19 KEYPROT: Key protection
When set, hardware-based key protection is enabled.
0: When KEYVALID is set and KEYSEL=0 application can transfer the ownership of the SAES, with its loaded key, to an application running in another security context (such as non-secure, secure).
1: When KEYVALID is set, key error flag (KEIF) is set when an access to any registers is detected, this access having a security context (for example, secure, non-secure) that does not match the one of the application that loaded the key.
Attempts to write the bit are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bit 18 KEYSIZE: Key size selection
This bitfield defines the length of the key used in the SAES cryptographic core, in bits:
0: 128
1: 256
When KMOD[1:0]=01 or 10 KEYSIZE also defines the length of the key to encrypt or decrypt.
Attempts to write the bit are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.
Bit 16 Reserved, must be kept at reset value.
Bits 15:13 Reserved, must be kept at reset value.

Bit 12 DMAOUTEN: DMA output enable
This bit enables/disables data transferring with DMA, in the output phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by SAES during the output data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bit 11 DMAINEN: DMA input enable
This bit enables/disables data transferring with DMA, in the input phase:
0: Disable
1: Enable
When the bit is set, DMA requests are automatically generated by SAES during the input data phase. This feature is only effective when Mode 1 or Mode 3 is selected through the MODE[1:0] bitfield. It is not effective for Mode 2 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.
Bit 6 Reserved, must be kept at reset value.

Bit 5 CHMOD: Chaining mode selection
This bit selects the AES chaining mode:
0: Electronic codebook (ECB)
1: Cipher-block chaining (CBC)
Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

| Bits 31:8 | Reserved, must be kept at reset value. |

#### Bits 4:3 MODE[1:0]: SAES operating mode

This bitfield selects the SAES operating mode:

- 00: Mode 1: encryption
- 01: Mode 2: key derivation (or key preparation for ECB/CBC decryption)
- 10: Mode 3: decryption
- 11: Reserved

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

#### Bits 2:1 DATATYPE[1:0]: Data type selection

This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping:

- 00: None
- 01: Half-word (16-bit)
- 10: Byte (8-bit)
- 11: Bit

For more details, refer to Section 42.4.11: SAES data registers and data swapping.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

#### Bit 0 EN: SAES enable

This bit enables/disables the SAES peripheral:

- 0: Disable
- 1: Enable

At any moment, clearing then setting the bit re-initializes the SAES peripheral.

This bit is automatically cleared by hardware upon the completion of the key preparation (Mode 2).

Note: With KMOD[1:0] other than 00, use the IPRST bit rather than the bit EN.
Bit 7 **KEYVALID**: Key Valid flag

This bit is set by hardware when the amount of key information defined by KEYSIZE in SAES_CR has been loaded in SAES_KEYx key registers.
0: No valid key information is available in key registers. EN bit in SAES_CR cannot be set.
1: Valid key information, defined by KEYSIZE in SAES_CR, is loaded in key registers.

In normal mode when KEYSEL equals to zero, the application must write the key registers in the correct sequence, otherwise the KEIF flag of the SAES_ISR register is set and KEYVALID stays at zero.

When KEYSEL is different from zero the BUSY flag is automatically set by SAES. When key is loaded successfully, the BUSY flag is cleared and KEYVALID set. Upon an error, the KEIF flag of the SAES_ISR register is set, the BUSY flag cleared and KEYVALID kept at zero.

When the KEIF flag is set, the application must clear it through the SAES_ICR register, otherwise KEYVALID cannot be set. See the KEIF bit description for more details.

For more information on key loading please refer to Section 42.4.12: SAES key registers.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY**: Busy

This flag indicates whether SAES is idle or busy during GCM payload encryption phase:
0: Idle
1: Busy

The flag is set upon SAES initialization, upon fetching random number from the RNG, or upon transferring a shared key to a target peripheral.

Bit 2 **WRERR**: Write error

This flag indicates the detection of an unexpected write operation to the SAES_DINR register (during computation or data output phase):
0: Not detected
1: Detected

The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the SAES_ISR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the SAES_ISR register.
The flag setting has no impact on the SAES operation. Unexpected write is ignored.

Bit 1 **RDERR**: Read error flag

This flag indicates the detection of an unexpected read operation from the SAES_DOUTR register (during computation or data input phase):
0: Not detected
1: Detected

The flag is set by hardware. It is cleared by software upon setting the RWEIF bit of the SAES_ISR register.
Upon the flag setting, an interrupt is generated if enabled through the RWEIE bit of the SAES_ISR register.
The flag setting has no impact on the SAES operation. Unexpected read returns zero.

Bit 0 **CCF**: Computation completed flag

This bit mirrors the CCF bit of the SAES_ISR register.
42.7.3 SAES data input register (SAES_DINR)

Address offset: 0x08
Reset value: 0x0000 0000
Only 32-bit write access type is supported.

</tr>
</tbody>
</table>

Bits 31:0 DIN[31:0]: Input data word

A four-fold sequential write to this bitfield during the input phase results in writing a complete 128-bit block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 128-bit input buffer.

The data signification of the input data block depends on the SAES operating mode:
- **Mode 1** (encryption): plaintext
- **Mode 2** (key derivation): the bitfield is not used (SAES_KEYRx registers used for input if KEYSEL=0)
- **Mode 3** (decryption): ciphertext

The data swap operation is described in Section 42.4.11: SAES data registers and data swapping on page 1548.

42.7.4 SAES data output register (SAES_DOUTR)

Address offset: 0x0C
Reset value: 0x0000 0000
Only 32-bit read access type is supported. Read when KMOD[1:0] = 01 or 10 while MODE[1:0] = 10 and EN = 1 triggers a read error.

</tbody>
</table>

DOUT[15:0]
Bits 31:0 **DOUT[31:0]**: Output data word
This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF set), virtually reads a complete 128-bit block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.
Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0]. The data signification of the output data block depends on the SAES operating mode:
- **Mode 1** (encryption): ciphertext
- **Mode 2** (key derivation): the bitfield is not used
- **Mode 3** (decryption): plaintext
The data swap operation is described in *Section 42.4.11: SAES data registers and data swapping on page 1548.*

### 42.7.5 SAES key register 0 (SAES_KEYR0)

**Address offset:** 0x10
**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]
This write-only bitfield contains the bits [31:0] of the AES encryption or decryption key, depending on the operating mode:
- In **Mode 1** (encryption), **Mode 2** (key derivation): the value to write into the bitfield is the encryption key.
- In **Mode 3** (decryption): the value to write into the bitfield is the encryption key to be derived before being used for decryption.
The SAES_KEYRx registers may be written only when KEYSIZE value is correct and when the SAES peripheral is disabled (EN bit of the SAES_CR register cleared). A special writing sequence is also required, as described in KEYVALID bit of the SAES_SR register. Note that, if KEYSEL is different from 0 and KEYVALID = 0, the key is directly loaded to SAES_KEYRx registers (hence writes to key register is ignored and KEIF is set).
Refer to *Section 42.4.12: SAES key registers on page 1550* for more details.

</table>

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 RNGEIE:** RNG error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)

**Bit 2 KEIE:** Key error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)

**Bit 1 RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)
1: Enabled (not masked)
Bit 0 **CCFIE**: Computation complete flag interrupt enable
   This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.
   0: Disabled (masked)
   1: Enabled (not masked)

</tr>
</tbody>
</table>

Bit 3 **RNGEIF**: RNG error interrupt flag
   This read-only bit is set by hardware when an error is detected on RNG bus interface (e.g. bad entropy).
   0: RNG bus is functional
   1: Error detected on RNG bus interface (random seed fetching error)
   RNGEIF bit is cleared when application sets the corresponding bit of SAES_ICR register. An interrupt is generated if the RNGEIF bit has been previously set in the SAES_IER register. Clearing this bit triggers the reload of a new random number from RNG peripheral.

Bit 2 **KEIF**: Key error interrupt flag
   This read-only bit is set by hardware when key information failed to load into key registers or key register usage is forbidden.
   0: No key error detected
   1: Key information failed to load into key registers, or key register use is forbidden
   Setting the corresponding bit of the SAES_ICR register clears the KEIF and generates interrupt if the KEIF bit of the SAES_IER register is set.
   KEIF is triggered upon any of the following errors:
   – SAES fails to load the DHUK (KEYSEL = 001 or 100).
   – SAES fails to load the BHK (KEYSEL = 010 or 100) respecting the correct order.
   – AES fails to load the key shared by SAES peripheral (KMOD=10).
   – When KEYVALID = 1 and (KEYPROT = 1 or KEYSEL is not 0x0), the security context of the application that loads the key (secure or non-secure) does not match the security attribute of the access to SAES_CR or SAES_DOUT. In this case, KEYVALID and EN bits are cleared.
   – SAES_KEYRx register write does not respect the correct order. (For KEYSIZE = 0, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE = 1, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse).
   KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.
Bit 1 **RWEIF**: Read or write error interrupt flag
- This read-only bit is set by hardware when a RDERR or a WRERR error flag is set in the SAES_SR register.
- 0: No read or write error detected
- 1: Read or write error detected (see SAES_SR register for details)
- RWEIF bit is cleared when application sets the corresponding bit of SAES_ICR register. An interrupt is generated if the RWEIF bit has been previously set in the SAES_IER register.
- This flags has no meaning when key derivation mode is selected.

Bit 0 **CCF**: Computation complete flag
- This flag indicates whether the computation is completed:
- 0: Not completed
- 1: Completed
- The flag is set by hardware upon the completion of the computation. It is cleared by software, upon setting the CCF bit of the SAES_ISR register.
- Upon the flag setting, an interrupt is generated if enabled through the CCFIE bit of the SAES_IER register.
- The flag is significant only when the DMAOUTEN bit is 0. It may stay high when DMA_EN is 1.

### 42.7.19 SAES interrupt clear register (SAES_ICR)

</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF**: RNG error interrupt flag clear
- Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2 **KEIF**: Key error interrupt flag clear
- Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1 **RWEIF**: Read or write error interrupt flag clear
- Setting this bit clears the RWEIF status bit of the SAES_ISR register, and both RDERR and WRERR flags in the SAES_SR register.

Bit 0 **CCF**: Computation complete flag clear
- Setting this bit clears the CCF status bit of the SAES_SR and SAES_ISR registers.

43 Hash processor (HASH)

43.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-224, SHA-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to \((2^{64} - 1)\) bits. It also computes 128-bit digests for the MD5 algorithm.

43.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, Digital Signature Standard (DSS)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321, MD5 Message-Digest Algorithm
- Fast computation of SHA-1, SHA-224, SHA-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits \((16 \times 32\) bits)
- Single 32-bit input register associated to an internal input FIFO, corresponding to one block size
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- \(8 \times 32\)-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel.
- Single or fixed DMA burst transfers of four words
• Interruptible message digest computation, on a per-block basis
  – Re-loadable digest registers
  – Hashing computation suspend/resume mechanism, including DMA

### 43.3 HASH implementation

The devices have a single instance of HASH peripheral.

### 43.4 HASH functional description

43.4.3About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below $2^{64}$ bits is provided on input, the HASH processing core produces respectively a fixed-length output string called a message digest, defined as follows:

- For MD5 digest size is 128-bit
- For SHA-1 digest size is 160-bit
- For SHA-224 and SHA-256, the digest size is 224 bits and 256 bits, respectively

The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017). Any change to a message in transit, with very high probability, results in a different message digest, and the signature fails to verify.

43.4.4Message data feeding

The message (or data file) to be processed by the HASH should be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “01100001 01100010 01100011” is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).
In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. Figure 367 shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 367. Message data swapping feature
43.4.5  Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. For MD5, SHA1 and SHA2, the block size is 512 bits.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in Section 43.4.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO.

In order to perform the hash computation on this data below sequence must be used by the application:

1. Initialize the hash processor using the HASH_CR register:
   a) Select the right algorithm using the ALGO bitfield. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH_CR.
   b) When the HMAC mode is required, set the MODE bit, as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (else keep LKEY cleared). Refer to Section 43.4.7: HMAC operation for details.
   c) Set MODE = 1 and select the key length using LKEY if HMAC mode has been selected.
   d) Update NBLW[4:0] to define the number of valid bits in last word of the message if it is different from 32 bits. NBLW[4:0] information are used to correctly perform the automatic message padding before the final message digest computation.

2. Complete the initialization by setting to 1 the INIT bit in HASH_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

Caution: When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW[4:0]).

3. Start filling data by writing to HASH_DIN register, unless data are automatically: transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   a) When data are filled by software:
      – Partial digest computation are triggered each time the application writes the first word of the next block, the block size being defined the NBWE bit of HASH_CR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
      – The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of the block size, the NBLW[4:0] bitfield in HASH_STR register must be written prior to writing DCAL bit (see Section 43.4.6 for details).
   b) When data are filled by DMA as a single DMA transfer (MDMAT bit = 0):
      – Partial digest computations are triggered automatically each time the FIFO is full. The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of the block size, the NBLW[4:0] field
in HASH_STR register must be written prior to enabling the DMA (see
Section 43.4.6 for details).

c) When data are filled using multiple DMA transfers (MDMAT bit = 1):
– Partial digest computations are triggered as for single DMA transfers. However the
final digest computation is not triggered automatically when the last block has
been transferred to the HASH_DIN register (DCAL bit is not set to 1 by hardware).
It allows the hash processor to receive a new DMA transfer as part of this digest
computation. To launch the final digest computation, the software must set
MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest
computation as it is done for single DMA transfers (see description before).

4. Once the digest computation is complete (DCIS = 1), the resulting digest can be read
from the output registers as described in Table 374.

For more information about HMAC detailed instructions, refer to Section 43.4.7: HMAC
operation.

43.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data
into the hash processor (with automatic partial digest computation every block transfer)
loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written
to the hash processor may have a valid number of bits between 1 and 32. This number of
valid bits in the last word, NBLW[4:0], has to be written to the HASH_STR register, so that
message padding is correctly performed before the final message digest computation.

Padding processing

Detailed padding sequences with DMA enabled or disabled are described in Section 43.4.5:
Message digest computing.

Padding example

As specified by Federal Information Processing Standards PUB 180-4, the message
padding consists in appending a “1” followed by \( k \) “0”s, itself followed by a 64-bit integer that
is equal to the length \( L \) in bits of the message. These three padding operations generate a
padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at
the bit position defined by the NBLW[4:0] bitfield, and the remaining upper bits are cleared
(“0”s).
Example from FIPS PUB180-4

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24:

```
<table>
<thead>
<tr>
<th>byte 0</th>
<th>byte 1</th>
<th>byte 2</th>
<th>byte 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>01100001 01100010 01100011</td>
<td>UUUUUUUU</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

<- 1st word written to HASH_DIN -->

NBLW[4:0] has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

The message length value, L, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered by following the below sequence:

1. **0xUU636261** is written to the HASH_DIN register (where ‘U’ means don’t care).
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits).
3. **0x10** is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0...4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

<table>
<thead>
<tr>
<th>HASH_HR0</th>
<th>HASH_HR1</th>
<th>HASH_HR2</th>
<th>HASH_HR3</th>
<th>HASH_HR4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xA9993E36</td>
<td>0x4706816A</td>
<td>0xBA3E2571</td>
<td>0x7850C26C</td>
<td>0x9CD0D89D</td>
</tr>
</tbody>
</table>
43.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC(message)} = \text{Hash}((\text{Key} | \text{pad} \oplus \text{opad}) | \text{Hash}((\text{Key} | \text{pad} \oplus \text{ipad}) | \text{message}))
\]

where:

- \( \text{opad} = [0x5C]_n \) (outer pad) and \( \text{ipad} = [0x36]_n \) (inner pad)
- \([X]_n\) represents a repetition of \(X\) \(n\) times, where \(n\) equal to the size of the underlying hash function data block (\(n = 64\) for 512-bit blocks).
- \( \text{pad} \) is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- \( \oplus \) represents the concatenation operator.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software writes the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading, that is writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW\([4:0]\) to HASH_STR register. Note: Endianness details can be found in Section 43.4.4: Message data feeding.
3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software writes DCAL bit to 1 in HASH_STR register, the NBLW\([4:0]\) bitfield must be written at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in Section 43.4.4: Message data feeding.
4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register then completing the transfer by writing DCAL bit to 1 and the correct NBLW\([4:0]\) to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HR7) as soon as DCIS bit is set to 1. Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 43.6: HASH processing time.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST.
Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen = blocklen", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is no padding), specified by NIST. As key length = 64, LKEY bit is set to 0 in HASH_CR register
   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617 18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F 30313233 34353637 38393A3B 3C3D3E3F

2. **Message** input (length = 34, that is padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don't care)
   53616D70 6C65737361 67652066 6F72206B 65796C65 53616D70 6C65737361 67652066 6F72206B 65796C65 53616D70 6C65737361 67652066 6F72206B 65796C65
   53616D70 6C65737361 67652066 6F72206B 65796C65 53616D70 6C65737361 67652066 6F72206B 65796C65
   53616D70 6C65737361 67652066 6F72206B 65796C65 53616D70 6C65737361 67652066 6F72206B 65796C65
   53616D70 6C65737361 67652066 6F72206B 65796C65

3. **Outer hash key** input (length = 64, that is no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers (x = 0 to 4), as shown below:

   - HASH_HR0 = 0x5FD596EE
   - HASH_HR1 = 0x78D5553C
   - HASH_HR2 = 0x8FF4E72D
   - HASH_HR3 = 0x266DFD19
   - HASH_HR4 = 0x2366DA29
43.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 368.

Figure 368. HASH suspend/resume mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described below.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0, then poll if the DINIS status bit is set to 1.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR and HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing is described below. In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see Figure 368).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data using the DMA to complete the current input block and launch a hash process.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in this register the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR, HASH_CR, and HASH_CSR0 to HASH_CSR37 registers. HASH_CSR38 to HASH_CSR53 registers must also be saved if an HMAC operation was ongoing.
To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

43.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information refer to Section 43.4.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[ NBLW[4:0] = \text{Len}(\text{Message}) \mod 32 \]

where \( x \mod 32 \) gives the remainder of \( x \) divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

43.4.10 HASH error management

No error flags are generated by the hash processor.

43.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the NVIC (nested vectored interrupt controller). Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of each maskable interrupt source can be read from the HASH_SR register. Table 375 gives a summary of the available features.
43.6 HASH processing time

*Table 376* summarizes the time required to process an intermediate block for each mode of operation.

1. Add the time required to load the block into the processor.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- \(1 \text{ to } 2.5\) for a hash message
- \(\sim 2.5\) for an HMAC input-key
- \(1 \text{ to } 2.5\) for an HMAC message
- \(\sim 2.5\) for an HMAC output key in case of a short key
- \(3.5 \text{ to } 5\) for an HMAC output key in case of a long key
43.7 HASH registers

The HASH core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

43.7.1 HASH control register (HASH_CR)

Address offset: 0x00
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-19</th>
<th>Bit 18-17</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **ALGO[1:0]: Algorithm selection**

   These bits select the hash algorithm.
   00: SHA-1
   01: MD5
   10: SHA-224
   11: SHA-256

   This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect.

   When ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

Bit 16 **LKEY: Long key selection**

   This bit selects between short key (≤ 64 bytes) or long key (> 64 bytes) in HMAC mode.
   0: the HMAC key is shorter or equal to 64 bytes. The actual key value written to HASH_DIN is used during the HMAC computation.
   1: the HMAC key is longer than 64 bytes. The hash of the key is used instead of the real key during the HMAC computation.

   This selection is only taken into account when the INIT bit is set and MODE = 1. Changing this bit during a computation has no effect.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT: Multiple DMA transfers**

   This bit is set when hashing large files when multiple DMA transfers are needed.
   0: DCAL is automatically set at the end of a DMA transfer.
   1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE: DIN not empty**

   Refer to DINNE bit of HASH_SR for the description.
   This bit is read-only.
Bits 11:8 **NBW[3:0]**: Number of words already pushed
Refer to NBWP[3:0] bitfield of HASH_SR for the description.
This bitfield is read-only.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **MODE**: Mode selection
This bit selects the HASH or HMAC mode for the selected algorithm:
0: Hash mode selected
1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.
This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

Bits 5:4 **DATATYPE[1:0]**: Data type selection
Defines the format of the data entered into the HASH_DIN register:
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data, or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data, or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data, or bit-string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE**: DMA enable
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the HASH core is ready to receive data.
After this bit is set it is cleared by hardware while the last data of the message is written into the hash processor.
Setting this bit to 0 while a DMA transfer is ongoing is not aborting this current transfer. Instead, the DMA interface of the IP remains internally enabled until the transfer is completed or INIT is written to 1.
Setting INIT bit to 1 does not clear DMAE bit.

Bit 2 **INIT**: Initialize message digest calculation
Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0 Reserved, must be kept at reset value.

### 43.7.2 HASH data input register (HASH_DIN)

Address offset: 0x04
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks. When the HASH_DIN register is programmed, the value presented on the AHB databus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.
When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:

- by writing new data into the HASH_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by writing the DCAL bit to 1 in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is set to 0.

Reading the HASH_DIN register returns zeros.

**Note:** When the HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

### 43.7.3 HASH start register (HASH_STR)

**Address offset:** 0x08

**Reset value:** 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **DCAL**: Digest calculation

Writing this bit to 1 starts the message padding, using the previously written value of **NBLW[4:0]**, and starts the calculation of the final message digest with all data words written to the input FIFO since the INIT bit was last written to 1.

Reading this bit returns 0.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **NBLW[4:0]**: Number of valid bits in the last word

When the last word of the message bit string is written in **HASH_DIN** register, the hash processor takes only the valid bits specified as below, after internal data swapping:

- 0x00: All 32 bits of the last data written are valid message bits that is **M[31:0]**
- 0x01: Only one bit of the last data written (after swapping) is valid that is **M[0]**
- 0x02: Only two bits of the last data written (after swapping) are valid that is **M[1:0]**
- 0x03: Only three bits of the last data written (after swapping) are valid that is **M[2:0]**
  ...
- 0x1F: Only 31 bits of the last data written (after swapping) are valid that is **M[30:0]**

The above mechanism is valid only if **DCAL** = 0. If **NBLW[4:0]** bitfield is written while **DCAL** is set to 1, the **NBLW[4:0]** bitfield remains unchanged. In other words it is not possible to configure **NBLW[4:0]** and set **DCAL** at the same time.

Reading **NBLW[4:0]** bitfield returns the last value written to **NBLW[4:0]**.
43.7.4 HASH digest registers

These registers contain the message digest result named as follows:
- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result
- HASH_HR0, HASH_HR1, HASH_HR2 and HASH_HR3 registers return A, B, C and D (respectively), as defined by MD5.
- HASH_HR0 to HASH_HR6 registers return the SHA-224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA-256 digest result.

In all cases, the digest most significant bit is stored in HASH_H0[31] and unused HASH_HRx registers are read as zeros.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

Note: When starting a digest computation for a new message (by writing the INIT bit to 1), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses.

HASH aliased digest register x (HASH_HRAx)

Address offset: 0x0C + 0x04 * x, (x = 0 to 4)
Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

Bits 31:2 Reserved, must be kept at reset value.

- **Bit 1 DCIE**: Digest calculation completion interrupt enable
  - 0: Digest calculation completion interrupt disabled
  - 1: Digest calculation completion interrupt enabled.

- **Bit 0 DINIE**: Data input interrupt enable
  - 0: Data input interrupt disabled
  - 1: Data input interrupt enabled
43.7.6 HASH status register (HASH_SR)

Address offset: 0x24
Reset value: 0x0000 0001

| Bit 31:21 | Reserved, must be kept at reset value. |
| Bit 20:16 | NBWE[4:0]: Number of words expected |
| This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register. NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR, and it is set to the expected block size when partial digest calculation ends. |
| Bit 15 | DINNE: DIN not empty |
| This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1. |
| 0: No data are present in the data input buffer |
| 1: The input buffer contains at least one word of data |
| Bit 14 | Reserved, must be kept at reset value. |
| Bit 13:9 | NBWP[4:0]: Number of words already pushed |
| This bitfield is the exact number of words in the message that have already been pushed into the FIFO. NBWP is incremented by one when a write access is performed to the HASH_DIN register. When a digest calculation starts, NBWP is updated to NBWP - block size (in words), and NBWP goes to zero when the INIT bit is written to 1. |
| Bit 8:4 | Reserved, must be kept at reset value. |
| Bit 3 | BUSY: Busy bit |
| 0: No block is currently being processed |
| 1: The hash core is processing a block of data |
43.7.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + x * 0x4, (x = 0 to 53)
Reset value: 0x0000 0002 (HASH_CSR0)
Reset value: 0x0000 0000 (HASH_CSR1 to 53)
### Table 377. HASH register map and reset values

| Offset  | Register name | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|---------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Refer to Section 2.3 on page 116 for the register boundary addresses.
44  On-the-fly decryption engine (OTFDEC)

This section only applies to STM32U585 devices.

44.1  Introduction

OTFDEC allows on-the-fly decryption of the AHB traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC.

OTFDEC uses AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed, the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR Flash.

Note: When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to access the Flash memory using the Memory-mapped mode of the Flash memory controller.

When security is enabled in the product, OTFDEC can be programmed only by a secure host.

44.2  OTFDEC main features

- On-the-fly 128-bit decryption during the OCTOSPI Memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with two 128-bit keystream buffers
  - Support for any read size
  - Physical address of the reads used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write-locking mechanism
  - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for OCTOSPI pre-fetching mechanism
- Possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher (execute only)
- Privileged-aware AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Secure only programming if TrustZone security is enabled in the product
- Encryption mode

The TZEN option bit in FLASH is used to activate TrustZone in the device.
- TZEN = 1: TrustZone security is enabled in the product.
- TZEN = 0: TrustZone security is disabled in the product.

44.3.3 OTFDEC on-the-fly decryption

Introduction

Typical usage for OTFDEC is shown on Figure 370.

Figure 370. Typical OTFDEC use in a SoC

Original purpose of OTFDEC is to protect the confidentiality of read-only firmware libraries stored in external SPI NOR Flash devices.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks. OTFDEC access to most registers can be made privileged-only by setting PRIV bit in OTFDEC_PRIVCFGR register. OTFDEC is only writeable by TrustZone CPU, when TrustZone security is activated.

When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to read the Flash memory using the Memory-mapped mode of the Flash controller.

On top of decrypting on-the-fly, OTFDEC can also encrypt 32-bit word at a time (see Section 44.5.3: Encrypting for OTFDEC for more details).

OTFDEC architecture

OTFDEC analyzes all AHB read transfers on the associated AHB bus. If the read request is within one of the four regions programmed in OTFDEC, the control logic triggers a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read transfer from the OCTOSPI AHB master, tying low the HREADYOUT signal of this master while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC region is programmed through OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR, OTFDEC_RxNONCER and...
OTFDEC_RxKEYR registers, where x = 1 to 4. In OTFDEC_RxCFGR, the MODE bits define the OTFDEC operating mode (standard or enhanced encryption).

Granularity for the region determination is 4096 bytes.

Note: Although OTFDEC does not prevent region overlapping, it is not a valid programming and it must be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

44.3.4 OTFDEC usage of AES in counter mode decryption

Figure 371 shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

Every 128-bit data block, a special keystream information is computed using AES block cipher, as defined below:

- initialization vector $AES\_IV[127:0] = RxNONCER1[31:0] || RxNONCER0[31:0] || 0b0000 0000 0000 0000 || RxCFGR[31:16] || 0b00 || (x-1) || ReadAddress[31:4]$
- key material $AES\_KEY[127:0] = RxKEYR3[31:0] || RxKEYR2[31:0] || RxKEYR1[31:0] || RxKEYR0[31:0]$

Note: Above $x$ is the RegionID of the selected encrypted region ($x=1$ to 4). ReadAddress is the AHB address of the encrypted data block, modulo 128-bit.

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- $AES\_DIN$ and $AES\_DOUT$ data blocks are constructed following the rule below ("||" represents a binary concatenation):
  $AES\_{Dx}[127:0]= AHB\_word(@ || 0xC)[31:0] || AHB\_word(@ || 0x8)[31:0] || AHB\_word(@ || 0x4)[31:0] || AHB\_word(@ || 0x0)[31:0]$, where $@$ is the hexadecimal address used to compute the keystream (ReadAddress[31:4] above).
When the read request is not within an encrypted region, or the decryption is not enabled in this region, the AHB data is not changed.

**Note:** When the application sets the MODE bitfield to 11 in OTFDEC_RxCFGR, an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode can only be used with instructions (execute-only region).

### 44.3.5 Flow control management

*Figure 372* shows how OTFDEC manages one INCR4 AHB burst that corresponds to one 128-bit AES data block.

*Figure 372. OTFDEC flow control overview (dual burst read request)*

with the following notes:

1. OTFDEC enforces HREADY signal from the AHB master low as it is not ready to decrypt data (keystream computation).
2. Thanks to the keystream buffer, OTFDEC can be ready to process a new batch of data within 12 cycles in this configuration (120 MHz AHB clock, 104 MHz SPI bus delivering 2 bytes per SPI clock).

### 44.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:

- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK = 1 in OTFDEC_RxCFGR, while the access is secure. If the security is disabled in the product, the same error occurs when the access is non-secure.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK = 1 in OTFDEC_RxCFGR (x = 1 to 4), while the access is secure. If the security is disabled in the product the same error occurs when the access is non-secure.
- Illegal read to an execute-only region (MODE[1:0] = 11). Such illegal request returns 0x0, without bus error.
- Execution request to a region while encryption is enabled (ENC = 1). The request returns 0x0, without bus error.
- Key error: read request to an encrypted region while its key registers are null or not properly initialized (KEYCRC = 0x0). Source of the error can be an incorrect key loading sequence (see KEYCRC in OTFDEC_RxCFGR) or it can be an abort event
On-the-fly decryption engine (OTFDEC) RM0456

(tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read request returns 0x0, without bus error.

- Write to any registers while the access is non-secure, if TrustZone security is enabled in the product.
  
  This last error is managed and cleared through TrustZone interrupt controller, as described in the GTZC section of the product reference manual.

For these errors (except the last one), an interrupt can be generated if the SEIE, XONEIE or KEIE bit is set in OTFDEC_IER register (see Section 44.4).

**Note:** After a key error, OTFDEC keys must be properly initialized again, and a reset of OTFDEC may be needed if registers are locked.

### 44.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see Section 44.3.6
- Illegal write to a region configuration while CONFIGLOCK = 1 (SEIF flag), see Section 44.3.6
- Read access to an execute-only region (MODE[1:0] = 11), triggering the XONEIF flag
- Executing while encryption is enabled (XONEIF flag)
- Key error (encrypted regions read as zero) triggering the KEIF flag, see Section 44.3.6.

Interrupt sources are connected to the same global interrupt request signal.

OTFDEC interrupt sources can be enabled/disabled by setting the corresponding SEIE, XONEIE or KEIE bit in OTFDEC_IER, as described in Table 379. Status of the interrupt event is found in OTFDEC_ISR, and this event can be cleared using OTFDEC_ICR.

**Table 379. OTFDEC interrupt requests**

### 44.5 OTFDEC application information

#### 44.5.1 OTFDEC initialization process

**Introduction**

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys. Two trusted initialization schemes are recommended here below.
**Note:** Those sequences are for production code, as during firmware development, it is not always recommended to lock the key or the region configuration. Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

**Initialization scheme 1: one key for all regions**

In this scheme, one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

1. For \( x = 1 \) to \( 4 \), write the correct MODE[1:0] value in OTFDEC_RxCFGR.
2. For \( x = 1 \) to \( 4 \), program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
3. For \( x = 1 \) to \( 4 \), check the key CRC. If OK, set KEYLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (key registers in this region \( x \) are no more writable).
4. To do to decrypt a region \( x \) (task that does not necessarily have to be performed by the entity that owns the decryption keys):
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG_EN.
   d) Set CONFIGLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (the region configuration is no more writable).

**Caution:** For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence, step 1 above must be done before step 2, and MODE bits must not be modified after step 2.

**Initialization scheme 2: one key per region**

In this scheme, one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

1. To do to decrypt a region \( x \) (this task **must** be performed by the entity that owns the corresponding key):
   a) Write the correct MODE[1:0] value in OTFDEC_RxCFGR.
   b) Program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
   c) Check the key CRC. If OK, set KEYLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (key registers are no more writable).
   d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).
   e) Enable decryption of this region using REG_EN.
   f) Set CONFIGLOCK bit in OTFDEC_RxCFGR. This bit cannot be cleared (the region configuration is no more writable).

**Caution:** For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and MODE bits must not be modified after step b).
44.5.2 OTFDEC and power management

Each time OTFDEC is reset, the correct key loading sequence described in Section 44.5.1 must be performed (in this case KEYCRC = 0 in OTFDEC_RxCFGR).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

44.5.3 Encrypting for OTFDEC

Code and data standard encryption

OTFDEC uses standard AES in counter mode when processing a binary stored in a protected region with MODE[1:0] = 10. When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. OTFDEC can be used as well, as described in enhanced encryption section below (with MODE[1:0] = 10).

Definition and endianness of the AES inputs and outputs are defined in Section 44.3.4: OTFDEC usage of AES in counter mode decryption.

Enhanced encryption with OTFDEC

OTFDEC uses a proprietary layer of protection on top of the standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.

Recommended sequence to encrypt using OTFDEC is described below:

1. The application in charge of the encryption sets the ENC bit in OTFDEC_CR. This application must run in TrustZone secure mode when TrustZone security is enabled in the product. If PRIV bit is set in OTFDEC_PRIVCFGR, this application must be privileged.

2. Encryption application initializes OTFDEC as described in Section 44.5.1: OTFDEC initialization process. OCTOSPI must also be properly clocked, so that OTFDEC is fully functional in encryption mode. This step can also be done before step 1.

3. Encryption application writes 32-bit of clear-text data at the expected protected address, then reads it back encrypted at the same address to store it in RAM. Note that this data stays inside the device, as it is intercepted by OTFDEC in encryption mode.

4. Encryption application goes back to previous step (changing the address) until the whole binary is processed.

5. Encryption application clears the ENC bit in OTFDEC_CR. Another application can then take the encrypted binary and flash it to the correct address in external Flash.

There are few important notes about this procedure:

- Encryption granularity is 32-bit (single 32-bit access is mandatory).
- While ENC bit is set, reads to non-encrypted regions return normal data (such as no encryption nor decryption). While in encryption mode, no access to OCTOSPI (including registers) must be done. This is because the OTFDEC cuts the communication with OCTOSPI while ENC bit is set.
- OTFDEC does not support execution while ENC = 1 (only encrypted data reads). Upon illegal execution detection a XONEIF flag is raised and zero is returned.
44.5.4 OTFDEC key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```c
uint8_t getCRC(uint32_t * keyin)
{
    const uint8_t CRC7_POLY = 0x7;
    const uint32_t key_strobe[4] = {0xA55AA55, 0x3, 0x18, 0xC0};
    uint8_t  i, j, k, crc = 0x0;
    uint32_t  keyval;

    for (j = 0; j < 4; j++)
    {
        keyval = *(keyin+j);
        if (j == 0)
        {
            keyval ^= key_strobe[0];
        }
        else
        {
            keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8) | crc;
        }

        for (i = 0, crc = 0; i < 32; i++)
        {
            k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1;
            crc <<= 1;
            if (k)
            {
                crc ^= CRC7_POLY;
            }
        }
        crc^=0x55;
    }
    return crc;
}
```
44.6 OTFDEC registers

44.6.1 OTFDEC control register (OTFDEC_CR)

Address offset: 0x0
Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ENC:** Encryption mode bit

When this bit is set, OTFDEC is used in encryption mode, during which application can write clear text data then read back encrypted data. When this bit is cleared (default), OTFDEC is used in decryption mode, during which application only read back decrypted data. For both modes, cryptographic context (keys, nonces, firmware versions) must be properly initialized.

When this bit is set, only data accesses are allowed (zeros are returned otherwise, and XONEIF is set). When MODE = 11, enhanced encryption mode is automatically selected.

0: OTFDEC working in decryption mode
1: OTFDEC working in encryption mode

**Note:** When ENC bit is set, no access to OCTOSPI must be done (registers and Memory-mapped region).

44.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR)

Address offset: 0x10
Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.
### OTFDEC Region x Configuration Register (OTFDEC_RxCFGR)

Address offset: 0x20 + 0x30 * (x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Write are ignored if CONFIGLOCK bit is set to 1.

#### Bits 31:1 Reserved, must be kept at reset value.
- **Bit 0 PRIV:** Privileged access protection.
  - 0: No additional protection is added on OTFDEC register accesses.
  - 1: An additional protection is added when accessing all registers except OTFDEC_PRIVCFGR:
    - Unprivileged read accesses to registers return zeros
    - Unprivileged write accesses to registers are ignored.

*Note:* This bit can only be written in privileged mode. There is no limitations on reads.

### OTFDEC On-the-fly decryption engine (OTFDEC)
Bits 31:16 \textbf{REGx\_VERSION}[15:0]: region firmware version

This 16-bit bitfield must be correctly initialized before the region corresponding REG\_EN bit is set in OTFDEC\_RxCFGR.

Bits 15:8 \textbf{KEYCRC}[7:0]: region key 8-bit CRC

When KEYLOCK = 0, KEYCRC bitfield is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new computation starts as soon as a new valid sequence is initiated, and KEYCRC is read as zero until a valid sequence is completed.

When KEYLOCK = 1, KEYCRC remains unchanged until the next reset.

CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm \(X^8 + X^2 + X + 1\) (according the convention). Source code is available in Section 44.5.4.

This field is read only.

\textit{Note: CRC information is updated only after the last bit of the key has been written.}

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 \textbf{MODE}[1:0]: operating mode

This bitfield selects the OTFDEC operating mode for this region:

10: All read accesses are decrypted (instruction or data).

11: Enhanced encryption mode is activated, and only instruction accesses are decrypted

Others: Reserved

When MODE \(\neq 11\), the standard AES encryption mode is activated.

When either of the MODE bits are changed, the region key and associated CRC are zeroed.

Bit 3 Reserved, must be kept at reset value.

Bit 2 \textbf{KEYLOCK}: region key lock

0: Writes to this region KEYRx registers are allowed.

1: Writes to this region KEYRx registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.

\textit{Note: This bit is set once: if this bit is set, it can only be reset to 0 if the OTFDEC is reset.}

Bit 1 \textbf{CONFIGLOCK}: region config lock

0: Writes to this region OTFDEC\_RxCFGR, OTFDEC\_RxSTARTADDR, OTFDEC\_RxENDADDR and OTFDEC\_RxNONCERY registers are allowed.

1: Writes to this region OTFDEC\_RxCFGR, OTFDEC\_RxSTARTADDR, OTFDEC\_RxENDADDR and OTFDEC\_RxNONCERY registers are ignored until next OTFDEC reset.

\textit{Note: This bit is set once. If this bit is set, it can only be reset to 0 if OTFDEC is reset. Setting this bit forces KEYLOCK bit to 1.}

Bit 0 \textbf{REG\_EN}: region on-the-fly decryption enable

0: On-the-fly decryption is disabled for this region.

1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.

\textit{Note: Garbage is decrypted if region context (version, key, nonce) is not valid when this bit is set.}
### 44.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR)

Address offset: \(0x24 + 0x30 \times (x-1)\) (x = 1 to 4)

Reset value: \(0x0000\ 0000\)

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 **REGx_START_ADDR[31:0]**: Region AHB start address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

**Note:** When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored. When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros.

### 44.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: \(0x28 + 0x30 \times (x-1)\) (x = 1 to 4)

Reset value: \(0x0000\ 0FFF\)

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

 Bits 31:0 **REGx_END_ADDR[31:0]**: Region AHB end address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

**Note:** When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.
On-the-fly decryption engine (OTFDEC)

44.6.6 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0)

Address offset: 0x2C + 0x30 * (x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 REGx_END_ADDR[31:0]: Region AHB end address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set, and OTFDEC_RxENDADDR must be strictly greater than OTFDEC_RxSTARTADDR to be valid.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in OTFDEC_RxCFGR is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.

When this register is accessed in read the 4 MSB bits return zeros and the 12 LSB bits return ones.

Bits 31:0 REGx_NONCE[31:0]: Region nonce, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Writing is discarded in this register if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR is set.
44.6.7 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1)
Address offset: 0x30 + 0x30 * (x -1) (x = 1 to 4)
Reset value: 0x0000 0000
Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.
Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 REGx_KEY[31:16]: Region key, bits [31:16]
This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.
Reading this register returns a zero value. Writing to this register is discarded if performed while the region CONFIGLOCK or KEYLOCK bit is set in the OTFDEC_RxCFGR.

Note: When application successfully changes MODE bits in OTFDEC_RxCFGR and OTFDEC_RxKEYR, and associated KEYCRC are erased.
44.6.9 **OTFDEC region x key register 1 (OTFDEC_RxKEYR1)**

Address offset: 0x38 + 0x30 * (x - 1) (x = 1 to 4)

Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Bits 31:0 KEIF| XONEIF| SEIF
r  r  r
Bits 31:3  Reserved, must be kept at reset value.

Bit 2  **KEIF**: Key error interrupt flag status

This bit is set by hardware and read only by application. The bit is set when a read access occurs on an encrypted region, while its key registers is null or not properly initialized (KEYCRC = 0x0).

This bit is cleared when the application sets in OTFDEC_ICR the corresponding bit to 1.

0: OTFDEC operates properly.

1: Read access detected on an enabled encrypted region with its key registers null or not properly initialized (KEYCRC = 0x0). OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to 1 in OTFDEC_IER.

After KEIF is set any subsequent read to the region with bad key registers returns a zeroed value. This state remains until those key registers are properly initialized (KEYCRC not zero).

Bit 1  **XONEIF**: Execute-only execute-never error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 11. Lastly, XONEIF is also set when an execute access is detected while encryption mode is enabled.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No execute-only error status. No interrupt pending.

1: Read access detected on one region with MODE bits set to 11 or execute access detected while ENC = 1. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to 1 in OTFDEC_IER.

Bit 0  **SEIF**: Security error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when at least one security error has been detected.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No security error status. No interrupt pending.

1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

### 44.6.13 OTFDEC interrupt clear register (OTFDEC_ICR)

Address offset: 0x304

Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.
On-the-fly decryption engine (OTFDEC)

**44.6.14 OTFDEC interrupt enable register (OTFDEC_IER)**

Address offset: 0x308

Reset value: 0x0000 0000

Non-secure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

**Bit 31:3 Reserved, must be kept at reset value.**

**Bit 2 KEIF: Key error interrupt flag clear**

This bit is written by application, and always read as 0.

0: KEIF flag status is not affected.

1: KEIF flag status is cleared in OTFDEC_ISR.

*Note:* Clearing KEIF does not solve the source of the problem (bad key registers). To be able to access again any encrypted region, OTFDEC key registers must be properly initialized again.

**Bit 1 XONEIF: Execute-only execute-never error interrupt flag clear**

This bit is written by application, and always read as 0.

0: XONEIF flag status is not affected.

1: XONEIF flag status is cleared in OTFDEC_ISR.

**Bit 0 SEIF: Security error interrupt flag clear**

This bit is written by application, and always read as 0.

0: SEIF flag status is not affected.

1: SEIF flag status is cleared in OTFDEC_ISR.
Bit 2  **KEIE**: Key error interrupt enable
   This bit is read and written by application. It controls the OTFDEC interrupt generation when KEIF flag status is set.
   0: Interrupt generation on key error flag KEIF is disabled (masked).
   1: Interrupt generation on key error flag KEIF is enabled (not masked).

Bit 1 **XONEIE**: Execute-only execute-never error interrupt enable
   This bit is read and written by application. It controls the OTFDEC interrupt generation when XONEIF flag status is set.
   0: Interrupt generation on execute-only error XONEIF is disabled (masked).
   1: Interrupt generation on execute-only error XONEIF is enabled (not masked).

Bit 0 **SEIE**: Security error interrupt enable
   This bit is read and written by application. It controls the OTFDEC interrupt generation when SEIF flag status is set.
   0: Interrupt generation on security error SEIF is disabled (masked).
   1: Interrupt generation on security error SEIF is enabled (not masked).

Refer to Section 2.3 for the register boundary addresses.
45 Public key accelerator (PKA)

This section only applies to STM32U585 devices.

45.1 Introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost these operations are executed in the Montgomery domain.

All needed computations are performed within the accelerator, so no further hardware/software elaboration is needed to process the inputs or the outputs.

45.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC.
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication.
- Built-in Montgomery domain inward and outward transformations.
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored).
45.3 PKA functional description

45.3.1 PKA block diagram

![PKA block diagram](image)

**Figure 373. PKA block diagram**

45.3.2 PKA internal signals

*Table 381* lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

<table>
<thead>
<tr>
<th>Signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pka_hclk</td>
<td>Digital input</td>
<td>AHB bus clock</td>
</tr>
<tr>
<td>pka_it</td>
<td>Digital output</td>
<td>Public key accelerator IP global interrupt request</td>
</tr>
<tr>
<td>pka_itamp_out</td>
<td>Digital output</td>
<td>PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets. This signal is asserted as soon as a fault is detected. When asserted read access to PKA registers are reset to 0 and writes are ignored. Signal is de-asserted when PKA memory is cleared.</td>
</tr>
</tbody>
</table>

45.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored.

According to the security policy applied to the device PKA RAM can also be reset following a tamper event. Refer to the Tamper detection and response in the System security section (if applicable to this product).
45.3.4 PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation \( y^2 = x^3 + ax + b \) (mod p). More information is found in Section 45.5.1: Supported elliptic curves.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in Table 382 and Table 383, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

</tbody>
</table>
Each of these operating modes has an associated code that has to be written to the MODE field in the PKA_CR register. If the application selects any value that is not documented below the write to MODE bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens a new operation must be selected after the error is cleared.

Some operations in Table 382 and Table 383 are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets are automatically erased from PKA RAM at the end of the protected operations (BUSY goes low).

Caution: For security reason it is very important to select protected modular exponentiation (MODE=0x3) when performing RSA decryption.

Montgomery space and fast mode operations

For efficiency reason the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming the application can decide to use a faster mode of operation, during which the precomputed Montgomery parameter is supplied before starting the operation. Performance improvement is detailed in Section 45.5.2: Computation times.

The only operation using fast mode is modular exponentiation (MODE=0x02).

45.3.5 Typical applications for PKA

Introduction

The PKA can be used to accelerate a number of public key cryptographic functions. In particular:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement

Specifications of the above functions are given in following publications:
- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories

The principles of the main functions are described in this section, for a more detailed description refer to the above cited documents.

**RSA key pair**

For the following RSA operations a public key and a private key information are defined as below:
- Alice transmits her public key \((n, e)\) to Bob. Numbers \(n\) and \(e\) are very large positive integers.
- Alice keeps secret her private key \(d\), also a very large positive integer. Alternatively this private key can also be represented by a quintuple \((p, q, dp, dq, qInv)\).

For more information on the above representations refer to the RSA specification.

**RSA encryption/decryption principle**

As recommended by the PKCS#1 specification, Bob, to encrypt message \(M\) using Alice’s public key \((n, e)\) must go through the following steps:
1. Compute the encoded message \(EM = ENCODE(M)\), where ENCODE is an encoding method.
2. Turn \(EM\) into an integer \(m\), with \(0 \leq m < n\) and \((m, n)\) being coprimes.
3. Compute ciphertext \(c = m^e \mod n\).
4. Convert the integer \(c\) into a string ciphertext \(C\).

Alice, to decrypt ciphertext \(c\) using her private key \(d\), follows the steps indicated below:
1. Convert the ciphertext \(C\) to an integer ciphertext representative \(c\).
2. If necessary retrieve the prime factors \((p, q)\) using \((n, e, d)\) information, then compute \(\phi = (p-1)(q-1)\). Please refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext \(m = c^d \mod n = (m^e)^d \mod n\). If the private key is the quintuple \((p, q, dp, dq, qInv)\), then plaintext \(m\) is obtained by performing the operations:
   - \(m_1 = c^{dp} \mod p\)
   - \(m_2 = c^{dq} \mod q\)
   - \(h = qInv (m_1 - m_2) \mod p\)
   - \(m = m_2 + h q\)
4. Convert the integer message representative \(m\) to an encoded message \(EM\).
5. Recover message \(M= DECODE(EM)\), where DECODE is a decoding method.

Above operations can be accelerated by PKA using **Modular exponentiation** \(A^e \mod n\) if the private key is \(d\), or **RSA CRT exponentiation** if the private key is the quintuple \((p, q, dp, dq, qInv)\).

**Note:** The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.
Note: For the decryption process protected version of modular exponentiation (MODE=0x3) is strongly recommended for security reason. For encryption process MODE=0x3 cannot be used, as it requires the knowledge of the private key.

Elliptic curve selection

For following ECC operations curve parameters are defined as below:
- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in Section 45.5.1: Supported elliptic curves.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (i.e. \( n \times G = \text{identity element O} \)).

ECDSA message signature generation

ECDSA (elliptic curve digital signature algorithm) signature generation function principle is the following: Alice, to sign a message \( m \) using her private key integer \( d_A \), goes through the following steps.
1. Calculate \( e = \text{HASH}(m) \), where \( \text{HASH} \) is a cryptographic hash function.
2. Let \( z \) be the \( L_n \) leftmost bits of \( e \), where \( L_n \) is the bit length of the group order \( n \).
3. Select a cryptographically secure random integer \( k \) where \( 0 < k < n \).
4. Calculate the curve point \( (x_1, y_1) = k \times G \).
5. Calculate \( r = x_1 \mod n \). If \( r = 0 \) go back to step 3.
6. Calculate \( s = k^{-1}(z + rd_A) \mod n \). If \( s = 0 \) go back to step 3.
7. The signature is the pair \((r, s)\).

Steps 4 to 7 are accelerated by PKA using:
- ECDSA sign or
- All of the operations below:
  - ECC Fp scalar multiplication \( k \times P \)
  - Modular reduction \( A \mod n \)
  - Modular inversion \( A^{-1} \mod n \)
  - Modular addition and Montgomery multiplication

ECDSA signature verification

ECDSA (elliptic curve digital signature algorithm) signature verification function principle is the following: Bob, to authenticate Alice’s signature, must have a copy of her public key curve point \( Q_A \).

Bob can verify that \( Q_A \) is a valid curve point going through the following steps:
1. check that \( Q_A \) is not equal to the identity element O
2. check that \( Q_A \) is on the agreed curve
3. check that \( n \times Q_A = O \).

Then Bob follows the procedure detailed below:
1. verify that \( r \) and \( s \) are integer in \([1, n-1]\)
2. calculate \( e = \text{HASH}(m) \), where \( \text{HASH} \) is the agreed cryptographic hash function
3. let \( z \) be the \( L_n \) leftmost bits of \( e \)
4. calculate \( w = s^{-1} \mod n \)
5. calculate \( u_1 = zw \mod n \) and \( u_2 = rw \mod n \)
6. calculate the curve point \((x_1, y_1) = u_1 \times G + u_2 \times Q_A\)
7. the signature is valid if \( r = x_1 \mod n \), it is invalid otherwise.

Steps 4 to 7 are accelerated by PKA using ECDSA verification.

45.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit to 1 in PKA_CR register enables the PKA peripheral. The PKA becomes available when INITOK bit is set in PKA_SR. When EN=0, the PKA peripheral is kept under reset, with PKA memory still accessible by the application through the AHB interface.

*Note:* When PKA is in the process of clearing its memory EN bit cannot be set.

*Note:* When setting EN bit in PKA_CR make sure that the value of MODE bitfield corresponds to an authorized PKA operation (see OPERRF in Section 45.3.7).

Clearing EN bit to 0 while a calculation is in progress causes the operation to be aborted. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For those operations the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only PKA registers can be accessed, with writes to EN bits ignored.

If INITOK bit stays at 0 make sure the RNG peripheral is clocked and properly initialized, then try to enable PKA again.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in Section 45.4.

Executing a PKA operation

Each of the supported PKA operation is executed using the following procedure:
1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE field of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set to “1”, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

*Note:* When PKA is busy (BUSY = 1) any access by the application to PKA RAM is ignored, and the flag RAMERRF is set in PKA_SR.

Selecting an illegal or unknown operation in step 2 triggers an OPERRF error, and step 3 (PROCENDF=1) never happens. See Section 45.3.7 for details.
Using precomputed Montgomery parameters (PKA Fast mode)

As explained in Section 45.3.4, when computing many operations with the same modulus it can be beneficial for the application to compute only once the corresponding Montgomery parameter (see, for example, Section 45.4.5). This is known as “Fast mode”.

To manage the usage of Fast mode it is recommended to follow the procedure described below:

1. Load in PKA RAM the modulus size and value information. Such information is compiled in Section 45.5.1.
2. Program in PKA_CR register the PKA in Montgomery parameter computation mode (MODE=“0x1”) then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set to “1”, then read back from PKA memory the corresponding Montgomery parameter, and then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.
4. Proceed with the required PKA operation, loading on top of regular input data the Montgomery information R2 mod m. All addresses are indicated in Section 45.4.

45.3.7 PKA error management

When PKA is used some errors can occur:

- The access to PKA RAM falls outside the expected range. In this case the Address Error flag (ADDRERRF) is set in the PKA_SR register.
- An AHB access to the PKA RAM occurred while the PKA core was using it. In this case the RAM Error Flag (RAMERRF) is set in the PKA_SR register, reads to PKA RAM return zero, while writes are ignored.
- The selected operating mode using MODE bitfield is not listed in PKA operating modes (or in bitfield description). In this case the operation error flag (OPERRF) is set in the PKA_SR register, and write to MODE bitfield is ignored.

For each error flag above PKA generates an interrupt if the application sets the corresponding bit in PKA_CR register (see Section 45.6 for details).

ADDRERRF, OPERRF and RAMERRF errors are cleared by setting the corresponding bit in PKA_CLRFR.

The PKA can be re-initialized at any moment by resetting the EN bit in the PKA_CR register.

OPERRF error must be cleared using OPERRFC bit in PKA_CLRFR before a new operation is written in PKA_CR register.

45.4 PKA operating modes

45.4.1 Introduction

The various operations supported by PKA are described in the following subsections, defining the format of the input data and of the results, both stored in the PKA RAM.

Caution: Validity of all input parameters to the PKA must be checked before starting any PKA operation. Indeed, the PKA assumes that all input parameters are valid and consistent with each other.
The following information applies to all PKA operations.

- PKA core processes 64-bit words in its RAM. Hence hereafter all word size is 64-bit
- When an element is written as input in the PKA RAM, an additional word with all bits equal to zero has to be added after the most significant input word. This rule does not apply if the operand has a fixed size of 1.
- All reported RAM storage addresses refer to the least significant word of the data, and to obtain the actual address to use application must add to the indicated offset the base address of the PKA.
- Supported operand “Size” are:
  - ROS (RSA Operand Size): data size is \(\frac{\text{rsa}_{\text{size}}}{64} + 1\) words, with \(\text{rsa}_{\text{size}}\) equal to the chosen modulus length in bits. For example, when computing RSA with an operand size of 1024 bits, ROS is equal to 17 words, or 1088 bits.
  - EOS (ECC Operand Size): data size is \(\frac{\text{ecc}_{\text{size}}}{64} + 1\) words, with \(\text{ecc}_{\text{size}}\) equal to the chosen prime modulus length in bits. For example, when computing ECC with an operand size of 192 bits, EOS is equal to 4 words, or 256 bits.
- Unless indicated otherwise all operands in the tables are integers.

Note: Fractional results for above formulas must be rounded up to the nearest integer since PKA core processes 64-bit words.

Note: The maximum ROS is 66 words (4160-bit max exponent size), while the maximum EOS is 11 words (640-bit max operand size).

As a first example (and to better understand the endianess in PKA memory), to prepare the operation **ECC Fp scalar multiplication**, when the application writes the x coordinate of point \(P\) for an ECC P256 curve (EOS = 5 words), the least significant bit must be placed in bit 0 at address offset 0x578, and the most significant bit in bit 63 at address offset 0x590. Then, as mentioned above, the application must write the empty word 0x0000000000000000 at address offset 0x598.

As a second example, still to prepare the operation **ECC Fp scalar multiplication**, when the application need to write the information \(a=-3\), on a curve with a modulus length of 224 bits (i.e. four 64-bit words, rounded up, plus one) following data must be written in PKA memory:

```
@RAM+410  0x0000000000000001 /* curve coefficient 'a' sign without extra word */
@RAM+418  0x0000000000000011 /* value of |a| LSB */
@RAM+420  0x0000000000000000 ...
@RAM+428  0x0000000000000000 ...
@RAM+430  0x0000000000000000 value of |a| MSB */
@RAM+438  0x0000000000000000 /* additional all 0 word */
```

### 45.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter \((R^2 \mod n)\) used by PKA to convert operands into the Montgomery residue system representation. This operation can be very useful when fast mode operation is used, because in this case the Montgomery parameter is passed as input, saving the time for its computation.

Note: This operation can also be used with ECC curves. In this case prime modulus length and EOS size must be used.
Operation instructions for Montgomery parameter computation are summarized in Table 384.

45.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications the PKA accelerates multiplication which has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \mod n$

The method to perform above operations are described below. Note that “$x$” function is this operation, and $A$, $B$, $C$ operands are in the natural domain.

1. Inward (or outward) conversion into (or from) Montgomery domain

   a) Let us assume $A$ is an integer in the natural domain
   
   Compute $r_2 \mod n$ using Montgomery parameter computation
   
   Result $A_R = A \times r_2 \mod n$ is $A$ in the Montgomery domain
   
   b) Let us assume $B_R$ is an integer in the Montgomery domain
   
   Result $B = B_R \times 1 \mod n$ is $B$ in the natural domain
   
   Similarly, above value $A_R$ computed in a) can be converted into the natural domain by computing $A = A_R \times 1 \mod n$

2. Simple modular multiplication $A \times B \mod n$

   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   
   b) Compute $A_R = A \times r_2 \mod n$. Output is in the Montgomery domain
   
   c) Compute $A_B = A_R \times B \mod n$. Output is in natural domain

3. Multiple modular multiplication $A \times B \times C \mod n$

   a) Compute $r_2 \mod n$ using Montgomery parameter computation
   
   b) Compute $A_R = A \times r_2 \mod n$. Output is in the Montgomery domain
   
   c) Compute $B_R = B \times r_2 \mod n$. Output is in the Montgomery domain
   
   d) Compute $A_B = A_R \times B \mod n$. Output is in the Montgomery domain
   
   e) Compute $C_R = C \times r_2 \mod n$. Output is in the Montgomery domain
   
   f) Compute $A_B = A_B \times C_R \mod n$. Output is in the Montgomery domain
   
   g) (optional) Repeat the two steps above if more operands need to be multiplied
   
   h) Compute $A_B = A_B \times C_R \times 1 \mod n$ to retrieve the result in natural domain

Operation instructions for Montgomery multiplication are summarized in Table 387.

<table>
<thead>

</tbody>
</table>

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples 2 and 3).
45.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of \( A^e \mod n \).

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on Table 388 and Table 389. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on Table 390, for security reason.

**Note:** Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

**Note:** When MODE=0x03 if the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

Operation instructions for modular exponentiation are summarized in Table 388 (normal mode), Table 389 (fast mode) and in Table 390 (protected mode). Fast mode usage is explained in Section 45.3.6.

45.4.7 Modular inversion

Modular inversion operation consists in the computation of multiplicative inverse $A^{-1} \mod n$. If the modulus $n$ is prime, for all values of $A$ ($1 \leq A < n$) modular inversion output is valid. If the modulus $n$ is not prime, $A$ has an inverse only if the greatest common divisor between $A$ and $n$ is 1.

If the operand $A$ is a divisor of the modulus $n$ the result is a multiple of a factor of $n$.

Operation instructions for modular inversion are summarized in Table 391.

1. Euler totient function of $n^1$ with phi = $(p - 1) \times (q - 1)$, where $p$ and $q$ are prime factors of modulus $n$ (see NIST SP800-56B Appendix C or RSA encryption/decryption principle for details). As optimization it is recommended to keep phi information as part of the key pair generation. Alternatively, it is stored in the key as $(p, q, e, d)$ instead of $(N, e, d, phi)$, in this case, to derive $N$ and phi using PKA arithmetic multiplier: $N = p \times q$, and phi = $(p - 1) \times (q - 1)$.

45.4.8 Modular reduction

Modular reduction operation consists in the computation of the remainder of $A$ divided by $n$. Operation instructions are summarized in Table 392.
45.4.9 Arithmetic addition

Arithmetic addition operation consists in the computation of $A + B$. Operation instructions are summarized in Table 393.

Table 393. Arithmetic addition

45.4.10 Arithmetic subtraction

Arithmetic subtraction operation consists in the following computations:
- If $A \geq B$ result equals $A - B$
- If $A < B$ and $M/32$ residue is $> 0$ result equals $A + 2^{\text{int}(M/32)}32+1 - B$
- If $A < B$ and $M/32$ residue is $0$ result equals $A + 2^{\text{int}(M/32)}32 - B$

For the last two bullets the 32-bit word following the most significant word of the output equals 0xFFFF FFFF as result is negative.

Operation instructions are summarized in Table 394.

45.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries like OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem:

- \( p \) and \( q \) are precomputed primes, stored as part of the private key
- \( d_p = d \mod (p-1) \)
- \( d_q = d \mod (q-1) \) and
- \( d_{\text{inv}} = q^{-1} \mod p \)
These values allow the recipient to compute the exponentiation \( m = A^d \pmod{pq} \) more efficiently as follows:

- \( m_1 = A^{dP} \pmod{p} \)
- \( m_2 = A^{dQ} \pmod{p} \)
- \( h = q_{\text{inv}} (m_1 - m_2) \pmod{p} \), with \( m_1 > m_2 \)
- \( m = m_2 + hq \)

Operation instructions for computing CRT exponentiation \( A^d \pmod{pq} \) are summarized in Table 397.

### 45.4.14 Point on elliptic curve Fp check

This operation consists in checking whether a given point \( P (x, y) \) satisfies or not the curves over prime fields equation \( y^2 = (x^3 + ax + b) \pmod{p} \), where \( a \) and \( b \) are elements of the curve.

Operation instructions for point on elliptic curve Fp check are summarized in Table 398.
### 45.4.15 ECC Fp scalar multiplication

This operation consists in the computation of a $k \times P (x_P, y_P)$, where $P$ is a point on a curve over prime fields and “$x$” is the elliptic curve scalar point multiplication. Result of the computation is a point that belongs to the same curve or a point at infinity.

Operation instructions for ECC Fp scalar multiplication are summarized in Table 399.

**Note:** Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

<td>RAM@0x680</td>
<td>64 bits</td>
</tr>
</tbody>
</table>
When performing this operation the following special cases must be noted:

- For $k = 0$ this function returns a point at infinity $(0, 0)$ if curve parameter $b$ is nonzero, $(0, 1)$ otherwise. For $k$ different from 0 it might happen that a point at infinity is returned. When the application detects this behavior a new computation should be carried out.

- For $k < 0$ (i.e. a negative scalar multiplication is required) multiplier absolute value $k = |-k|$ must be provided to the PKA. After the computation completion, the formula $-P = (x, -y)$ can be used to compute the $y$ coordinate of the effective final result (the $x$ coordinate remains the same).

Note: If the error output is different from 0xD60D all the memory content is cleared by PKA to avoid leaking information about the private key.

### 45.4.16 ECDSA sign

ECDSA signing operation (outlined in Section 45.3.5) is summarized in Table 400 (input parameters) and in Table 401 (output parameters).

The application has to check if the output error is equal to 0xD60D, if it is different a new $k$ must be generated and the ECDSA sign operation must be repeated.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.
Note: If the error output equals 0xD60D or 0xCBC9 all the memory content is cleared by PKA to avoid leaking information about the private key. If error output equals 0xA3B7 or 0xF946 PKA memory content is partially erased, keeping the error code readable.

Extended ECDSA support

PKA also supports extended ECDSA signature, for which the inputs and the outputs are the same as ECDSA signature (Table 400 and Table 401, respectively), with the addition of the coordinates of the point kG. This extra output is defined in Table 402.
45.4.17 **ECDSA verification**

ECDSA verification operation (outlined in Section 45.3.5) is summarized in Table 403 (input parameters) and Table 404 (output parameters).

The application has to check if the output error is equal to 0xD60D, if different the signature is not verified.

45.4.18 ECC complete addition

ECC complete addition computes the addition of two given points on an elliptic curve. Operation instructions are summarized in Table 405.

Note: The two input points and the resulting point are represented in Jacobian coordinates $(X, Y, Z)$. To input a point in affine coordinates $(x, y)$ conversion $(X, Y, Z) = (x, y, 1)$ can be used. To convert resulting point to Jacobian coordinates conversion $(x, y) = (X/Z^2, Y/Z^3)$ can be used.

45.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of $k*P + m*Q$, where $(P, Q)$ are two points on an elliptic curve and $(k, m)$ are two scalars. Operation instructions are summarized in Table 406.

If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0, 0).

Note: The two input points are represented in Jacobian coordinates $(X, Y, Z)$. To input a point in affine coordinates $(x, y)$ conversion $(X, Y, Z) = (x, y, 1)$ can be used. The result is represented in affine coordinates $(x, y)$.
45.4.20  ECC projective to affine

ECC projective to affine operation computes the conversion between the representation of a point P in homogeneous projective coordinates and the representation of the point P in affine coordinates. Namely, if the point is represented by the triple (X,Y,Z), it computes the affine coordinates (x,y) = (X/Y,Y/Z).

All the operations are performed modulo the modulus p of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals to (0,0).

Operation instructions are summarized in Table 407.

Table 406. ECC double base ladder

45.5 Example of configurations and processing times

45.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation \( y^2 = x^3 + ax + b \pmod{p} \).

**Note:** Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer \( p \), used as the modulus for all point arithmetic in the finite field \( GF(p) \)
- the (usually prime) integer \( n \), the order of the group generated by \( G \), defined below
- the base point of the curve \( G \), defined by its coordinates \( (Gx, Gy) \)
- the integers \( a \) and \( b \), coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define \( a \) as negative, PKA supports two representations:

1. **a defined as \( p-|a| \)** in the finite field \( GF(p) \), for example \( p-3 \):
   - Curve coefficient \( p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF \)
   - Curve coefficient a sign= 0x0 (positive)
   - Curve coefficient \( a = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF \)
2. **a defined as negative**, for example \(-3\):
   - Curve coefficient \( p = 0xFFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF \)
   - Curve coefficient a sign= 0x1 (negative)

</tr>
<tr>
<td></td>
<td>Normal</td>
<td>-</td>
</tr>
<tr>
<td></td>
<td>Fast</td>
<td>-</td>
</tr>
<tr>
<td></td>
<td>CRT(1)</td>
<td>-</td>
</tr>
</tbody>
</table>

1. CRT stands for chinese remainder theorem optimization (MODE bitfield= 0x07).

#### Table 410. ECC scalar multiplication(1)

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>160</td>
</tr>
<tr>
<td>-</td>
</tr>
</tbody>
</table>

1. These times depend on the number of “1”s included in the scalar parameter, and include the computation of Montgomery parameter R2.
Table 411. ECDSA signature average computation time(1) (2)

<table>
<thead>
<tr>
<th>Modulus length (in bits)</th>
<th>160</th>
<th>192</th>
<th>256</th>
<th>320</th>
<th>384</th>
<th>512</th>
<th>521</th>
<th>640</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
<td>1500000</td>
<td>2744000</td>
<td>4579000</td>
<td>7184000</td>
<td>14455000</td>
<td>16685000</td>
<td>24965000</td>
</tr>
</tbody>
</table>

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 412. ECDSA verification average computation times

<table>
<thead>

</tr>
</tbody>
</table>
There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see Section 45.3.7
2. Access to unmapped address (ADDRERRF), see Section 45.3.7
3. PKA RAM access while PKA operation is in progress (RAMERRF), see Section 45.3.7
4. PKA end of operation (PROCENDF).

The four interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the PKA control register (PKA_CR). Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 418 gives a summary of the available features.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.
Bits 13:8 **MODE[5:0]:** PKA operation code
- 000000: Montgomery parameter computation then modular exponentiation
- 000001: Montgomery parameter computation only
- 000010: Modular exponentiation only (Montgomery parameter must be loaded first)
- 000011: Modular exponentiation (protected, used when manipulating secrets)
- 100000: Montgomery parameter computation then ECC scalar multiplication
- 100100: ECDSA sign
- 100100: Point on elliptic curve Fp check
- 000111: RSA CRT exponentiation
- 001000: Modular inversion
- 001001: Arithmetic addition
- 001010: Arithmetic subtraction
- 001011: Arithmetic multiplication
- 001100: Arithmetic comparison
- 001101: Modular reduction
- 001110: Modular addition
- 001111: Modular subtraction
- 010000: Montgomery multiplication
- 100011: ECC complete addition
- 100111: ECC double base ladder
- 101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE bitfield is ignored.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1 START:** start the operation
Writing 1 to this bit starts the operation which is selected by MODE[5:0], using the operands and data already written to the PKA RAM. This bit is always read as 0.
When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

*Note:* START is ignored if PKA is busy.

**Bit 0 EN: PKA enable.**

- 0: Disable PKA
- 1: Enable PKA. PKA becomes functional when INITOK is set by hardware in PKA_SR.

When an illegal operation is selected while EN=1 OPERRF bit is set in PKA_SR. See PKA_CR.MODE bitfield for details.

*Note:* When EN=0 PKA RAM can still be accessed by the application.
45.7.2 PKA status register (PKA_SR)

Address offset: 0x04  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:22: Reserved, must be kept at reset value.

Bit 21 **OPERRF**: Operation error flag
- 0: No event error
- 1: An illegal or unknown operation has been selected in PKA_CR register 
  This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag
- 0: No address error
- 1: Address access is out of range (unmapped address) 
  This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag
- 0: No PKA RAM access error 
- 1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its 
  internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress). 
  This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18: Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA End of Operation flag
- 0: Operation in progress
- 1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: PKA operation is in progress
- This bit is set to 1 whenever START bit in the PKA_CR is set. It is automatically cleared when the 
  computation is complete, meaning that PKA RAM can be safely accessed and a new operation can 
  be started.
- 0: No operation is in progress (default)
- 1: An operation is in progress 
  If PKA is started with a wrong opcode, it is busy for a couple of cycles, then it aborts automatically 
  the operation and go back to ready (BUSY bit is set to 0).

Bits 15:1: Reserved, must be kept at reset value.

Bit 0 **INITOK**: PKA initialization OK
- This bit is asserted when PKA initialization is complete. When RNG is not able to output proper 
  random numbers INITOK stays at 0.
- 0: PKA is not initialized correctly. START bit cannot be set. 
- 1: PKA is initialized correctly and can be used normally.
### 45.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08  
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

- **Bit 21 OPERRRFC**: Clear operation error flag  
  0: No action  
  1: Clear the OPERRF flag in PKA_SR

- **Bit 20 ADDRERRRFC**: Clear address error flag  
  0: No action  
  1: Clear the ADDRERRF flag in PKA_SR

- **Bit 19 RAMERRRFC**: Clear PKA RAM error flag  
  0: No action  
  1: Clear the RAMERRF flag in PKA_SR

- **Bit 18 Reserved, must be kept at reset value.**

- **Bit 17 PROCENDFC**: Clear PKA End of Operation flag  
  0: No action  
  1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

**Note:** Reading PKA_CLRFR returns all 0s.

### 45.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA_AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

**Note:** PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 45.3.3: PKA reset and clocks.
### 45.7.5 PKA register map

#### Table 419. PKA register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000  | PKA_CR        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to Section 2.3 on page 116 for the register boundary addresses.
46 Advanced-control timers (TIM1/TIM8)

46.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 46.3.30: Timer synchronization.

46.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input capture (but channels 5 and 6)
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
46.3 TIM1/TIM8 functional description

46.3.1 Block diagram

Figure 374. Advanced-control timer block diagram

**Notes:**

- **MSG:** Preload registers transferred to active registers on UEV event according to control bit
- **~** Event
- **-->** Interrupt & DMA output

1. This feature is not available on all timers, refer to Section 46.3.2: TIM1/TIM8 pins and internal signals.
2. See Figure 421: Break and Break2 circuitry overview for details.
### 46.3.2 TIM1/TIM8 pins and internal signals

The tables in this section summarize the TIM inputs and outputs.

#### Table 420. TIM input/output pins

46.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 375 and Figure 376 give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 375. Counter timing diagram with prescaler division change from 1 to 2

Figure 376. Counter timing diagram with prescaler division change from 1 to 4
46.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

- `Auto-reload preload register` (FF 36)

Write a new value in TIMx_ARR
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
Figure 388. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6

1. Here, center-aligned mode 1 is used (for more details refer to Section 46.6: TIM1/TIM8 registers).

46.3.5 Repetition counter

Section 46.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 394). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the
overflow or on the underflow depending on when the RCR register was written and when
the counter was launched: if the RCR was written before launching the counter, the UEV
occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs
on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event
depending on when the RCR was written.

Figure 394. Update rate examples depending on mode and TIMx_RCR register settings

46.3.6 External trigger input

The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see Section 46.3.7)
- trigger for the slave mode (see Section 46.3.30)
- PWM reset input for cycle-by-cycle current regulation (see Section 46.3.9)

Figure 395 below describes the tim_etr_in input conditioning. The input polarity is defined
with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider
programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield. The
resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition
the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

**Figure 395. External trigger input block**

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[3:0] bitfield in the TIMx_AF1 register.

Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for the list of sources connected to the etr_in input in the product.

### 46.3.7 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

**Internal clock source (tim_ker_ck)**

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

**Figure 396** shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 0100 to 1111 are reserved.
For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set. The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

**External clock source mode 2**

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter counts at each rising or falling edge on the external trigger input tim_etr_in. The Figure 399 gives an overview of the external trigger input block.
1. Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals.

For example, to configure the upcounter to count each 2 rising edges on `tim_etr_in`, use the following procedure:

1. As no filter is needed in this example, write `ETF[3:0]=0000` in the `TIMx_SMCR` register.
2. Set the prescaler by writing `ETPS[1:0]=01` in the `TIMx_SMCR` register.
3. Select rising edge detection on the `tim_etr_in` input by writing `ETP=0` in the `TIMx_SMCR` register.
4. Enable external clock mode 2 by writing `ECE=1` in the `TIMx_SMCR` register.
5. Enable the counter by writing `CEN=1` in the `TIMx_CR1` register.

The counter counts once each 2 `tim_etr_in` rising edges.

The delay between the rising edge on `tim_etr_in` and the actual clock of the counter is due to the resynchronization circuit on the `tim_etrp` signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most $\frac{1}{4}$ of `tim_ker_ck` frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.
46.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 401 to Figure 404* give an overview of one capture/compare channel.

The input stage samples the corresponding *tim_tix* input to generate a filtered signal *tim_tixf*. Then, an edge detector with polarity selection generates a signal (*tim_tixfpy*) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

*Figure 401. Capture/compare channel (example: channel 1 input stage)*

The output stage generates an intermediate waveform which is then used for reference: *tim_ocxref* (active high). The polarity acts at the end of the chain.

*Figure 400. Control circuit in external clock mode 2*
Figure 402. Capture/compare channel 1 main circuit

Figure 403. Output stage of capture/compare channel (channel 1, idem ch. 2, 3 and 4)

1. `tim_ocxref`, where x is the rank of the complementary channel
Figure 404. Output stage of capture/compare channel (channel 5, idem ch. 6)

1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 46.3.9 Input capture mode

In Input capture mode, the capture/compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.

- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have
been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the tim_t1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

46.3.10 PWM input mode

This mode allows to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.
The period and the pulsewidth of a PWM signal applied on `tim_ti1` can be measured using the following procedure:

- Select the active input for `TIMx_CCR1`: write the CC1S bits to 01 in the `TIMx_CCMR1` register (`tim_ti1` selected).
- Select the active polarity for `tim_ti1fp1` (used both for capture in `TIMx_CCR1` and counter clear): write the CC1P and CC1NP bits to 0' (active on rising edge).
- Select the active input for `TIMx_CCR2`: write the CC2S bits to 10 in the `TIMx_CCMR1` register (`tim_ti1` selected).
- Select the active polarity for `tim_ti1fp2` (used for capture in `TIMx_CCR2`): write the CC2P and CC2NP bits to CC2P/CC2NP='10' (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the `TIMx_SMCR` register (`tim_ti1fp1` selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the `TIMx_SMCR` register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the `TIMx_CCER` register.

Figure 405. PWM input mode timing

46.3.11 Forced output mode

In output mode (CCxS bits = 00 in the `TIMx_CCMRx` register), each output compare signal (`tim_ocxref` and then `tim_ocx/tim_ocxn`) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (`tim_ocxref/tim_ocx`) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding `TIMx_CCMRx` register. Thus `tim_ocxref` is forced high (`tim_ocxref` is always active high) and `tim_ocx` get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The `tim_ocxref` signal can be forced low by writing the OCxM bits to 0100 in the `TIMx_CCMRx` register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 46.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 and 6 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 406.
46.3.13 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the Upcounting mode on page 1659.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1’. If the compare value is 0 then tim_ocxref is held at ‘0’. Figure 407 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Figure 407. Edge-aligned PWM waveforms (ARR=8)

- Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode on page 1663.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit...
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 1666.

Figure 408 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The *Figure 409* below presents the dithering principle applied to 4 consecutive PWM cycles.

**Figure 409. Dithering principle**

When the dithering mode is enabled, the register coding is changed as follows (see *Figure 410* for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CCIF flags must be cleared
5. The CEN bit can be set (eventually with ARPE = 1).

Figure 410. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{F_{\text{Tim}}}{F_{\text{pwm}}} \Rightarrow F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{\text{MaxResolution}}
\]

Dithering mode disabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65536} \)

Dithering mode enabled: \( F_{\text{pwmMin}} = \frac{F_{\text{Tim}}}{65535 + \frac{15}{16}} \)

Note: The maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 411 below, the dithering mode allows to increase the PWM resolution whatever the PWM frequency.
The duty cycle and/or period changes are spread over 16 consecutive periods, as described in the Figure 412 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 432 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

46.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 1.

Figure 414 represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
46.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ox output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 415 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
46.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, tim_oc2refc is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, tim_oc3refc is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
46.3.17 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output \texttt{tim\_ocx} or complementary \texttt{tim\_ocxn}) can be selected independently for each output. This is done by writing to the \texttt{CCxP} and \texttt{CCxNP} bits in the TIMx\_CCER register.

The complementary signals \texttt{tim\_ocx} and \texttt{tim\_ocxn} are activated by a combination of several control bits: the \texttt{CCxE} and \texttt{CCxNE} bits in the TIMx\_CCER register and the \texttt{MOE}, \texttt{OISx}, \texttt{OISxN}, \texttt{OSSI} and \texttt{OSSR} bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to Table 441: Output control bits for complementary \texttt{tim\_ocx} and \texttt{tim\_ocxn} channels with break feature on page 1767 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both \texttt{CCxE} and \texttt{CCxNE} bits, and the \texttt{MOE} bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 417. Complementary output with symmetrical dead-time insertion**

The DTAE bit in the TIMx_DTR2 allows to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on **Figure 418**.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN=1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 46.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.
Re-directing `tim_ocxref` to `tim_ocx` or `tim_ocxn`

In output mode (forced, output compare or PWM), `tim_ocxref` can be re-directed to the `tim_ocx` output or to `tim_ocxn` output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only `tim_ocxn` is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as `tim_ocxref` is high. For example, if CCxNP=0 then tim_ocxn=tim_ocxref. On the other hand, when both `tim_ocx` and `tim_ocxn` are enabled (CCxE=CCxNE=1) `tim_ocx` becomes active when `tim_ocxref` is high whereas `tim_ocxn` is complemented and becomes active when `tim_ocxref` is low.

### 46.3.18 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows to enable/disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 441: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature on page 1767 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous
and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIMx_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)
  - coming from a system break request (refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)

The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIMx_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per Figure 421 below.
An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to
their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

- If OSS1=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** If the MOE is reset by the CPU while the AOE bit is set, the outputs will be in idle state and forced to inactive level or Hi-Z depending on OSS1 value. If both the MOE and AOE bits are reset by the CPU, the outputs will be in disabled state and driven with the level programmed in the OISx bit in the TIMx_CR2 register.

**Note:** The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 46.6.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8). The LOCK bits can be written only once after an MCU reset.

*Figure 422* shows an example of behavior of the outputs in response to a break.
The two break inputs have different behaviors on timer outputs:

- The `tim_brk` input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- `tim_brk2` can only disable (inactive state) the PWM outputs.
The tim_brk has a higher priority than tim_brk2 input, as described in Table 434.

**Note:** tim_brk2 must only be used with OSSR = OSSI = 1.

Table 434. Behavior of timer outputs versus tim_brk/tim_brk2 inputs

Figure 423 gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

**Figure 423. PWM output state following tim_brk and tim_brk2 assertion (OSSI=1)**

![Figure 423](MSv62338V1)
### 46.3.19 Bidirectional break inputs

The TIM1/TIM8 are featuring bidirectional break I/Os, as represented on Figure 425.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIMxBDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (e.g. CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to '0' to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIMx_BKIN and TIMx_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 435).
Arming and re-arming break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

#### 46.3.20 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next update event (UEV) occurs. This function can only
be used in Output compare and PWM modes. It does not work in Forced mode.

tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etrf_in after the filter) by configuring the OCCS bit in the TIMx_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown on the Figure 426 below. Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for a list of sources available in the product.

**Figure 426. tim_ocref_clr input selection multiplexer**

When tim_etrf is chosen, tim_etrf_in must be configured as follows:

1. The External Trigger Prescaler must be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.  
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.  
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

*Figure 427* shows the behavior of the tim_ocxref signal when the tim_etrf Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.
46.3.21 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 428 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in 3 different examples of programmed configurations.

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.
46.3.22 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: \( CNT < CCRx \leq ARR \) (in particular, \( 0 < CCRx \))
- In downcounting: \( CNT > CCRx \)
For example one may want to generate a positive pulse on \texttt{tim\_oc1} with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the \texttt{tim\_ti2} input pin.

Let’s use \texttt{tim\_ti2fp2} as trigger 1:

- Map \texttt{tim\_ti2fp2} to \texttt{tim\_ti2} by writing \texttt{CC2S='01'} in the \texttt{TIMx\_CCMR1} register.
- \texttt{tim\_ti2fp2} must detect a rising edge, write \texttt{CC2P='0'} and \texttt{CC2NP='0'} in the \texttt{TIMx\_CCER} register.
- Configure \texttt{tim\_ti2fp2} as trigger for the slave mode controller (\texttt{tim\_trgi}) by writing \texttt{TS=00110} in the \texttt{TIMx\_SMCR} register.
- \texttt{tim\_ti2fp2} is used to start the counter by writing \texttt{SMS to ‘110’} in the \texttt{TIMx\_SMCR} register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the \texttt{TIMx\_CCCR1} register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (\texttt{TIMx\_ARR - TIMx\_CCR1}).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing \texttt{OC1M=111} in the \texttt{TIMx\_CCMR1} register. Optionally the preload registers can be enabled by writing \texttt{OC1PE='1'} in the \texttt{TIMx\_CCMR1} register and \texttt{ARPE} in the \texttt{TIMx\_CR1} register. In this case one has to write the compare value in the \texttt{TIMx\_CCR1} register, the auto-reload value in the \texttt{TIMx\_ARR} register, generate an update by setting the \texttt{UG} bit and wait for external trigger event on \texttt{tim\_ti2}. \texttt{CC1P} is written to ‘0’ in this example.

In our example, the \texttt{DIR} and \texttt{CMS} bits in the \texttt{TIMx\_CR1} register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the \texttt{TIMx\_CR1} register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the \texttt{TIMx\_CR1} register is set to ‘0’, so the Repetitive Mode is selected.
Particular case: tim_ocx fast enable:

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 46.3.23 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one-pulse mode described in Section 46.3.22:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

**Figure 430. Retriggerable one-pulse mode**

![Retriggerable one-pulse mode diagram](MSv62345V1)
46.3.24 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 431 below.

Figure 431. Pulse generator circuitry

The Figure 432 below shows how the pulse is generated for edge-aligned and encoder operating modes.
This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{PWPRSC[2:0]}) \times t_{tim\_ker\_ck}. \)

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

**Note:** If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 433 below).
### 46.3.25 Encoder interface mode

#### Quadrature encoder

To select Encoder Interface mode write SMS='0001' in the TIMx_SMCR register if the counter is counting on TIM1 edges only, SMS='0010' if it is counting on TIM2 edges only and SMS='0011' if it is counting on both TIM1 and TIM2 edges.

Select the TIM1 and TIM2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TIM1 and TIM2 are used to interface to a quadrature encoder. Refer to Table 436. The counter is clocked by each valid transition on TIM1 and TIM2 after input filter and polarity selection, TIM1fp=TIM1 if not filtered and not inverted, TIM2fp=TIM2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TIM1 or TIM2), whatever the counter is counting on TIM1 only, TIM2 only or both TIM1 and TIM2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TIM1 and TIM2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

The Figure 434 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S='01' (TIMx_CCMR2 register, tim_ti1fp2 mapped on tim_ti2).
- CC1P='0' and CC1NP='0' (TIMx_CCER register, tim_ti1fp1 non-inverted, tim_ti1fp1=tim_ti1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, tim_ti1fp2 non-inverted, tim_ti1fp2=tim_ti2).
- SMS='011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

**Figure 434. Example of counter operation in encoder interface mode.**

**Figure 435** gives an example of counter behavior when tim_t1fp1 polarity is inverted (same configuration as above except CC1P='1').

**Figure 435. Example of encoder interface mode with tim_t1fp1 polarity inverted.**

The **Figure 436** below shows the timer counter value during a speed reversal, for various counting modes.
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 437, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:
- 1010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 1011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity
The polarity of the direction signal on \( \text{tim}_\text{ti}1 \) is set with the \( \text{CC1P} \) bit: 0 corresponds to positive polarity (up-counting when \( \text{tim}_\text{ti}1 \) is high and down-counting when \( \text{tim}_\text{ti}1 \) is low) and \( \text{CC1P} = 1 \) corresponds to negative polarity (up-counting when \( \text{tim}_\text{ti}1 \) is low).

**Figure 437. Direction plus clock encoder mode**

**Directional Clock encoder mode**

In the “directional clock” mode on Figure 438, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the \( \text{SMS}[3:0] \) bitfield in the TIMx_SMCR register, as following:

- 1100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The \( \text{CC1P} \) and \( \text{CC2P} \) bits are coding for the clock idle state. \( \text{CCxP} = 0 \) corresponds to high-level idle state (refer to Figure 438 below) and \( \text{CCxP} = 1 \) corresponds to low-level idle state (refer to Figure 439 below).

- 1101: x1 mode, the counter is updated on a single clock edge, as per \( \text{CC1P} \) and \( \text{CC2P} \) bit value. \( \text{CCxP} = 0 \) corresponds to falling edge sensitivity and high-level idle state (refer to Figure 438 below), \( \text{CCxP} = 1 \) corresponds to rising edge sensitivity and low-level idle state (refer to Figure 439 below).

**Figure 438. Directional clock encoder mode (CC1P = CC2P = 0)**
The Table 437 here-below details how the directional clock mode operates, for any input transition.

**Index Input**

The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the tim_etn_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMX_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.
Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 440 below:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

Figure 440. Index gating options

The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on Figure 441 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulsewidth is greater or equal to 2 encoder period, the counter is reset multiple times.

Figure 441. Jittered Index signals

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B
state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:
- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIMx_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 442 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges per mechanical rotation).

**Figure 442. Index generation for IPOS[1:0] = 11**

The Figure 443 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:
- Counter set to 0 when encoder state is '11' (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the '11' state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.
Figure 443. Counter reading with index gated on channel A (IPOS[1:0] = 11)

The Figure 444. below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 444. Counter reading with index ungated (IPOS[1:0] = 00)

The Figure 445. below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.
The Figure 446 and Figure 447 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 446. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)
Figure 447. Counter reset Narrow index pulse (closer view, ARR = 0x07)

The Figure 448 below shows how the index is managed in x1 and x2 modes.
Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The Figure 449 below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

Note: The IDR[1:0] bitfield must be written when IE bit is reset (index mode disabled).

Note: The directional index sensitivity is not supported in clock + direction mode. When SMS[3:0] = 1010 or 1011, the IDIR[1:0] must be set to 00.
Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the Figure 450 below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Note: When FIDX = 1, the index can be issued twice (IDXF flag set) if the direction changes at position 0 (index active).

Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 451 below.
This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Index management in non-quadrature mode

The Figure 452 and Figure 453 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.
Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 454. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 455 below.

**Figure 455. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 456 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

**Figure 456. Down-counting encode error detection**

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder Interrupts**

The following interrupts are also available in encoder mode:

- **Direction change**: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- **Index event**: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 457 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMSPS bit in the TIMx_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting. This mode must be used only when index is disabled (bit IE = 0)
- SMSPS = 1: the transfer is triggered by the Index event

Figure 457. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

46.3.26 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

46.3.27 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register's bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.

46.3.28 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3. The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 458 below.

Figure 458. Measuring time interval between edges on 3 signals

46.3.29 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in Figure 459. The “interfacing timer” captures the 3 timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See Figure 401: Capture/compare channel (example: channel 1
The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.

Example: one wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIMx_CR2 register to ‘101’,

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

The Figure 459 describes this example.
46.3.30 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 47.4.23: Timer synchronization for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.
In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The timer starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 460. Control circuit in reset mode**

![Control circuit in reset mode](image)

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).
The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode allows to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:
1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

   A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

   The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

**Figure 463. Control circuit in external clock mode 2 + trigger mode**

![Control Circuit Diagram]

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
46.3.31 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 416 on page 1694.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

46.3.32 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 46.6.29: TIMx DMA control register (TIMx_DCR)(x = 1, 8) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address.
   – DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (see note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx
register is to be updated twice for example, the number of data to transfer should be 6. Let's
take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and
data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

46.3.33 TIM1/TIM8 DMA requests

The TIM1/TIM8 can generate a DMA request, as shown in the table below.

<table>
<thead>
<tr>
<th>DMA request signal</th>
<th>DMA request</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>tim_upd_dma</td>
<td>Update</td>

<td>COMDE</td>
</tr>
<tr>
<td>tim_trg_dma</td>
<td>Trigger</td>
<td>TDE</td>
</tr>
</tbody>
</table>

46.3.34 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter
can either continue to work normally or stop, depending on DBG_TIMx_STOP configuration
bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per
timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE
bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have
their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.
For more details, refer to section Debug support (DBG).

### 46.4 TIM1/TIM8 low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

### 46.5 TIM1/TIM8 interrupts

The TIM1/TIM8 can generate multiple interrupts, as shown in Table 440.

<table>
<thead>
<tr>
<th>Interrupt acronym</th>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
<th>Interrupt clear method</th>
<th>Exit from Sleep mode</th>

<tr>
<td>Note:</td>
<td>It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)</td>
</tr>
</tbody>
</table>
46.6.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)

Address offset: 0x004
Reset value: 0x0000 0000
Bits 31:26  Reserved, must be kept at reset value.

Bit 24  Reserved, must be kept at reset value.

Bits 23:20  **MMS2[3:0]: Master mode selection 2**

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

0000:  **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

0001:  **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010:  **Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

0011:  **Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

0100:  **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

0101:  **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

0110:  **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

0111:  **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

1000:  **Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

1001:  **Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

1010:  **Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

1011:  **Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

1100:  **Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1101:  **Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

1110:  **Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

1111:  **Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19  Reserved, must be kept at reset value.

Bit 18  **OIS6**: Output idle state 6 (tim_oc6 output)

Refer to OIS1 bit

Bit 17  Reserved, must be kept at reset value.

Bit 16  **OIS5**: Output idle state 5 (tim_oc5 output)

Refer to OIS1 bit

Bit 15  **OIS4N**: Output idle state 4 (tim_oc4n output)

Refer to OIS1N bit

Bit 14  **OIS4**: Output idle state 4 (tim_oc4 output)

Refer to OIS1 bit
Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1=0 (after a dead-time) when MOE=0
1: tim_oc1=1 (after a dead-time) when MOE=0

*Note:* This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection
0: The tim_ti1_in[15..0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15..0], tim_ti2_in[15..0] and tim_ti3_in[15..0] multiplexers outputs are XORed and connected to the tim_ti1 input
Bits 25, 6:4  **MMS[3:0]: Master mode selection**

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

- **0000: **Reset - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
- **0001: **Enable - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **0010: **Update - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.
- **0011: **Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).
- **0100: **Compare - tim_oc1refc signal is used as trigger output (tim_trgo)
- **0101: **Compare - tim_oc2refc signal is used as trigger output (tim_trgo)
- **0110: **Compare - tim_oc3refc signal is used as trigger output (tim_trgo)
- **0111: **Compare - tim_oc4refc signal is used as trigger output (tim_trgo)
- **1000: **Encoder Clock output - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.
- Other codes reserved

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3  **CCDS: Capture/compare DMA selection**

- **0:** CCx DMA request sent when CCx event occurs
- **1:** CCx DMA requests sent when update event occurs

Bit 2  **CCUS: Capture/compare control update selection**

- **0:** When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
- **1:** When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

*Note: This bit acts only on channels that have a complementary output.*

Bit 1  Reserved, must be kept at reset value.

Bit 0  **CCPC: Capture/compare preloaded control**

- **0:** CCxE, CCxNE and OCxM bits are not preloaded
- **1:** CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
46.6.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)

Address offset: 0x008
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:26</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 25</td>
<td><strong>SMSPS</strong>: SMS preload source</td>
</tr>
<tr>
<td></td>
<td>This bit selects whether the events that triggers the SMS[3:0] bitfield transfer from preload to active</td>

<td><strong>ECE</strong>: External clock enable</td>
</tr>
<tr>
<td></td>
<td>This bit enables External clock mode 2.</td>
</tr>
<tr>
<td></td>
<td>0: External clock mode 2 disabled</td>
</tr>
<tr>
<td></td>
<td>1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.</td>
</tr>
</tbody>
</table>

**Note:** Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS=111 and TS=00111).
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etr.
Bits 13:12 ETPS[1:0]: External trigger prescaler
External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etr frequency. It is useful when inputting fast external clocks on tim_etr_in.
00: Prescaler OFF
01: tim_etr_in frequency divided by 2
10: tim_etr_in frequency divided by 4
11: tim_etr_in frequency divided by 8

Bits 11:8 ETF[3:0]: External trigger filter
This bit-field then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
0000: No filter, sampling is done at fDTS
0001: fSAMPLING=fTim_ker_ck, N=2
0010: fSAMPLING=fTim_ker_ck, N=4
0011: fSAMPLING=fTim_ker_ck, N=8
0100: fSAMPLING=fDTS/2, N=6
0101: fSAMPLING=fDTS/2, N=8
0110: fSAMPLING=fDTS/4, N=6
0111: fSAMPLING=fDTS/4, N=8
1000: fSAMPLING=fDTS/8, N=6
1001: fSAMPLING=fDTS/8, N=8
1010: fSAMPLING=fDTS/16, N=5
1011: fSAMPLING=fDTS/16, N=6
1100: fSAMPLING=fDTS/16, N=8
1101: fSAMPLING=fDTS/32, N=5
1110: fSAMPLING=fDTS/32, N=6
1111: fSAMPLING=fDTS/32, N=8

Bit 7 MSM: Master/slave mode
0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 6:4  **TS[2:0]: Trigger selection**

This bitfield is combined with TS[4:3] bits. This bit-field selects the trigger input to be used to synchronize the counter.

- **0000**: Internal Trigger 0 (tim_itr0)
- **0001**: Internal Trigger 1 (tim_itr1)
- **0010**: Internal Trigger 2 (tim_itr2)
- **0011**: Internal Trigger 3 (tim_itr3)
- **00100**: tim_ti1 Edge Detector (tim_ti1f_ed)
- **00101**: Filtered Timer Input 1 (tim_ti1fp1)
- **00110**: Filtered Timer Input 2 (tim_ti2fp2)
- **00111**: External Trigger input (tim_etrf)
- **01000**: Internal Trigger 4 (tim_itr4)
- **01001**: Internal Trigger 5 (tim_itr5)
- **01010**: Internal Trigger 6 (tim_itr6)
- **01011**: Internal Trigger 7 (tim_itr7)
- **01100**: Internal Trigger 8 (tim_itr8)
- **01101**: Internal Trigger 9 (tim_itr9)
- **01110**: Internal Trigger 10 (tim_itr10)
- **01111**: Internal trigger 11 (tim_itr11)
- **10000**: Internal trigger 12 (tim_itr12)
- **10001**: Internal trigger 13 (tim_itr13)
- **10010**: Internal trigger 14 (tim_itr14)
- **10011**: Internal trigger 15 (tim_itr15)
- **Others**: Reserved

See Table 426: TIMx internal trigger connection for more details on tim_itrx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  **OCCS: OCREF clear selection**

This bit is used to select the OCREF clear source.

- **0**: tim_ocref_clr_int is connected to the tim_ocref_clr input
- **1**: tim_ocref_clr_int is connected to tim_etrf
Bits 16, 2:0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Quadrature encoder mode 1, x2 mode- Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

0010: Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

0011: Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

1010: Encoder mode: Clock plus direction, x2 mode.

1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

1100: Encoder mode: Directional Clock, x2 mode.

1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_t1f_ed is selected as the trigger input (TS=00100). Indeed, tim_t1f_ed outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
### 46.6.4 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 1, 8)

</table>
Bit 9  **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8  **B2IF**: Break 2 interrupt flag
This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
0: No break event occurred.
1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7  **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred.
1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6  **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5  **COMIF**: COM interrupt flag
This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
0: No COM event occurred.
1: COM interrupt pending.

Bit 4  **CC4IF**: Capture/compare 4 interrupt flag
Refer to CC1IF description

Bit 3  **CC3IF**: Capture/compare 3 interrupt flag
Refer to CC1IF description
Bit 2  CC2IF: Capture/compare 2 interrupt flag  
Refer to CC1IF description

Bit 1  CC1IF: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred  

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0  UIF: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
--At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
--When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
--When CNT is reinitialized by a trigger event (refer to Section 46.6.3: TIMx slave mode control register (TIMx_SMCR)(x = 1, 8)), if URS=0 and UDIS=0 in the TIMx_CR1 register.

46.6.6  TIMx event generation register (TIMx_EGR)(x = 1, 8)

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  B2G: Break 2 generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action  
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7  BG: Break generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action  
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
Bit 6  **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5  **COMG**: Capture/compare control update generation
This bit can be set by software, it is automatically cleared by hardware
0: No action
1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits
*Note:* This bit acts only on channels having a complementary output.

Bit 4  **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3  **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2  **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
**If channel CC1 is configured as output:**
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
**If channel CC1 is configured as input:**
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 46.6.7 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 1, 8)

Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).
Input capture mode:

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **IC2F[3:0]**: Input capture 2 filter

Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection
    This bit-field defines the direction of the channel (input/output) as well as the used input.
    00: CC2 channel is configured as output
    01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
    10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
    11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).*
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter
This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: fSAMPLING=ftim_ker_ck, N=2
0010: fSAMPLING=ftim_ker_ck, N=4
0011: fSAMPLING=ftim_ker_ck, N=8
0100: fSAMPLING=fDTS/2, N=6
0101: fSAMPLING=fDTS/2, N=8
0110: fSAMPLING=fDTS/4, N=6
0111: fSAMPLING=fDTS/4, N=8
1000: fSAMPLING=fDTS/8, N=6
1001: fSAMPLING=fDTS/8, N=8
1010: fSAMPLING=fDTS/16, N=5
1011: fSAMPLING=fDTS/16, N=6
1100: fSAMPLING=fDTS/16, N=8
1101: fSAMPLING=fDTS/32, N=5
1110: fSAMPLING=fDTS/32, N=6
1111: fSAMPLING=fDTS/32, N=8

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note:  CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

46.6.8  **TIMx capture/compare mode register 1 [alternate]**
(TIMx_CCMR1)(x = 1, 8)
Address offset: 0x018
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).
Output compare mode:

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12  **OC2M[3:0]**: Output compare 2 mode

Bit 11  **OC2PE**: Output compare 2 preload enable

Bit 10  **OC2FE**: Output compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working
only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).*

Bit 7  **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal
(tim_ocref_clr input or tim_etrf input)
**OC1M[3:0]: Output compare 1 mode**

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs (this mode is used to generate a timing base).
- **0001**: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.
- **0100**: Force inactive level - tim_oc1ref is forced low.
- **0101**: Force active level - tim_oc1ref is forced high.
- **0110**: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref='0') as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref='1').
- **0111**: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.
- **1000**: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.
- **1001**: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1010**: Reserved,
- **1011**: Reserved,
- **1100**: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.
- **1101**: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.
- **1110**: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.
- **1111**: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

**Note:** In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Note:** On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

### 46.6.9 TIMx capture/compare mode register 2 [alternate]

**(TIMx_CCMR2)(x = 1, 8)**

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 3 in input capture mode and channel 4 in output compare mode).
46.6.10 TIMx capture/compare mode register 2 [alternate]
(TIMx_CCMR2)(x = 1, 8)

Address offset: 0x01C
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 3 in input capture mode and channel 4 in output compare mode).

### Bits 31:25
Reserved, must be kept at reset value.

### Bits 23:17
Reserved, must be kept at reset value.

### Bit 15
**OC4CE**: Output compare 4 clear enable
Bits 24, 14:12 **OC4M[3:0]**: Output compare 4 mode
Refer to OC3M[3:0] bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC4 channel is configured as output
- 01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
- 10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
- 11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: **CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).**

Bit 7 **OC3CE**: Output compare 3 clear enable
**OC3M[3:0]: Output compare 3 mode**

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR3 and the counter TIMx_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 3 (TIMx_CCR3).

0011: Toggle - tim_oc3ref toggles when TIMx_CNT=TIMx_CCR3.

0100: Force inactive level - tim_oc3ref is forced low.

0101: Force active level - tim_oc3ref is forced high.

0110: PWM mode 1 - In upcounting, channel 3 is active as long as TIMx_CNT<TIMx_CCR3 else inactive. In downcounting, channel 3 is inactive (tim_oc3ref=‘0’) as long as TIMx_CNT> TIMx_CCR3 else active (tim_oc3ref=’1’).

0111: PWM mode 2 - In upcounting, channel 3 is inactive as long as TIMx_CNT<TIMx_CCR3 else active. In downcounting, channel 3 is active as long as TIMx_CNT> TIMx_CCR3 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIMxECR.

1011: Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

1100: Combined PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc is the logical OR between tim_oc3ref and tim_oc4ref.

1101: Combined PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc is the logical AND between tim_oc3ref and tim_oc4ref.

1110: Asymmetric PWM mode 1 - tim_oc3ref has the same behavior as in PWM mode 1. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc3ref has the same behavior as in PWM mode 2. tim_oc3refc outputs tim_oc3ref when the counter is counting up, tim_oc4ref when it is counting down.

*Note:* These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).

*Note:* In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.
### 46.6.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)

Address offset: 0x020

Reset value: 0x0000 0000

<table>

</tbody>
</table>

**Note:** CC3S bits are writable only when the channel is OFF (CC3E = ‘0’ in TIMx_CCER).
Bit 10  **CC3NE**: Capture/compare 3 complementary output enable  
Refer to CC1NE description  

Bit 9  **CC3P**: Capture/compare 3 output polarity  
Refer to CC1P description  

Bit 8  **CC3E**: Capture/compare 3 output enable  
Refer to CC1E description  

Bit 7  **CC2NP**: Capture/compare 2 complementary output polarity  
Refer to CC1NP description  

Bit 6  **CC2NE**: Capture/compare 2 complementary output enable  
Refer to CC1NE description  

Bit 5  **CC2P**: Capture/compare 2 output polarity  
Refer to CC1P description  

Bit 4  **CC2E**: Capture/compare 2 output enable  
Refer to CC1E description  

Bit 3  **CC1NP**: Capture/compare 1 complementary output polarity  

**CC1 channel configured as output:**  
0: tim_oc1n active high.  
1: tim_oc1n active low.  

**CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.  
Refer to CC1P description.  

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).  

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.  

Bit 2  **CC1NE**: Capture/compare 1 complementary output enable  
0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 1  **CC1P**: Capture/compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

- **CC1NP=0, CC1P=0**: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=0, CC1P=1**: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
- **CC1NP=1, CC1P=1**: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
- **CC1NP=1, CC1P=0**: the configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0  **CC1E**: Capture/compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

**When CC1 channel is configured as output**, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 441 for details.

**Note**: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.
### Table 441. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature

<td>18</td>
<td>17</td>
<td>16</td>
</tr>
</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]: Auto-reload value**

ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 46.3.3: Time-base unit on page 1657 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
Non-dithering mode (DITHEN = 0)
The register holds the auto-reload value.
Dithering mode (DITHEN = 1)
The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

46.6.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8)

Address offset: 0x030
Reset value: 0x0000

</tr>
</tbody>
</table>

Bits 15:0 **REP[15:0]: Repetition counter reload value**

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.
When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to:
– the number of PWM periods in edge-aligned mode
– the number of half PWM period in center-aligned mode.

CCR1[19:16]: Capture/compare 1 value

**If channel CC1 is configured as output:** CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  - The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:** CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  - The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

CCR2[19:16]: Capture/compare 2 value

**If channel CC2 is configured as output:** CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  - The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

**If channel CC2 is configured as input:** CR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  - The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:0  **CCR2[19:0]**: Capture/compare 2 value

*If channel CC2 is configured as output:* CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

**Non-dithering mode (DITHEN = 0)**

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

*If channel CC2 is configured as input:* CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

**Dithering mode (DITHEN = 1)**

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

CCR4[15:0]

- Bits 31:20: Reserved, must be kept at reset value.
- Bits 19:0: CCR3[19:0]: Capture/compare value
  - **If channel CC3 is configured as output**: CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
    - It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
    - The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.
  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.
  - **If channel CC3 is configured as input**: CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.
  - **Non-dithering mode (DITHEN = 0)**
    - The register holds the capture value in CCR3[15:0]. The CCR3[19:16] bits are reset.
  - **Dithering mode (DITHEN = 1)**
    - The register holds the capture in CCR3[19:4]. The CCR3[3:0] bits are reset.
Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR4[19:0]: Capture/compare value**

**If channel CC4 is configured as output:** CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on tim_oc4 output.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**

**If channel CC4 is configured as input:** CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
  - The register holds the capture value in CCR4[15:0]. The CCR4[19:16] bits are reset.

- **Dithering mode (DITHEN = 1)**
  - The register holds the capture in CCR4[19:4]. The CCR4[3:0] bits are reset.

### 46.6.20 TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8)

**Address offset:** 0x044

**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>RW</td>
<td>MOE</td>
</tr>
</tbody>
</table>

**Note:** As the bits BK2BID/BK2BID/BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **BK2BID**: Break2 bidirectional
       Refer to BK2BID description

Bit 28  **BKBID**: Break bidirectional
       0: Break input tim_brk in input mode
       1: Break input tim_brk in bidirectional mode
       In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.
       *Note*: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
       *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27  **BK2DSRM**: Break2 disarm
       Refer to BK2DSRM description

Bit 26  **BKDSRM**: Break disarm
       0: Break input tim_brk is armed
       1: Break input tim_brk is disarmed
       This bit is cleared by hardware when no break source is active.
       The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.
       *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25  **BK2P**: Break 2 polarity
       0: Break input tim_brk2 is active low
       1: Break input tim_brk2 is active high
       *Note*: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
       *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 24  **BK2E**: Break 2 enable
       This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 421: Break and Break2 circuitry overview).
       0: Break2 function disabled
       1: Break2 function enabled
       *Note*: The BRKIN2 must only be used with OSSR = OSSI = 1.
       *Note*: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
       *Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, tim_brk2 acts asynchronously
- **0001**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 2 \)
- **0010**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 4 \)
- **0011**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 8 \)
- **0100**: \( f_{\text{SAMPLING}} = f_{\text{DTS/2}} \), \( N = 6 \)
- **0101**: \( f_{\text{SAMPLING}} = f_{\text{DTS/2}} \), \( N = 8 \)
- **0110**: \( f_{\text{SAMPLING}} = f_{\text{DTS/4}} \), \( N = 6 \)
- **0111**: \( f_{\text{SAMPLING}} = f_{\text{DTS/4}} \), \( N = 8 \)
- **1000**: \( f_{\text{SAMPLING}} = f_{\text{DTS/8}} \), \( N = 6 \)
- **1001**: \( f_{\text{SAMPLING}} = f_{\text{DTS/8}} \), \( N = 8 \)
- **1010**: \( f_{\text{SAMPLING}} = f_{\text{DTS/16}} \), \( N = 5 \)
- **1011**: \( f_{\text{SAMPLING}} = f_{\text{DTS/16}} \), \( N = 6 \)
- **1100**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 5 \)
- **1101**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 6 \)
- **1110**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 8 \)

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, tim_brk acts asynchronously
- **0001**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 2 \)
- **0010**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 4 \)
- **0011**: \( f_{\text{SAMPLING}} = f_{\text{tim_ker_ck}} \), \( N = 8 \)
- **0100**: \( f_{\text{SAMPLING}} = f_{\text{DTS/2}} \), \( N = 6 \)
- **0101**: \( f_{\text{SAMPLING}} = f_{\text{DTS/2}} \), \( N = 8 \)
- **0110**: \( f_{\text{SAMPLING}} = f_{\text{DTS/4}} \), \( N = 6 \)
- **0111**: \( f_{\text{SAMPLING}} = f_{\text{DTS/4}} \), \( N = 8 \)
- **1000**: \( f_{\text{SAMPLING}} = f_{\text{DTS/8}} \), \( N = 6 \)
- **1001**: \( f_{\text{SAMPLING}} = f_{\text{DTS/8}} \), \( N = 8 \)
- **1010**: \( f_{\text{SAMPLING}} = f_{\text{DTS/16}} \), \( N = 5 \)
- **1011**: \( f_{\text{SAMPLING}} = f_{\text{DTS/16}} \), \( N = 6 \)
- **1100**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 5 \)
- **1101**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 6 \)
- **1110**: \( f_{\text{SAMPLING}} = f_{\text{DTS/32}} \), \( N = 8 \)

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event, OC and OCN outputs are disabled
   In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details (Section 46.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low
1: Break input tim_brk is active high

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per Figure 421: Break and Break2 circuitry overview).

0: Break function disabled
1: Break function enabled

*Note*: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note*: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 46.6.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note*: This bit cannot be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10  **OSSI**: Off-state selection for idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.
See OC/OCN enable description for more details ([Section 46.6.11: TIMx capture/compare enable register (TIMx_CCRER)](x = 1, 8)).

- 0:When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).
- 1:When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8  **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

- 00: LOCK OFF - No bit is write protected.
- 01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKIN/BK2IN/BKIO/PAOE bits in TIMx_BDTR register can no longer be written.
- 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCMER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
- 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note:** The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0  **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]×t_{d tg} with t_{d tg} = t_{DTS}.
DTG[7:5]=10x => DT=(64+DTG[5:0])×t_{d tg} with T_{d tg} = 2×t_{DTS}.
DTG[7:5]=110 => DT=(32+DTG[4:0])×t_{d tg} with T_{d tg} = 8×t_{DTS}.
DTG[7:5]=111 => DT=(32+DTG[4:0])×t_{d tg} with T_{d tg} = 16×t_{DTS}.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps

**Note:** This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 46.6.21 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8)

**Address offset:** 0x048

**Reset value:** 0x0000 0000

**Note:**

STI
Bit 31 **GC5C3**: Group channel 5 and channel 3
Distortion on channel 3 output:
0: No effect of tim_oc5ref on tim_oc3refc
1: tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR2).
Note: it is also possible to apply this distortion on combined PWM signals.

Bit 30 **GC5C2**: Group channel 5 and channel 2
Distortion on channel 2 output:
0: No effect of tim_oc5ref on tim_oc2refc
1: tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
Note: it is also possible to apply this distortion on combined PWM signals.

Bit 29 **GC5C1**: Group channel 5 and channel 1
Distortion on channel 1 output:
0: No effect of oc5ref on oc1refc
1: oc1refc is the logical AND of oc1ref and oc5ref
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload feature is selected in TIMxCCMR1).
Note: it is also possible to apply this distortion on combined PWM signals.

Bits 28:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR5[19:0]**: Capture/compare 5 value
CCR5 is the value to be loaded in the actual capture/compare 5 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC5PE). Else the preload value is copied in the active capture/compare 5 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc5 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.

46.6.22 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8)

1778/3040 RM0456 Rev 1
46.6.23 TIMx capture/compare mode register 3 (TIMx_CCMR3) (x = 1, 8)

Address offset: 0x050
Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

| Bit 31:25 | Reserved, must be kept at reset value. |
| Bit 23:17 | Reserved, must be kept at reset value. |
| Bit 15 | OC6CE: Output compare 6 clear enable |
| Bits 24, 14:12 | OC6M[3:0]: Output compare 6 mode |
| Bit 11 | OC6PE: Output compare 6 preload enable |
| Bit 10 | OC6FE: Output compare 6 fast enable |
| Bits 9:8 | Reserved, must be kept at reset value. |
| Bit 7 | OC5CE: Output compare 5 clear enable |
| Bits 16, 6:4 | OC5M[3:0]: Output compare 5 mode |
| Bit 3 | OC5PE: Output compare 5 preload enable |
| Bit 2 | OC5FE: Output compare 5 fast enable |
| Bits 1:0 | Reserved, must be kept at reset value. |
Advanced-control timers (TIM1/TIM8) RM0456

46.6.24 TIMx timer deadtime register 2 (TIMx_DTR2)(x = 1, 8)

Address offset: 0x054
Reset value: 0x0000 0000

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 DTPE: Deadtime preload enable
0: Deadtime value is not preloaded
1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 16 DTAE: Deadtime asymmetric enable
0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register
1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 DTGF[7:0]: Dead-time falling edge generator setup
This bit-field defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

\[ \text{DTGF}[7:5]=0xx \Rightarrow \text{DTF} = \text{DTGF}[7:0] \times \text{tdtg} \]
\[ \text{DTGF}[7:5]=10x \Rightarrow \text{DTF} = (64 + \text{DTGF}[5:0]) \times \text{tdtg} \]
\[ \text{DTGF}[7:5]=110 \Rightarrow \text{DTF} = (32 + \text{DTGF}[4:0]) \times \text{tdtg} \]
\[ \text{DTGF}[7:5]=111 \Rightarrow \text{DTF} = (32 + \text{DTGF}[4:0]) \times \text{tdtg} \]

Example if \( T_{\text{DTS}}=125\,\text{ns} \) (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
46.6.25 TIMx timer encoder control register (TIMx_ECR)(x = 1, 8)

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 **ETRSEL[3:0]: etr_in source selection**
These bits select the etr_in input source.
0000: tim_etr0: TIMx_ETR input
0001: tim_etr1
...
1111: tim_etr15
Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

*Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 13 **BKCMP4P: tim_brk_cmp4 input polarity**
This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity
This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity
This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity
This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 9 **BKINP**: TIMx_BKIN input polarity
This bit selects the TIMx_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: TIMx_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)
1: TIMx_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable
This bit enables the tim_brk_cmp8 for the timer’s tim_brk input. tim_brk_cmp8 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp8 input disabled
1: tim_brk_cmp8 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable
This bit enables the tim_brk_cmp7 for the timer’s tim_brk input. tim_brk_cmp7 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp7 input disabled
1: tim_brk_cmp7 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable
This bit enables the tim_brk_cmp6 for the timer’s tim_brk input. tim_brk_cmp6 output is ‘ORed’ with the other tim_brk sources.
0: tim_brk_cmp6 input disabled
1: tim_brk_cmp6 input enabled
*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 5 **BKCMP5E**: tim\_brk\_cmp5 enable

This bit enables the tim\_brk\_cmp5 for the timer’s tim\_brk input. tim\_brk\_cmp5 output is ‘ORed’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp5 input disabled
- 1: tim\_brk\_cmp5 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 4 **BKCMP4E**: tim\_brk\_cmp4 enable

This bit enables the tim\_brk\_cmp4 for the timer’s tim\_brk input. tim\_brk\_cmp4 output is ‘ORed’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp4 input disabled
- 1: tim\_brk\_cmp4 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 3 **BKCMP3E**: tim\_brk\_cmp3 enable

This bit enables the tim\_brk\_cmp3 for the timer’s tim\_brk input. tim\_brk\_cmp3 output is ‘ORed’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp3 input disabled
- 1: tim\_brk\_cmp3 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 2 **BKCMP2E**: tim\_brk\_cmp2 enable

This bit enables the tim\_brk\_cmp2 for the timer’s tim\_brk input. tim\_brk\_cmp2 output is ‘ORed’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp2 input disabled
- 1: tim\_brk\_cmp2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 1 **BKCMP1E**: tim\_brk\_cmp1 enable

This bit enables the tim\_brk\_cmp1 for the timer’s tim\_brk input. tim\_brk\_cmp1 output is ‘ORed’ with the other tim\_brk sources.

- 0: tim\_brk\_cmp1 input disabled
- 1: tim\_brk\_cmp1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **BKINE**: TIMx\_BKIN input enable

This bit enables the TIMx\_BKIN alternate function input for the timer’s tim\_brk input. TIMx\_BKIN input is ‘ORed’ with the other tim\_brk sources.

- 0: TIMx\_BKIN input disabled
- 1: TIMx\_BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.*
46.6.28  TIMx alternate function register 2 (TIMx_AF2)(x = 1, 8)

Address offset: 0x064
Reset value: 0x0000 0001

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  OCRSEL[2:0]: ocref_clr source selection
These bits select the ocref_clr input source.
000: tim_ocref_clr0
001: tim_ocref_clr1
... 111: tim_ocref_clr7
Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific information.
Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  BK2CMP4P: tim_brk2_cmp4 input polarity
This bit selects the tim_brk2_cmp4 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp4 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp4 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 12  BK2CMP3P: tim_brk2_cmp3 input polarity
This bit selects the tim_brk2_cmp3 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp3 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp3 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 11  BK2CMP2P: tim_brk2_cmp2 input polarity
This bit selects the tim_brk2_cmp2 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10  **BK2CMP1P**: tim_brk2_cmp1 input polarity
This bit selects the tim_brk2_cmp1 input sensitivity. It must be programmed together with the BK2P polarity bit.
0: tim_brk2_cmp1 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: tim_brk2_cmp1 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9  **BK2INP**: TIMx_BKIN2 input polarity
This bit selects the TIMx_BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.
0: TIMx_BKIN2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)
1: TIMx_BKIN2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8  **BK2CMP8E**: tim_brk2_cmp8 enable
This bit enables the tim_brk2_cmp8 for the timer’s tim_brk2 input. tim_brk2_cmp8 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp8 input disabled
1: tim_brk2_cmp8 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7  **BK2CMP7E**: tim_brk2_cmp7 enable
This bit enables the tim_brk2_cmp7 for the timer’s tim_brk2 input. tim_brk2_cmp7 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp7 input disabled
1: tim_brk2_cmp7 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 6  **BK2CMP6E**: tim_brk2_cmp6 enable
This bit enables the tim_brk2_cmp6 for the timer’s tim_brk2 input. tim_brk2_cmp6 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp6 input disabled
1: tim_brk2_cmp6 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 5  **BK2CMP5E**: tim_brk2_cmp5 enable
This bit enables the tim_brk2_cmp5 for the timer’s tim_brk2 input. tim_brk2_cmp5 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp5 input disabled
1: tim_brk2_cmp5 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 4  **BK2CMP4E**: tim_brk2_cmp4 enable
This bit enables the tim_brk2_cmp4 for the timer’s tim_brk2 input. tim_brk2_cmp4 output is 'ORed' with the other tim_brk2 sources.
0: tim_brk2_cmp4 input disabled
1: tim_brk2_cmp4 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Advanced-control timers (TIM1/TIM8)

Note: Refer to Section 46.3.2: TIM1/TIM8 pins and internal signals for product specific implementation.

46.6.29 TIMx DMA control register (TIMx_DCR)(x = 1, 8)

Address offset: 0x3DC

rw rw rw rw
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
rw rw rw rw rw rw rw rw rw rw rw
Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection
This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
0000: Reserved
0001: Update
0010: CC1
0011: CC2
0100: CC3
0101: CC4
0110: COM
0111: Trigger
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length
This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11010: 26 transfers

**Example**: Let us consider the following transfer: DBL = 7 bytes & DBA = TIM2_CR1.
- If DBL = 7 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:
  \[(\text{TIM}_x\_\text{CR1} \text{ address}) + \text{DBA} + (\text{DMA index}), \text{where DMA index} = \text{DBL}\]
In this example, 7 bytes are added to (TIMx_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx_CR1 address) + DBA
According to the configuration of the DMA Data Size, several cases may occur:
- If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on.
So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address
This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

**Example**:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR
...

Bits 31:0 DMAB[31:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

46.6.31 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

Reset value

**Note:** The reset value for each register is specified in the table.
Refer to Section 2.3 on page 116 for the register boundary addresses.
47 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

47.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 47.4.23: Timer synchronization.

47.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit or 32-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
### 47.3 TIM2/TIM3/TIM4/TIM5 implementation

47.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 465* and *Figure 466* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 465. Counter timing diagram with prescaler division change from 1 to 2

Figure 466. Counter timing diagram with prescaler division change from 1 to 4
### 47.4.4 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

---

**Figure 467. Counter timing diagram, internal clock divided by 1**

Figure 469. Counter timing diagram, internal clock divided by 4
Figure 470. Counter timing diagram, internal clock divided by N

Figure 471. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generate at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 473. Counter timing diagram, internal clock divided by 1**
Figure 474. Counter timing diagram, internal clock divided by 2

Figure 475. Counter timing diagram, internal clock divided by 4
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-
reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
Figure 478. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6

1. Here, center-aligned mode 1 is used (for more details refer to Section 47.5.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1871).

Note: Here, center_aligned mode 2 or 3 is updated with an UIF on overflow

1. Center-aligned mode 2 or 3 is used with an UIF on overflow.

Figure 481. Counter timing diagram, internal clock divided by N
Figure 482. Counter timing diagram, Update event with ARPE=1 (counter underflow)
47.4.5 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to: Using one timer as prescaler for another timer on page 1863 for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 484 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 01000 to 11111: tim_itr[15..0].

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper `tim_ti2_in[15:0]` source (internal or external) with the `TI2SEL[3:0]` bits in the TIMx_TISEL register.

2. Configure channel 2 to detect rising edges on the `tim_ti2` input by writing `CC2S='01` in the TIMx_CCMR1 register.

3. Configure the input filter duration by writing the `IC2F[3:0]` bits in the TIMx_CCMR1 register (if no filter is needed, keep `IC2F=0000`).

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing `CC2P=0` and `CC2NP=0` and `CC2NP=0` in the TIMx_CCER register.

5. Configure the timer in external clock mode 1 by writing `SMS=111` in the TIMx_SMCR register.

6. Select `tim_ti2` as the input source by writing `TS=00110` in the TIMx_SMCR register.

7. Enable the counter by writing `CEN=1` in the TIMx_CR1 register.

When a rising edge occurs on `tim_ti2`, the counter counts once and the TIF flag is set.

The delay between the rising edge on `tim_ti2` and the actual clock of the counter is due to the resynchronization circuit on `tim_ti2` input.

Figure 486. Control circuit in external clock mode 1

External clock source mode 2

This mode is selected by writing `ECE=1` in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input `tim_etr_in`.

Figure 487 gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the tim_etr_in by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.
47.4.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfp) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 489. Capture/compare channel (example: channel 1 input stage)
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 490. Capture/compare channel 1 main circuit

1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocxref clr int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.
In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 47.4.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_t1 input rises. To do this, use the following procedure:

1. Select the proper tim_t1x_in[15..0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_t1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxR bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_t1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_t1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** 
IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
### 47.4.8 PWM input mode

This mode allows to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two T1xFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_t1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15..0] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_t1 selected).
3. Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_t1 selected).
5. Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
47.4.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

Tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

47.4.10 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP polarity).
General-purpose timers (TIM2/TIM3/TIM4/TIM5) | RM0456

bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCXM=001), be set inactive (OCXM=010) or can toggle (OCXM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 0011 to toggle tim_ocx output pin when CNT matches CCRx
   b) Write OCxPE = 0 to disable preload register
   c) Write CCxP = 0 to select active high polarity
   d) Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 493.
47.4.11 PWM mode

Pulse width modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIM_ocx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_ocref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ‘111). This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Upcounting mode on page 1802.

In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then tim_ocxref is held at ‘1. If the compare value is 0 then tim_ocxref is held at ‘0. Figure 494 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to Downcounting mode on page 1805.

In PWM mode 1, the reference signal tim_ocxref is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit
(DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting)* on page 1808.

*Figure 495* shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

**Figure 495. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 496 below presents the dithering principle applied to 4 consecutive PWM cycles.

**Figure 496. Dithering principle**

<table>

</tbody>
</table>

![Figure 496. Dithering principle](MSv45752V1)

When the dithering mode is enabled, the register coding is changed as following (see Figure 497 for example):

- The 4 LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by 4 places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.
Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CCIF flags must be cleared
5. The CEN bit can be set (eventually with ARPE = 1)

The minimum frequency is given by the following formula:

\[
\text{Resolution} = \frac{f_{\text{Tim}}}{f_{\text{PWM}}} \Rightarrow f_{\text{PWMMin}} = \frac{f_{\text{Tim}}}{\text{MaxResolution}}
\]

Dithering mode disabled: \(f_{\text{PWMMin}} = \frac{f_{\text{Tim}}}{65536}\)

Dithering mode (16-bit timer): \(f_{\text{PWMMin}} = \frac{f_{\text{Tim}}}{65535 + \frac{15}{16}}\)

Dithering mode (32-bit timer): \(f_{\text{PWMMin}} = \frac{f_{\text{Tim}}}{268435454 + \frac{15}{16}}\)

Note: For 16-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part). For 32-bit timers, the maximum TIMx_ARR and TIMxCCRy values are limited to
0xFFFFFFEF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on the Figure 498 and Figure 499 below, the dithering mode allows to increase the PWM resolution.

**Figure 498. PWM resolution vs frequency (16-bit mode)**

![Figure 498](MSv47464V2)

**Figure 499. PWM resolution vs frequency (32-bit mode)**

![Figure 499](MSv50912V1)

The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the Figure 500 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 453 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.
The dithering mode is also available in center-aligned PWM mode (CMS bits in TIMx_CR1 register are not equal to ‘00’). In this case, the dithering pattern is applied over 8 consecutive PWM periods, considering the up and down counting phases as shown in the Figure 501 below.

**Figure 501. Dithering effect on duty cycle in center-aligned PWM mode**

![Dithering modes](msv50904v1)

Table 454 below shows how the dithering pattern is added in center-aligned PWM mode.
47.4.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

Note: The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 2.
Figure 502 shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 2).

**Figure 502. Generation of 2 phase-shifted PWM signals with 50% duty cycle**

### 47.4.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by TIMx_CCR1 and TIMx_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 503 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1
47.4.14 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocxref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocxref_clr_int source depends on the OCREF clear selection feature implementation, refer to Section 47.3: TIM2/TIM3/TIM4/TIM5 implementation. If the OCREF clear selection feature is implemented, the tim_ocxref_clr_int can be selected between the tim_ocxref input and the tim_etrf input (tim_etrf input after the filter) by configuring the OCCS bit in the TIMx_SMCR register. The tim_ocxref_clr input can be selected among several tim_ocxref克拉特[7:0] inputs, using the OCRSEL[2:0] bitfield in the TIMx_AF2 register, as shown in Figure 504 below.
If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etrf must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application’s needs.

Figure 505 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

47.4.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- CNT<CCRx ≤ ARR (in particular, 0<CCRx),

For example one may want to generate a positive pulse on tim_oc1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the tim_ti2 input pin.

Let’s use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15..0] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS=00110 in the TIMx_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one wants to build a waveform with a transition from ‘0 to ‘1 when a compare match occurs and a transition from ‘1 to ‘0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TIM_Ti2. CC1P is written to ‘0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low. Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: tim_ocx fast enable:**

In One-pulse mode, the edge detection on TIM_TiX input sets the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}}\text{min}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then TIM_OCnREF (and TIM_OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 47.4.16 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retrigerable one-pulse mode described in Section 47.4.15:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

**Note:** *In Retriggerable one-pulse mode, the CCxIF flag is not significant. The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones. This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.*
47.4.17 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on the Figure 508 below.

The Figure 509 below shows how the pulse is generated for edge-aligned and encoder operating modes.
Figure 509. Pulse generation on compare event, for edge-aligned and encoder modes

This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bit fields in TIMx_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

\[ t_{PW} = PW[7:0] \times t_{PWG} \]

where \( t_{PWG} = (2^{PWPRSC[2:0]}) \times t_{	ext{tim_ker_ck}} \).

This gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the 1st arriving trigger is extended (because of the re-trigger), while the pulse width of the last arriving trigger is correct (as shown on the Figure 510 below).
47.4.18 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS=’0001 in the TIMx_SMCR register if the counter is counting on tim_ti1 edges only, SMS=’0010 if it is counting on tim_ti2 edges only and SMS=’0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_ti1 and tim_ti2 are used to interface to an incremental encoder. Refer to Table 455. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1=tim_ti1 if not filtered and not inverted, tim_ti2fp2=tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the-quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 511 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, tim_ti1fp1 mapped on tim_ti1)
- CC2S= 01 (TIMx_CCMR2 register, tim_ti2fp2 mapped on tim_ti2)
- CC1P and CC1NP = ‘0’ (TIMx_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1=tim_ti1)
- CC2P and CC2NP = ‘0’ (TIMx_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2=tim_ti2)
- SMS= 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)

*Figure 512 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P=1).*
The Figure 513 below shows the timer counter value during a speed reversal, for various counting modes.

**Figure 513. Quadrature encoder counting modes**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

**Clock plus direction encoder mode**

In addition to the quadrature encoder mode, the timer offers support other types of encoders.

In the “clock plus direction” mode shown on Figure 514, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.
This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1010**: x2 mode, the counter is updated on both rising and falling edges of the clock
- **1011**: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

**Directional Clock encoder mode**

In the “directional clock” mode on Figure 515, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[3:0] bitfield in the TIMx_SMCR register, as following:

- **1100**: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to Figure 515 below) and CCxP = 1 corresponds to low-level idle state (refer to Figure 516 below).
- **1101**: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to Figure 515 below), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to Figure 516 below).
The Table 456 here-below details how the directional clock mode operates, for any input transition.
The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the `tim_etr_in` input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 517 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges

**Index Input**

The counter can be reset by an Index signal coming from the encoder, indicating an absolute reference position. The Index signal must be connected to the `tim_etr_in` input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIMx_ECR register. The IE bit must be set only in encoder mode, when the SMS[3:0] bitfield has the following values: 0001, 0010, 011, 1010, 1011, 1100, 1101, 1110, 1111.

Commercially available encoders are proposed with several options for index pulse conditioning, as per the Figure 517 below:

- gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulse width is up to one channel period, without any alignment to the edges
The circuitry tolerates jitter on index signal, whatever the gating mode, as show on Figure 518 below.

In ungated mode, the signal must be strictly below 2 encoder periods. If the pulse width is greater or equal to 2 encoder period, the counter is reset multiple times.

The timer supports the 3 gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (i.e. channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIMx_ECR register.

The Index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0)
- The counter is set to TIMx_ARR when down counting

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. The Figure 519 below shows at which position is the index generated, for a simplistic example (an encoder providing 4 edges par mechanical rotation).
Figure 519. Index generation for IPOS[1:0] = 11

The Figure 520 below presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is ‘11’ (ChA=1, ChB=1), when up-counting (DIR bit = 0).
- Counter set to TIMx_ARR when exiting the ‘11’ state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

Figure 520. Counter reading with index gated on channel A (IPOS[1:0] = 11)

The Figure 521 below presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.
The Figure 522 below shows how the ‘gated on A & B’ mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

The Figure 523 and Figure 524 detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.
Figure 523. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

Index leading state transition

Index delayed versus state transition
The Figure 525 below shows how the index is managed in x1 and x2 modes.
Figure 525. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)

Directional index sensitivity

The IDIR[1:0] bitfield in the TIMx_ECR register allows the index to be active only in a selected counting direction.

The Figure 526 below shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

Note: The IDR[1:0] bitfield must be written when IE bit is reset (index mode disabled).

Note: The directional index sensitivity is not supported in clock + direction mode. When SMS[3:0] = 1010 or 1011, the IDIR[1:0] must be set to 00.
Special first index event management

The FIDX bit in the TIMx_ECR register allows the Index to be taken only once, as shown on the Figure 527 below. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be re-armed by writing the FIDX bit to 0 and setting it again to 1.

Note: When FIDX = 1, the index can be issued twice (IDXF flag set) if the direction changes at position 0 (index active).

Index blanking

The Index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the Figure 528 below.
This mode is enabled using the IBLK[1:0] bitfield in the TIMx_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim ti4 input

**Figure 528. Index blanking**

Index management in non-quadrature mode

The Figure 529 and Figure 530 below detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[3:0] bitfield is equal to 1010, 1011, 1100, 1101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.
Encoder error management

For encoder configurations where 2 quadrature signals are available, it is possible to detect transition errors. The reading on the 2 inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on the Figure 531. below. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIMx_SR status register. A transition error interrupt is generated if the TERRIE bit is set in the TIMx_DIER register.

For encoder having an Index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The Index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIMx_ARR to 0 or decremented from 0 to TIMxARR value without any index event, this is reported as an Index position error.

The overflow threshold is programmed using the TIMx_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIMx_ARR = 3999 + 1 = 4000.
The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on Figure 532 below.

**Figure 532. Up-counting encoder error detection**
In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on Figure 533 below, to avoid any false error detection in case the encoder dithers between TIMx_ARR and 0 immediately after the index detection.

Figure 533. Down-counting encode error detection

An index error sets the IERRF interrupt flag in the TIMx_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIMx_DIER register.

**Functional encoder Interrupts**

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIMx_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIMx_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIMx_DIER register.

- Index event: the Index event sets the IDXF interrupt flag in the TIMx_SR status register. An Index interrupt is generated if the IDXIE bit is set in the TIMx_DIER register.
Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the Update interrupt rate, by switching from x4 to x2 to x1 mode, as show on the Figure 534 below.

For this purpose, the SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value can be selected with the SMPS bit in the TIMx_SMCR register.

- SMPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting. This mode must be used only when index is disabled (bit IE = 0).
- SMPS = 1: the transfer is triggered by the Index event.

Figure 534. Encoder mode change with preload transferred on update (SMPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIMx_CR2 register. It is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

47.4.19 Direction bit output

It’s possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIMx_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bit field to 1011 in the TIMx_CCMR2 register.
This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

47.4.20 **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

47.4.21 **Timer input XOR function**

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in *Section 37.3.25: Interfacing with Hall sensors on page 1243*.

47.4.22 **Timers and external trigger synchronization**

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.
3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

![Figure 535. Control circuit in reset mode](image)

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.
The configuration "CCxC=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.
Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode allows to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on tim_etr_in and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.
47.4.23 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 539* and *Figure 540* show examples of master/slave timer connections.

*Figure 538. Control circuit in external clock mode 2 + trigger mode*
The timers with one channel only (see Figure 540) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination timer tim_ker_ck clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

**Using one timer as prescaler for another timer**

For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to Figure 539. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

**Note:** If tim_ocx is selected on TIM_mstr as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM_slv.

**Using one timer to enable another timer**

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to Figure 539 for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck \(f_{\text{tim_cnt_ck}} = f_{\text{tim_ker_ck}}/3\).
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Enable TIM_slv by writing '1 in the CEN bit (TIM_slv_CR1 register).
6. Start TIM_mstr by writing '1 in the CEN bit (TIM_mstr_CR1 register).

Note: The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

**Figure 541. Gating TIM_slv with tim_oc1ref of TIM_mstr**

In the example in **Figure 541**, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to **Figure 542**), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing '0 to the CEN bit in the TIM_mstr_CR1 register:
1. Configure TIM_mstr master mode to send its Output Compare 1 Reference (tim_oc1ref) signal as trigger output (MMS=100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS=101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing '1 in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing '1 in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing '0xE7' in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing '1 in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing '1 in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing '0 in the CEN bit (TIM_mstr_CR1 register).

Figure 542. Gating TIM_slv with Enable of TIM_mstr

Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to Figure 539 for connections. TIM_slv starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0 to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck \( f_{\text{tim_cnt_ck}} = f_{\text{tim_ker_ck}}/3 \).

1. Configure TIM_mstr master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS=110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing '1 in the CEN bit (TIM_mstr_CR1 register).
As in the previous example, both counters can be initialized before starting counting. Figure 544 shows the behavior with the same configuration as in Figure 543 but in trigger mode instead of gated mode (SMS=110 in the TIM_slv_SMCR register).

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to Figure 539 for connections. To ensure the counters are aligned, TIM_mstr must be configured in Master/Slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):
1. Configure TIM_mstr master mode to send its Enable as trigger output (MMS=001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS=00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS=110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in Master/Slave mode by writing MSM=1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS=00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS=110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters start counting synchronously on the internal clock and both TIF flags are set.

**Note:** In this example both timers are initialized before starting (by setting their respective UG bits). Both counters start from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on TIM_mstr.

![Figure 545. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input](image)

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

### 47.4.24 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.
The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:
00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 47.5.23: TIMx DMA control register (TIMx_DCR)(x = 2 to 5) for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

47.4.25 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in Table 457.
47.4.26 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter can either continues to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

47.4.27 TIM2/TIM3/TIM4/TIM5 low-power modes

<td></td>
</tr>
</tbody>
</table>

Bits 15:13: Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering Enable
- 0: Dithering disabled
- 1: Dithering enabled

*Note: The DITHEN bit can only be modified when CEN bit is reset.*

Bit 11 **UIFREMAP**: UIF status bit remapping
- 0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
- 1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10: Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
- 00: tDTS = ttim_ker_ck
- 01: tDTS = 2 × ttim_ker_ck
- 10: tDTS = 4 × ttim_ker_ck
- 11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
- 0: TIMx_ARR register is not buffered
- 1: TIMx_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection
- 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
- 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.
- 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.
- 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*
Bit 4 DIR: Direction
0: Counter used as upcounter
1: Counter used as downcounter

Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 OPM: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 URS: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 UDIS: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 CEN: Counter enable
0: Counter disabled
1: Counter enabled

Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

CEN is cleared automatically in one-pulse mode, when an update event occurs.

47.5.2 TIMx control register 2 (TIMx_CR2)(x = 2 to 5)

Address offset: 0x004
Reset value: 0x0000 0000
Bits 31:26  Reserved, must be kept at reset value.

Bits 24:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: tim_ti1 selection

0: The tim_ti1_in[15..0] multiplexer output is to tim_ti1 input
1: The tim_ti1_in[15..0], tim_ti2_in[15..0] and tim_ti3_in[15..0] multiplexers outputs are XORed and connected to the tim_ti1 input. See also Section 37.3.25: Interfacing with Hall sensors on page 1243.

Bits 25, 6, 5, 4  **MMS[3:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)
0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)
0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)
0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[3:0] values: 0001, 0010, 0011, 1010, 1011, 1100, 1101, 1110, 1111. Any other SMS[3:0] code is not allowed and may lead to unexpected behavior.

Others: Reserved

*Note:* The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3  **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.

</tr>
<tr>
<td></td>
<td>It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).</td>
</tr>
<tr>
<td></td>
<td>If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.</td>
</tr>
</tbody>
</table>

| Bits 13:12 | **ETPS[1:0]**: External trigger prescaler |
|            | External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etrp_in. |
|            | 00: Prescaler OFF |
|            | 01: tim_etrp frequency divided by 2 |
|            | 10: tim_etrp frequency divided by 4 |
|            | 11: tim_etrp frequency divided by 8 |
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: fSAMPLING=ftim_ker_ck, N=2
0010: fSAMPLING=ftim_ker_ck, N=4
0011: fSAMPLING=ftim_ker_ck, N=8
0100: fSAMPLING=fDTS/2, N=6
0101: fSAMPLING=fDTS/2, N=8
0110: fSAMPLING=fDTS/4, N=6
0111: fSAMPLING=fDTS/4, N=8
1000: fSAMPLING=fDTS/8, N=6
1001: fSAMPLING=fDTS/8, N=8
1010: fSAMPLING=fDTS/16, N=5
1011: fSAMPLING=fDTS/16, N=6
1100: fSAMPLING=fDTS/16, N=8
1101: fSAMPLING=fDTS/32, N=5
1110: fSAMPLING=fDTS/32, N=6
1111: fSAMPLING=fDTS/32, N=8

Bit 7 **MSM**: Master/Slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4 \textbf{TS}[4:0]: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal trigger 0 (tim_itr0)
- 00001: Internal trigger 1 (tim_itr1)
- 00010: Internal trigger 2 (tim_itr2)
- 00011: Internal trigger 3 (tim_itr3)
- 00100: tim_ti1 edge detector (tim_ti1f_ed)
- 00101: Filtered timer input 1 (tim_ti1fp1)
- 00110: Filtered timer input 2 (tim_ti2fp2)
- 00111: External trigger input (tim_etrf)
- 01000: Internal trigger 4 (tim_itr4)
- 01001: Internal trigger 5 (tim_itr5)
- 01010: Internal trigger 6 (tim_itr6)
- 01011: Internal trigger 7 (tim_itr7)
- 01100: Internal trigger 8 (tim_itr8)
- 01101: Internal trigger 9 (tim_itr9)
- 01110: Internal trigger 10 (tim_itr10)
- 01111: Internal trigger 11 (tim_itr11)
- 10000: Internal trigger 12 (tim_itr12)
- 10001: Internal trigger 13 (tim_itr13)
- 10010: Internal trigger 14 (tim_itr14)
- 10011: Internal trigger 15 (tim_itr15)

Others: Reserved

See Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation details.

\textbf{Note}: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 \textbf{OCCS}: OCREF clear selection

This bit is used to select the OCREF clear source

- 0: tim_ocref_clr_int is connected to the tim_ocref_clr input
- 1: tim_ocref_clr_int is connected to tim_etrf

\textbf{Note}: If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to ‘0’. Section 47.3: TIM2/TIM3/TIM4/TIM5 implementation.
Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

- 0000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.
- 0001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.
- 0010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.
- 0011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.
- 0100: Reset Mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.
- 0101: Gated Mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 0110: Trigger Mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.
- 0111: External Clock Mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.
- 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.
- 1001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 1010: Encoder mode: Clock plus direction, x2 mode.
- 1011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.
- 1100: Encoder mode: Directional Clock, x2 mode.
- 1101: Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.
- 1110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.
- 1111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

**Note:** The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS=00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Bits 31:24 Reserved, must be kept at reset value.

#### Bit 23 TERRF: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to ‘0’.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

#### Bit 22 IERRF: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to ‘0’.
0: No index error has been detected.
1: An index error has been detected
Bit 21  **DIRF**: Direction change interrupt flag
   This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIMx_CR is changing). It is cleared by software by writing it to '0'.
   0: No direction change
   1: Direction change

Bit 20  **IDXF**: Index interrupt flag
   This flag is set by hardware when an index event is detected. It is cleared by software by writing it to '0'.
   0: No index event occurred.
   1: An index event has occurred

Bits 19:13  Reserved, must be kept at reset value.

Bit 12  **CC4OF**: Capture/Compare 4 overcapture flag
   refer to CC1OF description

Bit 11  **CC3OF**: Capture/Compare 3 overcapture flag
   refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
   refer to CC1OF description

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
   This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
   0: No overcapture has been detected.
   1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **TIF**: Trigger interrupt flag
   This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
   0: No trigger event occurred.
   1: Trigger interrupt pending.

Bit 5  Reserved, must be kept at reset value.

Bit 4  **CC4IF**: Capture/Compare 4 interrupt flag
   Refer to CC1IF description

Bit 3  **CC3IF**: Capture/Compare 3 interrupt flag
   Refer to CC1IF description
Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag  
Refer to CC1IF description  

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag  
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).  
0: No compare match / No input capture occurred  
1: A compare match or an input capture occurred  
If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.  
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).  

Bit 0  **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
At overflow or underflow and if UDIS=0 in the TIMx_CR1 register.  
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.  
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

Bit 3  **CC3G**: Capture/compare 3 generation  
Refer to CC1G description
47.5.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 IC2F[3:0]: Input capture 2 filter

Bits 11:10 IC2PSC[1:0]: Input capture 2 prescaler
Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC2 channel is configured as output.
- **01**: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.
- **10**: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.
- **11**: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

**Note**: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).**

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at f_DTS
- **0001**: \( f_{\text{Sampling}} = f_{\text{tim_ker_ck}} \), N=2
- **0010**: \( f_{\text{Sampling}} = f_{\text{tim_ker_ck}} \), N=4
- **0011**: \( f_{\text{Sampling}} = f_{\text{tim_ker_ck}} \), N=8
- **0100**: \( f_{\text{Sampling}} = f_{\text{DTS/2}} \), N=6
- **0101**: \( f_{\text{Sampling}} = f_{\text{DTS/2}} \), N=8
- **0110**: \( f_{\text{Sampling}} = f_{\text{DTS/4}} \), N=6
- **0111**: \( f_{\text{Sampling}} = f_{\text{DTS/4}} \), N=8
- **1000**: \( f_{\text{Sampling}} = f_{\text{DTS/8}} \), N=6
- **1001**: \( f_{\text{Sampling}} = f_{\text{DTS/8}} \), N=8
- **1010**: \( f_{\text{Sampling}} = f_{\text{DTS/16}} \), N=5
- **1011**: \( f_{\text{Sampling}} = f_{\text{DTS/16}} \), N=6
- **1100**: \( f_{\text{Sampling}} = f_{\text{DTS/16}} \), N=8
- **1101**: \( f_{\text{Sampling}} = f_{\text{DTS/32}} \), N=5
- **1110**: \( f_{\text{Sampling}} = f_{\text{DTS/32}} \), N=6
- **1111**: \( f_{\text{Sampling}} = f_{\text{DTS/32}} \), N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).

- **00**: no prescaler, capture is done each time an edge is detected on the capture input
- **01**: capture is done once every 2 events
- **10**: capture is done once every 4 events
- **11**: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output
- **01**: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
- **10**: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
- **11**: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

**Note**: **CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).**
47.5.8  **TIMx capture/compare mode register 1 [alternate]**  
(TIMx_CCMR1)(x = 2 to 5)

Address offset: 0x018  
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

- **OC2CE**: Output compare 2 clear enable
- **OC2M[3:0]**: Output compare 2 mode  
  refer to OC1M description on bits 6:4
- **OC2PE**: Output compare 2 preload enable
- **OC2FE**: Output compare 2 fast enable
- **CC2S[1:0]**: Capture/Compare 2 selection  
  This bit-field defines the direction of the channel (input/output) as well as the used input.  
  00: CC2 channel is configured as output  
  01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2  
  10: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)  
  **Note**: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCRER).**
- **OC1CE**: Output compare 1 clear enable  
  0: tim_oc1ref is not affected by the tim_ocref_clr_int input  
  1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 24, 14:12 **OC2M[3:0]**: Output compare 2 mode  
refer to OC1M description on bits 6:4

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output  
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2  
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)  
**Note**: **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCRER).**

Bit 7 **OC1CE**: Output compare 1 clear enable  
0: tim_oc1ref is not affected by the tim_ocref_clr_int input  
1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - tim_oc1ref toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - tim_oc1ref is forced low.

0101: Force active level - tim_oc1ref is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref=0) as long as TIMx_CNT>TIMx_CCR1 else active (tim_oc1ref=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc is the logical OR between tim_oc1ref and tim_oc2ref.

1101: Combined PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc is the logical AND between tim_oc1ref and tim_oc2ref.

1110: Asymmetric PWM mode 1 - tim_oc1ref has the same behavior as in PWM mode 1. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

1111: Asymmetric PWM mode 2 - tim_oc1ref has the same behavior as in PWM mode 2. tim_oc1refc outputs tim_oc1ref when the counter is counting up, tim_oc2ref when it is counting down.

**Note:** In PWM mode, the tim_ocref_clr level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
47.5.9  **TIMx capture/compare mode register 2 [alternate]**  
(TIMx_CCMR2)(x = 2 to 5)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

### 47.5.12 TIMx counter (TIMx_CNT)(x = 2 to 5)

Address offset: 0x024  
Reset value: 0x0000 0000

![TIMx_CNT Register](image)

**Bit 31** **CNT[31] or UIFCPY**: Value depends on IUFREMAP in TIMx_CR1.  
- If IUFREMAP = 0  
  - **CNT[31]**: Most significant bit of counter value  
  - **UIFCPY**: UIF Copy  
  - This bit is a read-only copy of the UIF bit of the TIMx_ISR register

**Bits 30:0** **CNT[30:0]**: Least significant part of counter value  
- **Non-dithering mode (DITHEN = 0)**  
  - The register holds the counter value.  
- **Dithering mode (DITHEN = 1)**  
  - The register holds the non-dithered part in CNT[30:0]. The fractional part is not available.

### 47.5.13 TIMx prescaler (TIMx_PSC)(x = 2 to 5)

Address offset: 0x028  
Reset value: 0x0000

![TIMx_PSC Register](image)

**Bits 15:0** **PSC[15:0]**: Prescaler value  
- The counter clock frequency \(f_{\text{tim}_\text{cnt}_\text{ck}}\) is equal to \(f_{\text{tim}_\text{psc}_\text{ck}} / (\text{PSC}[15:0] + 1)\).  
- PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).
### 47.5.14 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5)

Address offset: 0x02C  
Reset value: 0xFFFF FFFF

</tbody>
</table>

Bits 31:0 **ARR[31:0]:** Auto-reload value  
ARR is the value to be loaded in the actual auto-reload register.  
Refer to the Section 47.4.3: Time-base unit on page 1800 for more details about ARR update and behavior.  
The counter is blocked while the auto-reload value is null.  
**Non-dithering mode (DITHEN = 0)**  
The register holds the auto-reload value.  
**Dithering mode (DITHEN = 1)**  
The register holds the integer part in ARR[31:4]. The ARR[3:0] bitfield contains the dithered part.

### 47.5.15 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5)

Bits 31:0 **CCR1[31:0]**: Capture/compare 1 value

**If channel CC1 is configured as output:**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc1 output.

- **Non-dithering mode (DITHEN = 0)**
The register holds the compare value.
- **Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.

**If channel CC1 is configured as input:**
CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIMx_CCR1 register is read-only and cannot be programmed.

- **Non-dithering mode (DITHEN = 0)**
The register holds the capture value.
- **Dithering mode (DITHEN = 1)**
The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

Bits 31:0  **CCR2[31:0]**: Capture/compare 2 value

If channel CC2 is configured as output:
- CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)
- The register holds the compare value.

Dithering mode (DITHEN = 1)
- The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:
- CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIMx_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)
- The register holds the capture value.

Dithering mode (DITHEN = 1)
- The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

Bits 31:0  **CCR3[31:0]**: Capture/compare 3 value

**If channel CC3 is configured as output:**
CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc3 output.

**Non-dithering mode (DITHEN = 0)**
The register holds the compare value.
**Dithering mode (DITHEN = 1)**
The register holds the integer part in CCR3[31:4]. The CCR3[3:0] bitfield contains the dithered part.

**If channel CC3 is configured as input:**
CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIMx_CCR3 register is read-only and cannot be programmed.

**Non-dithering mode (DITHEN = 0)**
The register holds the capture value.
**Dithering mode (DITHEN = 1)**
The register holds the capture in CCR3[31:0]. The CCR3[3:0] bits are reset.

Bits 31:0 **CCR4[31:0]**: Capture/compare 4 value

**If channel CC4 is configured as output:**
CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on tim_oc4 output.

*Non-dithering mode (DITHEN = 0)*
The register holds the compare value.

*Dithering mode (DITHEN = 1)*
The register holds the integer part in CCR4[31:4]. The CCR4[3:0] bitfield contains the dithered part.

**If channel CC4 is configured as input:**
CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIMx_CCR4 register is read-only and cannot be programmed.

*Non-dithering mode (DITHEN = 0)*
The register holds the capture value.

*Dithering mode (DITHEN = 1)*
The register holds the capture in CCR4[31:0]. The CCR4[3:0] bits are reset.

Bits 7:6 **IPOS[1:0]:** Index positioning

- **IPOS[1:0]:** Index positioning
  - In quadrature encoder mode (SMS[3:0] = 0001, 0010, 0011, 1110, 1111), this bit indicates in which AB input configuration the Index event resets the counter.
    - 00: Index resets the counter when AB = 00
    - 01: Index resets the counter when AB = 01
    - 10: Index resets the counter when AB = 10
    - 11: Index resets the counter when AB = 11

  - In directional clock mode or clock plus direction mode (SMS[3:0] = 1010, 1011, 1100, 1101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.
    - 00: Index resets the counter when clock is 0
    - 01: Index resets the counter when clock is 1

  **Note:** IPOS[1] bit is not significant

Bit 5 **FDX:** First index

- This bit indicates if the first index only is taken into account
  - 0: Index is always active
  - 1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]:** Index blanking

- This bit indicates if the Index event is conditioned by the tim_ti3 input
  - 00: Index always active
  - 01: Index disabled hen tim_ti3 input is active, as per CC3P bitfield
  - 10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
  - 11: Reserved

Bits 2:1 **IDIR[1:0]:** Index direction

- This bit indicates in which direction the Index event resets the counter.
  - 00: Index resets the counter whatever the direction
  - 01: Index resets the counter when up-counting only
  - 10: Index resets the counter when down-counting only
  - 11: Reserved

**Note:** The IDR[1:0] bitfield must be written when IE bit is reset (index disabled).

Bit 0 **IE:** Index enable

- This bit indicates if the Index event resets the counter.
  - 0: Index disabled
  - 1: Index enabled
Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  **TI4SEL[3:0]**: Selects tim_ti4[0..15] input
            0000: tim_ti4_in0: TIMx_CH4
            0001: tim_ti4_in1
            ...
            1111: tim_ti4_in15
            Refer to Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation.

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **TI3SEL[3:0]**: Selects tim_ti3[0..15] input
            0000: tim_ti3_in0: TIMx_CH3
            0001: tim_ti3_in1
            ...
            1111: tim_ti3_in15
            Refer to Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **TI2SEL[3:0]**: Selects tim_ti2[0..15] input
            0000: tim_ti2_in0: TIMx_CH2
            0001: tim_ti2_in1
            ...
            1111: tim_ti2_in15
            Refer to Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **TI1SEL[3:0]**: Selects tim_ti1[0..15] input
            0000: tim_ti1_in0: TIMx_CH1
            0001: tim_ti1_in1
            ...
            1111: tim_ti1_in15
            Refer to Section 47.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals for product specific implementation.

- 0111: Trigger
- Others: reserved

Bits 15:13 Reserved, must be kept at reset value.
47.5.24 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x3E0
Reset value: 0x0000 0000
Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 47.5.25 TIMx register map

TIMx registers are mapped as described in the table below.

**Table 461. TIM2/TIM3/TIM4/TIM5 register map and reset values**

| Offset  | Register name       | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x000   | TIMx_CR1            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|         | Reset value         | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x004   | TIMx_CR2            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|         | Reset value         | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to Section 2.3 on page 116 for the register boundary addresses.
48 General purpose timers (TIM15/TIM16/TIM17)

48.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 48.4.25: Timer synchronization (TIM15).

48.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
48.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
48.4 TIM15/TIM16/TIM17 functional description

48.4.1 Block diagram

Figure 546. TIM15 block diagram

1. Refer to Section 48.4.15: Using the break function for details.

Notes:
- Preload registers transferred to active registers on UI event according to control bit
- Event
- Interrupt & DMA output

MSv62371V3
48.4.2 TIM15/TIM16/TIM17 pins and internal signals

Table 462 and Table 463 in this section summarize the TIM inputs and outputs.

Table 462. TIM input/output pins

<table>
<thead>
<tr>
<th>Pin name</th>
<th>Signal type</th>
<th>Description</th>
</tr>

### 48.4.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the
shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 548* and *Figure 549* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

![Figure 548. Counter timing diagram with prescaler division change from 1 to 2](image)
48.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Write a new value in TIMx_ARR
48.4.5 Repetition counter

Section 48.4.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 556). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
48.4.6 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
- Internal trigger inputs (tim_itrx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer to enable another timer for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 557 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 557. Control circuit in normal mode, internal clock divided by 1**

![Control circuit diagram](image)

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 558. tim_ti2 external clock connection example**

![External clock connection diagram](image)

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:
1. Select the proper \( \text{tim}_{-}\text{ti2}_{-}\text{in}[0..15] \) source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.

2. Configure channel 2 to detect rising edges on the \( \text{tim}_{-}\text{ti2} \) input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.

3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).

4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.

5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

6. Select \( \text{tim}_{-}\text{ti2} \) as the trigger input source by writing TS=00110 in the TIMx_SMCR register.

7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

**Note:** *The capture prescaler is not used for triggering, it is not necessary to configure it.*

When a rising edge occurs on \( \text{tim}_{-}\text{ti2} \), the counter counts once and the TIF flag is set.

The delay between the rising edge on \( \text{tim}_{-}\text{ti2} \) and the actual clock of the counter is due to the resynchronization circuit on \( \text{tim}_{-}\text{ti2} \) input.

**Figure 559. Control circuit in external clock mode 1**

---

### 48.4.7 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 560 to Figure 563* give an overview of one Capture/Compare channel.

The input stage samples the corresponding \( \text{tim}_{-}\text{tix} \) input to generate a filtered signal \( \text{tim}_{-}\text{tixf} \). Then, an edge detector with polarity selection generates a signal (\( \text{tim}_{-}\text{tixf}p\)) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

**Figure 560. Capture/compare channel (example: channel 1 input stage)**

**Figure 561. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 48.4.8 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding tim_icx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with '0'.

The following example shows how to capture the counter value in TIMx_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_ti1_in[1..15] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIMx_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on tim_ti1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
48.4.9 PWM input mode (only for TIM15)

This mode allows to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIMx_CCR1 register holds the period value (interval between two consecutive rising edges)
- The TIMx_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges)

This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two tim_icx signals are mapped on the same tim_tix input.
- These 2 tim_icx signals are active on edges with opposite polarity.
- One of the two tim_tixfpy signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on tim_ti1 using the following procedure (depending on tim_ker_ck frequency and prescaler value):

1. Select the proper tim_ti1_in[0.15] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_t1fp1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_t1fp2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (tim_t1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.
48.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP=0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

48.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP polarity bit).
bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxE = 0 to select active high polarity
   - Write CCxP = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 565*. 
48.4.12 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per TIM_ocx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1913.
In the following example, we consider PWM mode 1. The reference PWM signal `tim_ocxref` is high as long as `TIMx_CNT < TIMx_CCRx` else it becomes low. If the compare value in `TIMx_CCRx` is greater than the auto-reload value (in `TIMx_ARR`) then `tim_ocxref` is held at ‘1’. If the compare value is 0 then `tim_ocxref` is held at ‘0’. Figure 566 shows some edge-aligned PWM waveforms in an example where `TIMx_ARR`=8.

**Figure 566. Edge-aligned PWM waveforms (ARR=8)**

**Dithering mode**

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIMx_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. The Figure 567 below presents the dithering principle applied to 4 consecutive PWM cycles.
When the dithering mode is enabled, the register coding is changed as following (see Figure 568 for example):

- the 4 LSBs are coding for the enhanced resolution part (fractional part)
- the MSBs are left-shifted to the bits 19:4 and are coding for the base value.

**Note:** The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The ARR[3:0] bits must be reset
3. The DITHEN bit must be reset
4. The CCIF flags must be cleared
5. The CEN bit can be set (eventually with ARPE = 1).

The minimum frequency is given by the following formula:

\[ \text{Minimum Frequency} = \frac{1}{1 \text{ clock cycle}} \]

Average duty cycle

\[ \text{DC} = \frac{7}{5} \]

\[ \text{DC} = \frac{7 + \frac{1}{4}}{5} \]

\[ \text{DC} = \frac{7 + \frac{1}{2}}{5} \]

\[ \text{DC} = \frac{7 + \frac{3}{4}}{5} \]

\[ \text{DC} = \frac{8}{5} \]

Register format in dithering mode

- **MSB:** 16-bits, integer part
- **LSB:** 4-bits fractional part

Example

<table>
<thead>
<tr>
<th>b19</th>
<th>b0</th>
</tr>
</thead>
<tbody>
<tr>
<td>326</td>
<td>6</td>
</tr>
</tbody>
</table>

Base compare value is 20 during 16 periods
Additional 6 cycles are spread over the 16 periods
Note: The maximum TIMx_ARR and TIMxCCRx values are limited to 0xFFFFE in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).

As shown on the Figure 569 below, the dithering mode allows to increase the PWM resolution whatever the PWM frequency.

Figure 569. PWM resolution vs frequency

The duty cycle and / or period changes are spread over 16 consecutive periods, as described in the Figure 570 below.
The auto-reload and compare values increments are spread following specific patterns described in the Table 470 below. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

</table>
Combined PWM mode (TIM15 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs:

- tim_oc1refc (or tim_oc2refc) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 571** represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
48.4.14 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 477: Output control bits for complementary tim_oc1 and tim_oc1n channels with break feature (TIM16/TIM17) on page 1991 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform tim_ocxref, it generates 2 outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 572. Complementary output with symmetrical dead-time insertion.**

![Diagram](MSv62332V1)

The DTAE bit in the TIMx_DTR2 allows to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on **Figure 573.**

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIMx_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIMx_DTR2 register. The DTAE bit must be written before enabling the counter and must be not modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIMX_DTR2 register. The preload value is loaded in the active register on the next update event.

**Note:** If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 48.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1995 for delay calculation.
Re-directing tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be re-directed to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only tim_ocxn is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP=0 then tim_ocxref=tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE=CCxNE=1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

48.4.15 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, ECC / parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.

The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 475: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature (TIM15) on page 1965 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
The break is generated by the tim_brk inputs which has:
- Programmable polarity (BKP bit in the TIMx_BDTR register)
- Programmable enable bit (BKE bit in the TIMx_BDTR register)
- Programmable filter (BKF[3:0] bits in the TIMx_BDTR register) to avoid spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_AF1 register.

The sources for break (tim_brk) channel are:
- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to Section 48.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)
  - coming from a system break request on the tim_sys_brk inputs (refer to Section 48.4.2: TIM15/TIM16/TIM17 pins and internal signals for product specific implementation)

Break events can also be generated by software using BG bit in the TIMx_EGR register. All sources are ORed before entering the timer tim_brk inputs, as per Figure 576 below.

**Figure 576. Break circuitry overview**

**Caution:** An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.

- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the GPIO) else the enable output remains high.

- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 tim_ker_ck clock cycles).
  - If OSSI=0 then the timer releases the enable outputs (taken over by the GPIO which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the tim_brk input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 48.8.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1995. The LOCK bits can be written only once after an MCU reset.

The Figure 577 shows an example of behavior of the outputs in response to a break.
48.4.16 Bidirectional break input

The TIM15/TIM16/TIM17 are featuring bidirectional break I/Os, as represented on

*Figure 578.*
They allow to have:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged

The tim_brk input is configured in bidirectional mode using the BKBID bit in the TIMxBDTR register. The BKBID programming bit can be locked in read-only mode using the LOCK bits in the TIMxBDTR register (in LOCK level 1 or above).

The bidirectional mode requires the I/O to be configured in open-drain mode with active low polarity (using BΚΙΝP and BΚP bits). Any break request coming either from system (e.g. CSS), from on-chip peripherals or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software event (triggered by setting the BG bit) also causes the break I/O to be forced to '0' to indicate to the external components that the timer has entered in break state. However, this is valid only if the break is enabled (BKE = 1). When a software break event is generated with BKE = 0, the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN I/O.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM bit is set and the open drain control is released. This prevents the PWM output to be re-started as long as the break condition is present.
- The BKDSRM bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see Table 471)

Arming and re-ar Karxng break circuitry

The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).
The following procedure must be followed to re-arm the protection after a break event:

- The BKDSRM bit must be set to release the output control
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before re-arming)
- The software must poll the BKDSRM bit until it is cleared by hardware (when the application break condition disappears)

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

**Figure 578. Output redirection**

### 48.4.17 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). tim_ocxref remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The tim_ocref_clr_int input can be selected among several inputs, as shown on Figure 579 below.

**Figure 579. tim_ocref_clr input selection multiplexer**
48.4.18 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $\text{CNT} < \text{CCR}_x \leq \text{ARR}$ (in particular, $0 < \text{CCR}_x$)

**Figure 580. Example of one pulse mode.**

For example one may want to generate a positive pulse on TIM_OC1 with a length of $t_{\text{PULSE}}$ and after a delay of $t_{\text{DELAY}}$ as soon as a positive edge is detected on the TIM_TI2 input pin.

Let’s use TIM_TI2FP2 as trigger 1:

1. Select the proper TIM_TI2_IN[1..15] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TIM_TI2FP2 to TIM_TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TIM_TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TIM_TI2FP2 as trigger for the slave mode controller (TIM_TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TIM_TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one wants to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to '0' in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: tim_ocx fast enable

In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

48.4.19 Retriggerable one pulse mode (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 48.4.18:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
48.4.20  **UIF bit remapping**

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMx_CNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

48.4.21  **Timer input XOR function (TIM15 only)**

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins tim_ti1 and tim_ti2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 582.

**Figure 581. Retriggerable one pulse mode**

**Figure 582. Measuring time interval between edges on 2 signals**
48.4.22 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select tim_ti1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

**Figure 583. Control circuit in reset mode**

![Control circuit in reset mode](MSv62391V1)
**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_t1 input is low:

1. Configure the channel 1 to detect low levels on tim_t1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = ‘0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select tim_t1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_t1 is low and stops as soon as tim_t1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_t1 and the actual stop of the counter is due to the resynchronization circuit on tim_t1 input.

*Figure 584. Control circuit in gated mode*
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P='1' and CC2NP='0' in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select tim_ti2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

![Control circuit in trigger mode](image)

Slave mode selection preload for run-time encoder mode update

The SMS[3:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIMx_SMCR register. The trigger for the transfer from SMS[3:0] preload to active value is the update event (UEV) occurring when the counter overflows.

48.4.23 Slave mode – combined reset + trigger mode (TIM15 only)

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

48.4.24 Slave mode – combined reset + gated mode (TIM15 only)

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode allows to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).
48.4.25 Timer synchronization (TIM15)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 38.3.19: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

48.4.26 Using timer output as trigger for other timers (TIM16/TIM17)

The timers with one channel only do not feature a master mode. However, the OC1 output signal can be used to trigger some other timers (including timers described in other sections of this document). Check the “TIMx internal trigger connection” table of any timer on the device to identify which timers can be targeted as slave.

The OC1 signal pulse width must be programmed to be at least 2 clock cycles of the destination timer, to make sure the slave timer detects the trigger.

For instance, if the destination's timer CK_INT clock is 4 times slower than the source timer, the OC1 pulse width must be 8 clock cycles.

48.4.27 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,

The DBSS[3:0] bits in the TIMx_DCR register defines the interrupt source that triggers the DMA burst transfers (see Section 48.8.20: TIMx DMA control register (TIMx_DCR)(x = 16 to 17) for details).

For example, the timer DMA burst feature could be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into the CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every
CCRx register is to be updated twice for example, the number of data to transfer should be
6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5
and data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

48.4.28 TIM15/TIM16/TIM17 DMA requests

The TIM15/TIM16/TIM17 can generate a DMA requests, as shown in Table 472.

<table>
<thead>

</tr>
</tbody>
</table>

1. Available for TIM15 only.

48.4.29 Debug mode

When the microcontroller enters debug mode (Cortex®-M33 core halted), the TIMx counter
can either continue to work normally or stop.

The behavior in debug mode can be programmed with a dedicated configuration bit per
timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE
bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have
their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

For more details, refer to the debug section.
48.5 TIM15/TIM16/TIM17 low-power modes

Table 473. Effect of low-power modes on TIM15/TIM16/TIM17

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The timer operation is stopped and the register content is kept. No interrupt can be generated.</td>
</tr>
<tr>
<td>Standby</td>
<td>The timer is powered-down and must be reinitialized after exiting the Standby mode.</td>
</tr>
</tbody>
</table>

48.6 TIM15/TIM16/TIM17 interrupts

The TIM15/TIM16/TIM17 can generate multiple interrupts, as shown in Table 474.

Table 474. Interrupt requests

1. Available for TIM15 only.
48.7  **TIM15 registers**

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

### 48.7.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x00  
Reset value: 0x0000

| Bit 15:13 | Reserved, must be kept at reset value. |
| Bit 12 | DITHEN: Dithering enable  
0: Dithering disabled  
1: Dithering enabled  
*Note: The DITHEN bit can only be modified when CEN bit is reset.* |
| Bit 11 | UIFREMAP: UIF status bit remapping  
0: No remapping. UIF status bit is not copied to TIM15_CNT register bit 31.  
1: Remapping enabled. UIF status bit is copied to TIM15_CNT register bit 31. |
| Bit 10 | Reserved, must be kept at reset value. |
| Bits 9:8 | CKD[1:0]: Clock division  
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_tix)  
00: tDTS = tim_ker_ck  
01: tDTS = 2*tim_ker_ck  
10: tDTS = 4*tim_ker_ck  
11: Reserved |
| Bit 7 | ARPE: Auto-reload preload enable  
0: TIM15_ARR register is not buffered  
1: TIM15_ARR register is buffered |
| Bits 6:4 | Reserved, must be kept at reset value. |
| Bit 3 | OPM: One-pulse mode  
0: Counter is not stopped at update event  
1: Counter stops counting at the next update event (clearing the bit CEN) |
Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt if enabled. These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note*: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 48.7.2 TIM15 control register 2 (TIM15_CR2)
Address offset: 0x04
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

</tr>
</tbody>
</table>

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
0: tim_oc2=0 when MOE=0
1: tim_oc2=1 when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in the TIM15_BKR register).

Bit 9 **OIS1N**: Output Idle state 1 (tim_oc1n output)
0: tim_oc1n=0 after a dead-time when MOE=0
1: tim_oc1n=1 after a dead-time when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).

Bit 8 **OIS1**: Output Idle state 1 (tim_oc1 output)
0: tim_oc1=0 after a dead-time when MOE=0
1: tim_oc1=1 after a dead-time when MOE=0

*Note*: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM15_BKR register).
Bit 7 **TI1S**: tim_ti1 selection
- 0: The tim_ti1_in[15..0] multiplexer output is connected to tim_ti1 input
- 1: The tim_ti1_in[15..0] and tim_ti2_in[15..0] multiplexers output are connected to the tim_ti1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection
These bits allow to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:
- 000: **Reset** - the UG bit from the TIM15_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.
- 001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM15_SMCR register).
